Design, synthesis and evaluation of new methyl piperazine derivatives as anticancer agents

Singh, Mahaveer1; Jadhav, Hemant R.2; Choudhary, Amit3; Wadhwa, Pankaj41 Birla Institute of Technology and Sciences Pilani, Pilani Campus, Pilani, India (GRID:grid.418391.6) (ISNI:0000 0001 1015 3164); SVKM'S NMIMS University, Shirpur Campus, School of Pharmacy and Technology Management, Dhule, India (GRID:grid.444588.1) (ISNI:0000 0004 0635 4408)2 Birla Institute of Technology and Sciences Pilani, Pilani Campus, Pilani, India (GRID:grid.418391.6) (ISNI:0000 0001 1015 3164)3 Indian Institute of Integrative Medicine, Cancer Pharmacology Division, Jammu, India (GRID:grid.418225.8) (ISNI:0000 0004 1802 6428)4 Birla Institute of Technology and Sciences Pilani, Pilani Campus, Pilani, India (GRID:grid.418391.6) (ISNI:0000 0001 1015 3164); Lovely Professional University, School of Pharmaceutical Sciences, Phagwara, India (GRID:grid.449005.c) (ISNI:0000 0004 1756 737X)

ABSTRACT (ENGLISH)

Background

To overcome the problem of side effects and toxicity, development of new anticancer agents is needed. Recently, piperidine salicylanilide derivatives with nanomolar epidermal growth factor receptor (EGFR) inhibitory and cytotoxicity activity have been reported. In the present study effect of replacing piperidine in reported piperidine salicylanilide with *N*-methyl piperazine and changing substituent's of phenyl ring at other end on anticancer activity have been explored. A series of sixteen methyl piperazine incorporated phenyl benzamide and phenyl methanone derivatives have been synthesized and tested in a panel of three cancer cell lines (adenocarcinomic human alveolar basal epithelial cells (A-549), human colon carcinoma (HCT-116) and human pancreatic carcinoma (MIAPaCa-2)), using gefitinib as standard. Further, to study the probable mechanism, due to their structural similarity with EGFR inhibitors, docking interactions with EGFR active site were observed using Schrodinger suite.

Result

The results indicated that most of the compounds showed promising activity; out of which, compound A-11 was most active having cytotoxicity much better than that of gefitinib. It showed IC_{50} value of 5.71 μM against A-549 cell line, 4.26 μM against HCT-116 colon cancer line and 31.36 μM against MIAPaCa-2 cell line.

Conclusion

It was found that these compounds fit well in the active site and may be exhibiting anticancer activity via EGFR inhibition.

FULL TEXT

Background

Cancer results from uncontrolled cell growth, and remains one of the most potentially life threatening disease worldwide [1]. As per reports of the International Agency for Research on Cancer, in 2012, 14.1 million new cancer cases were reported, along with 8.2 million cancer deaths worldwide. The global burden of cancer is expected to grow to 21.7 million as new cancer cases and 13 million cancer deaths in 2030 despite the presence of variety of anticancer medicines, development of anticancer agents has received more attention of medicinal chemists, due to occurrence of side effects [2, 3].

EGFR amplification and overexpression are prevalent various cancers including NSCLC, occurring in up to 85% of patients with this type of cancer. Mutations typically arise in exons 18–21, which encompass the kinase domain of

the EGFR gene. The majority, around 90%, of these mutations manifest as either exon 21 L858R point mutations or deletions within exon 21. These genetic alterations lead to heightened EGFR kinase activity, resulting in increased downstream signaling. Conversely, most exon 20 insertion mutations are associated with reduced sensitivity to EGFR TKIs. Hence, in order to address resistance, there is a critical need for the development of novel ligands that function as inhibitors of EGFR [4].

In literature, quinazoline and piperazine containing compounds have been reported to inhibit various types of cancers [4]. Quinazoline derivatives are known for EGFR tyrosine kinase (TK) and other kinase inhibition in non small cell lung cancer (NSCLC) and other carcinomas. Gefitinib is one of the quinazoline derivatives which have been used for anticancer activity, especially in lung cancer. Unfortunately, resistance against quinazoline compounds develops within a short span of use [5].

Similarly, piperazine and benzothiazole piperazine derivatives have been evaluated for their anticancer potential against HCT-116 colon cancer cell line [6–8]. Piperazine substituted adamantanes have been reported for colon and pancreatic cancer, whereas piperazine methanone shows good potency against human breast adenocarcinoma cell line, MCF-7 and mouse embryonic fibroblast cell lines, NIH3T3 [9, 10]. Moreover, various piperazine derivatives have been patented as lung cancer chemotherapy agents [11]. Benzofuran with *N*-aryl piperazine derivatives have also been reported for anticancer activity as hybrid compounds [12]. Recently, phenyl piperazine benzoxazole and benzhydryl piperazine derivatives have been shown to inhibit lung, breast and other carcinomas [13–15].

Hu et al. have described novel piperidine salicylanilide derivatives having nanomolar EGFR TK inhibitory and cytotoxicity activity (Fig. 1) [16]. Using this structure as basis, scaffold I was considered wherein the piperidine was replaced with *N*-methyl piperazine and the phenyl ring on the amidic nitrogen was substituted with various electron donating and withdrawing substituent's, hypothesizing that these changes could enhance the anticancer potential. Further, in scaffold II, the amidic nitrogen was constrained in a piperazine ring and the effect of substituents on the phenyl ring on the other nitrogen was also evaluated.

Structures of reported piperidine salicylanilide, scaffolds I and II

Materials

For docking, Glide XP of Schrodinger suite was used and physicochemical properties of the compounds were predicted using Chemaxon Jchem for Excel. The docking protocol was validated to govern the reliability and reproducibility of the docking parameters used for the study. Reaction progress was monitored using analytical grade solvents and pre-coated Silicagel G TLC plates (Kieselgel 60_{F254}, Merck) and visualized in UV light. Melting points were measured with Buchi 530 melting point apparatus and were uncorrected. ^{1}H NMR spectra were recorded on a Bruker Avance-400 MHz system using $CDCl_3$ or DMSO as the solvent. Chemical shifts (d) are reported in parts per millions (ppm) relative to TMS as internal standard. FTIR spectra were performed on IR Prestige 21 Shimadzu using KBr as standard. MS were analyzed on MICROMASS Quattro-II LCMS system (Waters Corporation, Milford, USA). All reagents were obtained from commercial suppliers and used without further purification. Synthesized compounds were tested against A-549 (human lung carcinoma), HCT-116 (human colon cancrcinoma) and MIAPaCa-2 (human pancreatic carcinoma) for anticancer potential.

Method

The X-ray structure of EGFR bound with gefitinib as a cocrystallized ligand (pdb id: 2ITO) was obtained from the brookhaven protein database for docking purposes [17]. Docking of the compounds was performed using Glide 5.9. Running on maestro version 9.4, to investigate their putative binding mode in EGFR binding pocket. The Protein preparation wizard within the Schrödinger suite was employed to prepare the designated protein. The protein underwent distinct preprocessing stages, which involved the removal of the substrate co-factor and water molecules lacking hydrogen bonds, followed by the optimization of hydrogen bonds. Subsequently, a charge was assigned, and the energy was minimized, achieving a Root Mean Square Deviation (RMSD) value of 0.30 Å utilizing the Optimized Potentials for Liquid Simulations-2005 (OPLS-2005) force field. The structures of all compounds were

drawn using ChemSketch and converted into 3D structures through a 3D optimization tool. The ligands, drawn previously, were geometry optimized using the LigPrep 2.6 module, with partial atomic charges computed through the OPLS-2005 force field. The prepared ligands were then subjected to docking with the prepared protein utilizing the Glide 5.9 module, operating in extra precision mode (XP) [18]. The anticancer activity was measured by using the 3-(4,5-dimethylthiazolyl-2)-2,5-diphenyltetrazolium bromide (MTT) cell viability assay and Gefitinib was used as positive control.

Synthetic scheme

Total 10 derivatives of 4-(3-(4-methylpiperazin-1-yl)propoxy)-*N*-phenylbenzamide (scaffold I) and 6 derivatives of (4-phenyl)piperazin-1-yl)(4-(3-(4-methylpiperazin-1-yl)propoxy)phenyl)methanone (scaffold II) were synthesized. All the synthesized analogs were subjected to characterization using infrared spectroscopy (IR), proton nuclear magnetic resonance spectroscopy (1H NMR), and mass spectrometry (MS) to determine their molecular weight.
The compounds were synthesized using Scheme 1.

Scheme 1 [Images not available. See PDF.]

Synthesis scheme for piperazinyl phenyl benzamide and phenyl methanone derivatives **a** K_2CO_3, acetone, room temperature, 6 h; **b** K_2CO_3, acetonitrile, reflux, 6 h; **c** NaOH, reflux, 3 h; **d** HOBt, EDC.HCl, triethylamine, tetrahydrofuran, substituted anilines/phenyl piperazines, 0 °C, 12 h

Initially, *N*-methyl piperazine was alkylated using 1-bromo-3-chloropropane. Resultant 1-(3-chloropropyl)-4-methyl piperazine was refluxed with methyl 4-hydroxybenzoate in acetonitrile using potassium carbonate for *O*-alkylation. The methyl 4-[3-(4-methylpiperazin-1-yl) propoxy] benzoate formed was hydrolyzed with base to give 4-[3-(4-methylpiperazin-1-yl)propoxy]benzoic acid, which was then coupled with substituted anilines or phenyl piperazines to give final compounds using hydroxy-*O*-benztriazole (HOBt) and *N*-(3-dimethylaminopropyl)-*N'*-ethylcarbidiimide.HCl (EDC.HCl). Purity of the compounds was checked by High Performance Liquid Chromatography (HPLC). All the intermediates and final compounds were characterized by spectroscopic techniques.

Biological evaluation: cell viability/MTT assay

The reduction of tetrazolium salts was used to examine cell proliferation and growth inhibition. Gefitinib was used as positive control and IC_{50} (the concentration which resulted cytotoxicity in 50% cells) values are the mean of three independent experiments [19].

For in vitro evaluation, MTT assays for all compounds against three cell lines viz. A-549 human lung carcinoma, HCT-116 human colon cancer and MIAPaCa-2 human pancreatic carcinoma were performed. The DMEM, RPMI-1640, DMEM-F12, were used as culture mediums for A-549 human lung carcinoma, HCT-116 colon cancer and pancreatic MIAPaCa-2 cell lines, respectively. 10^4 Cells per well were grown in 96-well plates and exposed to different concentrations of various test compounds for 48 h. After 44 h treatment, 20 µl of MTT solution (2.5 mg/ml) was added to each well and incubated at 37 °C for 4 h in a humidified atmosphere containing 5% CO_2. In case of suspension cell lines, the plates were centrifuged at 1500 r.p.m. for 15 min, and the supernatant was discarded while in adherent cell lines, the media was removed without centrifugation. The MTT-formazan crystals were dissolved in 150 µl dimethyl sulfoxide. The absorbance was recorded at a wavelength of 570 nm in the microplate reader and cytotoxicity was calculated as % cell growth inhibition.%cell survival=(At-Ab)/(Ac-Ab)×100where At, Ab and Ac are absorbance of test, blank and control, respectively. Concentrations 1 µM, 10 µM, 20 µM, 30 µM, and 50 µM were used for assay.

Results

Spectral data

1-(3-chloropropyl)-4-methylpiperazine: Liquid, 80%, IR (KBr, cm^{-1}): 2954–2858 (Aliphatic-C-H stretching), 1355 (C-N); ^{1}H NMR (400 MHz, Chloroform-*d*) δ 3.54 (t, *J*=3.9 Hz, 2H), 2.61–2.50 (m, 8H), 2.90–2.570 (m, 2H), 2.32 (s, 3H), 1.98 (tt, *J*=6.4, 4.0 Hz, 2H).

Methyl-4-[3-(4-methylpiperazin-1-yl)propoxy]benzoate: Liquid, 75%, IR (KBr, cm^{-1}): 3217–3004 (Aromatic CH

stretching) 2954–2858 (Aliphatic CH stretching), 1750–1735 (–CO), 1373 (–CN); ^{1}H NMR (400 MHz, Chloroform-*d*) δ 7.90–7.84 (m, 2H), 7.05–6.99 (m, 2H), 3.99 (t, *J*=6.1 Hz, 2H), 3.94 (s, 3H), 2.61 (t, *J*=6.4 Hz, 2H), 2.58–2.50 (m, 8H), 2.32 (s, 3H), 1.83 (td, *J*=6.2 Hz, 2H).

Methyl-4-[3-(4-methylpiperazin-1-yl)propoxy]benzoic acid: White solid, 70%, (mp: 180–184 °C), IR (KBr, cm^{-1}), 3210–3010 (Aromatic C–H stretching) 2954–2858 (Aliphatic-CH stretching), 1703 (–CO), 1373 (–CN) 1280–1300 (CO ether); ^{1}H NMR (400 MHz, Chloroform-*d*) δ 7.90–7.84 (m, 2H), 7.05–6.99 (m, 2H), 3.99 (t, *J*=6.1 Hz, 2H), 2.61 (t, *J*=6.4 Hz, 2H), 2.58–2.50 (m, 8H), 2.32 (s, 3H), 1.83 (p, *J*=6.2 Hz, 2H).

A-1: 4-[3-(4-Methylpiperazin-1-yl)propoxy]-*N*-phenylbenzamide: White solid, 55%, (mp: 134–136 °C), IR (KBr, cm^{-1}), 3344.57 (–NH stretching) 3010–2980 (Aromatic CH stretching), 2881–2852 (Aliphatic CH stretching) 1633 (–CO amide); ^{1}H NMR (400 MHz, Chloroform-*d*), δ 8.04–7.98 (m, 2H), 7.73–7.67 (m, 2H), 7.36–7.29 (m, 2H), 7.09 (tt, *J*= 7.0, 1.2 Hz, 1H), 7.00–6.94 (m, 2H), 3.99 (t, *J*=6.1 Hz, 2H), 2.61 (t, *J*=6.4 Hz, 2H), 2.54 (d, *J*=1.2 Hz, 8H), 2.32 (s, 3H), 1.83 (td, *J*=6.2 Hz, 2H). ^{13}C-NMR (100 MHz, CDCl3): δ=164.7, 162.6, 137.8, 128.6, 128.9, 128.2, 128.3, 128.2, 125.8, 121.9, 114.5, 114.6, 73.1, 57.2, 57.9, 58.9, 55.4, 55.9, 46.9, 28.6, 27.02. ESI MS: m/z=354.21 (M+1 H)$^{+}$.

A-2: 4-[3-(4-Methylpiperazin-1-yl)propoxy]-*N*-(*p*-tolyl)benzamide: White solid, 58%, (138–140 °C), IR (KBr, cm^{-1}), 3350 (–NH) 3005–2933 (Aromatic CH stretching), 2875–2792 (Aliphatic CH stretching), 1651 (CO); ^{1}H NMR (400 MHz, Chloroform-*d*), δ 8.04–7.90 (m, 2H), 7.44–7.37 (m, 2H), 7.18–7.12 (m, 2H), 7.00–6.90 (m, 2H), 3.96 (t, *J*= 6.1 Hz, 2H), 2.61 (t, *J*=6.4 Hz, 2H), 2.57–2.51 (m, 8H), 2.31 (d, *J*=6.0 Hz, 6H), 1.86 (tt, *J*=6.2 Hz, 2H); ^{13}C-NMR (100 MHz, CDCl3): δ=164.7, 162.6, 137.8, 128.6, 129.9, 128.2, 129.3, 127.2, 125.8, 121.9, 114.5, 114.6, 73.1, 57.2, 57.9, 58.9, 55.4, 55.9, 46.9, 28.6, 27.02, 21.5, ESI MS: m/z=368.2 (M+1 H)$^{+}$.

A-3: 4-[3-(4-Methylpiperazin-1-yl)propoxy]-N-(*m*-tolyl)benzamide: Off white solid, 52%, (mp: 132–134 °C), IR (KBr, cm^{-1}), 3350 (–NH stretching) 3000–2931 (Aromatic CH stretching), 2875–2767 (Aliphatic CH stretching), 1643 (CO amide); ^{1}H NMR (400 MHz, Chloroform-*d*), δ 8.03–7.91 (m, 2H), 7.50 (t, *J*=1.9 Hz, 1H), 7.44 (ddd, *J*=7.7, 1.8, 1.1 Hz, 1H), 7.18 (t, *J*=7.9 Hz, 1H), 7.00–6.90 (m, 3H), 3.99 (t, *J*=6.1 Hz, 2H), 2.61 (t, *J*=6.4 Hz, 2H), 2.57–2.50 (m, 8H), 2.30 (s, 3H), 2.27 (d, *J*=0.7 Hz, 3H), 1.81 (p, *J*=6.2 Hz, 2H): ^{13}C-NMR (100 MHz, CDCl3): δ=164.7, 162.6, 138.8, 128.6, 129.9, 128.2, 129.3, 125.2, 125.8, 121.9, 118.5, 114.6, 114.9, 73.1, 56.2, 57.8, 58.9, 55.4, 55.9, 46.9, 28.6, 21.3; ESI MS: m/z=368.1 (M+1 H)$^{+}$.

Cell viability/MTT assay

In adenocarcinomic human alveolar basal epithelial cell line (Lung cancer, A-549) gefitinib showed IC_{50} value of 16.56 μM, in the human colon carcinoma cell line (HCT-116 cell line), it showed an IC_{50} value of 10.51 μM, whereas in human pancreatic carcinoma MIAPaCa-2 cell line, the IC_{50} value was 49.50 μM. Results of MTT assay for all the compounds are given in Table 1.

The most active compounds indicated in bold

In silico studies (docking and physiochemical properties)

The series was prepared keeping similar features to that of piperidine salicylanilide, having EGFR inhibitory activity. Therefore, it was thought to study the in silico docking of active compounds with EGFR to suggest the possible mechanism of action. Glide score and physicochemical propoerties of active compounds are given in Table 2 [20–23].

Discussion

Cell viability/MTT assay

In the A-549 lung cancer cell line, electron-donating substitution on the aniline portion showed better inhibition. Compound A6 (2,5 di-CH_3) with IC_{50} 7.74 μM showed better inhibition as compared to compound A4 (2,4 di-CH_3) and A5 (3,4 di-CH_3). Similarly, among scaffold-II compounds, A11 (3-OCH_3) and A12 (4-OCH_3) showed the IC_{50} value of 5.71 μM, 13.16 μM and A16 (4-CH_3)14.28 μM, respectively. In this cell line, *meta* substitution resulted in favorable activity and compounds with electron withdrawing groups (EWGs) such as, A8 (4-Cl), A9 (4-Br), A10 (4-F) were weakly active.

In the HCT-116 colon cancer line, three compounds showed better activity than gefitinib. Compounds A1 (-H) and A4 (2,4 di-CH_3) displayed IC_{50} value of 6.54 μM and 10.54 μM, respectively while compound A-11 having *meta* methoxy substitution was most active with IC_{50} of 4.26 μM. Again, in this cell line, electron donating substituted compounds exhibited good inhibition and compounds with electron withdrawing groups were inactive.

In the MIAPaCa-2 cell line, dimethyl substituted aniline derivatives showed better results when compared to mono substituted compounds. Compounds A-4 (2,4 di-CH_3), A-5 (3,4 di-CH_3) and A-6 (2,5 di-CH_3) showed IC_{50} values of 11.54, 6.26 and 14.98 μM respectively. From scaffold-II derivatives, compound A-11 (3-OCH_3) and compound A-16 (4-CH_3) showed better inhibition than gefitinib.

Overall, compound A-11 was found to be the most active in two of the three cell lines. Also, by observing the IC_{50} values of all the compounds, it can be said that compounds with electron-donating substituents on the aniline portion exhibited better inhibition as compared to compounds with electron withdrawing groups.

Docking

It was found that the docked ligand superimposed well with reference ligand (gefitinib, co-crystallized ligand) with root mean square deviation value of 0.458 Å. The gefitinib in active site of EGFR displayed hydrogen bonding interaction with MET793 of hinge region, which is essential. Additionally, it shows hydrophobic interactions with CYS797 and LEU792 of hinge region and LEU844 and MET766 in the C-helix with a glide score of − 7.31.

It was observed that compounds with electron-withdrawing substituents did not dock well in the active site and compounds with electron donating substituents fit well. Compound A-10 with *p*-fluoro substituent on scaffold I was the only compound with electron withdrawing substituent and weak in the MTT assay was found to have least activity glide score. Its glide score was less than the unsubstituted compound. It was observed that it does not take part in any hydrogen bonding interaction.

When all the compounds were docked, it was observed that hydrophobic interactions with CYS797, LEU792, MET793 of hinge region, LEU844 and MET766 in the C-helix were similar for all compounds. However, the compounds showed hydrogen bonding interaction with MET793 and those with better score also showed side chain hydrogen bonding with ASP855 in activation loop. This indicates that these compounds do show necessary interactions in active site and hence may exert anticancer activity by inhibiting as EGFR.

Docking interactions of representative compounds are shown in Fig. 2.

Conclusion

A range of 16 compounds consisting of methyl piperazine-incorporated phenyl benzamide and phenyl methanone derivatives were synthesized and assessed for their potential as anticancer agents against A-549 human lung carcinoma, HCT-116 human colon cancer, and MIAPaCa-2 human pancreatic carcinoma cell lines. It was noted that compounds possessing electron-donating groups exhibited heightened cytotoxicity across the three cell lines. Additionally, a hypothesis was put forward suggesting that the observed anticancer effects may stem from the inhibition of EGFR. Previous literature indicates that hydrogen bond interactions with MET793 have been linked to EGFR inhibition, and the compounds exhibiting superior anticancer activity were found to interact with MET793 within the EGFR binding site. The results suggest that these derivatives function as anticancer agents; nevertheless, further investigations are necessary to ascertain their specificity as EGFR inhibitors.

ABSTRACT (ENGLISH)

Background

This study aimed to formulate solid self-nanoemulsifying drug delivery systems (SNEDDS) for nimodipine (NIM). The selection of Cremophor RH 40, Lipoxol 300, and PEG 400 as oil, surfactant, and co-surfactant was based on solubility and self-emulsification assessments. A ternary phase diagram determined the optimal oil to Smix (surfactant/co-surfactant) ratio (40:60). By utilizing liquid SNEDDS (NIM-SNEDDS) as an adsorbate and chitosan EDTA microparticles, developed through spray drying (SD-CHEM) and solvent evaporation (SE-CHEM) as adsorbents, the solid SNEDDS were created (NIM-SD-SSNEDDS and NIM-SE-SSNEDDS, respectively).

Results

Both solid formulations exhibited favourable drug loading (NIM-SD-SSNEDDS = 79.67 ± 2.97%, NIM-SE-SSNEDDS = 77.76 ± 4.29%), excellent flowability, and drug amorphization as per XRD and DSC analysis. Scanning electron

microscopy revealed smoothening and filling of adsorbent surfaces by adsorbate (with size range NIM-SD-SSNEDDS = 10–15 µm, NIM-SE-SSNEDDS = 20–25 µm). FTIR confirmed no interaction of drug and excipients. Stability studies demonstrated the physical and thermodynamic stability of reconstituted nanoemulsions with droplet size, PDI, zeta potential, emulsification time, % transmittance and cloud temperature for NIM-SD-SSNEDDS as 247.1 nm, PDI 0.620, 1.353 mV, 38–41 s, 94.64%, 54 °C and for NIM-SE-SSNEDDS as 399.6 nm, PDI 0.821, 1.351 mV, 40–48 s, 92.96%, 49 °C, respectively. FE-SEM images showed globules formed with small sizes, and there was no coalescence evidence, implying the reconstituted nanoemulsions' stability. In vitro dissolution studies revealed a fourfold increase in drug dissolution for NIM-SD-SSNEDDS (84.43%) and NIM-SE-SSNEDDS (76.68%) compared to pure drug (28%). Ex vivo permeation studies indicated almost similar profiles for NIM-SD-SSNEDDS (22.61%) and NIM-SE-SSNEDDS (21.93%) compared to NIM-SNEDDS (25.02%).

Conclusion

NIM-SD-SSNEDDS exhibited superior performance compared to NIM-SE-SSNEDDS, highlighting the efficacy of microparticles developed by the spray drying method (SD-CHEM) as adsorbents for solidification. These results suggest enhanced dissolution and permeation for nimodipine in both the solid SNEDDS.

FULL TEXT

Background

Self-nanoemulsifying drug delivery systems (SNEDDS) showcase a significant capacity for improving the oral bioavailability and biological efficacy of drugs characterized by poor water solubility [1, 2]. Lipid-based systems like SNEDDS have proven effective in addressing the problem of breakdown by enzymes in the gastrointestinal tract during the oral administration of biomolecules [3]. SNEDDS pose various challenges and obstacles, encompassing concerns related to both physical and chemical instability. The fluid nature of SNEDDS introduces several difficulties, such as constraints on dosage manufacturing, restricted choices for dosage forms, reduced drug loading capacity, and intricate issues in handling and storage [4, 5]. This leads the researchers to investigate various approaches to solidify SNEDDS, streamlining a swift and uncomplicated development of solidification of product with the desired properties [6].

There has been a growing emphasis on solid self-nanoemulsifying drug delivery systems (S-SNEDDS). These systems are formulated by integrating a liquid self-nanoemulsifying drug delivery system into a solid dosage form. This approach combines the benefits of SNEDDS with those of a solid dosage form, effectively addressing the limitations associated with liquid formulations [7]. S-SNEDDS offer a multitude of advantages, such as increased surface area leading to improved solubility and bioavailability, enhanced stability, robustness, easy handling, easy scale-up, enhanced drug loading capacity, better flow, minimized drug precipitation, and economical manufacturing [8]. SNEDDS suits BCS (Biopharmaceutical classification system) class II drugs (with low water solubility and high permeability), which have a dissolution-restricted absorption. This restricted absorption can result in a lack of success in therapeutic action because of insufficient drug concentration [9, 10].

Nimodipine (NIM), a BCS class II drug, is a calcium antagonist (dihydropyridine) with poor water solubility (2.30 µg/ml) and high lipophilicity and permeability (log *P* = 3.41) [11]. Because of the high lipophilicity, it can reach the brain and cerebrospinal fluid by crossing the blood–brain barrier [12]. It is highly used in the treatment of delayed ischaemic neurological disorder in patients with subarachnoid haemorrhage and cerebral vasospasm, stroke, senile dementia (due to irreversible loss of neurons) and hemicrania [13–16]. It has a moderate anti-hypertensive effect and is used in sudden sensorineural hearing loss [17].

Its mechanism of action is to block the entry of calcium through specific channels (voltage-dependent) and stop the contraction of vascular smooth muscles, leading to the dilation of the blood vessels [18].

NIM has two polymorphic forms and two enantiomers with different aqueous solubilities [19]. Because of the rapid first-pass metabolism and P-glycoprotein efflux, it has a lower oral bioavailability (around 13%) and requires high dosing (360 mg per day) [20]. Nimodipine was used as a model drug for developing the S-SNEDDS with chitosan-EDTA microparticles developed by spray drying and solvent evaporation techniques.

Materials and methods

Nimodipine was a gift sample from Strides Pharma Science limited (India). Cremophor® RH-40 (Polyoxyl 40 hydrogenated castor oil) was procured from Himedia (India). Lipoxol 300 (PEG 300) was procured from Sasol Chemicals (USA). Polyethylene glycol 400 (PEG 400) was obtained from TCI (India). Caprol® ET (hexaglycerol octasterate), Captex® 200 (propylene glycol dicaprylate), Captex® 300 (glyceryl tricaprylate/tricaprate) were gift samples from Abitech (USA). Labrafac™ PG (propylene glycol dicaprylocaprate) from Gattefossé (Canada) was received as a gift sample. Propylene glycol and Ethylene diamine tetra acetic acid disodium (EDTA disodium) were obtained from CDH (India). Chitosan with 90% deacetylation (DA) was acquired from Marine Hydrocolloids (India). Except for the ones we talked about, we used high-quality chemicals for the research. We used them just as they were, without any changes.

Drug solubility analysis in different excipients

As discussed, NIM is a high-dosing drug, so it becomes vital to obtain maximum drug loading in the SNEDDS. To create and chart the emulsification area, examining how much NIM could dissolve in various excipients was crucial. A surplus of the drug was placed in a sealed container, which was then subjected to a 40 °C water bath for 15 min. The mixture was stirred in an orbital shaker incubator (Remi, India) at 100 revolutions per minute for 72 h [21]. Subsequently, the mixture underwent centrifugation using a Remi RC-8 centrifuge from India at a speed of 4000–5000 rpm for 30 min. The resulting supernatant was filtered through Whatman filter paper with a pore size of 0.45 µm nylon. NIM was quantified at 237 nm using a UV spectrophotometer (UV–VIS spectrophotometer-2371 EI, India). The experimental procedure was repeated three times for accuracy [22].

The capacity for self-emulsification is an important factor when choosing excipients for SNEDDS, in addition to the drug's high solubility in both oil and surfactant. A 10% (w/v) aqueous solution of each surfactant (demonstrating significant high drug solubility) was created to assess this. Subsequently, 10 ml of this solution was titrated with each type of oil, and the volume of oil required to make the emulsion cloudy was recorded.

The combination of oil and surfactant that emulsified a maximum quantity (of oil) was chosen [23]. The selected surfactant (in a 1:1 ratio) with each co-surfactant (which had high drug solubility) was taken to form a mixture (Smix). Using this Smix, various formulations were created with the chosen oil, ranging from 10 to 90% in concentration. Each formulation, consisting of 500 mg, was individually mixed in 500 ml of triple distilled water, and the transparency or appearance of the mixture was then noticed [24].

Plotting of ternary phase diagram

We generated a ternary phase diagram to identify the suitable excipient range for creating nanoemulsion. Ternary mixtures, each totalling 1 g and including equal drug amounts, were prepared with three components. The selected surfactant and co-surfactant were combined in 1:1, 1:2, and 2:1 ratios, forming Smix mixtures. Subsequently, the oil and Smix were combined in nine different weight proportions, ranging from 1:9 to 9:1, in distinct glass vials. The aim was to determine the maximum limits for analysis to outline the phase accuracy boundaries in the diagram. Each formulation underwent titration with 500 ml of triple distilled water to observe nanoemulsion formation. The formation of a transparent/clear solution affirmed nanoemulsion creation. The proportions of oil and Smix were recorded and illustrated in the diagram. Chemix software was utilized for diagram plotting, with ingredients delineating the sides of this representation [25].

Development of self-nanoemulsifying drug delivery system

From the ternary phase diagram experiment, the appropriate proportions of oil and Smix were chosen to create a self-nanoemulsifying drug delivery system. The selected components were Cremophor RH 40 (as the oil), Lipoxol 300 (as the surfactant), and PEG 400 (as the co-surfactant). Subsequently, a liquid self-nanoemulsifying drug delivery system for Nimodipine (NIM-SNEDDS) was formulated. The measured amount of the drug was slowly introduced into the oil in a beaker and stirred at 2000 rpm on a magnetic stirrer until a homogeneous solution was achieved. Dropwise, adding a 1:1 Smix to this solution produced an isotropic mixture under continuous stirring for 30 min. The mixture was left to equilibrate for 48 h at room temperature, and observations were made for any phase separation [26].

Fabrication of SNEDDS to solid self-nanoemulsifying drug delivery system

Our earlier research optimized and created advanced adsorbent microparticles using chitosan-EDTA through spray drying (SD-CHEM) and a solvent evaporation method (SE-CHEM) [27]. These microparticles exhibited heightened abilities to absorb and release oil. Analysis of their surface free energy components revealed increased dispersive features and dynamic advancing contact angles, favourable characteristics for the adsorbent in converting liquid self-nanoemulsifying drug delivery systems (SNEDDS) into Solid SNEDDS (S-SNEDDS).

In the SE-CHEM process, a chitosan-EDTA disodium solution (60:40) underwent solvent evaporation in a Rota evaporator (Micro technologies, India) at a drying temperature of 70 °C for 45–60 min. Subsequently, the resulting dry film was carefully scraped, further dried in an oven for 40–50 min at 70 °C to eliminate residual moisture, and eventually converted into powder using a pestle and mortar. For SD-CHEM, a Chitosan-EDTA disodium solution (50:50) was processed in a Spray dryer (SprayMate JISL, India) with inlet temperature set at 110 °C, aspirator speed at 1000–2000 rpm, atomization pressure at 3 kg/cm^2, and feed pump operating at 15 rpm. In continuation to our research work, we fabricated the developed liquid SNEDDS of NIM with adsorption or solid carrier technique to create a solid self-nanoemulsifying drug delivery system (S-SNEDDS). The microparticles, created through SD-CHEM and SE-CHEM, served as adsorbents for the NIM-SNEDDS (nimodipine self-nanoemulsifying drug delivery system). Sequentially, NIM-SNEDDS was added to SD-CHEM and SE-CHEM individually and thoroughly mixed in a mortar and pestle. This process resulted in the formation of NIM-SD-SSNEDDS (nimodipine solid self-nanoemulsifying drug delivery system with spray-dried microparticles) and NIM-SE-SSNEDDS (nimodipine solid self-nanoemulsifying drug delivery system with solvent-evaporated microparticles) [27, 28]. The ratio of the adsorbate (NIM-SNEDDS) to adsorbent (SD-CHEM &SE-CHEM) was optimized to achieve non-sticky, free-flowing powders, namely NIM-SD-SSNEDDS and NIM-SE-SSNEDDS, respectively.

Different evaluations of the NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS

Drug loading efficiency (%)

To assess the drug loading efficiency (%), 100 mg of NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS was individually taken in 10 ml of methanol and vortexed in an orbital shaker (Remi, India) for 10 min. The NIM-SNEDDS mixture in methanol was directly analysed after appropriate dilution and examined at 237 nm using a UV spectrophotometer (UV–VIS spectrophotometer-2371 EI, India). The remaining two mixtures (NIM-SD-SSNEDDS and NIM-SE-SSNEDDS) were centrifuged (Remi Rc-8, India) at 4000 rpm for 10 min, and the supernatant obtained was filtered through Whatman filter paper (0.45 µm nylon). Following suitable dilution, these were analysed in a UV spectrophotometer, and the procedure was repeated in triplicate [28]. The drug loading efficiency (%) was calculated using the specified equation.

1

$$\text{Drug loading efficiency}\% = \frac{\text{Actual quantity of NIM present in the known amount of formulation}}{\text{Initial drug NIM load}} \times 100$$

Flowability

For NIM-SD-SSNEDDS and NIM-SE-SSNEDDS, we determined the angle of repose using the fixed funnel method, along with apparent bulk density, tapped density, Carr's Index, and Hausner's ratio, employing standard methods to characterize their flow properties [29].

The angle of repose was determined by placing graph paper on a flat horizontal surface and clamping a funnel above it, maintaining a distance of approximately 7–8 cm between the paper and the funnel top. The powder samples (2 g) were measured and poured into the funnel until the top of the cone-shaped heap just reached the funnel's top. The height (h) and diameter of the cone-shaped heap of powder (D) were measured, and the angle of repose was calculated using the standard formula ($\tan \alpha = 2h/D$). A powder with an angle of repose less than 25° is considered to have excellent flow, while a powder with an angle of repose greater than 40° is considered to have poor flow.

The powder (2 g) was carefully weighed and levelled for bulk density determination without tapping into a graduated glass cylinder. The apparent volume before tapping read as an untapped volume using the USP method was considered for the standard formula (Bulk density = Weight/untapped volume), and values were calculated.

After 500 tapings, the volume of the powder-filled cylinder was measured. Tapping continued until the frequency

difference between the two sets of tapping was less than 0.2 per cent. The final volume was noted, and the tapped density in g/ml was calculated using the standard formula (Tapped density = Weight/tapped volume).
These readings were then utilized to calculate Carr's index (CI) and Hausner's ratio (HR) using the formulas {CI = [(Tapped density − Bulk density/Tapped density) × 100] and HR = Tapped density/Bulk density}. Carr's index values above 25 indicate poor flowability, while values below 15 suggest good flowability. Hausner's ratios below 1.25 signify better flow properties than those above 1.25 [30].

Characterization (solid state)

X-ray diffraction analysis

Following the grinding of each sample (NIM, SD-CHEM, SE-CHEM, NIM-SD-SSNEDDS and NIM-SE-SSNEDDS), the resulting powder was placed and compacted in a sample holder. X-ray diffraction patterns of the samples were then measured using the X-ray diffractometer (XRD Aeris, Malvern Panalytical, UK). The continuous scanning of samples occurred within the range of 10°–50° at a rate of 2° per minute, with 0.02° 2θ increments. The scanning process commenced at 5° and concluded at 50° (2θ), with the scans conducted at 25 °C and the generator configured at 45 kV [28].

Scanning electron microscopy

The surface characteristics of NIM, SD-CHEM, SE-CHEM, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS were examined using the scanning electron microscope (SEM) (ZEISS Sigma 360, Germany) at 20 kV. The samples were affixed to the SEM stub and coated with a thin layer of gold. Multiple images were captured at various magnifications [30].

FTIR spectroscopy

Different components of the formulations, as well as their physical mixtures, were examined for possible incompatibilities. To create a fine mixture, the prepared samples were dried under vacuum, mixed, and triturated with KBr at a 1:100 ratio. Pellets were formed by pressing this fine mixture in a KBr press. Subsequently, these pellets were placed in a sample cell, and FTIR-ATR analysis was conducted (FTIR Perkin Elmer Spectrum Two, USA) in the 500–4000 cm^{-1} spectral range at room temperature [31].

DSC analysis

Hermetically sealed aluminium pans containing samples (15 mg each) of NIM, NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS were utilized. These pans were positioned on the sample pan holder, while empty pans were placed on the reference pan holders in a differential scanning calorimeter (DSC-25 TA, USA). Thermograms for each sample were then recorded within a temperature range of 40–400 °C, employing a heating rate of 10 °C per minute in a nitrogen atmosphere.

Reconstituted nanoemulsion and NIM-SNEDDS evaluations

To assess reconstitution ability, 100 mg of NIM-SD-SSNEDDS and NIM-SE-SSNEDDS was dispersed separately in 100 ml of triple distilled water for 1 h. Subsequently, the dispersions were vortexed in an orbital shaker (Remi, India) for 10 min. The resulting suspension underwent centrifugation (Remi RC-8, India) at 4000 rpm for 10 min to eliminate undissolved particles. The obtained supernatant was reconstituted nanoemulsion and utilized for subsequent investigations. Additionally, a 1:100 w/v dilution of freshly prepared NIM-SNEDDS with triple distilled water was created, dispersed, and used for further analysis.

Droplet size, size distribution, and zeta potential determination

The size of the droplets, polydispersibility index, and zeta potential of the reconstituted nanoemulsions and NIM-SNEDDS were examined using the Zetasizer Nano ZS (at a wavelength of 633 nm) with a scattering angle of 90° at 25 °C. The analysis was conducted in triplicate using equipment from Malvern Panalytical, UK [32, 33].

Self-emulsification time

The NIM-SD-SSNEDDS and NIM-SE-SSNEDDS supernatants and NIM-SNEDDS (1 ml each) were dispersed in 500 ml of triple distilled water and stirred at approximately 100 rpm using a magnetic stirrer. Observations were made to determine the formation of emulsion and the time needed for dispersibility [34].

Per cent transmittance test

When formulating self-nanoemulsifying drug delivery systems for oral administration, drug precipitation is possible upon dilution in the gastrointestinal tract. To assess this, the supernatants of NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS were tested for per cent transmittance at 237 nm, with water as the blank, using a UV spectrophotometer (UV–VIS spectrophotometer-2371 EI, India). The test was conducted in triplicate for accuracy [35, 36].

Estimation of cloud point

The supernatants (NIM-SD-SSNEDDS and NIM-SE-SSNEDDS) and NIM-SNEDDS were subjected to a water bath with a gradual temperature increase. The temperature at which immediate turbidity was observed in the samples was recorded [37].

Field emission scanning electron microscopy

The supernatant (50 µl) of both NIM-SD-SSNEDDS and NIM-SE-SSNEDDS was drop-casted onto glass slides that had been cleaned beforehand. The dried samples were then gold-coated using a sputter-coater for 10–15 s under high vacuum conditions. High-resolution images were captured at 15 kV using an accelerating voltage in field emission scanning electron microscopy (FE-SEM) (Quanta 250, Bruker) [38].

Dissolution profile (in vitro)

For assessing the dissolution release of NIM, the pure NIM, NIM-SNEDDS, NIM-SD-SNEDDS, and NIM-SE-SNEDDS, equivalent to 10 mg, were individually filled into hard gelatin capsules. The release study used the USP dissolution apparatus II-paddle at 37 ± 0.5 °C (Electrolab India, India) in pH 4.5 acetate buffer as the dissolution medium, stirring at 50 rpm. At various time intervals, 2 ml of sample aliquot was withdrawn (instantly filtered), and fresh medium was added to maintain sink conditions. After appropriate dilution with pH 4.5 acetate buffer, samples were analysed at 237 nm using a UV spectrophotometer [39]. The experiments were repeated three times to ensure consistent and accurate results.

Ex vivo permeability profile

The ex vivo permeation method was applied, as described by Singh et al. [40]. In summary, the ex vivo permeation method involved utilizing the biological membrane from the porcine small intestine acquired from a local slaughterhouse in Srinagar Garhwal, Uttarakhand, India. The intestine, obtained within one hour of slaughter, was preserved in Kreb's ringer phosphate solution at 4 °C with aeration. A 10–12-cm section of the intestine was dissected, washed with saline, and placed on saline-soaked filter paper. After making a lengthwise cut to flatten it, the serosal membrane faced upward, and the muscle layer was removed using a scalpel. For the permeation study, the intestine member was mounted in a modified Franz diffusion cell with the mucosal layer facing the donor compartment side. A pH 4.5 acetate buffer in the receptor compartment served as the receptor medium, maintained at 37 ± 0.5 °C and stirred at 50 rpm. The donor compartment received pure NIM/NIM-SNEDDS/NIM-SD-SSNEDDS/NIM-SE-SSNEDDS (equivalent to 5 mg of NIM) on the mucosal side of the membrane. At various time intervals, a 1 ml sample was withdrawn and replaced with a fresh 1 ml pH 4.5 acetate buffer in the receptor compartment. The samples were analysed at 237 nm using a UV spectrophotometer after appropriate dilution to determine the amount of NIM diffused through the membrane. The experiments were repeated three times to ensure a consistent and accurate average value.

Stability study

The HDPE bottles (60 ml) containing 40 capsules of each NIM-SD-SSNEDSS and NIM-SE-SSNEDDS (each capsule equivalent to 20 mg of nimodipine) were subjected to accelerated conditions (40 ± 2 °C/75 ± 5% RH) in a stability (humidity) chamber (Newtronic, India) for six months post-sealing. Throughout this period, samples were periodically withdrawn and examined for physical appearance, percentage cumulative drug release (% CDR), and disintegration time [41].

Results

Drug solubility analysis in different excipients

Formulations often encounter the challenge of precipitation before undergoing in situ solubilization. Hence, to verify the stability of the formulation, understanding the drug's solubility in the chosen excipients becomes crucial. High

drug solubility in various formulation excipients is essential for achieving optimal drug loading and bioavailability [42]. For the development of an effective SNEDDS for NIM, it is essential that the drug readily mixes with the selected excipients, minimizing its incorporation into the mixture [43]. Figure 1 illustrates the solubility of NIM in different excipients.

Fig. 1 [Images not available. See PDF.]

Solubility of nimodipine in different excipients (mg/ml)

To achieve effective self-emulsification, it is essential to have the optimal combination of excipients. Analysis of the self-emulsification potential demonstrated that Lipoxol 300, combined with the highest quantity of Cremophor RH 40, resulted in successful emulsification, as illustrated in Fig. 2.

Fig. 2 [Images not available. See PDF.]

Self-emulsification of oils with surfactants ($n=3$)

Upon perceiving this finding, Cremophor RH 40 and Lipoxol 300 were chosen as the oil and surfactant, respectively. Polyethylene glycol 400 (PEG 400) was selected as the co-surfactant based on the broader range of nanoemulsion regions observed compared to propylene glycol (PG), as depicted in Table 1.

Table 1. Nanoemulsion region formation (Smix with different co-surfactants)

Composition		Nanoemulsion region	
Oil (%)	S_{mix} (%)	S_{mix} of Lipoxol 300: PEG 400 (1:1)	S_{mix} of Lipoxol 300: PG (1:1)
10	90	Yes	Yes
20	80	Yes	Yes
30	70	Yes	Yes
40	60	Yes	Yes
50	50	Yes	No
60	40	No	No
70	30	No	No
80	20	No	No
90	10	No	No

PEG 400 polyethylene glycol 400, *PG* propylene glycol

Increased surfactant levels can boost the self-emulsification process. Including a co-surfactant, such as PEG 400, does not compromise the surfactant's ability to decrease interfacial tension around the oily component. Utilizing a co-surfactant allows for a reduction in the overall amount of surfactant in the formulation [44]. In this specific formulation, PEG 400 serves as the co-surfactant.

Plotting of ternary phase diagram

In order to select the right proportion of excipients for self-nanoemulsifying drug delivery systems (SNEDDS) and observe self-emulsification in the nano-range, a ternary phase diagram was constructed with the inclusion of NIM. This diagram aids in comprehending the phase behaviour of nanoemulsions [45].

The water-titration method was employed to create a diagram, incorporating an oily vehicle ranging from 10 to 90% and varying Smix ratios (1:1, 1:2, and 2:1). Transparent regions, indicating nanoemulsion areas were identified, and ternary diagrams were constructed using this information, specifically for three Smix ratios (1:1, 1:2, and 2:1). The shaded portions in Fig. 3a–c represent the transparent nanoemulsion regions with low viscosity. In diagrams, each peak denotes 100% of the corresponding excipient.

Fig. 3 [Images not available. See PDF.]

Pseudo ternary phase diagrams **A** with Smix 1:2, **B** with Smix 2:1, and **C** with Smix 1:1

According to Fig. 3a (for oil and Smix 1:2), when the oil content is less and PEG 400 is more, the shaded nanoemulsion region is observed, and when the oil content is increased and PEG 400 is reduced, the biphasic system can be seen. In the case of Smix 2:1 with oil, the increase in Lipoxol 300 gives a greater nanoemulsion area (in Fig. 3b). As per Fig. 3c, (oil and Smix 1:1) the 30–50% of Cremophor RH 40, and less percentage of Smix is resulting in a nanoemulsion region. When PEG 400 increases, the nanoemulsion region is reduced because of the limited capability of PEG 400 to the interfacial tension. At the same time, Lipoxol 300 has a greater effect of reducing the interfacial tension by making a layer around the oil droplets. The Smix ratio of 1:1, serving as a surfactant/co-surfactant mixture, was identified as suitable.

Development of self-nanoemulsifying drug delivery system and fabrication of SNEDDS to solid self-nanoemulsifying drug delivery system

Based on the findings from the two studies of the ternary phase diagram (Fig. 3c) and nanoemulsion region formation (Table 1), it was clear that a 40:60 ratio of oil (Cremophor RH 40) to Smix (Lipoxol 300: PEG 400 = 1:1; serving as a surfactant/co-surfactant mixture), was producing nanoemulsion. This 40:60 ratio had a significant amount of oil (part), which remains essential for maximum drug solubilization and high drug loading into the formulation. Hence, this was chosen for the development of the SNEDDS development. Following the outlined procedure, the liquid NIM-SNEDDS was created and stored in an airtight container. The ultimate composition of NIM-SNEDDS consisted of 100 mg of NIM, 400 mg of Cremophor RH 40, 300 mg of Lipoxol 300, and 300 mg of PEG 400. The microparticles created through spray drying (SD-CHEM) and the chitosan EDTA microparticles using the solvent evaporation method (SE-CHEM) showcased their capabilities with high oil adsorption and desorption capacities. These microparticles also demonstrated favourable enhancements in surface free energy components and dynamic advancing contact angles. The solid self-nanoemulsifying drug delivery systems (S-SNEDDS) were independently formulated for both SD-CHEM and SE-CHEM through an adsorption or solid carrier technique. Among the two ratios of adsorbate (NIM-SNEDDS) to adsorbent (SD-CHEM), namely 1:1.5 and 1:2.5, the 1:2.5 ratio was identified as yielding a non-sticky, free-flowing powder for NIM-SD-SSNEDDS. For NIM-SE-SSNEDDS, considering two ratios of adsorbate (NIM-SNEDDS) to adsorbent (SE-CHEM), namely 1:2 and 1:2.5, the 1:2.5 ratio was determined to result in a non-sticky, free-flowing powder. This adsorption technique is particularly advantageous for thermolabile drugs as it avoids subjecting the system to heat treatment. The resultant NIM-SD-SSNEDDS, NIM-SE-SSNEDDS, and NIM-SNEDDS (liquid) were subsequently assessed.

Different evaluations of the NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS

Drug loading efficiency (%)

As indicated in Table 2, the drug loading efficiency for NIM-SD-SSNEDDS and NIM-SE-SSNEDDS was found to be 79.67 ± 2.97% and 77.76 ± 4.29%, respectively. As anticipated, the drug loading efficiency (%) for NIM-SNEDDS was 82.75 ± 3.56%. Notably, a certain loss in drug loading occurred during the solidification process from NIM-SNEDDS to NIM-SD-SSNEDDS and NIM-SE-SSNEDDS using the adsorption technique.

Table 2. Flow properties, physical characterization, dissolution, and permeation profiles of the formulations

	NIM-SNEDDS	NIM-SD-SSNEDDS	NIM-SE-SSNEDDS
Flow properties			
Bulk density (g/cm^3)	–	0.893±0.209	0.752±0.116
Tapped density (g/cm^3)	–	0.928±0.194	0.861±0.251

Values are presented as mean±standard deviation (S.D.), (n=3)

Flowability

For NIM-SD-SSNEDDS and NIM-SE-SSNEDDS, the resulting flow properties were calculated and are presented in Table 2. The bulk density of NIM-SD-SSNEDDS and NIM-SE-SSNEDDS was 0.893 ± 0.209 g/cm^3 and 0.758 ± 0.116 g/cm^3, indicating the presence of gaps between powder particles, which is crucial in the industry (for efficient capsule filling). The tapped density for NIM-SD-SSNEDDS and NIM-SE-SSNEDDS was 0.928 ± 0.194 g/cm^3 and 0.752 ± 0.116 g/cm^3. The minimal difference between these densities (bulk and tapped), along with Carr's index (NIM-SD-SSNEDDS = 5.119 ± 0.083 and NIM-SE-SSNEDDS = 13.588 ± 0.236), Hausner's ratio (NIM-SD-SSNEDDS = 1.051 ± 0.074 and NIM-SE-SSNEDDS = 1.135 ± 0.071), and angle of repose (NIM-SD-SSNEDDS = 10.752 ± 2.145 and NIM-SE-SSNEDDS = 9.734 ± 1.921), signifies excellent flow properties for the formulations.

Characterization (solid state)

X-ray diffraction analysis

Detecting changes in polymorphism, dissolution rate (solubility), and stability depends on the critical quality attribute of particle crystallinity, as determined by XRD analysis. Figure 4 illustrates the X-ray diffraction (XRD) analysis of NIM, SD-CHEM, SE-CHEM, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS. NIM exhibited diffraction peaks at 2θ values of 12.53°, 13.06°, 17.54°, 19.89°, 20.51°, 25.11°, and 29.43°. These peaks align with the distinctive crystalline pattern of NIM [19]. The SD-CHEM samples exhibited diffraction peaks at 2θ values of 18.51°, 21.41°, 26.61°, and 29.67°. In the SE-CHEM samples, almost indistinct diffraction peaks at 2θ values of 21.2° and 23° were observed, along with significantly broadened peaks at 26.5° and 29.8°. For NIM-SD-SSNEDDS, diffraction peaks were observed at 2θ values of 18.11°, 20.9°, 22.69°, 26.18°, and 29.28°. NIM-SE-SSNEDDS displayed diffraction peaks at 2θ values of 18.24°, 22.26°, 26.30°, and 29.36°. The absence of distinctive crystalline peaks of NIM in solid SNEDDS suggests the amorphization of the drug in the formulation. This amorphization, coupled with nanometric sizes and the absence of crystallinity, contributes to the anticipated improved dissolution behaviour in self-nanoemulsifying formulations. Importantly, the investigation indicates no signs of NIM precipitation when incorporated into S-SNEDDS.

Fig. 4 [Images not available. See PDF.]

XRD analysis of NIM, SD-CHEM, SE-CHEM, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS

Scanning electron microscopy

To comprehend the structure and surface characteristics of the solid formulations, scanning electron microscope (SEM) images of NIM, SD-CHEM, SE-CHEM, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS were captured (as depicted in Fig. 5). In Fig. 5 (a,b), the pure NIM sample is illustrated, and Fig. 5c displays SD-CHEM, exhibiting a spherical shape with uneven surfaces and substantial void spaces, facilitating effective oil adsorption and desorption. Figure 5d showcases SE-CHEM, presenting a flaky appearance with an irregular surface, providing an increased surface area for the adsorption of liquid SNEDDS. Figure 5e depicts NIM-SD-SSNEDDS with a size range of 10–15 µm. The adsorption process with NIM-SNEDDS is evident in these images, as seen by the smoothing of uneven surfaces and void spaces present in SD-CHEM. Likewise, in Fig. 5f, NIM-SE-SSNEDDS exhibits smooth, flaky structures compared to SE-CHEM, with a 20–25 µm size range.

Fig. 5 [Images not available. See PDF.]

FTIR spectroscopy

Figure 6 shows all the FTIR spectra. The absorption bands of 3390.4 cm^{-1}, 3371.4 cm^{-1} and 3391 cm^{-1} confirm the O–H stretching, and the absorption bands 2922.1 cm^{-1}, 2875.3 cm^{-1}, and 2873.5 cm^{-1} correspond to the C–H bonds, the absorption peaks, 1249.5 cm^{-1}, 1249.6 cm^{-1} and 1249.4 cm^{-1} confirms the C–O–C stretching (ether) in Cremophor RH 40, Lipoxol 300 and PEG 400, respectively [46–48]. The absorption peak at 1782.5 cm^{-1} confirms the carbonyl group (of ester) in Cremophor RH 40. The absorption bands near 1457 cm^{-1} confirm CH_2 with bending vibrations in Lipoxol 300 and PEG 400, respectively. SE-CHEM and SD-CHEM displayed absorption bands within the range of 1676–1657 cm^{-1} and 1693–1667 cm^{-1}, respectively, indicating the presence of the amide linkage.

Additionally, they exhibited absorption bands between 2378 and 2373 cm^{-1}, suggesting the presence of free acetate moieties. This implies that not all acetate moieties are engaged in the amide linkage. The FTIR spectra of NIM showed all the fingerprint bands of it [49]. The absorption band at 3295.2 cm^{-1} confirms the presence of primary and secondary amines, indicated by N–H stretching vibrations. The absorption band within the 2967.4–2879.5 cm^{-1} range corresponds to alkyl groups, specifically C–H stretching vibrations. The absorption band at 1693.4 cm^{-1} confirms the presence of the ester group, as indicated by C=O stretching vibration. Furthermore, 1645 cm^{-1} and 1620 cm^{-1} absorption bands confirm C=C stretching and C=C aromatic functionalities. Additionally, absorption bands at 1521.4 cm^{-1}, 1381.9 cm^{-1}, and 1133.2 cm^{-1} are attributed to $–NO_2$, $–C–CH_3$, and –C–O– ester, respectively.
Fig. 6 [Images not available. See PDF.]

FTIR spectra of **A** Cremophor RH 40, **B** Lipoxol 300, **C** PEG 400, **D** NIM-SNEDDS, **E** NIM-SD-SSNEDDS, **F** NIM-SE-SSNEDDS, **G** NIM, **H** SD-CHEM, and **I** SE-CHEM

In the spectra of NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS, no notable changes were observed concerning the characteristic peaks of NIM. In the NIM-SNEDDS spectra, absorptions were detected at 3440.5 cm^{-1}, 3085.6 cm^{-1}, 2871.2 cm^{-1}, 1647.1 cm^{-1}, 1460 cm^{-1}, and 1108.9 cm^{-1}. The NIM-SD-SSNEDDS spectra exhibited absorptions at 3392.6 cm^{-1}, 2919 cm^{-1}, 2853.5 cm^{-1}, 1629.3 cm^{-1}, 1472 cm^{-1}, and 1106.7 cm^{-1}. Similarly, the NIM-SE-SSNEDDS spectra displayed absorptions at 3424.1 cm^{-1}, 2923.3 cm^{-1}, 1629.3 cm^{-1}, 1459.6 cm^{-1}, and 1107 cm^{-1}. Some peaks exhibited broadening and negligible shifts, potentially attributed to hydrogen bonding between the drug and surfactants [19]. The occurrence of hydrogen bonding could lead to shifts in wavelengths, reducing intensities, or even causing peaks to disappear [50].

DSC analysis

DSC analysis was employed to detect potential polymorphic changes induced by the interaction between the drug and excipients. The thermograms of NIM, NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS were obtained and are presented in Fig. 7. The characteristic endothermic peak of NIM, signifying its crystallinity, was observed at 128 °C [51]. In NIM-SNEDDS and NIM-SD-SSNEDDS, this endothermic peak disappeared, while in NIM-SE-SSNEDDS, a broad peak near 128 °C was observed. The disappearance of the characteristic endothermic peak indicates that the NIM is in amorphous form in formulations.

Reconstituted nanoemulsion and NIM-SNEDDS evaluations

Droplet size, size distribution, and zeta potential determination

Determining droplet size is crucial in assessing the self-nanoemulsification characteristics of the system, as it influences drug release and absorption. Smaller droplet sizes in the nanometric range provide a larger interfacial surface area, facilitating better drug absorption. In Table 2, the droplet sizes (and polydispersibility index-PDI) of NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS are 245.5 nm (PDI–0.715), 247.1 nm (PDI–0.620), and 399.6 nm (PDI–0.821). The results show that the droplet size of NIM-SD-SSNEDDS is comparable to NIM-SNEDDS, while NIM-SE-SSNEDDS exhibits a significant difference. PDI values for all formulations are closely aligned. Thus, SD-CHEM and SE-CHEM surfaces exhibit small droplet sizes and similar PDI. SD-CHEM (NIM-SD-SSNEDDS), as an adsorbent, outperforms SE-CHEM in producing small droplets and PDI. The zeta potential results for NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS are 1.961 mV, 1.353 mV, and 1.351 mV, respectively.

Self-emulsification time

The emulsification times for NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS were recorded as 24–36, 38–41, and 40–48 s, respectively, as outlined in Table 2. This indicates that all systems possess the capability to disperse swiftly in aqueous conditions with agitation.

Per cent transmittance test

The outcomes of per cent transmittance for NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS, as

depicted in Table 2, exceeded 90%, substantiating the effectiveness of self-emulsification. This transparency further validates the stability of the reconstituted nanoemulsion and eliminates the risk of drug precipitation [52].

Estimation of cloud point

The cloud point temperature signifies the temperature at which the clear appearance of the SNEDDS transforms into a cloudy or turbid state, indicating a change in phase behaviour. This temperature should ideally be higher than the anticipated usage temperature, typically 37 °C. In the case of NIM-SNEDDS, NIM-SD-SSNEDSS, and NIM-SE-SSNEDDS, all recorded cloud point temperatures were above 37 °C, affirming their thermodynamic stability [53].

Field emission scanning electron microscopy

The FE-SEM images in Fig. 8a–c illustrate the reconstituted NIM-SD-SSNEDDS, while Fig. 8d–f displays NIM-SE-SSNEDDS, both captured at various magnifications. The images clearly depict that the reconstituted globules from both solid SNEDDS forms were spherical. Additionally, these images corroborate with the sizes analysed through Zetasizer, as indicated in Table 2. The globules formed exhibited fine sizes, and there was no coalescence evidence, implying the reconstituted nanoemulsions' stability.

Fig. 8 [Images not available. See PDF.]

FE-SEM images (at different magnifications) **A**, **B,** and **C** reconstituted nanoemulsion NIM-SD-SSNEDDS, **C** and **D** reconstituted nanoemulsion NIM-SE-SSNEDDS

Dissolution profile (in vitro)

The in vitro dissolution test investigated the release of pure NIM, NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS, with the per cent cumulative drug release (% CDR) graph displayed in Fig. 9. In six hours, the % CDR for pure NIM, NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS was 28%, 88.84%, 84.43%, and 76.68%, respectively. Notably, there was a significant increase in drug dissolution for NIM in both NIM-SD-SNEDDS and NIM-SE-SSNEDDS compared to pure NIM. This study has revealed the improvement of dissolution of the drug after formulating into the SNEDDS and S-SNEDDS, this must be due to the loading of the drug into the micelles of the SNEDDS [54].

Fig. 9 [Images not available. See PDF.]

Dissolution profile (% cumulative drug release) of **A** NIM **B** NIM-SE-SSNEDDS, **C** NIM-SD-SSNEDDS, and **D** NIM-SNEDDS

Ex vivo permeability profile

This investigation assessed drug permeability through a biological membrane as a diffusion barrier. A comparative analysis was conducted for pure NIM, NIM-SNEDDS, reconstituted NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS. Figure 10 presents the cumulative amount permeated per cm^2, while Fig. 11 illustrates the flux and permeability constant. Flux, represented as the drug permeated per unit area per unit time ($\mu g/min/cm^2$) $\times 10^{-2}$ (slope of the permeability curve), and permeability constant, defining the ease of drug diffusion from the permeable membrane (flux/drug conc.), were evaluated. The results indicated that the cumulative drug permeability (%) for NIM, NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS was 2.93, 25.02, 22.6, and 21.9, respectively. In Fig. 11, higher values of both flux and permeability constant of NIM-SNEDDS, NIM-SD-SSNEDDS, and NIM-SE-SSNEDDS as compared to NIM, indicated the enhancement in permeation across the biological membrane and facilitation of the drug across the membrane by SNEDDS and S-SNEDDS, respectively.

Ex vivo permeation profile of **A** NIM **B** NIM-SE-SSNEDDS, **C** NIM-SD-SSNEDDS, and **D** NIM-SNEDDS

Fig. 11 [Images not available. See PDF.]

Ex vivo permeation parameters of NIM, NIM-SE-SSNEDDS, NIM-SD-SSNEDDS, and NIM-SNEDDS. Flux refers to the quantity of drug that permeates a diffusion barrier per unit area and time, expressed as micrograms per minute

per square centimetre (μg/min/cm^2) × 10^{-2} (the slope of the permeability curve). The permeability constant is calculated as the ratio of flux to drug concentration

Stability study

The summarized results of the stability study are presented in Table 3. Analysis of the data reveals that both formulations, NIM-SD-SSNEDDS and NIM-SE-SSNEDDS, remained stable throughout the six-month accelerated stability testing at 40 ± 2 °C/75 ± 5% RH. Therefore, it can be concluded that both NIM-SD-SSNEDDS and NIM-SE-SSNEDDS successfully passed the stability assessment.

Discussion

Because of the number of advantages of solid SNEDDS over SNEDDS, this study aimed to formulate solid self-nanoemulsifying drug delivery systems (S-SNEDDS) for nimodipine (NIM). NIM used as a model drug remains a suitable candidate for SNEDDS due to low hydrophilicity and high lipophilicity. Cremophor RH 40, Lipoxol 300, and PEG 400 were chosen after checking how well they dissolve and form emulsions. A ternary phase diagram determined the optimal oil to Smix (surfactant/co-surfactant) ratio (40:60). The liquid NIM-SNEDDS was used as the material to adsorb on microparticles synthesized from chitosan EDTA by spray drying (SD-CHEM) and solvent evaporation (SE-CHEM) as the absorbents to make solid SNEDDS. Both solid forms had good drug loading (NIM-SD-SSNEDDS = 79.67 ± 2.97%, NIM-SE-SSNEDDS = 77.76 ± 4.29%) and excellent flow properties. XRD analysis revealed drug amorphization as the characteristic diffraction peaks were absent; this offers a great advantage in improvement of drug dissolution.

SEM images revealed smoothening and filling of adsorbent surfaces by adsorbate. For NIM-SD-SSNEDDS, the size was 10–15 μm, and for NIM-SE-SSNEDDS, it was 20–25 μm. The SEM images provide visual evidence of the effective adsorption behaviour of microparticles, validating the excellent adsorption of liquid SNEDDS for both SD-CHEM and SE-CHEM.

FTIR confirmed no interaction of drug and excipients with the broadening of some characteristic drug peaks in the solid formulations because of the hydrogen bonding with surfactants. DSC analysis also confirmed the amorphization of the drug with the disappearance of the characteristic crystalline peaks of NIM.

Stability assessments confirmed the physical and thermodynamic robustness of reconstituted nanoemulsions, considering parameters such as droplet size, polydispersity index (PDI), zeta potential, emulsification time, per cent transmittance, and cloud temperature. For NIM-SD-SSNEDDS, these values were observed as follows: droplet size of 247.1 nm, PDI of 0.620, zeta potential of 1.353 mV, emulsification time ranging from 38 to 41 s, per cent transmittance of 94.64%, and a cloud temperature of 54 °C. On the other hand, for NIM-SE-SSNEDDS, the corresponding values were 399.6 nm, PDI 0.821, zeta potential 1.351 mV, emulsification time ranging from 40 to 48 s, per cent transmittance of 92.96%, and a cloud temperature of 49 °C. These findings suggest that solid SNEDDS closely resemble liquid SNEDDS, indicating the stability of the reconstituted nanoemulsion.

FE-SEM images displayed the formation of droplets characterized by small sizes, with no observable evidence of coalescence, suggesting the stability of the reconstituted nanoemulsions. In vitro dissolution studies indicated a notable fourfold enhancement in drug dissolution for NIM-SD-SSNEDDS (84.43%) and NIM-SE-SSNEDDS (76.68%) when contrasted with the pure drug (28%). The ultimate drug release from liquid SNEDDS and solid SNEDDS exhibited similar patterns, demonstrating comparable release profiles. Ex vivo permeation studies revealed nearly identical profiles for NIM-SD-SSNEDDS (22.61%) and NIM-SE-SSNEDDS (21.93%) when compared to NIM-SNEDDS (25.02%). Stability study of both NIM-SD-SSNEDDS and NIM-SE-SSNEDDS confirmed that the preparations were stable for six months of accelerated stability study. Notably, NIM-SD-SSNEDDS demonstrated superior performance compared to NIM-SE-SSNEDDS, emphasizing the effectiveness of microparticles developed through the spray drying method (SD-CHEM) as adsorbents for solidification. These findings suggest that NIM-SD-SSNEDDS and NIM-SE-SSNEDDS can generate nanosized droplets in nanoemulsion containing the drug, facilitating successful drug diffusion across the biological membrane. These findings indicate improved dissolution and permeation for nimodipine in both solid SNEDDS formulations.

Conclusion

This study aimed to develop effective solid self-nanoemulsifying drug delivery systems (SNEDDS) for nimodipine with Cremophor RH 40, Lipoxol 300, and PEG 400 as the oil, surfactant, and co-surfactant. SNEDDS was formulated with an oil to Smix (surfactant/co-surfactant) ratio of 40:60, determined through a ternary phase diagram. Solid SNEDDS were created using previously developed microparticles (SD-CHEM and SE-CHEM) as adsorbents for NIM-SD-SSNEDDS and NIM-SE-SSNEDDS, respectively, with NIM-SNEDDS as an adsorbate for both. The final adsorbate (liquid NIM-SNEDDS): adsorbent ratio for NIM-SD-SSNEDDS and NIM-SE-SSNEDDS was 1:2.5. Both

formulations exhibited favourable drug loading and flow properties. XRD analysis confirmed drug amorphization in both formulations, and SEM images verified uniform adsorption of liquid SNEDDS over solid microparticles. FTIR analysis indicated no interactions between excipients, while DSC analysis revealed the amorphous form of the drug in both solid SNEDDS. Both formulations showed nanometric globule sizes with minimal polydispersity indices. Stability studies and FE-SEM images confirmed reconstituted nanoemulsions' physical and thermodynamic stability. In vitro dissolution studies demonstrated nearly a fourfold increase in drug dissolution compared to pure drug. Both in vitro and ex vivo permeation studies revealed similar dissolution and permeation profiles for NIM-SD-SSNEDDS and NIM-SE-SSNEDDS compared to NIM-SNEDDS. Notably, NIM-SD-SSNEDDS outperformed NIM-SE-SSNEDDS, indicating the superior performance of microparticles developed by the spray drying method (SD-CHEM) as adsorbents for solidification. Enhanced dissolution and permeation for nimodipine in solid SNEDDS were achieved. Both the formulation systems have proved their efficacy as S-SNEDDS, and the chitosan EDTA microparticle developed by spray drying and solvent evaporation can be utilized in future studies of different drugs SNEDDS to fabricate solid SNEDDS.

ABSTRACT (ENGLISH)

Background

The Analytical Quality by Design (AQbD) methodology extends the application of Quality by Design (QbD) principles to the management of the analytical procedure life cycle, encompassing method creation, optimization, validation, and continuous improvement. AQbD assists in creating analytical procedures that are robust, reliable, precise, and cost-efficient. Opdualag™ is a combination of Nivolumab and Relatlimab, which are antibodies that block programmed death receptor-1 (PD-1) and lymphocyte-activation gene 3 (LAG-3) receptors, used to treat advanced melanoma. This work aims to develop and validate a reversed-phase ultra-performance liquid chromatography (RP-UPLC) method using AQbD principles to determine NLB and RTB in pharmaceutical products.

Results

A central composite design (CCD) comprising three factors arranged in five distinct levels was implemented via Design-expert® software to optimize the chromatographic conditions. A mathematical model was constructed and the effects of three independent factors namely flow rate (X_1), percentage of methanol in the mobile phase (X_2), and temperature (X_3) on responses including retention time ($Y_{1–2}$), resolution factor (Y_3), theoretical plates ($Y_{4–5}$), and tailing factor ($Y_{6–7}$) were investigated. The software determined the optimal chromatographic conditions for the separation of NLB and RTB, which were as follows: 32.80% methanol in the mobile phase, 0.272 mL/min flow rate, 29.42 °C column temperature, and 260 nm UV detection. The retention time for NLB and RTB were 1.46 and 1.88 min, respectively. The method exhibited linearity across the concentration ranges of 4–24 µg/mL for RTB and 12–72 µg/mL for NLB. The limits of detection (LOD) and limit of quantification (LOQ) for NLB and RTB, respectively,

were 0.89 µg/mL, 2.69 µg/mL and 0.15 µg/mL and 0.46 µg/mL. The percentage relative standard deviation (%RSD) of intraday and interday precision for NLB and RTB was below 2. The recovery percentages for NLB and RTB were determined to be 99.57–100.43% and 99.59–100.61%, respectively. Both drugs were found to be susceptible to oxidative and photolytic degradation in forced degradation studies.

Conclusions

Employing the AQbD-based methodology, a straightforward, fast, accurate, precise, specific, and stability-indicating RP-UPLC method has been established for the quantitative analysis of NLB and its RTB in pharmaceutical formulations.

FULL TEXT

Background

Melanoma is the most aggressive form of skin cancer that develops from melanocytes, the skin pigment-producing cells. Although melanoma only makes up a small fraction of skin malignancies (approximately 1–2%), it is the leading cause of skin cancer-related mortality. The 5-years survival rate for melanoma is 94% when detected early, but it drops dramatically after the cancer has spread to other parts of the body. Melanoma that has progressed beyond its initial skin location to other organs, lymph nodes, or distant tissues is known as metastatic melanoma. Surgical procedures, radiation treatments, chemo, immunotherapy, and targeted therapies are all viable treatment choices [1, 2].

Among all, treatment with immunotherapy drugs such as immune checkpoint inhibitors and interleukin-2 significantly improved the outcome in patients by boosting the body's immune response to selectively target and destroy cancer cells [3]. Recently (March 18, 2022), the United States Food and Drug Administration (FDA) approved a fixed dose combination of two immunotherapy antibodies Nivolumab and Relatlimab (Opdualag™) for adults and paediatric patients (12 years or above) with unresectable and metastatic melanoma [4] (Fig. 1). Both drugs are immune checkpoint inhibitors and act by restoring the T cell's natural ability to target cancer cells by suppressing immune checkpoint proteins, which prevent excessive immune responses. Nivolumab blocks programmed cell death protein 1 (PD-1) in immune cells (T cells) and is widely used to treat melanoma and other cancers. Relatlimab blocks Lymphocyte-activation gene 3 (LAG-3) in immune cells and restores the effector function of exhausted T cells [5]. This combination therapy results in longer progression-free survival and fewer side effects in patients when compared to Nivolumab plus Iipilimumab and Nivolumab alone [6–8]. Opdualag™ is available as an intravenous injection containing 240 mg of NLB and 80 mg of RTB in 20 mL clear to opalescent, colorless to slightly yellow solution in a single-dose vial. Nevertheless, it is not included in any of the official pharmacopoeial monographs. Hence it is of utmost importance to develop an analytical method for estimation of NLB and RTB in commercially available formulations.

Fig. 1 [Images not available. See PDF.]

Structure of Nivolumab (**A**) and Relatlimab (**B**)

The analytical Quality by Design (AQbD) approach is an extension of the quality by design (QbD) concept, used in the pharmaceutical industry to ensure the quality of analytical methods. This approach emphasizes a thorough understanding of the method's critical parameters and their impact on the analytical results, leading to more efficient and effective analytical development and validation processes. AQbD helps in the identification and optimization of significant factors, and their interaction effect and provides appropriate chromatographic conditions for the estimation of analyte. A central composite design is the most predominant experimental design used in response surface methodology for the optimization of chromatographic conditions. These designs provide a great deal of information with a minimum number of experimental trials and are very cost effective [9–11].

The literature study revealed that there are limited analytical methods available for the determination of NLB alone and in combination with different drugs in plasma and pharmaceutical dosage forms. These methods include RP-UPLC [12], LC–MS/MS [13], ELISA [14], LC–MS/HRMS [15], UPLC-MS/MS [16], and the UHPLC/UV-

(HESI/Orbitrap™) MS approach [17]. An RP-UPLC approach was developed to simultaneously determine NLB and RTB in Opdualag™ formulations [18]. However, no analytical method has been reported for the estimation of NLB and RTB using AQbD principles.

The current work focused on the development and optimization of an RP-UPLC method using AQbD principles (central composite design) for the estimation of NLB and RTB in pharmaceutical products.

Methods

Chemicals

Reference standards of NLB (purity 99.80%), and RTB (purity 99.80%) were obtained from Akrivis Pharma Private Limited, Hyderabad. Fisher Scientific (Mumbai, India) provided HPLC-grade methanol and acetic acid. The ultrapure water was acquired from the Millipore Direct-Q®3 UV water purification equipment by Merck Millipore in India. All remaining reagents and chemicals met analytical grade standards.

Instrumentation and chromatographic conditions

The method was developed using a Waters Acquity UPLC system H-class equipped with binary pumps, a tunable UV (TUV) detector, and an autosampler. The Empower 2 software was used for data acquisition and processing. A BEH C18 column (50 × 2.5 mm i.d. particle size of 1.7 µm) was used to accomplish the chromatographic separation. The mobile phase is made up of 32.8:67.2% v/v methanol and 0.01 N phosphate buffer, which is pumped at a flow rate of 0.27 mL/min. The temperature of the column was kept at 29.4 °C, and 260 nm was used for detection. The overall chromatographic run time was 3 min and the injection volume was 5 µL. A 50/50 v/v mixture of methanol and water was utilized as the diluent.

Preparation of standard stock solutions

NLB (24 mg) and RTB (8 mg) were accurately weighed and transferred to a 50 mL clean dry volumetric flask. Add 10 mL of diluent and sonicate for 10 min to completely dissolve them. The volume was increased to 50 mL with diluent to achieve concentrations of 480 µg/mL for NLB and 160 µg/mL for RTB. To create working standard solutions, aliquots of each stock solution were diluted with the diluent to achieve concentrations of 12, 24, 36, 48, 60, and 72 µg/mL for NLB and 4, 8, 12, 16, 20, and 24 µg/mL for RTB.

Preparation of sample solution

Transfer 20 mL of Opdualag™ solution (240 mg NLB and 80 mg RTB) to a 100 mL volumetric flask. Add 50 mL of diluent and sonicate for 25 min. The volume was increased to 100 mL with diluent to achieve concentrations of 2400 µg/mL of NLB and 800 µg/mL of RTB. To acquire the final concentrations of NLB (18 µg/mL) and RTB (16 µg/mL), 0.2 mL of the aforesaid solutions was diluted to 10 mL. The resulting solution was utilized for the assay of NLB and RTB in its marketed formulation.

Method optimization by experimental design

The developed method's chromatographic conditions were optimized using Design-expert® software (Version 11.1.0.1, Stat-Ease Inc., USA) employing a central composite design (CCD) with three factors at five levels (−α, −1, 0, +1, and +α). The mobile phase was chosen based on preliminary investigation using methanol and 0.01N phosphate buffer. The three independent variables chosen were flow rate (X_1),% methanol (X_2), and temperature (X_3), while the dependent variables were retention time of NLB (Y_1), retention time of RTB (Y_2), resolution factor (Y_3), number of theoretical plates of NLB (Y_4), number of theoretical plates of RTB (Y_5), tailing factor of NLB (Y_6), and tailing factor of RTB (Y_7) (Table 1). The Design expert® program proposed twenty runs based on the central composite design. All experiments employed a standard concentration of 48 µg/mL of NLB and 16 µg/mL of RTB.

Table 1. Variables and their levels used in central composite design

Name	−α	−1	0	+1	+α
Independent variables					

X_1: Flow rate (mL/min)	0.2495	0.27	0.30	0.33	0.3505
X_2: % methanol (v/v)	26.59	30.00	35.00	40.00	43.41
X_3: Temperature (°C)	24.95	27.00	30.00	33.00	35.05
Dependent variables					
Y_1: Retention time of NLB					
Y_2: Retention time of RTB					
Y_3: Resolution factor					
Y_4: Number of theoretical plates of NLB					
Y_5: Number of theoretical plates of RTB					
Y_6: Tailing factor of NLB					
Y_7: Tailing factor of RTB					

Method validation

Following ICH Q2 (R1) criteria, the developed RP-UPLC method was validated for system suitability, linearity, LOD, LOQ, precision, accuracy, and robustness [19]. System suitability testing involves injecting six replicates of NLB (48 µg/mL) and RTB (16 µg/mL) standard solutions, evaluating their theoretical plates, tailing factor, resolution, % RSD of retention time and peak area. The linearity of the method was verified by plotting the calibration curve of peak area against concentration for six concentrations of NLB (12–72 µg/mL) and RTB (4–24 µg/mL) working standard solutions. LOD and LOQ were determined using the standard deviation (σ) and slope (S) of the calibration curve: $LOD = 3.3 \times \sigma/S$ and $LOQ = 10 \times \sigma/S$. The method's precision was confirmed by intra-day and inter-day variance investigations. Three concentrations of NLB (12, 36, and 72 µg/mL) and RTB (4, 12, and 24 µg/mL) were tested three times per day for intra-day precision (repeatability), whereas three concentrations on three different days were assessed for inter-day accuracy (intermediate precision). Accuracy was assessed by computing the mean percentage recovery of NLB and RTB standard solutions spiked at different concentration levels (50, 100, and 150%) to the pre-analyzed NLB and RTB samples. The method's specificity was verified by comparing the representative chromatograms of the blank, placebo, and NLB/RTB standard solutions. Robustness was evaluated by purposefully modifying the ideal chromatographic parameters, including flow rate (0.1 and 0.3 mL), methanol percentage (±5% in mobile phase), and column temperature (±5 °C).

Sample solution stability

The stability of the NLB and RTB in the solution was determined by keeping the samples in a volumetric flask at normal ambient laboratory conditions for a period of 24 h. After 24 h, the retention time and peak area of the NLB and RTB were calculated and compared against the initial readings.

Forced degradation studies

Forced degradation studies of NLB and RTB were carried out in various stress conditions. The NLB and RTB solutions were exposed to acid (2N HCl, 60 °C for 30 min), alkaline (2N NaOH, 60 °C for 30 min), dry heat (105 °C for 6 h), oxidizing (60% H_2O_2 60 °C for 30 min), neutral (water at 60 °C for 6 h) and photolytic (UV light for 7 days)

degradation. Following the exposure, the resultant solutions were diluted to obtain 18 µg/mL of NLB and 16 µg/mL of RTB. Five microliters of each solution were then injected into the system, and chromatograms were recorded to evaluate the sample's stability.

Statistical analysis

Data were reported as mean ± SD. The regression coefficient, mean, SD, and % RSD were calculated in Excel. Model and model term significance was determined using Analysis of variance (ANOVA). Model and model terms were significant if the *p*-value was less than 0.05.

Results

Method development studies

The development of the LC method involves the use of complex mobile phases with various solvents (acetonitrile, methanol, ethanol, water and phosphate buffer at a specific pH), different modes of flow (isocratic/gradient), different columns (C_{18}, and C_8) and temperature settings for the separation of compounds. The preliminary trials suggested the use of methanol and 0.01N phosphate buffer as suitable mobile phase for the separation of NLB and RTB with excellent peak shape, shorter retention time and less tailing.

Method optimization by experimental design

The present study employed a central composite design with 20 trials to examine the effect of three independent variables on seven dependent variables. The independent variables include flow rate (X_1), % methanol (X_2), and temperature (X_3). The dependent variables are retention time of NLB (Y_1), retention time of RTB (Y_2), resolution factor (Y_3), number of theoretical plates of NLB (Y_4), number of theoretical plates of RTB (Y_5), tailing factor of NLB (Y_6), and tailing factor of RTB (Y_7). The results are summarized in Table 2. The impact of the independent variables on each dependent variable was examined by fitting the collected responses to different mathematical models and then generating second-order polynomial equations. Analyzing the model and its terms using analysis of variance (ANOVA) allowed us to establish their statistical significance. To better understand the relationship between the dependent and independent variables, 3D-response surface plots and 2D-contour plots were generated. Finally, the numerical optimization technique was used to predict the optimal chromatographic conditions based on the given acceptance criteria.

Fitting of responses to the model

The best-fit model was determined by fitting the observed responses from all 20 runs to each of the mathematical models using the Design-Expert program. All models' values of SD, correlation coefficient (R^2), adjusted and predicted R^2s, coefficient of variation (CV), and predicted residual sums of squares (PRESS) are displayed in Table 3. High R^2 values, low SD, CV, and PRESS, and close proximity between adjusted and predicted R^2 values were the criteria for selecting the best-fitting model across all responses. For all the responses, (Y_1–Y_7), the quadratic model was found to be the best fit.

Table 3. Regression analysis for different responses Y_1 to Y_7 for fitting to different polynomial models

Effect of independent variables on the Retention time of NLB (Y_1)

The following quadratic equation describes the relationship between the independent variables and the retention time of NLB (Y_1).

1

Y1RetentiontimeofNLB=1.33-0.15X1-0.03X2-0.16X3+0.002X1X2-0.0005X1X3-0.042X2X3+0.0035X12-0.0004X22+0.03X32

The equation shows a negative relationship between the flow rate (X_1), percentage of methanol (X_2), and temperature (X_3) with the retention time of NLB. This indicates that when the flow rate, methanol percentage, and temperature increase, the retention time decreases. The high coefficient value of X_3 indicates that, among the three variables, temperature has the most impact on the retention time of NLB. The combined interaction terms X_1X_2, X_1X_3 and X_2X_3 have a positive effect on the retention time of NLB. Table 4 shows the results of the ANOVA for the NLB

retention time data. An F-value of 122.69 indicates statistical significance for the model. The likelihood of an F-value this high being caused by random chance is 0.01%. The significance of model terms is indicated by *p*-values below 0.0500. Significant model terms here are X_1, X_2, X_3, X_2X_3, and X_3^2. There is a reasonable match between the predicted R^2 of 0.9289 and the corrected R^2 of 0.9829. The signal-to-noise ratio is a good indicator of adequate precision. Optimal ratios are greater than 4. The obtained ratio of 39.438 suggested an adequate signal. It is possible to navigate the design space using this model. The 3D response surface plots and the associated 2D contour plots in Fig. 2A, B illustrate how independent variables affect the retention time of NLB (Y_1). It was observed from the plots that an increase in flow rate, % methanol, and temperature decreased the retention time.

Table 4. Analysis of variance (ANOVA) test results and adequate precision for various responses

Fig. 2 [Images not available. See PDF.]

The 3D response surface plots (**A**) and the associated 2D contour plots (**B**) illustrating the effect of independent variables on the retention time of NLB (Y_1)

Effect of independent variables on the retention time of RTB (Y_2)

The following quadratic equation can be used to illustrate how the independent variables affect the retention time of RTB (Y_2).

2

Y2RetentiontimeofRTB=1.65-0.22X1-0.053X2-0.16X3-0.038X1X2+0.058X1X3-0.059X2X3+0.083X12-0.008X22+0.077X32

The equation shows that flow rate (X_1), % methanol (X_2), and temperature (X_3) have a negative effect on the RTB retention time. As flow rate, methanol percentage, and temperature increase, the retention time of RTB decreases. The high coefficient value of X_1 shows that flow rate affects RTB retention time more than % methanol and temperature. X_1X_2 and X_2X_3 negatively affect RTB retention time, while X_1X_3 positively affects it. The ANOVA results for the data of the retention time of RTB are demonstrated in Table 4. The F-value of 115.89 indicates the significance of the model. In this case X_1, X_2, X_3, X_1X_2, X_2X_3, X_1^2, and X_3^2 are significant model terms. The predicted R^2 of 0.9278 matches the adjusted R^2 of 0.9820. Precision measures signal-to-noise ratio. A ratio over 4 is ideal. The obtained ratio of 38.524 suggests a good signal. This model can be used to navigate the design space. The 3D response surface plots and 2D contour plots in Fig. 3A, B show how independent variables affect the retention time of RTB. It was observed from the plots that an increase in flow rate, % methanol, and temperature decreased the retention time.

Fig. 3 [Images not available. See PDF.]

The 3D response surface plots (**A**) and the associated 2D contour plots (**B**) illustrating the effect of independent variables on the retention time of RTB (Y_2)

Effect of independent variables on the resolution factor (Y_3)

The quadratic equation below explains how independent factors affect the resolution factor (Y_3).

3

Y3(ResolutionFactor)=3.30-0.34X1-0.42X2-0.21X3+0.012X1X2+0.087X1X3-0.037X2X3+0.049X12-0.074X22+0.119X32

The equation displays that the flow rate (X_1), % methanol (X_2) and temperature (X_3) have a negative effect on the resolution factor. This means that the resolution factor decreases with an increase in the flow rate, % methanol, and

temperature. The high coefficient value of X_2 shows that % methanol affects the resolution factor more than the flow rate and temperature. The combined interaction term X_1X_2, and X_1X_3 has a positive effect and X_2X_3 has a negative effect on the resolution factor. The ANOVA results for the data of the resolution factor are demonstrated in Table 4. The F-value of 135.89 indicates the significant model. Model terms with *p*-values under 0.050 are significant. Here, X_1, X_2, X_3, X_1X_3, X_1^2, X_2^2, and X_3^2 are significant model terms. *p*-values less than 0.0500 indicate model terms are significant. The predicted R^2 0.9618 matches well with the adjusted R^2 0.9846. A precision ratio of 45.170 suggests a good signal. Hence the quadratic model can navigate design space. The 3D response surface plots and 2D contour plots in Fig. 4A, B show how independent variables affect the resolution factor. It was observed from the plots that an increase in flow rate, % methanol, and temperature decreased the resolution factor between NLB and RTB.

Fig. 4 [Images not available. See PDF.]

The 3D response surface plots (**A**) and the associated 2D contour plots (**B**) showing the effect of independent variables on the resolution factor (Y_3)

Effect of independent variables on the number of theoretical plates of NLB (Y_4)

The quadratic equation below explains how independent factors affect the theoretical plate of NLB (Y_4).

4

Y4TheoreticalPlatesofNLB=3426.78-752.09X1+134.39X2-364.95X3-163.68X1X2-211.63X1X3+177.25X2X3-96.57X12+62.60X22+99.56X32

The equation displays that the flow rate (X_1), and temperature (X_3) have a negative effect whereas % methanol (X_2) has a positive effect on the theoretical plates of NLB. This means that the number of theoretical plates of NLB decreases with an increase in the flow rate and temperature and increases with an increase in % methanol. The large coefficient value of X_1 shows that flow rate affects the theoretical plate of NLB more than other variables. The interaction terms X_1X_2 and X_1X_3 negatively affect NLB theoretical plates, while X_2X_3 positively affects them. Table 4 shows the ANOVA findings of the obtained data. The F-value of 125.00 indicates the model is significant. Model terms with *p*-values under 0.05 are significant. In this case X_1, X_2, X_3, X_1X_2, X_1X_3, X_2X_3, X_1^2, X_2^2, and X_3^2 are important model terms. The predicted R^2 of 0.9833 is in fair agreement with the adjusted R^2 value of 0.9335. Adequate precision measures signal-to-noise ratio. A ratio over 4 is ideal. The obtained ratio of 38.332 suggests a good signal. Hence the quadratic model can be used to navigate the design space. The 3D response surface plots and 2D contour plots in Fig. 5A, B show how independent variables affect the theoretical plates of NLB. It was observed from the plots that an increase in flow rate, and temperature decreased the theoretical plates of NLB whereas an increase in % methanol increased the theoretical plates of NLB.

Fig. 5 [Images not available. See PDF.]

The 3D response surface plots (**A**) and the associated 2D contour plots (**B**) showing the effect of independent variables on the theoretical plates of NLB (Y_4)

Effect of independent variables on the number of theoretical plates of RTB (Y_5)

The following quadratic equation explains how independent variables affect the theoretical plate of RTB.

5

Y5TheoreticalplatesofRTB=4332.06-1131.82X1+203.81X2-675.57X3-39.63X1X2-138.03X1X3+156.45X2X3+46.75X12+138.27X22+27.69X32

The equation shows that flow rate (X_1) and temperature (X_3) negatively affect RTB theoretical plates, whereas % methanol (X_2) positively affects them. This implies that theoretical plates of RTB decrease with flow rate and temperature and increase with % methanol. The flow rate affects the theoretical plates of RTB more than other variables, as shown by the large coefficient value of X_1. The interaction terms X_1X_2 and X_1X_3 negatively affect the theoretical plates of RTB, while X_2X_3 positively affects them. ANOVA findings for obtained data are in Table 4. The model F-value of 730.29 suggests the model is significant. The *p*-values (<0.05) imply X_1, X_2, X_3, X_1X_3, X_2X_3, X_1^2,

and X_2^2 are significant terms. The predicted R^2 of 0.997 is consistent with the adjusted R^2 of 0.9883. The adequate precision ratio of 93.860 indicates a good signal. So, the quadratic model can navigate the design space.
The 3D response surface plots and 2D contour plots in Fig. 6A, B show how independent variables affect the theoretical plates of RTB. It was observed from the plots that an increase in flow rate, and temperature decreased the theoretical plates of RTB whereas an increase in % methanol increased the theoretical plates of RTB.
Fig. 6 [Images not available. See PDF.]

The 3D response surface plots (**A**) and the associated 2D contour plots (**B**) showing the effect of independent variables on the theoretical plates of RTB (Y_5)

Effect of independent variables on the tailing factor of NLB (Y_6)

The following quadratic equation explains how the independent variables affect the tailing factor of NLB.

6

Y6Tailingfactorof;NLB=1.30-0.0419X1+0.0137X2-0.0125X3-0.0175X1X2-0.0575X1X3-0.0125X2X3+0.0081X12+0.0488X22-0.0166X32

According to the equation, the tailing factor of NLB is positively affected by % methanol (X_2) and negatively affected by flow rate (X_1) and temperature (X_3). This means that the tailing factor of NLB decreases with an increase in the flow rate and temperature and increases with an increase in % methanol. A higher coefficient value for X_1 indicates that, relative to other variables, the flow rate significantly affects the tailing factor of NLB. The interaction terms X_1X_2, X_1X_3, and X_2X_3 have a detrimental impact on the tailing factor of NLB. The results of the ANOVA for the collected data are shown in Table 4. An F-value of 128.71 indicates statistical significance for the model. Model terms are considered significant when the *p*-value is less than 0.0500. Here, important model terms include X_1, X_2, X_3, X_1X_2, X_1X_3, X_2X_3, X_1^2, X_2^2, and X_3^3. The predicted R^2 of 0.9837 is reasonably close to the adjusted R^2 of 0.9371. The adequate precision' ratio of 37.845 indicates a good signal. Therefore, the quadratic model serves as a useful tool for exploring the design space. Figure 7A, B show the 3D response surface plots and 2D contour plots, respectively, that illustrate the effect of the independent variables on the NLB tailing factor. It was observed from the plots that an increase in flow rate, and temperature decreased the tailing factor of NLB whereas an increase in % methanol increased the tailing factor of NLB.
Fig. 7 [Images not available. See PDF.]

The 3D response surface plots (**A**) and the associated 2D contour plots (**B**) showing the effect of independent variables on the tailing factor of NLB (Y_6)

Effect of independent variables on the tailing factor of RTB (Y_7)

The impact of the independent variables on the tailing factor of RTB can be elucidated by the subsequent quadratic equation.

7

Y7TailingfactorofRTB=1.28+0.025X1-0.034X2+0.023X3+0.043X1X2+0.028X1X3+0.043X2X3+0.004X12-0.009X22-0.007X32

The equation indicates that the flow rate (X_1) and temperature (X_3) positively influence the tailing factor of RTB, whereas the percentage of methanol (X_2) has a negative impact. This means that the tailing factor of RTB increases with an increase in the flow rate and temperature and decreases with an increase in % methanol. The large coefficient value of X_2 shows that % methanol affects the RTB tailing factor more than other factors. The tailing factor of RTB is positively affected by the combined interaction term X_1X_2, X_1X_3 and X_2X_3. Table 4 displays the ANOVA results for the collected data. An F-value of 136.02 indicates a significant model. Model terms are considered significant when the *p*-value is less than 0.05. X_1, X_2, X_3, X_1X_2, X_1X_3, X_2X_3, X_1^2, X_2^2, and X_3^2 are significant terms in this model. Both the predicted R^2 of 0.9453 and adjusted R^2 of 0.9846 are within reasonable range. The adequate precision' ratio of 50.283 specifies an adequate signal. Hence the quadratic model useful tools for exploring design space. Figure 8A, B shows the 3D response surface plots and their related 2D contour plots that

demonstrate the impact of independent factors on the tailing factor of RTB, respectively. According to the graphs, the tailing factor of RTB increased with increasing temperatures and flow rates, while it reduced with increasing methanol concentrations.

Fig. 8 [Images not available. See PDF.]

Selection of optimized chromatographic condition

To choose the best chromatographic parameters, the Design expert® software's numerical optimization method was employed. The program gave the optimal chromatographic parameters for the separation of NLB and RTB, which included a mobile phase consisting of 32.80% methanol, a flow rate of 0.272 mL/min, a column temperature of 29.42 °C, and ultraviolet detection at 260 nm. A standard concentration of 48 µg/mL of NLB and 16 µg/mL of RTB were injected into the UPLC system with optimized chromatographic conditions and their responses were recorded. Table 5 displays the anticipated and observed values for the responses, as well as their percentage residual values. The residual values ranged from −0.320 to 2.53, indicating that the QbD design used for selecting optimum chromatographic conditions for separating NLB and RTB was valid. The validation of the developed method was conducted using the optimized chromatographic conditions. The validity of the central composite design used was confirmed by the low % residual error values obtained for the observed values.

Table 5. The predicted and observed values of the responses obtained from the optimized chromatographic conditions

Response	Predicted value	Observed value	Residual values (%)
Retention time NLB (min)	1.53	1.50	1.96
Retention time RTB (min)	1.97	1.92	2.53
Resolution factor	3.90	3.90	0.00
Theoretical plates NLB	3980	3993	−0.32
Theoretical plates RTB	5468	5451	0.31
Tailing factor NLB	1.33	1.33	0.00
Tailing factor RTB	1.29	1.29	0.00

Method validation

Table 6 displays the system suitability parameters and their corresponding acceptance criteria. The number of theoretical plates (3956 ± 34 for NLB and 5436 ± 19 for RTB), tailing factor (1.33 for NLB and 1.28 for RTB), resolution factor (3.90) and % RSD for the retention time and peak area (< 1 for NLB and RTB) meet the specified reference values (theoretical plates > 2000, tailing factor < 2, resolution factor < 2, and % RSD < 2). The standard calibration curves were linear within the concentration ranges of 12–72 µg/mL for NLB and 4–24 µg/mL for RTB, as depicted in Fig. 9. The regression coefficient (r^2) values for NLB were found to be 0.9998 with its regression equation $y = 22997x + 2505.9$. In the case of RTB, the regression coefficient (r^2) was found to be 0.9997 with regression equation $y = 21594 + 1344.2$. The LOD and LOQ values were determined to be 0.89 µg/mL and 2.69 µg/mL for NLB and 0.15 µg/mL and 0.46 µg/mL for RTB respectively. The % RSD of intraday and interday precision for NLB and

RTB was found to be less than <2 (Table 7). The % recovery was found to be in the range of 99.57–100.43% for NLB and 99.59–100.61% for RTB (Table 8). The specificity of the developed method is shown in Fig. 10. No co-eluting interfering peaks from the formulation excipients were found at the retention time of NLB and RTB in the placebo and blank samples indicating the specificity of the established method. The results of the robustness data are shown in Table 9. The % RSD values for peak area and retention time were both below 2%, indicating minimal variance. System suitability characteristics including theoretical plates, tailing factor and resolution factor showed no significant variation. The percentage assay of drug content was found to be 99.46 for NLB and 99.98 for RTB in the marketed formulation. The negligible changes in the peak areas of the NLB and RTB before and after keeping the solutions at room temperature for 24 h indicate the solution stability of both drugs.

Table 6. System suitability test parameters (n = 6)

Parameter*	NLB (48 µg mL^{-1})	RTB (16 µg mL^{-1})	Acceptance criteria
Retention time (t_R, min)	1.46 ± 0.005	1.88 ± 0.005	–
RSD % of retention time	0.35	0.27	<1 for n ≥ 5
Peak area	1,110,380 ± 3844	346,204 ± 1968	–
RSD % of peak area	0.34	0.56	<1 for n ≥ 5
Theoretical plates (N)	3956 ± 34	5436 ± 19	>2000
Tailing factor (T)	1.33 ± 0.004	1.28 ± 0.005	≤ 2.0
Resolution (R_s)		3.90 ± 0.001	>2.0

Forced degradation studies

The results of the forced degradation studies of NLB and RTB under different stress conditions are shown in Fig. 11 and Table 10. Both NLB and RTB undergo a negligible extent of degradation (less than 2%) under the specified acid, alkali, thermal and neutral conditions. Under oxidative degradation, NLB showed 5.81% degradation whereas RTB showed 6.19% degradation with one degradation peak at 1.71 min. In the case of photolytic degradation, both NLB and RTB showed a degradation of 8.79 and 7.27% with three degradation peaks at 1.25, 2.21 and 2.67 min. Further, it was observed that there was no interference from the degradation peaks.

Fig. 11 [Images not available. See PDF.]

Table 10. Stability studies of NLB and RTB

Stress condition	Treatment	% Degradation	
NLB	RTB	Acid hydrolysis	2N HCl, 60 °C for 30 min
0.43	0.59	Alkaline hydrolysis	2N NaOH, 60 °C for 30 min
1.72	1.87	Oxidative degradation	60% H_2O_2 60 °C for 30 min
5.81	6.19	Thermal degradation	105 °C for 6 h
0.93	0.48	Photolytic degradation	UV light for 7 days
8.79	7.27	Neutral hydrolysis	Water at 60 °C for 6 h

Discussion

The current research utilized AQbD to develop an RP-UPLC method for estimating NLB and RTB. A central composite design (CCD) with three components at five levels was employed to optimize chromatographic conditions for the developed method utilizing Design-expert® software (Stat-Ease Inc., USA). Polynomial equations, 3D response plots, and 2D contour plots were created to analyze the impact of three independent factors (flow rate, % methanol, and temperature) on dependent variables (retention time, resolution factor, number of theoretical plates, and tailing factor). ANOVA was employed to assess the statistical significance of the model and its terms. Subsequently, a numerical optimization technique was utilized to predict the ideal chromatographic conditions. According to the polynomial equations and 3D-response plot, temperature and flow rate were the most significant factors affecting the retention time of NLB and RTB respectively. The resolution factor was highly influenced by % methanol in the mobile phase in comparison to flow rate and temperature. The flow rate was found to have a more pronounced effect on the number of theoretical plates for both drugs. In the case of the tailing factor, flow rate was found to be the more influential factor for NLB whereas % methanol was the more decisive factor for RTB. The QbD model effectively selected optimum chromatographic conditions for estimating NLB and RTB, as shown by the minimal residual error and close agreement between actual and anticipated values.

Analytical methods are validated to confirm their reliability and suitability for their purpose. The developed RP-UPLC method was validated as per ICH Q2 R1 guidelines. An essential component of method development is the system suitability test, which has been used to guarantee that the selected chromatographic system is operating properly throughout the analysis. All evaluated parameters such as theoretical plates, tailing factor, resolution factor and %RSD for peak area and retention time were well within the suggested ranges proving the suitability of the chromatographic system. The correlation coefficient (r^2) values>0.999 for both drugs indicate a good correlation and excellent linearity over the proposed concentration ranges. Low LOD and LOQ values showed that the proposed method was very sensitive for estimating RTB and NLB in pharmaceutical dosage forms. Analytical precision refers

to the degree of agreement between measurements taken from multiple samples under similar conditions. The % RSD values for both intraday and interday precision studied at three different levels were less than 2% demonstrating the good precision of the developed method. Recovery studies assess how closely the experimental result matches the true value. The % recovery values for NLB and RTB ranged from 99.57 to 100.43% and 99.59 to 100.61% respectively demonstrating minimal variability and high agreement between experimental and actual values. An analytical method's specificity is defined as its ability to assess the target analyte even when interferences from contaminants, degradation agents, and excipients are present in commercially available formulations. The developed method is specific for the quantification of NLB and RTB from pharmaceutical dosage forms, as there are no co-eluting interference peaks at the retention time of both drugs. Robustness refers to a method's ability to remain consistent despite small changes in chromatographic parameters, demonstrating the method's reliability in everyday use. The low % RSD values, and lack of significant changes in system suitability parameters following deliberate changes in experimental conditions demonstrated good robustness of the developed method. The percentage assay results (99.46–99.98% for label claim) indicate the applicability of the developed RP-UPLC method for the estimation of NLB and RTB in marketed formulations. The stability investigation confirmed that NLB and RTB remained stable in solution at room temperature for 24 h.

Stability studies are crucial for evaluating the quality of pure drugs and drug products. The method's ability to evaluate the stability of NLB and RTB is demonstrated by assessing their degradation following exposure to different stress situations. Both drugs were unstable under oxidative and photolytic conditions but exhibited great stability under acidic, alkaline, thermal, and neutral conditions. These findings indicate the stability indicating the nature of the developed method.

Conclusions

An analytical quality by design methodology, specifically central composite design, was effectively utilized to optimize the RP-UPLC method for quantifying NLB and RTB. The optimized chromatographic conditions for the separation of NLB and RTB consisted of 32.80% v/v methanol in the mobile phase, 0.272 mL/min flow rate, column temperature of 29.42 °C, and UV detection at 260 nm. The method showed well-resolved peaks at the retention time of 1.46 and 1.88 min for NLB and RTB respectively. The method was verified according to ICH criteria and demonstrated linearity, accuracy, precision, sensitivity, specificity, and robustness. The forced degradation studies showed well-resolved peaks of NLB and RTB along with degradation peaks. The findings of the present study conclude that AQbD is an effective methodology for method optimization and the established method is suitable for the accurate determination of NLB and RTB in pharmaceutical dosage forms.

Expanding telmisartan's therapeutic horizon: exploring its multifaceted mechanisms beyond cardiovascular disorders

Ahire, Yogesh S.1 ; Bairagi, Vinod A.1; Somavanshi, Deepak B.1; Jadhav, Smruti R.1; Jadhav, Swapnil B.1; Jagtap, Shekhar D.11 KBHSS Trust Institute of Pharmacy, Department of Pharmacology, Malegaon, Nashik, India

ABSTRACT (ENGLISH)

Background

Telmisartan, a potent angiotensin II type-1 receptor blocker as well as partial PPAR–gamma agonist, has emerged as a versatile therapeutic agent with diverse pharmacological actions beyond its primary indication for essential hypertension. This review explores the complex mechanisms of action of telmisartan and clarifies its effectiveness in an inflammation, cancer, metabolic, and CNS disorders.

Main body

Telmisartan inhibits many biochemical processes involved in the control of the cardiovascular system, such as vascular smooth muscle contraction, aldosterone production, and sympathetic tone modulation, by specifically targeting the angiotensin II type-1 receptor. Its distinct partial agonist action toward peroxisome proliferator-activated receptor gamma also imparts anti-inflammatory, antiproliferative, and antioxidant activities, making it a viable treatment for various diabetic patients who have atherosclerosis and myocardial infarction.

Conclusion

Telmisartan's diverse pharmacological actions, encompassing anti-inflammatory, neuroprotective, nephroprotective, anticancer, and anti-anxiety properties, position it as a promising treatment option for a broad spectrum of medical conditions.

FULL TEXT

Background

Telmisartan, a nonpeptide antagonist directed at the angiotensin II type-1 (AT1) receptor, has surfaced as a versatile therapeutic option, demonstrating notable effectiveness and longevity in managing essential hypertension [1]. Its unique mode of action entails the targeted and enduring inhibition of the AT1 receptor's reactivity to angiotensin II, while preserving the functionality of other receptor systems implicated in cardiovascular control [2]. This selectivity

not only forms the basis of its powerful antihypertensive action but also lays the groundwork for its diverse pharmacological characteristics [3].

In addition to its role as an angiotensin receptor blocker (ARB), telmisartan exhibits partial agonist activity toward the peroxisome proliferator-activated receptor gamma (PPAR-γ) [4]. This unique dual activity confers a myriad of additional benefits, including antioxidative, anti-inflammatory, and antiproliferative effects, particularly in conditions such as atherosclerosis [5]. Such pleiotropic effects position telmisartan as a promising therapeutic option for diabetic patients with myocardial infarction, offering a comprehensive approach to cardiovascular management beyond blood pressure control [6].

Additionally, telmisartan's capacity to mitigate fibrotic alterations linked to diabetes-related cardiac fibrosis by activating endogenous PPARδ [4] and enhancing STAT3 [7, 8] expression highlights its potential in addressing diverse pathological pathways [9]. The activation of PPARδ not only maintains a balance in metabolism and inflammation [10] but also contributes to cardiac protection, thereby broadening telmisartan's therapeutic scope beyond hypertension [11].

Furthermore, telmisartan's influence extends beyond cardiovascular well-being, encompassing a range of advantageous effects on metabolic syndrome, neuroprotection [12], and nephroprotection. Its anti-inflammatory [13], antioxidative [14], antineoplastic [15], and nephroprotective [16] attributes further emphasize its potential as a valuable therapeutic agent across various diseases and disorders [17].

In this extensive review, we explore the multifaceted mechanisms of action of telmisartan, shedding light on its diverse pleiotropic effects and underscoring its potential as a fundamental component in the management of cardiovascular conditions and beyond. In this study, we examined over 323 research papers, with 199 of them being thoroughly included in our analysis. By meticulously analyzing the available literature, our objective is to offer valuable insights into the wide-ranging therapeutic capabilities of telmisartan, facilitating its exploration across diverse clinical scenarios.

Methodology

The scope of the review article on telmisartan will encompass its pharmacological properties, therapeutic indications, and emerging research trends for treatment of other than cardiovascular disorders. The objectives include evaluating the efficacy of telmisartan in the management of various CNS, cancer, diabetes, and its complications, exploring its potential mechanisms of action, and discussing its comparative effectiveness. For comprehensive coverage of literature on telmisartan, relevant databases such as PubMed, Web of Science, Scopus, and Google Scholar were utilized. A comprehensive search strategy was developed using keywords such as “telmisartan plus neurological disorders,” “telmisartan + metabolic syndrome,” “telmisartan and Diabetes,” Cancer and telmisartan, etc., and search filters will be employed to refine the search and capture relevant literature on telmisartan's pharmacology. Search results were screened based on relevance to the review's objectives. Titles and abstracts were reviewed to assess their suitability for inclusion in the review. Studies focusing on telmisartan's pharmacological properties were prioritized for further evaluation. Inclusion criteria include studies published in English, observational studies, meta-analyses investigating telmisartan's efficacy for other than cardiovascular disorders in preclinical studies. Exclusion criteria comprise clinical trials, case reports, and studies with insufficient data or irrelevant outcomes. During the study, we examined over 323 research papers, with 199 of them being thoroughly included in our analysis. Full-text articles of potentially relevant studies were retrieved through institutional subscriptions, interlibrary access, or direct contact with authors. Selected studies were critically evaluated for their quality and validity. Factors including study design, sample size, methodology, and risk of bias were considered in the assessment.

Relevant data from selected studies were extracted using a standardized data extraction form. Key information including study characteristics, type of animal models, intervention details, outcomes, and conclusions was systematically recorded for creation of review. Findings from the selected studies were synthesized to address the review's research questions and objectives. Synthesized information was organized and presented in a tabular form for different disorders and diseases.

The review process involved continuous literation, with ongoing refinement of search strategies and inclusion/exclusion criteria to ensure comprehensive coverage of literature and alignment with the review's objectives. Additionally, updates were made to incorporate new findings and emerging research trends on telmisartan's therapeutic applications beyond cardiovascular disorders. (Methodology section was included to provide clarity and reproducibility).

Neuroinflammation and telmisartan

Angiotensin receptor II induces inflammation and oxidative stress via ROS production through the NADPH oxidase complex [18, 19]. Toll-like receptors (TLRs) and PPARγ receptors in the CNS play vital roles in neuroinflammation [20]. Excessive RAS activation, especially through AT1 receptors, contributes to brain inflammation [21, 22]. IL-1β, generated by microglia, has diverse roles and is implicated in neurodegenerative disorders [23, 24].

Telmisartan induces PPARγ activation independently of AT1R, preventing NFκB-mediated inflammatory cascades [13]. PPARγ activation leads to a dose-dependent increase in SARM expression, a negative regulator of pro-inflammatory cytokines [25].

Telmisartan reduces LPS-induced inflammation in neuronal cells via SARM activation through TLR4 signaling independently of AT1R [13]. TLR4 activation triggers NFκB, AP1, and IRF3, with a focus on MyD88-mediated pro-inflammatory cytokine mechanisms [26].

Telmisartan reduces IL-1β-induced COX-2 expression, PGE2 release, and ROS production. Telmisartan mitigates IL-1β-induced upregulation of IL-1R1 receptor and NOX-4 mRNA expression [27]. Telmisartan attenuates hydrogen peroxide-induced COX-2 gene expression and reduces JNK and c-Jun activation. Telmisartan's neuroprotective effects are independent of PPARγ activation, as confirmed in primary rat cortical neurons [28, 29].

In conclusion, telmisartan demonstrates a multifaceted approach to neuroprotection by modulating specific pathways associated with inflammation and oxidative stress. These findings highlight its potential therapeutic role in neurodegenerative diseases.

Ocular inflammation and telmisartan

Endotoxin-induced uveitis (EIU) serves as an animal model for acute ocular inflammation induced by lipopolysaccharide (LPS) [30, 31]. Severe vision impairment complications include retinal vasculitis, retinal detachment, and glaucoma. Angiotensin II, a key renin-angiotensin system effector, interacts with AT_1 and AT_2 receptor [32, 33]. Recent studies reveal diverse biological roles of angiotensin II, including modulation of angiogenesis, vascular remodeling, and inflammation [34]. Angiotensin II enhances vascular permeability [35], induces chemokines and adhesion molecules, and influences inflammatory cell proliferation and differentiation. AT1R blockade, including telmisartan, effectively attenuates these inflammatory processes [36–38]. Upregulation of AT1R is associated with ocular inflammation in EIU [39]. Telmisartan effectively attenuates inflammatory parameters, including ICAM-1-mediated leukocyte adhesion and infiltration in EIU eyes. LPS stimulation leads to the upregulation of inflammatory mediators contributing to EIU development. ICAM-1 plays a pivotal role in leukocyte adhesion; its upregulation is inhibited by telmisartan. Telmisartan suppresses retinal ICAM-1 upregulation and mitigates various EIU-induced cytokines [40, 41]. The anti-inflammatory effects are associated with downregulation of NF-κB-induced molecules [42]. Insights into the RAS highlight its involvement in various inflammatory conditions, such as atherosclerosis, cerebral infarction, and pancreatitis [36]. Telmisartan substantially reduces anterior-chamber cell infiltration but shows limited impact on protein leakage [43].

Anti-inflammatory effects of telmisartan in Experimental Autoimmune Uveitis (EIU), a model for studying ocular inflammation. Telmisartan is noted for its ability to target important inflammatory mediators such as ICAM-1 (intercellular adhesion molecule-1), various cytokines, and molecules induced by NF-κB (nuclear factor-kappa B), a key transcription factor involved in inflammation. The reference to ICAM-1 suggests that telmisartan may inhibit the adhesion of immune cells to vascular endothelial cells, thereby reducing inflammation. Additionally, by modulating cytokines, which are signaling molecules involved in the immune response, telmisartan likely attenuates the inflammatory cascade in EIU. NF-κB-induced molecules further emphasize the drug's ability to interfere with transcriptional processes that promote inflammation.

Diabetes-induced vascular inflammation and telmisartan

Individuals with diabetes experience exposure of the endothelium to uncontrolled high glucose levels [44]. Endothelial dysfunction is the fundamental pathophysiology in diabetic macrovascular complications [45, 46]. Hyperglycemia triggers inflammatory responses crucial in the development of diabetic macrovascular diseases, including atherosclerotic coronary artery and cerebrovascular diseases [39]. Adhesion of inflammatory leukocytes to the vascular endothelium is a pivotal step in atherosclerosis development [47]. Adhesion molecules like VCAM-1, intercellular adhesion molecule-1, and endothelial-leukocyte adhesion molecule-1 play a role in leukocyte adhesion, leading to vascular inflammation [48]. Angiotensin II type-1 receptor blockers (ARBs), including telmisartan, are prescribed for hypertensive patients with diabetes mellitus [49]. Early reduction of inflammatory leukocyte homing and attachment to the endothelium is considered an effective therapeutic strategy. Telmisartan, an ARB, protects against vascular inflammation induced by hyperglycemia. Reports suggest that telmisartan reduces vascular inflammation by inhibiting the expression of IKKβ in endothelial cells [1]. Telmisartan induces GSK3β-Ser9 phosphorylation in endothelial cells. GSK3β-Ser9 phosphorylation decreases hyperglycemia-induced NFκB p65-Ser536 phosphorylation, VCAM-1 expression, and adhesion of THP-1 monocytes. GSK3β-S9A, a constitutively active mutant of GSK3β, restores the inhibition of NFκB p65-Ser536 phosphorylation, VCAM-1 expression, and THP-1 monocyte adhesion by telmisartan [1].

Telmisartan inhibits IKKβ expression in a GSK3β-Ser9 phosphorylation-dependent manner. Among various ARBs, only telmisartan demonstrates an increase in GSK3β-Ser9 phosphorylation. Telmisartan treatment mitigates HFD-induced upregulation of NFκB p65-Ser536 phosphorylation, VCAM-1 expression, and IKKβ expression in aortic tissues. Telmisartan alleviates hyperglycemia-exacerbated vascular inflammation by inducing GSK3β-Ser9 phosphorylation, inhibiting IKKβ expression, NFκB p65-Ser536 phosphorylation, and VCAM-1 expression in a PPARγ-independent manner. Telmisartan operates within diabetes by engaging with crucial signaling molecules implicated in inflammation and vascular irregularities, including GSK3β, IKKβ, NF-κB, and VCAM-1. Through its influence on these pathways, telmisartan can alleviate the inflammatory reactions linked to diabetes and its accompanying complications, offering promising therapeutic possibilities for individuals with diabetes.

Chronic inflammation

The renin–angiotensin system produces angiotensin II, activating the AT1 receptor, leading to oxidative stress and inflammation [50]. Telmisartan, an AT1 receptor antagonist, also acts as a partial agonist on peroxisome proliferator-activated receptor-γ (PPAR-γ), providing antioxidative and anti-inflammatory effects [51]. Recent studies highlight telmisartan's additional PPAR-γ partial agonist activity, impacting metabolic and inflammatory pathways, improving left ventricular functions, and showing benefits in post-infarct ventricular remodeling [51, 52]. Telmisartan's dose–response relationship in animal models of chronic inflammation suggests antiproliferative and anti-arthritic activities, inhibiting inflammatory reactions [53]. Tissue injury triggers pro-inflammatory cytokine release, but telmisartan's PPAR-γ activation decreases hypertrophic prostanoid production, potentially modulating inflammation [54, 55]. Telmisartan's antioxidant and anti-inflammatory effects involve preventing nuclear factor-κB (NF-κB) signaling pathway activation [56].

Telmisartan exhibits pleiotropic effects, including anti-inflammatory, antioxidative, and antiproliferative actions in atherosclerosis and myocardial infarction.

It also demonstrates a protective effect against gastric mucosal lesions induced by stress and indomethacin [56, 57]. Telmisartan functions as a partial agonist at PPAR-γ, inducing catalase gene expression and inhibiting NF-κB. These actions collectively combat oxidative stress and downregulated a majority of pro-inflammatory responses [51, 58].

The anti-inflammatory impact of telmisartan is attributed to its PPAR-γ agonist activity. The modulation of PPAR-γ expression observed during various inflammatory disorders provides a robust foundation for utilizing potent PPAR-γ ligands, like telmisartan, to attenuate or modulate the progression of inflammation. This finding underscores the potential of PPAR-γ as a therapeutic target in inflammatory conditions, given its altered expression in several inflammatory disorders [59].

This sequence outlines the key mechanisms of action of telmisartan, emphasizing its dual role as an AT1 receptor antagonist and a partial agonist at PPAR-γ, contributing to its multifaceted effects on inflammation, oxidative stress, and related pathways.

Ulcerative colitis and telmisartan

There is a global rise in inflammatory bowel diseases (IBDs), particularly UC. Anti-TNF antibodies are commonly used for UC treatment. Telmisartan is a promising therapeutic candidate with anti-inflammatory properties. Telmisartan suppresses TNF-α-induced activation of nuclear factor-kB (NF-κB) in vascular endothelial cells [60]. Varying doses of telmisartan lead to decreased tissue levels of TNF-α and increased anti-inflammatory activity. Telmisartan's benefits extend to modulating colonic inflammation, oxidative stress, and apoptosis in inflammatory bowel disease [61].

Telmisartan administration mitigates pathological changes induced by arachidonic acid (AA)-induced colitis model, including oxidative stress, alterations in colonic weight, ulceration, tissue necrosis, and inflammatory infiltrate [62]. Telmisartan treatment accelerates the shift from the acute to the chronic phase of inflammation in UC [63]. Effectively it reduces neutrophil infiltration, as indicated by diminished myeloperoxidase (MPO) levels [64]. Telmisartan suppresses the expression of TNF-α and intervenes in the AA-induced colitis model by reducing malondialdehyde (MDA) levels, showcasing its protective role against oxidative cellular injury. Telmisartan increases levels of interleukin-10 (IL-10), known for its anti-inflammatory properties [63].

Telmisartan offers diverse anti-inflammatory effects in treating ulcerative colitis. By inhibiting NF-κB activation triggered by TNF-α, it reduces tissue TNF-α levels and enhances overall anti-inflammatory activity. Telmisartan also combats oxidative stress and apoptosis, common in colonic inflammation, and shields against AA-induced colitis. It expedites the shift from acute to chronic inflammation, curtails neutrophil infiltration, and dampens TNF-α expression. Furthermore, it lowers malondialdehyde levels, indicating defense against oxidative cellular harm, and boosts IL-10 levels, reinforcing its anti-inflammatory prowess. These combined actions highlight telmisartan's promise as a therapeutic option for ulcerative colitis.

Crohn’s disease and telmisartan

Crohn’s disease (CD) patients are often underweight, and there's a significant increase in the ratio of intra-abdominal adipose tissue to total abdominal fat in these individuals [65]. Mesenteric fat serves as a crucial indicator of intestinal inflammation in CD [66].

MAT in CD patients exhibits notable inflammatory infiltrate and altered adipocyte morphology compared to healthy subjects [67]. MAT comprises various cell types, including adipocytes, preadipocytes, macrophages, endothelial cells, fibroblasts, and leukocytes. Telmisartan administration has a positive impact on mesenteric adipocytes in a mouse model of spontaneous colitis, restoring morphological changes and increasing adipocyte diameter. Mesenteric adipocytes contribute to C-reactive protein production in CD [68]. Leptin and adiponectin, hormones produced by adipose tissue, play roles in IBD pathogenesis [69].

Telmisartan treatment significantly alters the production of leptin and adiponectin in MAT, potentially influencing inflammatory processes. The neurotensin/miR-155 signaling pathway, involved in adipose inflammation and adipocyte differentiation, is modulated by telmisartan [70, 71].

Telmisartan treatment inhibits this pathway in MAT, suggesting a potential therapeutic contribution to attenuate MAT alteration and gut inflammation in CD. The renin-angiotensin system plays a role in the pathophysiology of colitis. Angiotensin receptor antagonists, including telmisartan, demonstrate effectiveness in preventing experimental colitis. Telmisartan exhibits a multifaceted impact on visceral adipose tissues, reducing leptin expression, increasing adiponectin levels, and attenuating MAT inflammatory parameters [72]. Telmisartan administration has a beneficial effect in an animal model of spontaneous colitis, reducing MAT inflammation, cytokine production, and ameliorating mesenteric adipose tissue alterations[73].

In conclusion, Telmisartan shows promise as a therapeutic option for managing inflammatory bowel diseases, particularly Crohn's disease, by influencing various aspects of adipose tissue composition, hormone regulation, and inflammatory pathways. The diverse actions of Telmisartan suggest its potential as a comprehensive approach to

address the complex mechanisms associated with CD (Table 1 and Fig. 1).

Table 1. Role of telmisartan in inflammation

Type of study	Route of administration	Treatment duration	Target	Effect	References
a) Colitis					
3 mg/kg/day IL-10¯/¯mice	Oral	12 weeks	IFN-g and TNF-a, IL-6 and IL-17, leptin Adipoleptin	Increased adiponectin decrease in levels of leptin, IL-6, and IL-17	Li et al. [196]
b) Ulcerative colitis					
5 mg/kg (Wistar rats)	Oral	3 day before and 2h &24 h after induction of disease	TNF-alpha, MPO, and MDA IL-10	Increase level of TNF-alpha, MPO, and MDA IL-10	Guerra et al. [2]
c) Neuronal Inflammation					
10 µmol/l (SK-N-SH human neuroblasts and primary rat cortical neurons)	Incubation of cells	Cells were incubated for 3 h	NADPH oxidase-4 (NOX-4) mRNA expression, NADPH oxidase activity, ROS generation, hydrogen peroxide-induced COX-2 gene expression, c-Jun N-terminal kinase (JNK), and c-Jun activation	Decreases in the IL-1β, mRNA expression, NADPH, hydrogen peroxide-induced COX-2 expression,	Pang et al. [27, 28]
d) Vasculitis					
5 mg/kg (Nephrectomized rats (Nx))	Intraperitoneal		PPAR-γ, NADPH, VCAM-1, Osteopontin,	Increase PPAR-γ, decrease NADPH oxidase, osteopontin, VCAM-1	Toba et al. [113]
e) Skin inflammation (psoriasis)					

40 mg/kg (K14-IL-17A ind/+and IL-17A ind/+mice)	Oral	4 weeks	IL-17A, AT II, PASI,	Increase in IL-17A, erythema, scaling, skin thickness, the affected area, and cumulative psoriasis area and severity index (PASI), decrease systolic blood pressure	Wild *et* al. [197]
f) Neuroinflammation					
100 µg/ml (Mouse Neuro2A neural cells)	Incubation of cells	Cells incubated for 24 h	PPAR-γ β-Actin, NF-κB, MyD88, cytokines IL-10	NF-κB, MyD88 activation, cytokines, motor co-ordination, cognitive functions, and activated SARM and PPAR-γ protein levels β-Actin, Increase secretion of IL-10	Balaji et al. [198]
g) Vascular Inflammation					
5 mg/kg (Male C57BL/6 mice)	Oral	13 weeks	GSK3b Ser^{9} phosphorylation, NF-kB p65	Inhibited hyperglycemia-induced NF-kB p65, inhibit GSK3b activity	Song et al. [1],
h) Acute colitis					
0.01 and 5 mg/kg (Female C57Bl/6 J mice)	Rectal route	6 days	Tumor necrosis factor (TNF)-a, transforming growth factor (TGF)-b1, interleukin-1b and monocyte chemoattractant protein (MCP)-1, caspase-3 and -7	Increase anti-apoptotic protein Bcl-2, Decrease in mRNA levels of pro-inflammatory cytokines such as tumor necrosis factor a, interleukin-1b, interleukin-6 and monocyte chemoattractant protein 1 as well as cellular DNA damage, caspase-3 and -7	Arumugam et al. [199]
i) Chronic inflammation					

(0.1, 0.2. 0.4, 0.6, 1.5, 3 mg/kg) (Wistar rats)	Oral	6 days	Nuclear factor-jB signaling pathway, PPAR-c	Decreases paw edema, reactive oxygen species and pro-inflammatory mediators, PPAR-c	Walid et al. [200]
j) Endothelial Inflammation					
Human umbilical vein endothelial cell (HUVEC)s	Incubation of cells	48 h	Vascular (VCAM-1) and intercellular (ICAM-1)	Decrease in TNF-α-stimulated VCAM-1	Cianchetti et al. [207]
k) Retinal inflammation					
20 mg/kg (C57BL/6 mice)	Intraperitoneal	2 days	AT1R and AT2R	Increase in angiotensin II expression, decrease in synaptophysin and rhodopsin expression	Kurihara et al. [208]

Fig. 1 [Images not available. See PDF.]

Target effectors of telmisartan in inflammation. VCAM-1: Vascular cell adhesion molecule-1, RANK: receptor activator of nuclear factor-kappa B, MPO: myeloperoxidase, TNF-ά: tumor necrosis factor alpha, MDA: malondialdehyde, TLR4: toll-like receptors, IkB: inhibitor nuclear factor-kappa B

Telmisartan in CNS disorders

Depression, characterized by anhedonia and persistent sadness, poses significant threats to life and cognitive functions [74, 75]. Stress plays a crucial role in depression development and associated memory issues. Ethical concerns limit direct research on depression causes and treatments in affected individuals. Chronic stress contributes to oxidative stress, leading to the generation of reactive oxygen species and compromised central nervous system functioning [76].

Chronic unpredictable mild stress (CUMS) rat model, introduced by Willner, simulates daily stressors and is instrumental in exploring depression origins and testing antidepressant interventions [77]. Telmisartan, a commonly used angiotensin receptor blocker (ARB), easily crosses the blood–brain barrier, inducing central AT1 receptor blockade [78].

Telmisartan holds promise as a potential oral antidepressant, possessing neuroprotective properties and mitigating cognitive impairments induced by chronic stress in rats [79].

Chronic stress results in decreased locomotor activity, sucrose preference, and impaired novel object recognition [80]. Telmisartan, especially at 1 mg/kg/day, significantly improves the impaired ability of novel object recognition, suggesting a potential antidepressant effect. AT1 receptor blockers, including telmisartan, gain attention for potential antidepressant effects [81].

The renin-angiotensin system (RAS) plays a crucial role in the body's response to stress [82].

Resting-state functional magnetic resonance imaging (r-fMRI), measuring intrinsic neural activity, is valuable in neuropsychiatric disorder research [83]. Telmisartan's impact on depression explored using ALFF and ReHo methods in a rat model was the first study of its kind. Telmisartan's effects on stress-induced alterations in brain regions were explored using ALFF and ReHo methods. Telmisartan at 1 mg/kg showed potential in reversing or attenuating stress-induced alterations in brain regions. Telmisartan demonstrated potential in decreasing hypercoordination of neural activity, particularly in the thalamus. Increased ReHo in limbic system regions and

altered connectivity in various cerebral regions suggested neuroimaging markers for depression [81].
Telmisartan alleviated depressive behaviors induced by unpredictable chronic mild stress in BALB/c mice.
Telmisartan's antidepressant effects were linked to its impact on serotonin transporter expression through PPARδ activation [84, 85].
Telmisartan's neuroprotective and antidepressant properties were associated with its impact on oxidative stress and pro-inflammatory mediators [86].
Its partial PPARδ agonistic property was considered crucial for reducing cytokine levels and improving cognitive decline [87].
Depression is a significant contributor to morbidity and mortality, requiring a multifaceted approach for accurate diagnosis and treatment [88, 89].
Telmisartan's dual action as an AT1 receptor blocker and PPAR-gamma agonist provides neuroprotection against various brain disorders, including depression [17, 90].
Telmisartan shows promise as a depression treatment through multiple mechanisms. It protects neurons, enhances cognition, and influences the body's stress response by modulating the renin-angiotensin system. Telmisartan also restores neural activity in stressed brain regions, impacting serotonin transporter expression via PPARδ activation. Its anti-inflammatory and antioxidant properties, partially through PPARδ agonism, alleviate depressive symptoms. Acting as both an AT1 receptor blocker and PPAR-gamma agonist, telmisartan offers comprehensive neuroprotection against depression.

Telmisartan in epilepsy

Epilepsies involve sudden, abnormal, and excessive neuronal activity in the brain, affecting 5–10% of the population. Long-term therapy challenges and medication side effects contribute to issues with compliance. Epilepsy may be associated with comorbid conditions like hypertension, diabetes, and renal disorders. Research suggests that drugs addressing these disorders, including ACE inhibitors and AT II receptor antagonists, may have a role in preventing seizures. The brain's RAS influences various functions, including regulating cerebral blood flow, stress, depression, seizures, and memory consolidation. Angiotensin II, a RAS component, acts as a neurotransmitter in the central nervous system, influencing the release of other neurotransmitters [91]. Angiotensin II inhibits GABAergic synaptic transmission by activating presynaptic AT1 receptors. Drugs like ACE inhibitors and AT1 receptor antagonists, including telmisartan, have the potential to enhance GABAergic transmission, beneficial in preventing seizures. Telmisartan, an AT1 receptor antagonist, improves the anticonvulsant effects of medications like valproate, lamotrigine, and topiramate in mouse models.
Telmisartan's unique properties, including potential depression-like effects, contribute to its anticonvulsant properties. Telmisartan exhibits neuroprotective effects by reducing local angiotensin II expression, blocking AT1 receptors, and promoting the relative upregulation of AT2 receptor function. In a rat model, ACE and AT1 receptors were upregulated in the brain after repetitive seizures. Telmisartan, especially at a 10 mg/kg dose, significantly decreases hind limb extension duration in the maximal electroshock (MES) model. Telmisartan exhibits substantial seizure inhibition and protection in the pentylenetetrazol (PTZ) test, suggesting dose-dependent antiepileptic activity. Telmisartan's slow dissociation from receptors, penetration of the blood–brain barrier, and increased potency at brain AT1 receptors contribute to its effectiveness. Telmisartan modulates the renin-angiotensin system, affecting glutamate/GABA release, decreasing glutamate levels, increasing GABA levels, and facilitating seizure prevention. AT1 receptor blockers, including telmisartan, contribute to decreased glutamate levels, increased GABA levels, and potential seizure prevention [92].
Telmisartan's higher lipophilicity and potency at brain AT1 receptors make it effective in modulating these neurological functions [93]. Angiotensin affects ion channels, including voltage-dependent potassium and calcium currents, influencing neuronal excitability and seizures [94].
Stress-induced changes in cortical BZ1 receptor expression are regulated by AT1 receptor activity. AT1 receptor antagonists may protect against seizures induced by inflammatory cytokines in chronic inflammatory disorders [95]. Seizure generation involves the activation of inflammatory cytokines, and AT1 receptor antagonists can be

considered for epilepsy treatment [96].
Telmisartan, with its AT1 receptor antagonistic properties, demonstrates promising antiepileptic effects. Understanding its mechanisms involving GABAnergic transmission, modulation of RAS, and impact on ion channels provides insights for potential therapeutic applications in epilepsy treatment. Together, these mechanisms underscore telmisartan's potential as an antiepileptic agent, providing neuroprotection, seizure management, modulation of neurotransmitter balance, and regulation of inflammatory pathways.

Telmisartan traumatic brain injury and cerebral edema

Cerebral edema is a serious complication of TBI, leading to elevated intracranial pressure and unfavorable clinical outcomes [97, 98].
The RAS is implicated in neuroinflammation and neurodegenerative disorders [99, 100].
Angiotensin receptor blockers (ARBs), especially telmisartan, effectively inhibit angiotensin II, offering anti-inflammatory and neuroprotective effects [101, 102]. Telmisartan, with its high lipid solubility, effectively penetrates brain tissue. Recognized for neuroprotective effects through angiotensin II receptor type-1 (AT1R) blockade [103]. Scientists investigated the anti-edemic effect of telmisartan through single oral gavage administration. Reduction in cerebral edema observed at 12 and 24 h post-TBI. The anti-edemic effect of telmisartan was not strictly dose-dependent [104]. Telmisartan demonstrated sustained inhibitory effects on AT1R, presenting an extended window for pharmacological intervention. IL-1β, a pro-inflammatory cytokine elevated in TBI, is implicated in cerebral edema [105, 106].
Telmisartan has shown efficacy in mitigating IL-1β-induced inflammatory responses in various brain injury models. Telmisartan improved neurological function, reduced lesion volume, and exhibited neuroprotective effects in the TBI model. Investigation into telmisartan's impact on the pro-inflammatory cytokine IL-1β. Telmisartan was found to inhibit the assembly and activation of the NLRP3 inflammasome [105, 107]. This inhibition provides a mechanism for telmisartan's anti-edemic role in TBI. The study confirmed the role of NLRP3 inflammasome-regulated IL-1β in traumatic cerebral edema. Telmisartan demonstrated potential in sustaining BBB integrity, reducing edema, and improving neurological function through NLRP3 inflammasome modulation [108].
Telmisartan, an angiotensin receptor blocker, offers a versatile approach to managing brain injury and cerebral edema. By inhibiting angiotensin II activity, it provides anti-inflammatory and neuroprotective benefits. Its lipid solubility enables direct brain tissue access for targeted action, primarily inhibiting AT1R to reduce inflammation and enhance neurological function. Telmisartan also disrupts NLRP3 inflammasome activation, reducing IL-1β-induced inflammation. Its sustained AT1R inhibition diminishes cerebral edema post-TBI, while also maintaining blood–brain barrier integrity. Telmisartan shows promise as a therapeutic agent for brain injury and cerebral edema management.

Anxiolytic effect of telmisartan

Anxiety disorders, affecting 7–30% of the world's population, represent a significant mental health challenge, contributing to economic burdens and health concerns [109]. Neurotransmitters like serotonin and GABA are implicated in anxiety pathophysiology, with selective serotonin reuptake inhibitors (SSRIs) recommended as first-line drugs. Emerging evidence suggests the involvement of the brain renin-angiotensin system in anxiety states, where angiotensin modulates neurotransmitter release [110]. Angiotensin receptor blockers (ARBs), used for cardiovascular conditions, have been associated with increased anxiety prevalence, particularly due to the blockade of AT1>AT2 receptors in the brain [111]. Telmisartan, crossing the blood–brain barrier, exhibits significant anti-anxiety effects, possibly through AT1 receptor blockade in circumventricular organs and potential cerebral AT receptor blockade. The mechanism of telmisartan's anti-anxiety effects involves hypothesized upregulation of angiotensin levels and receptors in the brain during anxiety, influencing neurotransmitters like noradrenaline and serotonin [112]. Telmisartan's additional activities via PPAR-gamma and NADPH oxidase may contribute to its role in oxidative stress management, providing added benefits. [113].
In summary, telmisartan, through its action on the RAS and neurotransmitter modulation, emerges as a promising agent in managing anxiety, offering potential avenues for novel treatments targeting neurogenesis, plasticity, and

cell survival (Table 2).

Table 2. Role of telmisartan in CNS disorders

Type of study	Route of administration	Treatment duration	Target	Effect	References
a) Stress-induced depression					
1 mg/kg (male Sprague–Dawley rats)	Oral	5 weeks	ReHo in the motor cortex, pons, thalamus, visual cortex, midbrain, cerebellum, hippocampus, hypothalamus, and olfactory cortex, B-A/B + A in the ORT	Decreased ReHo in the motor cortex and pons, increased ReHo in the thalamus, visual cortex, midbrain, cerebellum, hippocampus, hypothalamus, and olfactory cortex, Improved B-A/B + A in the ORT	Li et al. [81]
1 mg/kg (male BALB/c mice), (Rat-derived hippocampus H19-7)	Oral	6–7 weeks	PPAR-δ and 5-HTT	Reduced level of PPARδ and 5-HTT in hippocampus, Increased level of PPARδ and 5-HTT in H19-7 cell lines	Li et al. [89]
2 mg/kg (male albino mice)	Oral	2 weeks (15 days)	PPAR-gamma	Increased in PPAR-gamma, decrease in the immobility time	Brattiya and Sivaraman [90]
b) Epilepsy					
5 mg/kg, 10 mg/kg (Swiss albino mice)	Oral	1 h after test and standard drug administration	AT1, AT2	Blockade of AT1 receptors, increase in activity of AT2 receptors, Decease in hindlimb extensor phase, tonic hind limb extension	Pushpa et al. [92]
c) Cerebral edema					

5, 10, and 20 mg/kg (male C57BL/6 mice)	Oral	72 h	NLRP3, IL-1b, IL-18,	Decrease in NLRP3, IL-1b, IL-18, mRNA, and protein levels	Wei et al. [104]
d) Anxiety					
5 and 10mg/kg (Swiss albino mice	Oral	2 weeks	AT1	Stimulation of AT1, increase time spent in social interaction test, increase time spent in open arms	Swetha et al. [201]

Telmisartan in *cancer*

Endometrial *cancer*

Endometrial cancers are prevalent malignant tumors affecting the female genital tract, with a rising incidence [114, 115]. Despite the increasing incidence, effective agents for advanced and recurrent cases are lacking [115]. Peroxisome proliferator-activated receptor gamma and its ligands are known to induce apoptosis in various cancer types, including endometrial cancer [116, 117].

PPAR-gamma belongs to a nuclear hormone receptor family linked to endometrial carcinoma risk factors like obesity, excess estrogen, type II diabetes, and hypertension [118, 119].

Telmisartan emerges as a therapeutic option, inducing DNA damage and apoptosis in endometrial cancer cells. Telmisartan, acting as a partial agonist of PPAR-gamma, activates the receptor independently through AT1R interaction [51].

Telmisartan induces DNA double-strand breaks (DSBs) before triggering apoptosis in endometrial cancer cells. Among ARBs, only telmisartan inhibits cell viability in endometrial cancer, and this effect is diminished by a PPAR-gamma inhibitor (GW9662) [120].

PPAR-gamma immunoreactivity is detected in endometrial carcinoma tissue, and PPAR-gamma ligands show antiproliferative activity [116].

In vivo experiments using a nude mouse model demonstrate apoptosis within the tumor area in mice treated with telmisartan. Telmisartan's antitumor activity without major side effects suggests potential effectiveness in individuals with minimal residual disease post-surgery, chemotherapy, or radiotherapy [120].

In summary, telmisartan exhibits promise in endometrial cancer treatment through its involvement in PPAR-gamma mediated pathways, highlighting its potential as a therapeutic agent for individuals with minimal residual disease.

Telmisartan in colon *cancer*

Telmisartan, an angiotensin II receptor blocker (ARB) for hypertension, has been found to activate PPARγ in colon cancer cells, suppressing malignancy through differentiation and apoptosis [121].

Telmisartan effectively reduces cell viability, inhibits proliferation, and induces apoptosis in selected colon cancer cell lines [15].

The addition of GW9662, a PPARγ blocker, did not hinder telmisartan's inhibition of cell proliferation and viability, suggesting a PPARγ-independent pathway. Combined use of telmisartan and GW9662 intensified the reduction in cell viability and antiproliferative effects, particularly in SW-480 and SW-620 cells. Telmisartan demonstrated an apoptotic effect similar to pioglitazone, and this effect was not hindered by GW9662, indicating PPARγ-independent apoptosis induction [122]. Ligand-dependent activation of PPARγ resulted in the downregulation of PPARγ mRNA and upregulation of target genes, including CSTA. Telmisartan, in a dose-dependent manner, affected relative PPARγ mRNA expression and upregulated CSTA [123].

Addition of GW9662 led to significant downregulation in relative PPARγ mRNA expression, suggesting a PPARγ-independent pathway. Telmisartan's effects were superior to pioglitazone in certain cells, especially in the presence

of the PPARγ blocker GW9662 [122].
Telmisartan's apoptotic effect was comparable to the full PPARγ agonist pioglitazone, and this action appeared to be independent of PPARγ [124, 125].
Examination of gene expression shed light on the influence of GW9662 on PPARγ and CSTA mRNA expression, providing valuable insights into the molecular mechanisms underlying telmisartan's effects on colon cancer cells [123].
In summary, telmisartan exhibits notable effects on colon cancer cells through a PPARγ-independent pathway, with enhanced efficacy in combination with GW9662. The study provides crucial molecular insights into telmisartan's actions on colon cancer cells, emphasizing its potential as a therapeutic agent.

Hepatocellular carcinoma

Hepatocellular carcinoma (HCC) is the primary liver malignancy and a significant cause of cancer-related deaths globally [126, 127]. Telmisartan's impact on proliferation was assessed in various HCC cells, including HLF, HLE, HepG2, HuH-7, and PLC/PRF/5. Telmisartan effectively inhibited the proliferation of poorly differentiated HCC cells (HLF, HLE, and HepG2) while showing reduced sensitivity in well-differentiated HCC cells (HuH-7 and PLC/PRF/5) [128].
Telmisartan induced G0/G1 cell cycle arrest in HLF cells by impeding the G0-to-G1 transition [129].
The observed cell cycle arrest was accompanied by a significant reduction in the levels of cyclin D1, cyclin E, and other cell cycle-related proteins [130].
Telmisartan increased the activity of the AMP-activated protein kinase (AMPK) pathway and concurrently inhibited the mammalian target of rapamycin (mTOR) pathway [131, 132].
Telmisartan contributed to apoptosis in HLF cells, as indicated by an increase in caspase-cleaved cytokeratin 18 (cCK18) levels and a reduction in the phosphorylation of ErbB3. The study identified 163 differentially expressed miRNAs in response to telmisartan, emphasizing its inhibitory effects, particularly in poorly differentiated HCC cells.
Telmisartan's mechanisms involve cell cycle regulation, apoptosis induction, and modulation of key signaling pathways like AMPK/mTOR [14].
Telmisartan exhibits potent antiproliferative effects against hepatocellular carcinoma (HCC), especially in poorly differentiated cells. It arrests the cell cycle at G0/G1 phase, reduces cyclin D1 and cyclin E expression, and activates the AMPK pathway while inhibiting mTOR, hampering HCC proliferation. Telmisartan also induces apoptosis by increasing cCK18 levels and decreasing ErbB3 phosphorylation in HLF cells. Altered miRNA expression underscores its efficacy, particularly in poorly differentiated HCC. Overall, telmisartan regulates the cell cycle, induces apoptosis, and modulates key signaling pathways like AMPK/mTOR, making it a promising therapy for HCC.

Ovarian *cancer* and telmisartan

Ovarian cancer, ranking third in incidence among female reproductive system malignancies, poses a significant health challenge with epithelial ovarian cancer having the highest mortality rate among gynecological tumors [133]. Challenges at advanced stages highlight the critical need for early detection strategies [134].
Peroxisome proliferator-activated receptor gamma (PPARγ), a key player in various cancers, emerges as a potential avenue for cancer intervention [135]. Telmisartan, primarily an antihypertensive agent, gains attention for activating PPARγ. In HEY cells, telmisartan inhibits growth in a time- and dose-dependent manner, inducing apoptosis and reducing caspase-3 activity, consistent with outcomes in other cancer cells [136].
PPARγ's role takes center stage in regulating physiological processes, including ovarian tissue functions crucial for reproduction [137, 138]. Telmisartan's ability to elevate PPARγ expression reinforces its potential as a multifaceted therapeutic. Telmisartan's impact on MMP-9 expression, linked to cancer progression, further supports its potential in ovarian cancer treatment [139].
PPARγ agonists, including telmisartan, exhibit positive effects in contexts like renal fibrosis and early pregnancy chorionic villi, influencing trophoblast cell invasion [140]. Telmisartan's reduction in MMP-9 expression in HEY cells aligns with potential therapeutic effects observed in periodontitis and acute myocardial infarction [141, 142].

Telmisartan's mechanism of action in ovarian cancer encompasses PPARγ activation, suppressing cancer cell growth, promoting apoptosis, regulating MMP-9 expression, and offering potential multifaceted therapeutic effects (Fig. 2 and Table 3).

Table 3. Role of telmisartan in cancer

Type of study	Route of administration	Treatment duration	Target	Effect	References
a) Human endometrial cancer cells					
1–100 mM (HHUA human endometrial cancer cell line, immunodeficient mice)	Incubation of cells	Cells are incubated for 48 h	Annexin V+/PI2, HHUA cells, caspase-3 and -7, PPAR-c, Bcl-2, Bcl-x	Increase annexin V+/PI2 fraction (early apoptotic) and annexin V+/PI+(late apoptotic) subpopulations, cleaved PARP in HHUA cells, caspase-3 and -7 Decrease in expression of Bcl-2 and Bcl-x	Koyama et al. [120]
b) Human colon cancer cells					
0.2–5 μM (Human colon cancer cells) (HT-29, SW-480, and SW-620)	Incubation of cells	Incubation of cells for 24 h with drug	PPARγ	Reduced cell survival in the HT-29, SW-480 and SW-620 cell, PPARγ mRNA expression, cell viability	Lee et al. [122]
c) Human Lung Adenocarcinoma					
10–100 μM (A549 cells)	Incubation of cells	Incubation of cells for 24–48 h with drug	PPARγ, mRNA, protetn,	Increase in mRNA and protetn expression of PPARγ, DNA binding activity of PPARγ, decrease in mRNA and protetn expression of ICAM-1 and MMP-9 survival rates and cell viabilities of A549 cells	Li et al. [196]
d) Colorectal cancer					

0.2mM (The human primary tumor (SW-480), metastatic (SW-620) colon cancer cell lines, and human immortal keratinocyte (HaCaT)	Incubation of cells	Incubation of cells for 24 h with drug	PPAR-gamma, HEY cells	Increase the expression of PPARγ, Inhibit growth of HEY cells	Puta et al. [202]
e) Lung cancer					
40 μM (A549, HCC-15)	Incubation of cells	Incubation of cells for 24 h with drug	ROS, DR5	Increase ROS production, Increase DR5 upregulation	Rashed uzzaman et al. [203]
f) Ovarian cancer					
10 and 100 μM (HEY human ovarian cancer cell)	Incubation of cells	Incubation of cells for 48 and 72 h with drug	PPARγ, MMP-9 protein	upregulating PPARγ, Increase Apoptosis, cell viability Decrease in MMP-9 protein expression,	Pu et al. [204]

Telmisartan in diabetes

Telmisartan, recognized as an angiotensin II receptor antagonist specifically targeting the angiotensin II type-1 receptor, has become a widely utilized medication for the management of hypertension. In recent times, the focus on telmisartan's impact on peroxisome proliferator-activated receptors (PPARs) has expanded [10]. PPARs, belonging to the nuclear hormone receptor superfamily, are ligand-activated transcription factors. Telmisartan's distinctive feature lies in its reported partial PPARγ-agonistic effect, avoiding safety concerns associated with full PPARγ agonists [10].

Renowned for its partial PPARγ-agonistic effect, telmisartan exhibits capabilities in the regulation of glucose and lipid metabolism, improvement of insulin resistance, and potential effectiveness in addressing metabolic syndrome [10, 143].

Telmisartan's ability to lower glucose levels is linked to its capacity to inhibit reactive oxygen species and its agonistic influence on PPARγ [10]. The medication has demonstrated a reduction in oxidative stress, elevation of antioxidant levels, and enhancement of insulin sensitivity in individuals with diabetes [144]. The dual impact of telmisartan, involving partial activation of PPARγ and angiotensin type-1 receptor blockade, holds significance in preventing and managing type 2 diabetes mellitus (T2DM), metabolic syndrome, and atherosclerotic cardiovascular disease [10]. In hypertensive patients with T2DM, telmisartan exhibits favorable effects on insulin sensitivity, blood pressure, glucose and lipid metabolism, and endothelial function. Its cardioprotective attributes encompass the reduction of cardiac fibrosis and hypertrophy, prevention of adverse cardiac remodeling, and potential mitigation of diabetic cardiomyopathy [145]. Telmisartan's dual action on angiotensin type-1 receptor and PPARγ positions it as a valuable therapeutic option for hyperlipidemia, insulin resistance, hypertension, and stroke [146]. Additionally, the medication has displayed efficacy in improving the lipid profile, with notable reductions in triglycerides and increases in high-density lipoprotein cholesterol levels. Its potential hepatic partial PPARα agonist activity further contributes to its anti-dyslipidemic effects [147].

Telmisartan emerges as a promising therapeutic agent for T2DM, offering a comprehensive approach by addressing glucose regulation, lipid metabolism, insulin resistance, and providing cardiovascular and renal protection [10]. Telmisartan, known for its action as an angiotensin II receptor antagonist, also exhibits partial agonistic effects on PPARγ, distinct from full agonists. This feature enables telmisartan to regulate glucose and lipid metabolism and improve insulin sensitivity, making it valuable in managing type 2 diabetes mellitus (T2DM) and metabolic syndrome. By inhibiting reactive oxygen species and enhancing antioxidant levels through PPARγ activation, telmisartan reduces oxidative stress and enhances insulin sensitivity in diabetic individuals. Its dual action on PPARγ and angiotensin type-1 receptors provides a multifaceted approach to managing T2DM and metabolic syndrome.

Diabetic nephropathy

The renin-angiotensin system, vital for cardiovascular and renal functions, involves Angiotensin II (Ang II) binding to AT1 and AT2 receptors. Ang II, through AT1 receptor activation, induces vasoconstriction, sodium reabsorption, and various cellular processes in the kidney. Reactive oxygen species (ROS) [148] play a role in Ang II signaling, influencing critical events like transactivation of the epidermal growth factor receptor [149, 150].

In diabetic nephropathy (DN), PKC-α activation varies across renal structures, with implications for Na+-K+-ATPase inhibition and albumin uptake [151, 152]. Increased PKC-α expression correlates with TGF-β1 and VEGF levels, contributing to DN pathogenesis [153]. Telmisartan, an AT1R blocker, attenuates PKC-α and VEGF expression, suggesting nephroprotective effects via PKC-α in the RAS-PKC signaling cascade [154].

In vitro, telmisartan suppresses ROS generation induced by high glucose levels, protecting against cellular damage [155]. In diabetic mice, telmisartan reduces albuminuria, mesangial expansion, and inflammation-associated markers, demonstrating protective effects [156]. Telmisartan decreases oxidative stress markers (8-OHdG, Nox4), apoptosis (Bax), and improves kidney function and structure in diabetic rats. It regulates mitochondria-related pathways, inhibiting oxidative stress [157, 158].

Telmisartan's dual action as a PPAR-gamma agonist and AT1 receptor inhibitor contributes to renal protection It downregulates gene expression in the oxidative phosphorylation pathway, potentially inhibiting excessive mitochondrial ROS production [159, 160]. The upregulation of nephrin and podocin, crucial components of the slit diaphragm, signifies protective effects against diabetic nephropathy [161, 162].

Telmisartan exhibits multifaceted renoprotective effects, addressing oxidative stress, inflammation, and apoptosis in diabetic nephropathy. Its actions on PKC-α and various pathways provide valuable insights, suggesting its therapeutic potential in managing diabetic kidney disease (Fig. 3).

Fig. 3 [Images not available. See PDF.]

Diabetic neuropathy

Nerve healing is influenced by various factors, including the time between trauma and surgery, severity of trauma, type of damaged nerve, patient's age, and surgeon's experience [163]. Peripheral nerve regeneration is closely tied to apoptosis, and inhibiting the renin-angiotensin system (RAS) receptors, especially AT1 receptors, reduces apoptosis, inflammation, and oxidative stress [102]. Telmisartan, with its high affinity for AT1 receptors, demonstrates anti-inflammatory effects, supporting positive effects on nerve healing [102, 164].

The PPAR-γ ligand in telmisartan mediates its positive effects by inhibiting post-ischemic inflammation, neuronal degeneration, and apoptosis regeneration [165]. Telmisartan attenuates hemorrhage expansion, perihematomal edema formation, and neuropathic pain, attributed to its anti-inflammatory properties [102, 166]. It prevents nerve cells from injury by decreasing the apoptotic pathway, inhibiting caspase-3 activity, and reducing inflammatory cytokines [167, 168]. In conditions like chronic constriction injury (CCI), RAAS overactivation is associated with increased inflammatory mediators, oxidative stress, and pain-related markers [169, 170]. Telmisartan, by modulating RAAS components and downregulating signaling pathways like JAK2/STAT3 and P38-MAPK, [171] exerts beneficial

effects in neuropathic pain modulation. ACE-Is are superior to ARBs in neuroprotective and antioxidant effects [172]. Telmisartan administration in diabetic rats prevents the progression of diabetic neuropathy (DN) and enhances thermal and mechanical analgesia [12]. Its anti-inflammatory and neuroprotective properties, [27] attributed to PPAR-γ activation, alleviate hyperglycemia-associated alterations and reduce pro-inflammatory biomarkers [12]. Telmisartan suppresses the production of inflammatory cytokines and inhibits thermal hyperalgesia development and progression. It attenuates nerve growth factor degeneration and behavioral abnormalities in diabetic animals [173].

In summary, telmisartan's multifaceted actions, involving anti-inflammatory, neuroprotective, and antioxidant effects, position it as a potential therapeutic candidate in nerve healing and diabetic neuropathy. Its modulation of RAAS components and downstream signaling pathways contributes to its beneficial effects on nerve regeneration and pain modulation (Fig. 4).

Diabetic retinopathy

The activation of the renin-angiotensin system, particularly through the angiotensin II type-1 receptor (AT1R), has been identified as a potential mechanism for damaging retinal neurons in individuals with diabetes [174]. TNFα, a key inflammatory factor, can disrupt the blood-retinal barrier (BRB), leading to leukocyte accumulation in the retina and promoting cell death [175]. Caspase, indicators of cell death, are activated early in the retina of individuals with diabetes. Telmisartan effectively reduces caspase-3 activity in the diabetic retina, providing protection against neuronal damage [174]. The AT1R blocker effect extends to modulating levels of brain-derived neurotrophic factor (BDNF), ciliary neurotrophic factor (CNTF), tyrosine hydroxylase (TH), glutathione (GSH), and caspase activity in the retina [174]. Telmisartan, by inhibiting AT1R activation, addresses imbalances in these factors contributing to neurodegeneration in diabetic retinopathy. Telmisartan's ability to inhibit AT1R, which is stimulated by angiotensin II, presents a promising approach for treating diabetic retinopathy (DR) [176]. Telmisartan demonstrates a multifaceted protective role in diabetic retinopathy (DR). By inhibiting the activation of the angiotensin II type-1 receptor (AT1R) [177], telmisartan intervenes in the renin-angiotensin system (RAS), a potential mechanism implicated in damaging retinal neurons in diabetes [178].

The drug effectively reduces caspase-3 activity, providing protection against early cell death in the diabetic retina. Telmisartan's impact extends to the modulation of various factors crucial for neurodegeneration in diabetic retinopathy. It addresses imbalances in brain-derived neurotrophic factor (BDNF), ciliary neurotrophic factor (CNTF), tyrosine hydroxylase (TH), and glutathione (GSH), offering a promising approach for treating DR [179]. Its high affinity for AT1 receptor subtypes allows telmisartan to effectively block the RAS, leading to a sustained protective effect and slowing down the progression of diabetic retinopathy [180, 181]. The neuroprotective effects of telmisartan are further highlighted by its ability to elevate BDNF and GSH levels in both blood and the retina, responding to oxidative stress. By blocking AT1R activation induced by diabetes [182], telmisartan may deactivate NADPH oxidase, reducing oxidative stress and potentially increasing BDNF levels. The preservation of neurons, indicated by increased levels of TH, reinforces the protective impact of Telmisartan, particularly on dopaminergic amacrine cell functionality [183]. In addition, telmisartan effectively suppresses the elevated expression of VEGF-A, RAGE, and TNF-α in the retina, contributing to the mitigation of retinal complications [184]. Its specific binding to intraocular angiotensin receptor 1 (ATR 1) inhibits excessive activation of the Ang II-mediated RAS system, postponing the breakdown of the blood-retinal barrier (BRB) [184]. Telmisartan's actions encompass inhibition of AT1R, modulation of neuroprotective factors, reduction of oxidative stress, and suppression of pro-inflammatory mediators [185].

Telmisartan exerts a multifaceted protective effect against retinal damage in diabetic retinopathy by inhibiting AT1R,

modulating neuroprotective factors, reducing oxidative stress, suppressing pro-inflammatory mediators, and preserving the blood-retinal barrier (Fig. 5).

Telmisartan and diabetic ulceration

Patients diagnosed with type 2 diabetes mellitus frequently experience a high incidence of acute gastric inflammation and ulcer disease, and this occurrence is notably linked to the duration of diabetes. Moreover, peptic ulcers associated with diabetes mellitus tend to be more severe, exhibiting a delayed healing rate and a higher propensity for complications, including gastrointestinal bleeding [186, 187].

The heightened vulnerability of gastric mucosa in diabetic animals to damage involves a multifaceted mechanism. This includes changes in gastric motility [188] compromised duodenal bicarbonate secretion, and diminished angiogenesis, along with dysfunction in capsaicin-sensitive neurons crucial for safeguarding the gastric mucosa [189]. Telmisartan, a medication utilized for various conditions, exhibits antioxidant and anti-inflammatory properties attributed to its inhibition of the nuclear factor-κB (NF-κB) signaling pathway. This pathway plays a pivotal role in the transcription of genes involved in oxidative stress and inflammation, including NADPH oxidase, tumor necrosis factor-α (TNF-α), and inducible nitric oxide synthase (iNOS). Angiotensin II, a known inducer of oxidative stress, activates NADPH oxidase, leading to the production of reactive oxygen species (ROS) like superoxide anion, hydrogen peroxide, and hydroxyl radicals [190]. Moreover, it triggers inflammatory pathways, promoting the synthesis of TNF-α, contributing to gastric mucosa damage. Telmisartan acts as a partial agonist for the nuclear peroxisome proliferator-activated receptor-γ (PPAR-γ). Activation of PPAR-γ stimulates the expression of the catalase gene and inhibits NF-κB activity, thereby mitigating oxidative stress and reducing pro-inflammatory reactions [191, 192]. Stimulation of PPAR-γ also enhances the production of leptin protein, known for its ability to reduce gastric acid secretion [193]. The drug's impact on gastric health extends to blocking the activation of caspase-3 in the stomach lining, preventing the cascade of events leading to cell apoptosis [194]. Pro-inflammatory cytokines, especially TNF-α, and oxygen-derived free radicals are triggers of cell death by activating caspases. Telmisartan's ability to inhibit apoptosis is likely due to its capacity to reduce reactive oxygen species production and inhibit the synthesis of TNF-α and excessive nitric oxide [102, 195].

In summary, Telmisartan's mechanism of action involves inhibiting NF-κB signaling, reducing oxidative stress, suppressing inflammatory responses, and preventing apoptosis, collectively contributing to its potential therapeutic role in protecting against gastric ulcer formation (Fig. 6 and Table 4).

Fig. 6 [Images not available. See PDF.]

Table 4. Role of telmisartan in diabetes

a) Diabetic Nephropathy

5mg/kg/day Telmi [Male db/db and db/m mice]	Intraperitoneal	9 weeks	CD68, MCP-1, TGF-β osteopontin 8-OHdG Nox4 Bax, ROS	Reducing oxidative stress, decreased expression of 8-OHdG and Nox4, increased expression levels of the macrophage marker CD68, the chemokine MCP-1	Sato-Horiguchi et al. [156]
9 mg/kg/day—Telmi, [100 mg/kg-STZ (i.p.), Male C57BL/6 mice]	Orally	6 weeks	PKC-α pathway, ARB	Increased expressions of TGF-β1 and VEGF, decreased activation of PKC-α	Yao et al. [205]
5 and 10 mg/kg—Telmi 60mg/kg-STZ (i.p.), [Male Sprague–Dawley rats]	Orally	12 weeks	Analyses of individual genes, pathway enrichment, GO terms annotation, oxidative phosphorylation pathway, PPAR-g pathway, slit diaphragm	Increased glucose, H2O2, decreased MDA, inhibit overproduction in superoxide and ROS, suppressed AT1R expression	Zhang et al. [162]
b) Diabetic Neuropathy					
10 mg/kg-Telmi, [Male Wistar rats] Traumatization of sciatic nerves	Orally	4 weeks	(IL-1β) gene expression, TNF-alpha and interferon-gamma (IFN-γ), caspase-3 mRNA expression, PPAR-γ pathway	Increase mRNA expression, decrease caspase-3,	Yuksel et al. [167]
5 mg/kg-Telmi [Male albino rats] CCI of the sciatic nerve	Orally	2 weeks	NFκB signaling pathway TNF-α, NADPH oxidase and catalase, STAT3 activation, P38-MAPK pathway ACE, AT1R, AT2R, ACE, ARBs	Increased GFAP expression, COX-2, PGE2 level, decreased MBP expression,	Hegazy et al. [7, 172]
5 and 10 mg/kg/day-Telmi, (55 mg/kg)-STZ (i.p.) [male Wistar albino rats]	Orally	4 weeks	Tumor necrosis factor-α, interleukin-1β, and interleukin-6, Nerve growth factor (NGF), COX-2, MMP-2, and MMP-9, PPAR-γ activation pathway	Increase in pro-inflammatory biomarkers, inhibited NGF levels, decrease in glucose levels, mean body weights	Al-Rejaie et al. [12]

c) Diabetic Retinopathy					
10 mg/kg/day-Telmi, 55 mg/kg-STZ (i.p.), [Male Wistar rats]	Orally	9–10 weeks	RAS receptors, AT1R blockers, NADPH oxidase	Increases the GSH level, improving the protein expression level of BDNF, CNTF, and TH, decreases the caspase-3	Ola et al. [174]
10mg-Telmi, 50mg/kg-STZ (i.p.), [C57BL/6J mice]	Intravitreal	6 months	ATR1, RAAS system, VEGF, RAGE, TNF-ά, NF-κB and PKC pathways	Increase endothelial vascular growth inducer, decrease in tight junction proteins	Cao et al. [184]
d) Diabetic ulceration					
1 mg/kg/day-Telmi, 60 mg/kg-STZ (i.p.), [Male Sprague–Dawley rats]	Orally	1 week	Tumor necrosis factor-α, nuclear factor-κB, Caspase-3 PPARγ pathway	Increased lipid peroxidation, decreased the vulnerability of the gastric mucosa	Fouad et al. [206]

Conclusion

Telmisartan demonstrates neuroprotective effects by targeting inflammation and oxidative stress pathways, potentially useful in neurodegenerative diseases. It also exhibits significant anti-inflammatory properties, particularly in mitigating acute ocular inflammation associated with endotoxin-induced uveitis (EIU). It shows promise in mitigating diabetes-induced vascular inflammation by reducing adhesion molecule expression and inflammatory leukocyte attachment. It also exhibits nephroprotective benefits by modulating PKC-α and VEGF expression. Telmisartan, alleviate neuropathic pain by modulating RAAS components and suppressing JAK2/STAT3 and P38-MAPK signaling pathways. Telmisartan, acting as an AT1 receptor antagonist and PPAR-γ partial agonist, displays antioxidative and anti-inflammatory effects, impacting metabolic and inflammatory pathways. It suppresses TNF-α-induced NF-κB activation, reducing neutrophil infiltration in ulcerative colitis.

Additionally, its ACE inhibitor and AT1 receptor antagonist properties may augment GABAergic transmission, potentially benefiting seizure prevention and reducing edema in traumatic brain injury. Telmisartan shows anti-anxiety effects by blocking AT1 receptors in the brain and may inhibit cerebral AT receptors. It also demonstrates potential as a therapy for endometrial and colon cancer by inducing DNA damage and apoptosis through PPAR-gamma activation. Telmisartan inhibits the proliferation of poorly differentiated hepatocellular carcinoma cells and reduces MMP-9 expression in ovarian cancer cells.

Limitations

Our findings are limited by our main focus on preclinical studies, which means we did not review the effects of telmisartan in clinical studies. Moreover, our attention was directed toward assessing telmisartan's impact on common diseases and disorders, rather than those that are rare.

Cyclodextrin inclusion complex and amorphous solid dispersions as formulation approaches for enhancement of curcumin's solubility and nasal

epithelial membrane permeation

Schoeman, Carmen1; van Niekerk, Suzanne1 ; Liebenberg, Wilna1; Hamman, Josias11 North-West University, Centre of Excellence for Pharmaceutical Sciences (Pharmacen™), Potchefstroom, South Africa (GRID:grid.25881.36) (ISNI:0000 0000 9769 2525)

ABSTRACT (ENGLISH)

Background

Curcumin is a compound that occurs in the rhizomes of the turmeric plant (*Curcuma longa*) and has shown potential for the treatment of illnesses including certain neurodegenerative diseases. The bioavailability of curcumin is hindered by its extremely poor aqueous solubility.

Results

This study aimed to apply formulation strategies such as inclusion complex formation with hydroxypropyl-β-cyclodextrin (HPβCD), as well as amorphous solid dispersion (ASD) formation with poly(vinylpyrrolidone-*co*-vinyl acetate) (PVP VA64) and hydroxypropyl methylcellulose (HPMC) to increase curcumin's solubility and thereby its nasal epithelial membrane permeation. The curcumin formulations were evaluated by means of DSC, TGA, FT-IR, XRPD, microscopic imaging, aqueous solubility and membrane permeation across nasal respiratory and olfactory epithelial membranes. The solubility of curcumin was substantially increased by the formulations from 8.4 µg/ml for the curcumin raw material to 79.0 µg/ml for the HPβCD inclusion complex, 256.4 µg/ml for the HPMC ASD and 314.9 µg/ml for the PVP VA64 ASD. The HPMC ASD only slightly changed the membrane permeation of curcumin, while the PVP VA64 ASD decreased the membrane permeation of curcumin. The HPβCD inclusion complex enhanced the nasal epithelial membrane permeation of curcumin statistically significantly across the olfactory epithelial tissue and extensively across the respiratory epithelial tissue.

Conclusion

Complexation of curcumin with HPβCD enhanced the solubility of curcumin and thereby also increased its permeation across excised nasal respiratory and olfactory epithelial tissue. This indicated high potential of the curcumin-HPβCD complex for nose-to-brain delivery of curcumin for treatment of neurodegenerative diseases by means of intranasal administration.

FULL TEXT

Background

Turmeric, a spice that originates from the rhizomes of the *Curcuma longa* plant, has been used for centuries in Asia and India as an alternative herbal medicine for many acute and chronic diseases (e.g., certain cancers, bacterial infections, inflammatory conditions and oxidative conditions) [1–6]. The biologically active compound found in turmeric is a natural polyphenol identified as curcumin (1,7-bis[4-hydroxy-3-methoxyphenyl]-1,6-heptadiene-3,5-dion) [2, 4, 7]. Curcumin extracted from *C. longa* is accompanied by two other closely related curcuminoids, namely demethoxycurcumin and bis-demethoxycurcumin [1]. Curcumin has been proven to be safe and well-tolerated by many studies, even at doses as high as 8 g/day [3, 4, 6]. In a review by Gupta et al. [3], curcumin's clinical relevance is made prominent with reference to the different diseases that can be treated with this compound, which includes neurodegenerative diseases. Although the exact pharmacological mechanism of action for the many therapeutic actions of curcumin is not yet fully understood, previous studies indicated the possibility of biochemical pathway modulation to suppress inflammation and various other cellular activities [4, 8].

Curcumin's therapeutic potential is hindered by its extremely low solubility, and in addition, it also exhibits relatively low membrane permeability and is susceptible to rapid metabolism [4]. Consequently, curcumin has very low oral bioavailability, which means that large oral doses are required to achieve the desired therapeutic outcomes. This

necessitates the consideration of using a different route of administration than the oral route. The nasal route of drug administration is a favorable alternative as the nasal cavity is highly vascularized and bypasses first-pass metabolism [9]. This route of drug administration also has the unique capability of bypassing the blood–brain barrier for improved drug delivery into the brain [10]. The respiratory region of the nasal cavity contains the trigeminal nerve that is linked to the pons and cerebrum [9–11], through which molecules such as curcumin can reach the brain. More importantly, the olfactory region in the nasal cavity has been associated with direct nose-to-brain drug delivery [9–11]. This region is innervated by the olfactory nerves that directly connect the nasal cavity to the brain through the olfactory epithelium [9, 12]. Drug molecules can move to the brain from the olfactory region via different mechanisms including passive diffusion across the olfactory epithelium, along the olfactory neuron's axon or through the gaps between the olfactory nerves and ensheathing cells [9].

The concentration gradient required to drive the passive diffusion process can be aided by enhancing curcumin's solubility [13], which can be done by utilizing formulation strategies such as preparation of inclusion complexes with hydroxypropyl-β-cyclodextrin (HPβCD) as well as the formation of amorphous solid dispersions (ASD) with polymers. HPβCD is a cyclic oligosaccharide with a cone-shaped conformation that has a hydrophobic core and hydrophilic outer surface, making it an ideal carrier for hydrophobic molecules such as curcumin to enhance its solubility [14]. ASDs are formulations where the active compound is dispersed within the matrix of a hydrophilic polymer, thereby altering the crystalline packing of the molecules, resulting in the stable amorphous state with increased solubility [15].

Methods and materials

Materials

The curcumin (98%) raw material used in this study was obtained from Toronto Research Chemicals Inc., Toronto, Canada. The purity of the curcumin raw material was provided on a Certificate of Analysis by the supplier and also determined by comparing the concentration of the same quantity of a curcumin reference standard by means of HPLC analysis. The hydroxypropyl-β-cyclodextrin (HPβCD), poly(vinylpyrrolidone-*co*-vinyl acetate) (PVP VA64) and hydroxypropyl methylcellulose (HPMC) were sourced from DB Fine Chemicals, Johannesburg, South Africa. All solvents used in the preparation of the formulations, including ethanol and methanol, were purchased from ACE Chemicals, Johannesburg, South Africa. The ingredients to produce Krebs-Ringer Bicarbonate Buffer (KRB) used in the permeation studies and Lucifer yellow (LY) were acquired from Sigma-Aldrich, Johannesburg, South Africa. Consumables used, which include 100 µl crimp cells, were purchased from Mettler Toledo, Greifensee, Switzerland; 1-µm Acrodisc® Glass Fiber membrane filters were sourced from Pall Corporation, Bengaluru; Costar® 96-well plates were obtained from The Scientific Group, Randburg, South Africa; hydrochloric acid was sourced from Merck, Johannesburg, South Africa; acetic acid glacial and *n*-hexane were sourced from ACE Chemicals, Johannesburg, South Africa, while dimethylsulfoxide was purchased from Merck Chemicals (Pty) Ltd, Johannesburg, South Africa. The dialysis membranes (Membra-Cel™, 34 mm, 14 k Da) used in the compound release studies were sourced from Viskase® Companies, Inc, Illinois, USA.

Methods

Analytical methods

Ultraviolet (UV) spectroscopic analytical method

All samples were quantified for curcumin content by means of UV absorbance spectroscopy at a wavelength of 432 nm using a Spectramax® Paradigm Multi-Mode microplate reader (Molecular Devices, San José, California, USA). The UV absorbance analytical method was validated in terms of linearity, repeatability (intra-day precision), intermediate precision (inter-day precision), specificity and accuracy [16]. The limit of detection (LOD) and the limit of quantification (LOQ) were also determined. The stock solution of curcumin (42 µg/ml) used for the serial dilution was prepared in 40% *v/v* methanol (MeOH) in ultrapure water (UPH_2O).

Fluorescence spectrophotometric analytical method

Lucifer yellow containing samples collected during the membrane integrity experiment were analyzed using fluorescence spectroscopy with a Spectramax® Paradigm Multi-Mode microplate reader with the excitation

wavelength set to 485 nm and emission wavelength set at 525 nm [17]. The fluorescence analytical method was also validated in terms of linearity, repeatability (intra-day precision), intermediate precision (inter-day precision) and accuracy, and the LOD and LOQ were also determined.

Curcumin–cyclodextrin inclusion complex preparation

The inclusion complex prepared between curcumin and HPβCD in this study was conducted according to a previously reported solvent evaporation method by Yadav et al. [18]. In order to obtain a stoichiometric ratio of 2:1 for HPβCD:curcumin in solution, a quantity of 1.00 g curcumin was added to 400 ml of methanol, which was stirred until a clear solution was obtained and then a quantity of 6.12 g HPβCD was added to the curcumin solution and stirred until everything was dissolved. The solution was left at room temperature on a magnetic stirrer in a fume hood for 72 h to evaporate the solvent. The dry powder (i.e., curcumin-HPβCD inclusion complex) obtained was then passed through a sieve (aperture size: 850 μm), and the product was stored in an amber bottle in a desiccator.

Curcumin-polymer amorphous solid dispersion (ASD) preparation

The curcumin ASDs were prepared based on a solvent evaporation method published by Wegiel et al. [19]. Two ASDs were prepared, each with a different polymer by employing a 1:4 weight ratio of curcumin:polymer.

For preparation of the curcumin ASD with PVP VA64, a quantity of 1.00 g curcumin was added to 400 ml ethanol, which was stirred until a clear solution was obtained. A quantity of 4.00 g PVP VA64 was then added to the curcumin solution and stirred until a clear solution was obtained. The solution was placed in a round-bottom flask and placed on a rotary evaporator (Rotavapor R-210 and heating bath B-491, Buchi Flawil, Switzerland) at 40 °C for 1 h. The residue was emptied into a glass baking dish that was placed in the fume hood (at room temperature) and left to evaporate all the remaining solvent overnight. The crystals obtained were ground into a fine powder with a mortar and pestle.

To prepare the ASD consisting of curcumin and HPMC, the following method was employed. A mixture of water and an organic solvent (ethanol) was used to ensure sufficient solubility of both curcumin and the polymer [13]. A quantity of 1.99 g curcumin was allowed to dissolve in 85% v/v ethanol in water solution. When fully dissolved, a quantity of 8.00 g HPMC was gradually added, while stirring until no solid particles were visible. The solution was then transferred to a round-bottom flask and placed on a rotary evaporator (Rotavapor R-210 and heating bath B-491, Buchi Flawil, Switzerland) for 2 h at 40 °C. The residue was decanted into a glass baking dish and left overnight in a fume hood to evaporate all the solvent at room temperature. The powder (i.e., ASD) obtained after evaporation was ground into a fine powder with a mortar and pestle.

Characterization of curcumin–cyclodextrin inclusion complex and amorphous solid dispersions

Fourier transform infrared spectrometry (FT-IR)

Fourier transform infrared spectrometry (FT-IR) was employed to identify if complex formation occurred between curcumin and HPβCD, as well as the formation of ASDs with the two selected polymers. FT-IR spectra were recorded for the curcumin-HPβCD inclusion complex, the curcumin-PVP VA64 ASD, the curcumin-HPMC ASD, simple physical mixtures of all the combinations and each of the raw materials individually, with a Shimadzu IR Tracer-100 spectrophotometer (Shimadzu, Kyoto, Japan), utilizing a spectral range of 750–4000 cm^{-1}, 64 scans and a 4 cm^{-1} resolution.

X-ray powder diffraction (XRPD)

X-ray powder diffraction (XRPD) is an analytical technique commonly used to identify the presence of crystalline material within a sample of solid material. The sample is exposed to the radiation of X-rays, and the diffractometer then measures the intensity and the scatter provided by the sample. The diffractogram of a specific material is unique to its crystal structure [20]. An XRPD pattern or diffractogram was generated using a PANalytical Empyrean diffractometer (PANalytical, Almelo, Netherlands) for each of the following: the curcumin-HPβCD-complex, the curcumin PVP VA64 ASD, the curcumin-HPMC ASD, physical mixtures of all the combinations and each raw material. The diffractograms were recorded under the following conditions: target, copper; voltage, 40 kV; current, 30 mA; divergence slit, 2 mm; anti-scatter slit; 0.6 mm; detector slit, 0.2 mm; monochromator; scanning speed, 2°/min (stepsize 0.025°; step time, 1.0 s).

Simultaneous thermal analysis (DSC/TGA)

To observe any heat flow endotherms and weight changes, simultaneous differential scanning calorimetry (DSC) and thermogravimetrically analysis (TGA) were performed. Thermograms of the curcumin-HPβCD inclusion complex, curcumin-PVP VA64 ASD, curcumin-HPMC ASD, physical mixtures of all the combinations and each raw material were recorded using a Mettler DSC 3+(Mettler Toledo, Greifensee, Switzerland) connected to a computer equipped with Mettler STARe Default DB V14.00 software (V16.30a). A quantity of 5–6 mg of each material was transferred to crimp cells (100 µl) and placed in an automatic sampler, which transferred the cells into the furnace. The samples were heated to 195 °C at a heating rate of 10 °C/min and purged with nitrogen gas at a rate of 5 ml/min. An empty 100 µl crimp cell was implemented as the reference.

Visual inspection with polar and light microscopy

Microscopic inspection of the samples was carried out using a Nikon Eclipse E4000 microscope equipped with a Nikon DS-Fi1 camera (Nikon, Japan). A small quantity of each material was centrally placed on a microscopic slide and inspected with the microscope at a magnification of 4× and 10×. The first comparison was drawn between the curcumin-HPβCD complex and a physical mixture of curcumin and HPβCD in the 1:2 molar ratio without the polarity filter. The second comparison was between the ASD and their physical mixtures, each containing 25% curcumin, assessed with the polarity filter.

Aqueous solubility

Solubility studies were executed similar to a method published by Mangolim et al. [21]. The solubility was determined over a period of 3 h in accordance with the time of exposure of each material in solution to the excised nasal epithelial membranes during the ex vivo permeation studies. For the aqueous solubility studies, a sufficient quantity of curcumin-HPβCD inclusion complex, curcumin-PVP VA64 ASD, curcumin-HPMC ASD, physical mixtures of all the combinations and curcumin raw material was added to 10 ml of ultrapure water in amber glass tubes to provide supersaturated solutions (5 mg/ml). The solubility studies were conducted in triplicate ($n=3$). A water bath was preheated to 37 °C (±2 °C) and the samples were then placed onto a rotary axis within the water bath. The tubes were rotated for 3 h whereafter it was removed, contents filtered (1-µm glass fiber membrane filter) and analyzed for curcumin concentration using UV–visible spectroscopy (wavelength=432 nm).

Curcumin inclusion efficiency in hydroxypropyl-β-cyclodextrin complex

A method previously published by Mendes et al. [22] was used to determine the quantity of curcumin included in the complex formed with HPβCD. This method is based on the practical insolubility of cyclodextrin and its complexes in *n*-hexane [22]. Approximately 5 mg of the complex was accurately weighed to which 0.1 ml acetic acid was added and it was then made up to 5 ml with *n*-hexane to remove the free curcumin molecules not included in the cyclodextrin complex. The supernatant was then removed and analyzed for curcumin content, which represented the free curcumin. The residue (curcumin-HPβCD complex) was dried at 35 °C for 20 min or until it was dry. After drying, 400 µl DMSO and 400 µl 2% *v/v* acetic acid were added to the powder. The mixture was allowed to precipitate over a period of 12 h. Thereafter, it was centrifuged at 3000 rpm for 10 min. The supernatant was diluted with MeOH (ratio: 1:1) and analyzed for curcumin content, which represented the curcumin included in the cyclodextrin complex. Analysis was performed using the validated UV absorbance analysis method on a Spectramax® paradigm plate reader at a wavelength of 426 nm. The percentage curcumin included into the cyclodextrin complex (i.e., % inclusion efficiency) was calculated with the following equation:

1

$$\%\,\text{inclusion efficiency} = \frac{\text{Complexed curcumin}}{\text{Free curcumin} + \text{Complexed curcumin}} \times 100$$

Ex vivo permeation studies

Preparation of nasal epithelial tissue

The sheep nasal epithelial tissue was excised from animals slaughtered at an abattoir and prepared for the ex vivo permeation studies as previously published by Haasbroek-Pheiffer et al. [17] and Gerber et al. [23]. In brief, a reciprocating saw was used to remove the snout from a slaughtered sheep's head at an abattoir by a horizontal cut anterior to the eyes. The snout was then immersed in cold KRB (±4 °C) and taken to the laboratory. At the

laboratory, the skin was removed via blunt dissection and the snout was separated along the septal medial line using a bandsaw, allowing the abstraction of the septum and exposing the respiratory tissue (ventral nasal conchae). First, a vertical incision across the most distal part of the ventral conchae was made slightly proximal to its round edge, followed by a second horizontal incision across the inferior portion of the ventral conchae parallel to the hard palate. This allowed the separation of the respiratory epithelial tissue from the underlying cartilage, providing a sheet of epithelial tissue. The olfactory epithelial tissue was removed from ethmoid conchae in a similar way by carefully detaching it from the cartilage. The dissected epithelial tissue was then cut into strips (approximately 1 cm × 2.5 cm) that were mounted onto the half-cells of a Sweetana–Grass diffusion chamber. After assembly of the half-cells of the Sweetana–Grass diffusion apparatus, a volume of 7 ml pre-heated KRB was added to each chamber, then placed into a heating block and connected to a carbogen source, containing 95% oxygen and 5% carbon dioxide. The mounted tissue was equilibrated at 34 °C for 30 min before the commencement of the permeation study.

Determining the integrity of the mounted nasal epithelial tissue

Lucifer yellow (LY) was used as an exclusion marker molecule to provide evidence that the nasal epithelial tissues (i.e., respiratory and olfactory) mounted in between the Sweetana–Grass half-cells remained intact for the duration of the permeation study. LY permeation was determined as previously published by Haasbroek-Pheiffer et al. [17] and Gerber et al. [23]. In brief, a LY stock solution (50 µg/ml) was prepared in pre-heated (34 °C) KRB and 7 ml of this solution was placed into each of the six apical chambers of the Sweetana–Grass diffusion chamber apparatus. The basolateral chamber contained pre-heated KRB with 5% *v/v* ethanol. Samples (180 µl) were withdrawn from the basolateral chamber at 20-min intervals over a period of 2 h. The withdrawn volume (180 µl) was replaced with an equal amount of pre-heated KRB containing 5% *v/v* ethanol. The samples were collected in a Costar 96-well plate, and the samples were analyzed for LY content by means of fluorescence spectroscopy (excitation: 485 nm, emission: 525 nm) using a Spectramax® Paradigm Multi-Mode microplate reader as described above.

Curcumin permeation across nasal olfactory and respiratory epithelial tissue

For the curcumin permeation studies done in the absorptive direction, experimental solutions were prepared for each curcumin material (i.e., curcumin raw material alone, curcumin-HPβCD complex, curcumin-PVP VA64 ASD and curcumin-HPMC ASD) in pre-heated KRB (34 °C) at a concentration of 3 mg/ml curcumin. A volume of 7 ml of each experimental solution was placed into each apical chamber, while a volume of 7 ml pre-heated (34 °C) KRB containing 5% *v/v* ethanol was placed into each basolateral chamber. At pre-determined time intervals (i.e., 20, 40, 60, 80, 100 and 120 min) samples, 1000 µl) was withdrawn from the basolateral chamber, which was immediately replaced with the equal quantity of pre-heated (34 °C) KRB containing 5% *v/v* ethanol. The samples were collected in a transparent Costar 96-well plate and assessed for curcumin content. This was done by measuring UV absorbance at a wavelength of 432 nm, utilizing a Spectramax® Paradigm Multi-Mode microplate reader from Molecular Devices in San José, California.

Curcumin entrapment in nasal olfactory and respiratory epithelial tissue

At the end of the permeation study (i.e., at 120 min), the nasal epithelial tissue was removed from the chamber and cut into small pieces with dissection scissors and placed in 1 ml methanol, after which it was ultrasonicated for 10 min, centrifuged and a sample was withdrawn from the supernatant to determine the quantity of curcumin retained in the tissue. These samples were collected in a clear Costar 96-well plate and analyzed for curcumin concentration with UV absorbance at a wavelength of 432 nm using a Spectramax® Paradigm Multi-Mode microplate reader (Molecular Devices, San José, California).

The permeation studies were conducted across respiratory and olfactory nasal tissues with six independent repeats (n=6) for each experimental solution.

Curcumin release and permeation across synthetic dialysis membrane

To assess curcumin release from the cyclodextrin inclusion complex and ASD formulations (i.e., from the curcumin-HPβCD complex, curcumin PVP VA64 ASD and curcumin HPMC ASD), permeation studies were conducted across a synthetic dialysis membrane (Membra-Cel™, 34 mm, 14 k Da). Segments of the synthetic dialysis membrane,

approximately 1 cm × 2.5 cm in size, were prepared and mounted on the half-cell of the Sweetana–Grass diffusion chamber apparatus. The experimental solutions were prepared following the same procedure for the permeation studies across the nasal epithelial tissue. The apical chamber was filled with the experimental solutions (n = 3), after which 180 µl samples were extracted from the basolateral chamber every 20 min for a duration of 2 h. These samples were then analyzed for curcumin content utilizing the validated UV absorbance method on a Spectramax® Paradigm Multi-Mode microplate reader.

Data processing

The percentage permeation of curcumin across nasal epithelial tissue

To calculate the percentage of curcumin permeated across the excised nasal epithelial tissue at each withdrawal time point of each experimental group, Eq. 2 was employed.

2

%Curcuminpermeation=CurcuminconcentrationattimeintervalCurcuminconcentrationapplied×100

Furthermore, the apparent permeability coefficient (P_{app}) values for each experimental group have been calculated employing Eq. 3 [17].

3

P_app=(dc)/(dt)(1/(A×60×C_0))where dcdt is the permeability rate (concentration/min, slope of the graph of percentage permeation as a function of time), A is the area of the tissue across which diffusion takes place (cm^2), and C_0 is the initial concentration (3 mg/ml) of curcumin applied to the apical chamber.

Statistical analysis

Statistical analysis of the permeation data was performed utilizing a one-way ANOVA (analysis of variance). Subsequently, the data were subjected to measurements of normality and homogeneity after which the post hoc tests were conducted using the Tukey adjustment method.

Results

Analytical method validation

The validation results for the ultraviolet (UV) spectroscopic (for analysis of curcumin samples) and fluorescence spectrophotometric (for analysis of Lucifer yellow samples) analytical methods are portrayed in Table 1.

Table 1. Validation results for the ultraviolet (UV) spectroscopic and fluorescence spectrophotometric analytical methods

Validation parameter	Ultraviolet (UV) spectroscopic method	Fluorescence spectrophotometric method
Linearity (R^2)	0.9993	0.9993
Intra-day precision (%RSD)	1.78	0.86
Inter-day precision (%RSD)	0.78	0.29
Accuracy (%)	99.84	101.46
Limit of detection (µg/ml)	1.91	2.22
Limit of quantification (µg/ml)	5.80	6.74
Selectivity	Yes	N/A (single compound)

The validation results for both the UV spectroscopic and fluorescence spectrophotometric methods complied with previously published criteria for validation of these analytical methods (i.e., linearity: R^2>0.998, precision: %RSD <2% and accuracy: 98–102%) [16, 24].

Characterization of inclusion complex and amorphous solid dispersions

Fourier transform infrared spectrometry (FT-IR)

The FT-IR spectra for curcumin raw material (Cur RM), HPβCD raw material (CD RM), a physical mixture thereof (Cur-CD PM) and the prepared curcumin-HPβCD inclusion complex (Cur-CD complex) are presented in Fig. 1.

Fig. 1 [Images not available. See PDF.]

FT-IR spectra of curcumin raw material (Cur RM), HPβCD raw material (CD RM), a physical mixture of curcumin and HPβCD (Cur-CD PM), and the prepared inclusion complex between curcumin and HPβCD (Cur-CD Complex)

The first characteristic peak of the Cur RM spectra showcases the presence of free phenolic O–H stretching vibration with an absorption band located at 3505 cm^{-1} [25–27]. Additionally, two absorption bands appear at 2967 cm^{-1} and 2841 cm^{-1}, resembling the asymmetric vibrations associated with the methyl group and methoxy group, respectively [27]. Furthermore, the stretching seen at 1627 cm^{-1} is evidence of the keto-enol [17] located on the curcumin molecule and vibrations at 1510 cm^{-1} reveal C=O and C=C on the curcumin molecule. In the CD RM spectrum two absorption bands can be seen, which resemble the O–H and the $C–H_2$ molecules of the HPβCD, located at 3406 cm^{-1} and 2927 cm^{-1}, respectively [25]. Another characteristic band on the CD RM spectra is assigned to the C–O–C bond of this molecule and exhibits stretching at 1033 cm^{-1} [25–27]. In the spectrum for the physical mixture of curcumin and HPβCD, the absorption peaks of each of them are evident. On the other hand, the spectral data of the curcumin-HPβCD complex differ from those of the individual components.

The FT-IR results obtained for the curcumin-polymer ASDs are displayed in Fig. 2. The FT-IR spectrum for HPMC raw material exhibits a broad absorption band located at 3458 cm^{-1}. The same spectrum shows characteristic peaks of HPMC, at 1497 cm^{-1} and at 950 cm^{-1}. The physical mixture, containing curcumin and HPMC, showed a combination of the two component's spectra. A noteworthy peak broadening and shift from 1602 to 1587 cm^{-1} showcase a bond between the HPMC and curcumin.

Fig. 2 [Images not available. See PDF.]

FT-IR spectra of **a** curcumin raw material (Cur RM), HPMC raw material (HPMC RM), a physical mixture of curcumin and HPMC (Cur HPMC PM) and the prepared curcumin-HPMC ASD (Cur HPMC ASD) and **b** curcumin raw material (Cur RM), PVP VA64 raw material (PVP VA64 RM), a physical mixture of curcumin and PVP VA64 (Cur PVP VA64 PM) and the curcumin-PVP VA64 ASD (Cur PVP VA64 ASD)

The FT-IR spectrum of PVP VA64 presented with characteristic peaks at 1668 cm^{-1} and 1737 cm^{-1}. The physical mixture consisting of curcumin and PVP VA64 exhibited a combination of the peaks on the spectra of each individual material. When observing the FT-IR spectrum of curcumin-PVP VA64 ASD (Fig. 2b), an amine bending vibration can be seen at 1584 cm^{-2}.

X-ray powder diffraction (XRPD)

The XRPD diffractogram of the respective raw materials and physical mixtures, the inclusion complex between curcumin and HPβCD (Cur CD complex) and the ASDs formed between curcumin and the two selected polymers, namely PVP VA64 (Cur PVP VA64 ASD) and HPMC (Cur HPMC ASD), are shown in Fig. 3.

Fig. 3 [Images not available. See PDF.]

XRPD diffractogram **a** of curcumin raw material (Cur RM), HPβCD raw material (CD RM), a physical mixture of curcumin and HPβCD (Cur-CD PM), the prepared curcumin-HPβCD inclusion complex (Cur-CD Complex), diffractogram **b** ASD prepared with curcumin and HPMC (Cur HPMC ASD), relevant raw materials and physical mixture, and, diffragtogram **c** with PVP VA64 (Cur PVP VA64 ASD), relevant raw materials and physical mixture

In Fig. 3a, curcumin raw material exists in a crystalline state presenting a diffractogram with high-intensity peaks,

whereas HPβCD produced a diffractogram showcasing its amorphous form [25]. As expected, the simple physical mixture produced a diffractogram with a combination of the peaks in both its components, where these peaks were less potent and may be due to the dilution effect of HPβCD and curcumin. The prepared Cur-CD complex on the other hand produced the loss of some peaks that are present in the abovementioned materials such as 9.07°, 14.67°, 17.36°, 18.28° (2Θ). Furthermore, additional peaks appeared for the inclusion complex (14.2°, 26.01° and 27.14° (2Θ)) that did not previously exist in the other materials.

A striking difference can be observed in the X-ray powder diffractogram of the HPMC ASD prepared with HPMC and curcumin (Fig. 3b), and the same phenomenon can be observed when comparing the curcumin diffractogram to that of the curcumin PVP VA 64 ASD (Fig. 3c).

Differential scanning calorimetry (DSC)

The DSC thermograms of the relevant raw materials, their physical mixture and the Cur-CD complex are shown in Fig. 4a. Curcumin exhibited an intensive endothermic peak at 182.24 °C. In contrast to this, the DSC thermogram of the CD RM did not exhibit any endotherm in the scanned temperature region. The DSC thermogram of the physical mixture showcased a combination of the individual components with a melting point of 182.24 °C, corresponding with that of curcumin. The Cur-CD complex exhibited a shift in the endothermic peak at 173.73 °C.

Fig. 4 [Images not available. See PDF.]

DSC thermograms of curcumin raw material (Cur RM) including that of **a** HPβCD raw material, physical mixture (PM) as well as inclusion complex (Cur-CD complex), **b** HPMC raw material, physical mixture (PM) and ASD, c) PVP VA64 raw material, physical mixture (PM) and ASD

Figure 4b and c shows the DSC thermograms for the ASDs of curcumin prepared with PVP VA64 and HPMC, respectively. The polymers (HPMC and PVP VA64) exhibited no endotherm, characteristic of the amorphous state thereof. The physical mixture of the above-mentioned polymers and curcumin produced a thermogram that had a subtle curcumin melting peak, possibly due to the dilution effect of curcumin by the polymer. The curcumin-HPMC and -PVP VA64 ASDs, on the other hand, showed no endotherms, therefore indicating the amorphous state of these ASDs [28].

Thermogravimetric analysis (TGA)

The TGA thermograms of curcumin raw material, HPβCD, PVP VA64, HPMC, their physical mixtures, the curcumin-HPβCD inclusion complex, curcumin-PVP VA64 ASD and curcumin-HPMC ASD are shown in Fig. 5.

Fig. 5 [Images not available. See PDF.]

TGA thermograms of the prepared formulations prepared with curcumin (Cur RM), and different polymers (HPMC RM and PVP VA64 RM). **a** TGA of curcumin-HPβCD, **b** TGA of curcumin HPMC ASD and **c** TGA of curcumin PVP VA64 ASD

In the TGA thermogram Fig. 5a, curcumin did not show any weight loss at the temperatures scanned and the Cur-CD physical mixture had a 3.45% weight loss. The CD RM produced a 4.73% weight loss, whereas the Cur-CD complex produced a noteworthy difference with a 9.02% weight loss.

Displayed in Fig. 5b and c are the TGA thermograms of the prepared curcumin-HPMC ASD and curcumin-PVP VA64 ASD formulations, respectively. The total weight loss of the HPMC sample was 3.5% between 40 and 90 °C. The curcumin-HPMC ASD, PVP VA64 raw material and curcumin-PVP VA64 ASD presented with an 5.3%, 8.5% and 7.6%, weight loss, respectively.

Visual inspection with polar and light microscopy

In Fig. 6, the visual differences between the particles of the prepared Cur-CD inclusion complex powder and the physical mixture between curcumin and HPβCD can be seen. The HPβCD in the physical mixture appears as spherically shaped transparent particles and the curcumin appears as bright orange particles. The Cur-CD inclusion complex (Fig. 4b) appears as light, yellow-colored particles with uniformity in texture and no distinction could be made between the two components.

Fig. 6 [Images not available. See PDF.]

Light microscope photographic images of **a** a physical mixture of curcumin and HPβCD and **b** a curcumin-HPβCD (Cur-CD) inclusion complex (magnification ×10)

Figure 7a displays the polarized microscopic image of a physical mixture of curcumin and HPMC, while Fig. 7b displays the polarized microscopic image of the Cur-HPMC ASD. It is evident that in the physical mixture, crystalline curcumin particles are visible in the microscopic image, whereas the microscopic image of the curcumin-HPMC ASD particles indicates it exists in the amorphous state. The second ASD formulation showcases the curcumin PVP VA64 ASD (Fig. 7d) and its physical mixture (Fig. 7c), and the same birefringence can be seen for the crystalline curcumin inside the physical mixture with none in the ASD.

Fig. 7 [Images not available. See PDF.]

Cyclodextrin inclusion efficiency

An inclusion efficiency of 98.86% was achieved by the curcumin-HPβCD complex prepared in this study.

Aqueous solubility

Different values have previously been reported for the solubility of curcumin in aqueous media with values ranging from 0.60 µg/ml [29], 0.98 µg/ml [30], 0.011 µg/ml [31] to 40.00 µg/ml [32].

In this study, the solubility of curcumin raw material was found to be 8.4 µg/ml at 3 h in water at 37 °C. The aqueous solubility of curcumin was substantially enhanced by the formation of the Cur-CD inclusion complex (79.0 µg/ml), Cur-HPMC ASD (256.4 µg/ml) and Cur-PVP VA64 ASD (314.9 µg/ml).

Curcumin permeation across nasal olfactory and respiratory epithelial tissue as well as the dialysis membrane

The ex vivo permeation results (P_{app} values) for curcumin across excised nasal respiratory and olfactory epithelial tissues after the application of curcumin raw material (RM) as well as the CD inclusion complex and two ASDs are presented in Fig. 8.

Fig. 8 [Images not available. See PDF.]

Apparent permeability (P_{app}) values of curcumin raw material (CURCUMIN RM), curcumin-HPβCD complex (CD COMPLEX) and the ASD formulation with curcumin and HPMC (HPMC ASD) as well as curcumin and PVP VA64 (PVP VA64 ASD), respectively, across excised sheep nasal mucosa as well as the dialysis membrane. *The curcumin-HPβCD complex group showed a statistically significant ($p<0.05$) difference when compared to the curcumin raw material (control) across the olfactory nasal tissue. #The curcumin-PVP VA64 ASD also resulted in a statistically significant ($p<0.01$) difference when compared to the control across both tissue types

The permeation of curcumin raw material (Fig. 8) was extremely low across the excised sheep nasal respiratory epithelial tissue ($P_{app} = 7.1 \times 10^{-8}$ cm/s) as well as across the excised sheep nasal olfactory epithelial tissue ($P_{app} = 6.1 \times 10^{-8}$ cm/s). The permeation of curcumin, when applied as the HPMC ASD, was lower than that of curcumin raw material ($P_{app} = 6.2 \times 10^{-8}$ cm/s) across the respiratory epithelial tissue. On the other hand, it was slightly higher than curcumin raw material across the olfactory epithelial tissue ($P_{app} = 6.6 \times 10^{-8}$ cm/s). The permeation of curcumin when applied as the PVP VA64 ASD was significantly lower across both the respiratory epithelial tissue ($P_{app} = 2.7 \times 10^{-8}$ cm/s) and olfactory epithelial tissue ($P_{app} = 2.4 \times 10^{-8}$ cm/s) as compared to that of curcumin raw material. Curcumin released from the HPMC ASD ($P_{app} = 3.03 \times 10^{-8}$ cm/s) across the dialysis membrane was slightly higher than that of the PVP VA64 ASD, but it was still relatively low (Fig. 8).

Curcumin permeation from of the Cur-CD inclusion complex was significantly higher across the olfactory epithelial tissue ($P_{app} = 8.9 \times 10^{-8}$ cm/s) and markedly higher across the respiratory epithelial tissue ($P_{app} = 8.2 \times 10^{-8}$ cm/s) as compared to that of curcumin raw material. In addition, the HPβCD inclusion complex demonstrated the highest

permeation (P_{app} = 4.9 × 10^{-8} cm/s) of the three formulations across the dialysis membrane.

Curcumin entrapment in nasal olfactory and respiratory epithelial tissue

A comparison of the percentage of curcumin entrapped in the nasal olfactory and respiratory epithelial tissue at the end of the permeation experiment (120 min) for each experimental group can be seen in Fig. 9.

Fig. 9 [Images not available. See PDF.]

Percentage entrapment values of curcumin alone (CURCUMIN RM), curcumin HPβCD complex (CD COMPLEX) and the two ASD formulations with curcumin and HPMC (HPMC ASD) as well as curcumin and PVP VA64 (PVP VA64 ASD), respectively, across excised sheep nasal mucosa. #The curcumin-HPβCD complex showed a statistically significant (p<0.01) difference when compared to both nasal tissue types. ##The curcumin PVP VA64 ASD also resulted in a statistically significant (p<0.01) difference when compared to the control across the olfactory tissue. *The HPMC ASD resulted in a statistically significant (p<0.05) difference compared to curcumin across the olfactory epithelia

Curcumin PVP VA64 ASD produced a statistically significantly lower entrapment percentage of curcumin in the olfactory tissue (0.22%) when compared to that of the curcumin RM (1.26%). The curcumin-HPMC ASD presented with a significantly higher quantity of curcumin entrapped in the olfactory tissue (2.38%) when compared with the curcumin RM. The curcumin entrapped in the respiratory tissue (1.13%) was markedly higher than that of curcumin raw material (0.79%).

In line with the membrane permeation results obtained, the curcumin-HPβCD complex showed the highest membrane entrapment values, which were significantly higher than that of curcumin raw material in both nasal epithelial tissue types with 3.09% in the olfactory epithelial tissue and 2.51% in the respiratory tissue.

Discussion

The FT-IR spectral data of the curcumin–cyclodextrin inclusion complex and raw materials can be seen in Fig. 1. Cur RM spectra exhibited characteristic resemblances with previously published results [25, 33]. Seeing that the Cur RM did not exhibit a carbonyl stretch at ± 1700 cm^{-1} (characteristic of its di-keto form), it can be concluded that the keto-enol form of curcumin was used. The FT-IR spectrum of the CD RM also displayed similar characteristics as previously obtained [3, 25]. When referring to the physical mixture of curcumin and HPβCD, the absorption peaks of each of them are evident. On the other hand, the spectral data of the curcumin-HPβCD complex differ from those of the individual components. The overpowering absorption peaks seen are allocated to the CD RM, disguising the characteristic peaks associated with curcumin. The unique C-O and C–C stretching vibration seen at 1516 cm^{-1} confirms the conformation of a Cur-CD complex [25].

The FT-IR spectral data of the curcumin-polymer ASDs and raw materials can be seen in Fig. 2. The broad absorption band located at 3458 cm^{-1} in the HPMC raw material spectrum (Fig. 2a) is indicative of the O–H group found in HPMC [34]. Characteristic peaks of HPMC are visible, at 1497 cm^{-1}, indicating vibration of the O–H group, and the peak at 950 cm^{-1} reveals a C–O stretching [29], which is in accordance with previously published literature [34]. The physical mixture of curcumin and HPMC presented with a combination of the two component's spectra. The fingerprint zone found between 1500 and 750 cm^{-1} has a unique pattern for each compound normally consisting of bending vibrations [35]. A noteworthy peak broadening and shift from 1602 to 1587 cm^{-1} showcase a bond between the HPMC and curcumin. This corresponds with a similar bond identified by Chai, Isa [36]. The intermolecular interactions observed on the FT-IR spectrum of the prepared curcumin-HPMC ASD material and the disappearance of some crystalline peaks of curcumin are suggestive thereof that an ASD was indeed formed between curcumin and HPMC as polymer.

A recent article published by Dong et al. [37] noted that there are two characteristic peaks on the FT-IR spectrum of PVP VA64, namely the C=O located on the pyrrolidone ring at 1668 cm^{-1} and the other being the vinyl acetate at 1737 cm^{-1}. The physical mixture of curcumin and PVP VA64 presented with a combination of the spectra of each individual material. The PVP VA64 polymer within the curcumin-PVP VA64 ASD conceals most of the curcumin peaks except the amine bending vibration at 1584 cm^{-2}. From the FT-IR spectra, it can be concluded that the

curcumin-PVP VA64 ASD has been formed.

The formation of an inclusion complex between curcumin and cyclodextrin has been confirmed by the XRPD diffractogram (Fig. 3), These findings align with results published in a previous study by Mangolim et al. [21]. ASD formation with both HPMC and curcumin and PVP VA 64 and curcumin was confirmed by its characteristic amorphous state. The difference between the ASD diffractograms and the curcumin RM is due to a halo-pattern characteristic of the amorphous state of the ASD, which has been described in previously published work as a confirmation of ASD formation [38–40]. A possible restricting factor of XRPD analysis is its inability to differentiate between the amorphous phases. The distinguishing of these phases is beneficial to identify phase separation (drug-rich or polymer-rich phases) in ASDs and the possibility of subsequent recrystallization [41]. When DSC analysis is performed in conjunction with XRPD, this problem can be overcome [41].

DSC thermograms (Fig. 4) confirmed the endothermic peak for curcumin raw material at 182.24 C which correlates with the melting point of this compound [42]. The CD RM did not exhibit an endotherm reaction, while the physical mixture presented with a melting point of 182.24 °C. A shift in the endothermic peak was observed at 173.73 °C by the Cur-CD complex, indicating an interaction between curcumin and HPβCD. This phenomenon was recently reported by Low et al. [43] as confirmation of the inclusion of curcumin into an HPβCD complex. It was not possible to identify the glass transition temperature (Tg) of the ASDs at the temperature range scanned. This aligns with the findings of Li et al. [44], who reported that when the curcumin content is below 25%, the ASD has no recrystallization or melting point and is therefore regarded as amorphous and protected from recrystallization at high temperatures. Weight loss determined by the thermogravimetric analysis (TGA) of the physical mixture of Cur-CD can be ascribed to the loss of water [42]. The weight loss presented by the HPMC RM can be attributed to sorbed water in the polymer matrix McPhillips et al. [45]. In addition, water was used as a solvent in the preparation of the HPMC ASD. It is well-established in the literature that PVP molecules exhibit a pronounced affinity for water absorption [46]; therefore, the TGA thermogram in Fig. 5c presented a greater weight loss for the PVP VA64 raw material, which may be due to curcumin molecules replacing water molecules.

Light microscope images of a physical mixture of curcumin and HPβCD and a curcumin-HPβCD (Cur-CD) inclusion complex align with results previously published by Benucci et al. [47], who concluded that the lighter-colored powder particles were inclusion complexes that enhanced the solubility of curcumin. Polarized light microscopy is a technique used to confirm the crystallinity of a compound in solid state. As discussed by Chasse et al. [48], it utilizes a polarizing filter that results in crystalline materials exhibiting polarization colors also known as birefringence and the amorphous state of a drug will appear dark.

The solubility of curcumin was substantially enhanced by the formation of the Cur-CD inclusion complex, Cur-HPMC ASD and Cur-PVP VA64 ASD. When curcumin is entrapped in the hydrophilic cavity of HPβCD, it causes a solubilization effect and thereby increases the apparent solubility of curcumin [49]. Prepared ASDs have potential energy, which was released during the dissolution process, enabling curcumin to reach a supersaturated state [50]. The increased solubility of curcumin could provide a higher concentration gradient across the membrane, which could act as a thermodynamic driving force to propel the curcumin molecules across the membrane [13]. Another advantage described for ASD formulations is the ability to form liquid–liquid phase separation, which can produce small curcumin-rich droplets in solution that will serve as a reservoir and replace the curcumin in the solution that permeates across the membrane [51].

Finally, the curcumin RM, CD inclusion complex, Cur-HPMC ASD and Cur-PVP VA64 ASD were evaluated in terms of permeability across excised ovine respiratory, olfactory and dialysis membrane. Permeation from the HPMC ASD was lower than that of curcumin raw material across the respiratory epithelial tissue and only slightly higher across olfactory epithelial tissue, while permeation from the PVP VA64 ASD was significantly lower than the curcumin RM across both respiratory and olfactory tissue.

The permeation of curcumin from the HPMC ASD showcased a higher permeation when compared to the PVP VA64 ASD across both epithelial tissue types, which can possibly be explained by an interaction between the charged chains of HPMC and the phospholipid bilayer of the epithelial membrane. This may have contributed to the

increased membrane permeability, due to the phospholipid bilayer disruption [52, 53]. Although the HPMC ASD showcased an increased permeation when compared to that of the PVP VA64 ASD, it did not increase the permeation of curcumin when compared to the raw material (control), probably due to the relatively slow release of the curcumin molecules as observed in the results obtained from the dialysis membrane permeation study.
Yu et al. [54] explained that the in vitro release of the compound from the ASD is directly proportional to the compound/polymer ratio, where a higher compound/polymer ratio (e.g., 1:30) resulted in a slower drug release rate. In the PVP VA64 ASD, a 1:25 curcumin:polymer ratio was used and it is hypothesized that this has caused a slow release rate of curcumin from the polymer matrix in the ASD, which restricted the membrane permeation of the curcumin molecules. Maincent, Williams [50] mentioned that the diffusion pathway of compound molecules from the polymer matrix in ASDs decreases as the polymer swells, thereby restricting the diffusion of compound molecules from the polymer matrix. Another possibility was proposed by Schittny et al. [55] namely that the polymer formed a gel-like layer on its outer surface through which the compound will have to diffuse before it is released in order to become available to permeate across the membrane. This explanation was substantiated by the results obtained from the curcumin release study conducted across the dialysis membrane from the PVP VA64 ASD (incorporated in Fig. 8). Given that the combined molecular size of the ASD containing curcumin and the PVP VA64 polymer exceeded the 14 kDa cutoff limit, curcumin molecules that were not released into the solution were unable to traverse the membrane, which resulted in the relatively low P_{app} value of 2.64×10^{-8} cm/s. It can therefore be concluded that the poor release of curcumin from the PVP VA64 polymer could have contributed to the poor membrane permeation.
The increase in permeation was possibly due to the increased concentration gradient as a result of the solubility increase of curcumin when formulated as a cyclodextrin inclusion complex [56]. Another characteristic of the curcumin-HPβCD complex is that the compound is directly deposited onto the cell membrane after dissociation from the complex [57], resulting in an additional factor to increase the concentration gradient and therefore contributing to a higher passive diffusion rate [56].
From all the formulations investigated, the curcumin molecules were therefore released at the highest rate from the HPβCD complex. Although the permeation of curcumin across the dialysis membrane (without a phospholipid bilayer) was not as high as across the nasal epithelial tissue from the HPβCD complex, it can possibly be attributed to the interaction of cyclodextrin with the cholesterol composition of the biological membrane that increased the permeation of curcumin. According to dos Santos et al. [58] and López et al. [59], HPβCD can increase biological membrane fluidity by disruption (removal of cholesterol molecules) and this can increase drug permeation across the membrane.
In general, the permeation of curcumin was higher across the excised olfactory epithelium than across the respiratory epithelium. This is in agreement with previously published work by Fransén et al. [60]. They proposed that it was possibly due to transport along the olfactory nerves, the gaps between the nerves and other diffusion mechanisms. Furthermore, Du et al. [61] explained that the differences in the morphology and thickness of the epithelial tissue types from the different nasal regions may contribute to the difference in their permeability.
Similar to the permeation results, the curcumin PVP VA64 ASD produced a significantly lower entrapment percentage of curcumin within the olfactory tissue than the curcumin RM, and as previously discussed, it could likely be due to the curcumin molecules being released at a low rate and extent from the PVP VA64 polymer matrix [50]. The higher percentage curcumin entrapped within the respective nasal tissues after administration of the curcumin-HPMC ASD could be due to the higher concentration gradient combined with mucoadhesion [48, 54] and potential membrane disturbance [17, 54], can be caused by the charged HPMC polymer chains, which might have been responsible for the increase in the percentage of curcumin delivered into the membrane. Due to the highly lipophilic properties of the curcumin molecules, they remained inside the membrane and did not partition into the aqueous environment on the basolateral side. The significant membrane entrapment of curcumin from the curcumin-HPβCD complex is ascribed to the increased concentration gradient across the membrane providing the driving force to increase the diffusion of curcumin molecules into the membranes. However, due to the highly lipophilic nature of

curcumin, it did not partition out into the aqueous environment on the basolateral side [56].

Conclusion

The curcumin–cyclodextrin (HPβCD) inclusion complex elevated the solubility and nasal epithelial membrane permeation of curcumin substantially across the respiratory epithelial tissue and statistically significantly across the olfactory epithelial tissue. The HPβCD inclusion complex therefore showed potential as a formulation approach to enhance intranasal delivery of curcumin into the systemic circulation (across respiratory epithelial tissue) and into the brain (olfactory epithelial tissue). Enhanced solubility and intranasal delivery of curcumin by means of HPβCD inclusion complex formation means that lower doses can be administered to reach effective concentrations at the site of action. This has the additional advantage of decreasing side effects. Both the ASD formulations (HPMC and PVP VA64) increased the solubility of curcumin noticeably. However, the HPMC ASD only slightly influenced the curcumin permeation as compared to that of curcumin raw material, while the PVP VA64 ASD decreased the permeation significantly probably due to slow release of the curcumin molecules. The ASDs formulated for curcumin with the selected polymers (HPMC and PVP VA64) therefore did not show potential as a formulation approach to enhance intranasal delivery of curcumin.

Recent application of green analytical chemistry: eco-friendly approaches for pharmaceutical analysis

Mehta, Meshwa1 ; Mehta, Dhara1; Mashru, Rajashree11 The Maharaja Sayajirao University of Baroda, Department of Pharmacy, Vadodara, India (GRID:grid.411494.d) (ISNI:0000 0001 2154 7601)

ABSTRACT (ENGLISH)

Background

The substantially operated analytical instruments dealing in the area of analytical chemistry are traditional methods like high-performance liquid chromatography (HPLC) and gas chromatography (GC). Since they use solvents, produce trash, and require energy, these methods seriously compromise the natural milieu. The excessive consumption of an enormous number of organic solvents, along with the trash created from it, can contaminate the environment. As a result, researchers are now creating novel Green Analytical Chemistry approaches to address these environmental problems and create an ecologically preferable replacement.

Main body of the abstract

Ecologically preferable replacement can be accomplished by using a green solvent, such as ethanol or water, in place of harmful solvents. Additionally, the need for solvent can be decreased by omitting the sample preparation stage wherever possible or by utilising alternate green extraction methods. Adoption of compact methods like ultra-high-performance liquid chromatography (UHPLC) may also result in a decrease in the amount of energy used and trash produced during analysis.

Short conclusion

This review features information on using sustainable practises in analytical chemistry as well as details on using green solvents and sample preparation methods such as Solid Phase Extraction (SPE), Qucheers. It also provides information related of application of green analytical techniques such UHPLC, High-Performance Thin Layer Chromatography (HPTLC), and Thin Layer Chromatography (TLC).

FULL TEXT

Background

Implementing green chemistry and placing a focus on it in the laboratory are two themes that are becoming more and more popular in the chemical world. Chemists all across the world are striving to adapt more sustainable, energy-efficient processes and reactions for conventional ones. Green chemistry can take many different shapes, such as redesigning experiments with more environmentally friendly ingredients or actively managing waste [1]. Anastas initially defined "green chemistry" as a field that aims to eliminate or significantly reduce the production of dangerous compounds during any type of chemical process [2]. Although Anastas coined the phrase “green chemistry,” Badami, Nameroff, and Keltz are responsible for starting and maintaining the notion [3, 4]. The first steps in the exertion of green analytical chemistry (GAC) in the analytical chemistry field were taken in 1995 when Anastas highlighted the need to create GAC ideologies in an editorial that was published in a special issue of the Analyst journal that was devoted to the miniaturisation, containment, and reagent replacement in analytical methods [5].

To compare the efficiency of green chemistry approaches to conventional methods, many systems have been devised. This tactic is based on the twelve guiding Principles of Green Analytical Chemistry, which are listed in Table 1 [6–10] and may be remembered by the term significance.

Table 1. 12 Principles of green analytical chemistry

Principle	Green analytical chemistry
1	Use direct analysis wherever feasible
2	Reduce sample size and quantity as much as possible
3	Analysis ought to be done on-site wherever possible
4	Process integration between operations and analysis is necessary to conserve resources
5	Analyses ought to be automated if feasible
6	Refrain from derivatizing
7	Waste output should be kept to a minimum, and good waste management is crucial
8	To reduce the quantity of testing necessary, the technique should, if feasible, be optimised for usage on several analytes
9	Energy usage should be kept to a minimum
10	It is preferable to use renewable and sustainable reagents
11	Less dangerous, poisonous, and safer chemicals are recommended
12	Operator security is essential

One instance area that is making an effort to incorporate green chemistry ideas into equipment and analytical procedures is analytical chemistry. Creating more effective and resilient sample preparation protocols is one of the biggest concerns in analytical chemistry [11–13]. Therefore, as shown in Table 1, the first principle specifies that introducing the sample with minimal or no preparation is the most viable approach to decrease waste. However, most analytes require matrix extraction prior to analysis. The second, fifth, seventh, ninth, tenth, eleventh, and twelve principles may and should be used in situations when sample preparation is required. Techniques for preparing samples should be improved to the greatest extent feasible to decrease the amount of energy needed, solvent usage, waste output, and employee contact. This may be done in an assortment of manners, such as by limiting the amount and quantity of representative, using utile sample extraction equipment, and staying away from organic solvents that are hazardous [14]. Chromatographic strategies, which are used for distinguishing between the components of complicated mixtures in diverse matrices, are one of the topics of chemical analysis that GAC is passionate about. In the procedure of chromatographic analysis, the detrimental effects of harmful solvents to the health of humans and the environment must be ignored. The trash produced by a traditional chromatographic process, that demands a lot of organic solvent and can produce 1–1.5 L of scrap per day, must be dismissed of [15]. Since the majority of utilised organic solvents are volatile, they can quickly disperse and damage the surroundings. Thus, it is the duty of analytical scientists to reduce the detrimental impact produced by their work and to prevent, or at the at least, minimise it.

This systemic analysis review will give information on implementation of sustainable practises in analytical chemistry as well as details on using green solvents and sample preparation methods. Additionally, we have described the

execution of GAC principles for the validation and development of analytical methods utilising HPLC, UHPLC, Ultraviolet–Visible spectroscopy (Uv–Visible Spectroscopy), HPTLC, and TLC.

Main text

Outline of sample preparation approaches and the effects they have on analytical green techniques

Since the processes shown in Fig. 1 may entail the employ of hazardous substances and/or volatile solvents, the sample preparation stage tends to be the analytical method that causes the greatest pollution [Grob, 1984].

Fig. 1 [Images not available. See PDF.]

Analytical methods for measuring an analyte in matrix sample

The use of direct chromatographic methods in the absence of sample preparation

Based on the perspective of the GAC, direct analytical techniques—i.e. those that do not need sample preparation—are especially preferred. It is vital to adopt direct chromatographic procedures as the vast majority of chromatographic studies performed and the likelihood to produce residues during sample preparation. Direct injection of both liquid &solid samples may be effectively carried out by GC or liquid chromatography (LC) analysis, according to Tobiszewski and Namiesnik's 2009 statement [16]. It used to be discouraged to add the sample straight into the chromatographic capillary column, which may be water or a water–ethanol combination. A thick, nonpolar column stationary phase is utilised because water is thought to promote column bleeding, specifically when polar stationary phases are used. Significant improvements in column stationary phase quality and state-of-the-art cross-linking tactics have boosted resistance to deterioration triggered by water. When environmental water is injected into a column, notably when the water carries an immense amount of salt, performance issues with the column and decreased detector sensitivity can arise. In order to keep organic non-volatile &inorganic salts substances out of the analytical column, deactivated pre-columns must be positioned in front of it. The initial on-column injection techniques were the primary aim of the direct gas chromatographic approaches Grob et al. developed in 1978 [17]. In order to identify halogenated chemicals in sample of water by direct aqueous injection, Grob et al. developed an amalgamation of on-column injection and electron capture detection in 1984 [18]. A different approach was created using direct aqueous injection-gas chromatography and mass spectrometric detection to identify polar and nonpolar volatile chemical molecules in sample of water [19]. High-boiling volatile organic chemicals in surface water have recently been identified using greater volume direct aqueous injection-gas chromatography with flame ionisation detection, electron capture detection, and flame photometric detection [20]. The main drawback of these approaches is that they are restricted to the sample with generally pure matrices free of suspended debris [21]. The degradation of the chromatographic column might happen quickly if the analysed sample is not sufficiently clean due to an accumulation of particulates or non-volatiles that cannot release out of the column. Spirits &petroleum portions are illustrative of clean matrix that may be infused onto chromatography columns without any preparation. Since they merely call for straightforward sample preparation methods like filtering, dilution, or centrifugation, several approaches may be categorised as almost direct [22–24]. Thus, there are two ways that direct chromatographic procedures connect to green chemistry. They adhere to the principles of waste reduction and decreased usage of solvents, auxiliaries, and energy by skipping the sample preparation stage.

Green sample preparation

1. Solid Phase Extraction (SPE)

The substantially operated methods for preparing samples is SPE. In SPE, solutes are adsorbed onto a short column of a compatible solid sorbent after an aqueous sample is run over it. The analysed substances are retrieved from the absorbent in minuscule amounts of highly eluting organic solvents, which results in their enrichment [25]. Small quantities of solvent are used during solid phase extraction, which also produces minimal waste. It is therefore regarded as an environmentally beneficial method. SPE may be mechanised with the use of basic, low-cost apparatus, increasing laboratory throughput while increasing accuracy and precision. Despite this method's

advantages, there are certain possible drawbacks that should be taken into account to prevent ineffective analyte extraction. One of the problems is the unevenness of the packing material's bed, that might result in a reduction in efficiency. A secure solution to this issue is through the utilisation of commercial cartridges. Insufficient retention of extremely polar molecules may also result from certain traditional sorbents' low selectivity. Another problem is the conflict over retention between analytes and sample matrix, which has a significant negative influence on analyte recovery. As a result, rigorous process optimisation is necessary to guarantee successful analyte extraction [26].

1. QuEChERS Extraction Methodology

Popular extraction technique QuEChERS is known for being rapid, simple, inexpensive, efficient, robust, and safe. Anastassiades et al. [27] established the comprehensive QuEChERS technique in 2002. This method is regarded as a green extraction method since it only adopts a tiny number of organic solvents in comparison with other extraction means. Two essential phases are included in QuEChERS procedures: the extraction of solvents and sample clean-up. The sample is vigorously shaken throughout the solvent extraction process together with buffer (to safeguard base-sensitive analytical agents inside the sample), anhydrous magnesium sulphate, sodium chloride (to salt out). In order to get rid of interfering matrix components such carbohydrates &fatty acids, the sample cleansing phase is essential. Implementing magnesium sulphate (to soak any remaining water) and a weak anion exchanger known as "primary secondary amine" (PSA) absorbent as the dispersive solid-phase extraction agent, rapid dispersive SPE is enhancing purity of the extract [28]. Several applications used QuEChERS for extracting analytes of interest from blood specimens, including the eradicating a variety of pollutants from human specimens of blood [29], and removing amphetamine, opiate, and cocaine from blood through tandem mass spectroscopy and liquid chromatography [30], and the recently completed extraction of tetrahydrocannabinol (THC) [31].

1. Solid Phase Microextraction (SPME)

The process of extraction &enrichment might be combined using SPME, resulting in solvent-free sample preparation. The initial version of this approach was created in 1990 by Arthur and Pawliszyn. This method makes use of silica fibre that has been coated with the appropriate adsorbent phase. Direct extraction of the analyte from the solution and concentration on the fibre layer are both used [32]. In the SPME approach, the effectiveness of the analyte preliminary concentration might vary depending on a no. of facets, along with the fibre type, sample stirring, extraction duration, etc. [33]. By using SPME in conjunction with, high-performance liquid chromatography (HPLC), GC/mass spectrometry (MS), GC, and LC–MS, substances in food samples could be isolated. Minimal expenditure, ease of use, the removal of solvent disposal expenses, quick sample duration of preparing samples, dependability, susceptivity, and perceptiveness are certain main benefits of SPME. However, there are some shortcomings that need to be identified to prevent adverse outcomes. They include the fibre's brittleness, which makes it potentially breakable when handled, the risk of coating damage from recurrent Competitive absorption when sorbent-type coatings are put to use, the profound impact of mass &temperature transmit factors on equalisation, matrix effects, and so on. [34].

1. Stir-Bar Sorptive Extraction (SBSE)

As a substitution to SPME, SBSE is an environment friendly, free of solvent extraction method that was launched in 1999. The isolation and purification of volatile analytes from the water-based matrix was the original purpose of SBSE. Later, its uses were expanded to include non-volatile analytes in conjunction with HPLC and the examination of the headspace over liquid/ solid samples, or gaseous samples, and other samples. SBSE uses sorptive extraction, just as SPME. Analytical substances get absorbed into a polymer (such as polydimethylsiloxane) matrix

wrapped around a magnetic stir rod in this instance as opposed to a fibre, however. The substantially higher amount of the sorptive phase employed in SBSE compared to SPME is the primary distinction between the two. Better sensitivity is the outcome, particularly when utilising high sample volumes or substances with low partition coefficients. This approach is entirely without solvent in this instance since the coating's ability to capture volatile analytes allows them to be thermally desorbed right into a GC. Non-volatile analytical substance is desorbed using tiny amounts of a diluent, upholding the method's environmentally friendly nature [35].

1. Dispersive Liquid–Liquid Microextraction (DLLME)

The method uses three-phase solution that includes an aqueous sample, an extracting solvent that is immiscible with water, &some dispersive fluid which is solvable with in all the phases. The two distinct solvents are combined, &resulting solutions quickly introduced in the samples to create an extremely fine emulsion. As a result, the analytes may be transferred in the dispersed extraction solution extremely quickly. After the emulsion is created, it is centrifuged. The phase of increasing extraction density is retrieved by using a micro syringe and added to a preferred analytical device. DLLME has a number of benefits, including a small sample volume, little solvent consumption, high enrichment factor, excellent reproducibility, and high recovery. Enormous areas of proximity among the watery part &the solvent mixture are produced by the emulsion created following adding it to the fluid amalgam. As a result, the extraction is effective and the equilibration happens quickly [36].

1. Pressurised fluid extraction (PFE)

This methodology, referred as accelerated solvent extraction (ASE), involves doing the extracting using high pressures &temperatures that are beyond the solvent's boiling point at atmospheric pressure. The analytes’ solubility and diffusion rate rise at the higher temperature, while the solvent’s viscosity and surface tension decrease. Increased pressure makes it easier for the extractant to enter the matrix pores. PFE is regarded as a green technology since it uses less solvent, enables utilizing eco-friendly solvents like ethanol, methanol, and achieves quick and effective extraction in a lesser amount of period with less energy [36].

1. Microwave-Assisted Extraction (MAE)

Microwave radiation is employed in MAE to speed up the extraction procedure. The MAE principle relies on heating the system as a result of polar molecules absorbing microwaves, which heats the solvent that interact with the material to enable the extraction of analytes into a solvent or a water-based solution. It is possible to use the entire range of the microwave frequency, which ranges from 300 MHz to 100 GHz; traditional ovens should only function at 2.45 GHz. The major benefits of the MAE are its quick heating, elevated temperatures, and simplicity of use. Its one drawback is the restricted heating up investigated solvent caused by the dielectric constant [37].

1. Ultrasound-Assisted Extraction (UAE)

Since there are several drawbacks associated with traditional or other newer procedures, such as costly capital investment, the use of energy, and the use of harmful organic compounds for extraction, the use of ultrasound for extraction has grown over the past ten years. Ultrasound-assisted extraction (UAE) is a technique that uses ultrasound during the preapplication processes, and it might be favoured since it is a clean and ecologically friendly extraction approach [38]. As a result, the usage of UAE is now acknowledged as a safe and practical alternative to traditional food production methods. Therefore, when compared to other extraction procedures, ultrasound is a simple to use, multidirectional, versatile, and little investment required technology. Application of ultrasound broadens the range of commonly regarded as safe solvents.

1. Supercritical Fluid Extraction (SFE)

Supercritical fluid extraction (SFE) is an environmentally friendly, simple, and fully automated analytical technique. The term “environmentally benign sample preparation method” (e.g. “typical SFE”) refers to a technique that employs water or other non-toxic solvents. Short extraction times, lower pressures, and temperatures, together with the ability to preserve the integrity of food's functional components, allow SFE to almost minimise the possibility of activity loss [39]. The benefits of SFE include clean extract since less solvent is used and the extraction process takes less time. The extraction of the analytes is completed with no additional clean-up procedures. The sample pretreatment step of this approach lends itself to the most widespread usage of nontoxic and non-polluting extraction fluids [40]. Carbon dioxide, nitrous oxide, ethane, propane, n-pentane, ammonia, and sulphur hexafluoride are some of the most popular supercritical fluids. Due to its lack of abrasive and explosive properties, CO_2 is the most often used gas. Quantitative, straightforward, quick, selective, and ecologically friendly are the SFE's key benefits [41] (Table 2).

Table 2. Green sample preparation technique

	Organic solvent consumption	Energy consumption	Reusability	Laboratory waste	Automation

Greener organic solvents in analytical chemistry

The most ecologically conscious and long-lasting solvent that might be used in analytical chemistry is unquestionably with zero solvent. But in order to make samples liquid and make it easy to separate useful components, both sample preparation and analytical procedures need solvent. In order to alter traditional organic solvents, which are recognized due to their great volatility, combustibility, and toxicity, current developments in embracing the concepts of green chemistry into analytical procedures leads to the invention and use of novel solvents [42]. Solvent selection guides (SSGs) are instruments that help in the choosing of green organic solvents [43]. A replacement to traditional organic solvents, emphasising the three most significant green solvent types: amphiphilic solvents (encompassing alcohols, carboxylic acids and surfactants), ionic liquids (ILs) and analogues [44], and deep eutectic solvents (DESs) [45]. All of these solvents have been applied to the preparation of analytical

samples (as extraction solvents) as well as to liquid chromatography (LC) (mostly as mobile phase enhancers or in the form of pseudo stationary phases).

1. Alternative solvents for sample preparation

Water is the most ecologically friendly, economically viable, ecologically sound, and harmless solvent. Maceration is the most basic and widely employed method for doing extraction with water as the solvent. Specific additives can be used to subtly alter the characteristics of water. Water plus an additional substance—a surfactant or a hydrotrope, respectively—are necessary for both micellar and hydrotropic extractions. By producing micelles and aggregates, respectively, these amphiphilic molecules can increase the dissolution of water hating substances in aqueous conditions [46, 47]. Micellar extraction mimics a method of two-liquid-phase but hydrotropic extraction simply includes a continuous liquid phase. Additionally, nonpolar molecules can be extracted with water using subcritical water extraction (SWE).

Natural Deep Eutectic Solvents (NADESs) are combinations of naturally occurring solids with melting points that are far less than any of their separate constituents. The primary cause of this specificity is the formation of between molecules hydrogen bonds connecting hydrogen bond donors &acceptors. Since NADESs are solvent that are ecologically beneficial and easily recyclable [48, 49].

According to the agro-sector from where they were created, the "bio-based solvents" collect an enormous number of biomolecules that may be splited into three groups: wood, oleo-proteaginous, and cereal/sugar. Representatives of bio-based solvents include ethanol, ethyl acetate, lactic acid esters, succinic acid derivatives, and furfural and its derivatives, such as 2-methyl-tetrahydrofuran, cyclopentyl methyl ether (CPME), and others [50, 51].

Gases that may liquefy in its vapour pressure inside of a pressurised vessel at a pressure (1–100 bar) are referred to be liquefied gases. Due to their volatility, they make it simple to separate them from the extracts and have the benefits of dissolving natural ingredients at temperatures that are comparatively low, protecting delicate components from degradation. Increasing numbers of research document, the usage of liquefied gases as eco-friendly solvents for extraction such as dimethyl ether, n-propane &n-butane [52]

Substances at temperatures and pressures over their vital points are referred to as supercritical fluids (SFs). The major benefit of an SFs is that it can be tailored for density by adjusting temperature and/or pressure, allowing for selective extraction of specific analytes. Additionally, SFs have virtually zero surface tension, which enables them to enter microporous surfaces and leave essentially little solvent residue in the final extract. The most often used SF is carbon dioxide (CO_2) because of its modest significant pressure and temperature, which are 31 °C and 74 bar, respectively. Additionally, this fluid is tasteless, odourless, affordable, not combust ecologically friendly, and inert [53].

1. Using more sustainable solvents as mobile phase

High-purity organic solvents are needed in quite enormous quantities as the mobile phase in chromatography. The transition to reversed phase chromatography from normal phase, which used nonpolar, poisonous solvents, was the initial step towards environmentally friendly chromatography [54]. Methanol (MeOH), Ethanol (EtOH), Acetonitrile (ACN), acetone, ethyl acetate, or their combinations, or their mixes with water, are often used in reversed phase liquid chromatography. Among these solvents, EtOH, acetone, and ethyl acetate are preferred in terms of environmental friendliness, and some attempts are made to replace the more hazardous acetonitrile and methanol with them [55]. The disadvantage of ethanol compared to acetonitrile is that it has a somewhat high viscosity [56]. Ethanol is slightly harmful organic mobile phase ingredients. While the separation efficiency is statistically equivalent, acetone is another more environmentally friendly alternative to acetonitrile [57]. With water containing

0.04% triethylamine as the mobile phase, the use of polyethylene glycol as the stationary phase enabled successful partition of all 4 basic and acidic chemicals [58]. Only 0.85 mL EtOH was used per chromatographic run when a water-based mobile phase was used in extreme temperature liquid chromatography [59, 60].

Normal phase systems are used to determine some samples which are nonpolar and non-volatile (such as lipids), hence it's important to focus on applying more environmentally conscious solvents in this field. As mobile phase ingredients, cyclopentyl methyl ether, hexamethyldisiloxane, isopentyl acetate &2-methyltetrahydrofuran, have all been employed satisfactorily [61, 62] (Figs. 2, 3 and Table 3).

Supercritical CO_2	Nonpolar	Supercritical fluid chromatography
Liquid CO_2	Nonpolar	Flash chromatography

Recent applications of green technology

By using green solvents in HPLC

Elsheikh et al. have developed and optimised straightforward, accurate, and reliable stability-indicating chromatographic methods, such as the HPLC method supported with the Central Composite Design, to achieve an environmentally conscious time- as well as money-saving approach. He attempted to employ benign solvents here to detect zonisamide (ZNS) even in the presence of its breakdown product. By using a Kromasil MS C18 (150 mm, 4.6 mm, i.d. 5 µm) column at 35 °C with a green and safe mobile phase (MP) containing EtOH: H_2O (30:70%v/v), at (1 mL/min), and for detection, a photodiode array detector was used at 280 nm, ZNS was chromatographically separated from its degradation product. ZNS 50 g/mL HPLC chromatogram (retention time, Rt-2.806) and its degraded form 10 g/mL (Rt-1.553). Reproducible results were obtained in the range of (2–10 µg/band). The newly developed HPLC procedures have ECO Scale scores of 91 with modest green colours. The comparison of the results with the official USP procedure (81 eco scale score) demonstrates that the recommended methods were more environmentally friendly [72].

Kokilambigai et al. had optimised the HPLC technique in evaluation of atorvastatin calcium using analytical Quality

by design (AQbD) and more environmentally conscious solvent approaches. The Central Composite Design was employed to filter out factors that could have an impact on method development. The analysis was done using a Zorbax Eclipse plus C18 column (150×4.6 mm, 5 µm). Since neat EtOH along water as mobile phase produces broad peaks with unnecessary fronting and asymmetry, the best chromatographic analysis was accomplished utilising 0.5% v/v aqueous acetic acid: EtOH (42.5: 57.5%v/v) with a flow of 0.91 mL/min. Detection was performed at 246 nm using photodiode array. For atorvastatin, the Rt was 6.27 min, while the run-time was 12 min. There was good linearity between 10 and 150 µg/mL, with a correlation coefficient (R^2>0.9999). According to a forced degradation research, atorvastatin is more vulnerable to degradation when exposed to acidic stress. The created approach received a total score of 90, indicating that it adhered to all green standards and was therefore ecologically benign [73].

By using a Quality by Design-based HPLC approach, Perumal et al. discussed a rapid, simple, specific, accurate, reproducible, and environmentally friendly approach for determining the existence of escitalopram (ESC) &etizolam (ETZ) in the formulation. Utilising Phenomenex column C18 with EtOH and phosphate buffer (60:40%v/v), with a flow rate maintained at 1 mL/min, and detected at 254 nm using a dual absorption detector, is the best method for separating ESC and ETZ and the products of their deterioration. It was discovered that the ESC and ETZ had retention durations of 3.5 and 6.5 min, respectively. 99.55 and 99.94 percent, respectively, were found to be the percentage recovered for ESC &ETZ. This technique was tested and shown linearity ranges from 5 to 30 µg/mL for ESC, 2–12 µg/mL for ETZ, precision, repeatability, and selectivity with R^2 values of 0.9975 and 0.9987 for ESC and ETZ, respectively. In the forced degradation trials, ESC deteriorated significantly in an acidic environment, then most under photodegradation stress. In alkaline condition, ETZ's % recovery decreased, indicating the drug's susceptible to alkali. According to the analytical greenness metric approach (AGREE), the method's greenness was assessed, and the result was a score of 0.78 [74].

In order to quantify zidovudine (ZDV), lamivudine (3TC), and nevirapine (NVP), Vieira-Sellai et al. devised an environmentally sustainable HPLC approach. This method employs ethanol as the sample preparation solvent and as the MP for the analysis of the drugs. The analysis was carried by lowering the prepared solution's solvent volume and analysis time, as well as the column's diameter (3 mm as rather than 4.6 mm). Utilizing C18 column (ARV4 5 µm 250×3.0 mm, Interchim), the analysis was done in a gradient mode by injecting volume of 10 µL, with a flow rate 0.4 mL/min, while detection is done at 270 nm on a photodiode array (PDA) detector. Linearity was evaluated by preparing five standard solutions in the range from 80 to 120% of nominal concentration (37.5 µg/mL for 3TC, 75.0 µg/mL for ZDV and 50.0 µg/mL for NVP). As the mean recoveries fall between the range of 99.95% and 100.27%, the approach assures good accuracy. This technique obtains a count of 75 on the ECO Scale, indicating that it is environmentally friendly [75]

Dharuman et al. show the novel inclusion of analytical quality by design with GAC in the establishment of analytical approach for measurement of Benidipine hydrochloride (BEN) &Chlorthalidone (CTD) in bulk and formulations. For optimisation, a central composite design was employed. Using a MP of ratio 40:60%v/v of EtOH &potassium dihydrogen orthophosphate analysis was accomplished utilising an Agilent Eclipse Plus (C18, 250 mm 4.6 mm i.d, 5 µm) at 1 ml/min, and was detected via a diode array detector at 230 nm. The buffer solution (pH adjusted to 3.5) was chosen because it elutes analytes from the stationary phase more quickly, needs fewer time, and yields the best retention period with excellent peak symmetry, little tailing, and theoretical plates CTD and BEN had retention times of 3.1 and 5.1 min, respectively. Linearity range of 3.2–4.8 µg/mL for BEN and 5.0–7.5 µg/mL for CTD was obtained. The values for LOD and LOQ were obtained to be 1.812 and 5.493 µg/ml, respectively. The medication CTD was more likely to decompose under acidic and alkaline circumstances, whereas BEN was more vulnerable to

hydrogen peroxide, according to the forced degradation trials. The developed techniques' ECO Scale score is 93, with mild green colours [76].

Sukumar et al. proposed an easy, effective, and reproducible approach to analyse Atorvastatin (ATO), Ezetimibe (EZB), and Fenofibrate (FF), utilising stress studies and RP-HPLC green analytical chemistry principles. The buffer (0.1% triethanolamine in water) and EtOH was used to separate these medicines in the ratio of 90:10 on MP, whereas stationary phase (SP) used is Inertsil ODS 3 (250 mm × 4.6 mm), 5 µm column, employing a photodiode array detector (PDA) detector at a wavelength of 256 nm. The forced degradation investigations revealed that EZB decay greater than 15% at alkali hydrolysis, while the ATR has >5% deterioration in acid, peroxide, and heat deterioration. The Rt of ATO, EZB, and FF are 2.86, 6.723, and 11.13, respectively. ECO Scale of the developed methods show a score of 91 with faint green colours [77].

By combining UV spectrophotometric &HPLC techniques, Perumal et al. devised an analytical quality by design approach that is quick, affordable, accurate, precise, and environmentally friendly. Analysis of Molnupiravir and its breakdown products was done on C18 column having a MP of EtOH and phosphate buffer in ratio of 42.5:57.5% v/v, at flow rate of 0.9 mL/min, and detected at 235 nm. Utilizing the UV and HPLC techniques, the molnupiravir linearity ranges were 4–9 and 10–150 g/mL; also, the R^2 values showed 0.9999 and 0.9999. For molnupiravir, the recovery rate ranged from 98 to 102%. The proposed strategy received a 94 on the ECO Scale, signifying that it is beneficial to the environment [78].

By combining analytical quality design with green analytical chemistry concepts, Kannaiah et al. devised a green, straightforward, and trustworthy approach for estimation of betamethasone dipropionate (BD) and calcipotriene (Cal) through a UHPLC method. The Central Composite Design (CCD) was utilised to filter out factors that could have an impact on method development. Dikma Endeversil C18 ODS (2.1 × 50 mm, 1.8 µm) column was used for separation. For best chromatographic separation, EtOH and potassium dihydrogen phosphate (3.0 pH) buffer were mixed 51:49 (%v/v), at a flow of 0.31 mL/min, and detected at 254 nm. Betamethasone and Calcipotriene had linear detector responses at 125–750 and 12.5–75 µg/mL, with detection limits and quantifications of 12.484, 37.831 and 3.229, 9.785 µg/mL, respectively. The recovery percentage was shown to be within tolerances of less than 1.5%. BD showed a degrades of more than 15% in the alkali, while degradation in Cal was nearly 15% in oxidation, according to a forced degradation research. AGREE metrics software program shows the total score of 0.89, greenest in all respects [79].

A single reversed-phase HPLC technique devised by Vijaykumar et al. for the estimation of apremilast, its enantiomer and its seven impurities in the medicinal material. Apremilast chromatographic separation from its enantiomer product was achieved by utilising immobilised chiral SP having a chiral selector "tris (3,5-dimethyl phenyl carbamate) derived from amylose-Chiralpak IA-3 (250 mm × 4.6 mm, 3 µm) column at 25 °C with green MP consists of buffer (0.01 M NH_4HCO_3, PH 8.0) and ACN in equal ratio at (0.4 mL/min). Two contaminants, impurity-2 (open ring acid impurity) and impurity-5 (deacetylated impurity), were discovered through forced degradation research. The impurity recoveries range from 96.1 to 102.1%. It was discovered that the suggested method's AGREE matric score was 0.66 as its consumption of ACN is comparatively less than previous established methods [80].

Kowtharapu et al. devised a linear, exact, accurate, particular, robust, environmentally friendly and sustainable LC method for determining olopatadine hydrochloride. A Boston eco-friendly C8 column (150 × 4.6 mm, 5 µm i.d.) was used to optimise and validate the isocratic chromatography procedure. With flow rate of 1.0 mL/min and a column temperature of 30 °C, a MP of sodium dihydrogen phosphate buffer of pH 3.5 and ACN in the ratio of 75:25 (%v/v) was utilised. The detection was carried out at 299 nm. The accuracy outcomes varied from 99.9 to 100.7%, the relative standard deviation (RSD) from the precision was 0.5, and the correlation coefficient from the linearity

experiment was more than 0.999. Analytical eco scale tool was used which gave an outstanding analytical eco-score of 77 was discovered [81].

Kowtharapu et al.; optimised the High-Performance Liquid Chromatographic technique for evaluating ondansetron hydrochloride utilising AQbD design approaches. The devised approach is straightforward, considerate and beneficial to the environment. A Discovery (250 × 4.6) mm, 5 µm column using phosphate buffer pH 5.7 and acetonitrile as the MP, at flow rate fixed at 0.9 mL/min, and detected at 216 nm were used to achieve separation. The relative standard deviation for the accuracy findings ranged between 0.55 and 2.72% for all contaminants. The linearity experiment yielded correlation coefficients greater than 0.995 for both contaminants and analyte. The accuracy ranged from 88.4 to 113.0% for all impurities. Results for accuracy varied from 99.9 to 100.7% [82].

For the simultaneous analysis of the innovative combination of metformin hydrochloride (MTF), pioglitazone hydrochloride (Pio), and glibenclamide (GBC) and also with MTF toxic impurities, Fawzy et al. proposed a reliable, specific, eclectic, and environmentally conscious HPLC–UV technique. With a short run time and less environmental risks, the suggested approach is green. On a VDSpher Pur 100 C18-E (250 mm × 4.6 mm, 5 m) column, contaminants and antihyperglycemic medications were separated and quantified using gradient elution with a mobile phase made up of 0.1 M heptane sulfonic acid having a pH 2.2 and ACN under a flow of 1.5 mL/min and detection done at 225 nm using photodiode array detector (PDA). Retention intervals for MTF = 3.640, Pio = 5.062, and GBC = 7.788 min, respectively. Analytical AGREE tool reveal the score of 0.76 suggesting it as green [83].

The four medications, tamsulosin HCl (TAM), tadalafil, alfuzosin HCl, and solifenacin succinate (SOL), were examined by Abdel-moety et al. utilising a mix of GAC and AQbD techniques using HPLC–DAD methodologies. Derringer's desirability function and CCD was utilised to identify and optimise key technique limits. Optimal chromatographic separation was achieved using EtOH and phosphate buffer (pH 4.0) in a ratio of 40:60 (%v/v) for mixture I and in equal ratio for mixture II flowing at 2.3 mL/min, and detected through UV detector at 210 nm. Separation was performed on Agilent HPLC–DAD system C18 column (100 mm × 4.6 mm). The suggested approaches also make effective utilization of monolithic-based columns by enabling high throughput analysis with just a little under 4 millilitres of ethanol and a roughly 3-min run time. The percentage recoveries ranged between 98 and 102%. Linear concentration was in a range of 3–70 µg/mL for TAM, 5–110 µg/mL for tadalafil and 5–90 µg/mL for both alfuzosin &SOL. The Analytical Eco Scale was employed to measure the method's greenness, and the result was a score of 94[84].

For the determination of ketoconazole along with beclomethasone utilising RP-HPLC &multi-analytical UV spectrophotometric approach, Kannaiah et al. developed a straightforward, dependable, exact, effective, and ecologically friendly technique. The absorption ratio, first-order the absorption ratio, and area under curve approaches are the three environmentally friendly approaches covered by the spectroscopy technique for estimate, which is the initial approach. The second method employed an eco-friendly rotatable CCD analytical quality via a design-based RP-HPLC technique and an ODS reversed-phase column (250 × 4.6 mm, 5 µm). The best chromatographic separation was obtained through a MP of EtOH: 0.1 M potassium dihydrogen phosphate buffer (pH 2.5) 33: 67%v/v with a flow of 1.0 mL/min. Analytical eco scale, green analytical procedure index (GAPI), and AGREE were used to examine the technique's greenness, and it was determined that the approach is green [85].

Badr-Eldin et al. suggested a simple, recursive, quick, accurate, exact, repeatable, resilient, specific, and stability-indicating RP-HPLC technique for identifying clonazepam and its associated compounds. With an ODS column and a mobile phase made up of 2% sodium dodecyl sulphate, 0.05 M sodium acetate buffer pH 3.5, and isopropanol in the ratio (25:55:20%v/v/v), with a flow of 1.5 mL/min the chromatography process was optimised and verified. Detected at 254 nm using a DAD detector. The recovered percentage ranged from 101.33 to 99.40%. Linearity for

clonazepam and its associated compounds was between the range of 4–140 µg/mL and 4–64 µg/mL, respectively. Clonazepam and its related compound have LOD of 0.024 µg/mL and 0.380 µg/mL while LOQ of 0.0799 µg/mL and 1.2870 µg/mL for, respectively. It was discovered that clonazepam breaks down more quickly in oxidative environments. The approach is also straightforward in terms of susceptibility, utilisation of an ecologically friendly MP, straightforward extraction techniques, considerably shorter Rt [86].

For the simultaneous testing of a combination of sofosbuvir and ledipasvir, El-Shorbagy et al. proposed a straightforward, quick, prudent, linear, exact, accurate, and environmentally conscious RP-HPLC–UV-Fluorescence approach. On C18 (250 mm × 4.6 mm, 5 µm in particle size), isocratic elution at a flow rate of 1.2 mL/min was used at room temperature. The UV and fluorescence detectors are both installed in the column. The MP contained 35: 35: 30 (%v/v/v) acetonitrile, methanol, and 0.01% triethylamine that had been pH-adjusted to 3. The UV detector was operated at 261 nm until the SOF was eluted, at which point it switched to 333 nm (the LED maximum) for five minutes. By using a UV detector, it was discovered that the mean % recovery of sofosbuvir and ledipasvir was 100.33 and 100.06, respectively. Linearity for sofosbuvir was between the range of 1 and 40 µg/mL while for ledipasvir 0.4–20 µg/mL. LOD for sofosbuvir was 0.012 µg/mL while for ledipasvir was 0.011 µg/mL. LOQ were 0.040 µg/mL and 0.036 µg/mL for sofosbuvir and ledipasvir, respectively [87].

Subhadip et al. devised an ecologically sound, resilient, quick, accurate, specific, linear, and exact RP-HPLC technique for predicting favipiravir in its medicinal dosage form, and compared it using ANOVA and in-vitro dissolution studies. With a C18 column (4.6 mm × 150 mm, 3 µm spherical particles), MeOH, EtOH, and H_2O (25:35:40%v/v/v) as the MP, with a flow of 0.80 mL/min, a Rt of 7.216 min, at temp of 25 °C, and detected at 236 nm, in isocratic mode, with a run-time of 10 min, separation was accomplished. Oxidative stress was shown to cause the greatest deterioration percentage. The average recovery rate was more than 98%. The created procedures have an eco scale score of 92, which means they are more considerably secure as well as environmentally friendly [88].

A green and environmentally friendly HPLC technique was created by Khaled et al. to measure vitamin D_3 and calcium levels in atorvastatin. In less than 10 min, the two medicines were separated using a gradient of 0.1% orthophosphoric acid (OPA) having pH = 2.16 and EtOH as the MP &a photodiode array detector. The column was Symmetry column C18 (100 × 4.6 mm, 3.5 µm). The column temperature had been set 40 °C while the MP was introduced at a rate of 1 ml/min. Atorvastatin calcium &vitamin D_3 were detected at wavelengths of 246 and 264 nm, respectively. The average recovery for atorvastatin calcium &vitamin D_3 was determined to be 102.87% &101.35%, respectively. Linearity of the method was verified in the range from 5 to 40 µg/mL for atorvastatin calcium and 1–8 µg/mL for vitamin D_3 while LOD are 0.475 µg/mL and 0.041 µg/mL for atorvastatin calcium and vitamin D_3. They evaluated the greenness of our suggested procedure such as AGREE &GAPI tools. The developed approach has a score of 0.75 and is a semi-automatic, miniature method [89].

Using a Teknokroma C18 (150 mm × 4.6 mm, 5 µm particle size) reversed-phase guard column, Sepideh et al. devised a straightforward, quick, economical, and environmentally friendly HPLC test for estimating capecitabine in plasma. An oral 5-fluorouracil (5-FU) prodrug called capecitabine is frequently administered to people with colorectal and breast cancer. Formic acid solution (pH = 3): EtOH (55:45%v/v) flowing in a flow rate of 1.0 mL/min along with UV detection at 310 nm was used as the MP for the extraction. The temperature inside the column was fixed at 50 °C. Protein was precipitated from the sample using a zinc sulphate-ethanol solution. This approach yields a high capecitabine recovery in human plasma, which can vary from 95.98 to 102.50% [90].

For determining domperidone aspirin and in bulk or formulation using HPLC, Sneha et al. devised an analytical approach that is affordable, quick (short retention time), straightforward, precise, reliable, and sustainable. On a

Prontosil C-18 column (4.6×250 mm, 5 µ particle size), separation was carried out isocratically using a MP of 10 mM KH_2PO_4: ACN (20:80%v/v) pH 3.5. Chromatograms were taken at 231 nm by a UV–visible detector [91].

Nazrul et al. devised a simple, rapid, reliable, precise, robust, specific, environmentally friendly &stability determining technique for quick measurement of rosuvastatin calcium in conventional medicines utilising HPLC–UV. As a sustainability-conscious green eluent, a mixture of EtOH, MeOH, and ethyl acetate (6:3:1%v/v/v) at a rate of 1.0 mL/min was chosen to produce a quick and straightforward assay with a reasonable run time (5 min), which was the most effective to detect rosuvastatin calcium &its separation. A NUCLEODUR 150 mm 4.6 mm RP C8 column filled with 5 m filler as the SP was used to identify rosuvastatin calcium, with detection taking place at 254 nm. The estimated Rt for rosuvastatin calcium is 1.52 min. Linear concentration was found in range of 0.1–100 µg/mL with correlation coefficient of 0.996. The % recovery was found to be 99.99%. According to investigations on forced degradation, rosuvastatin calcium deteriorated under oxidative stress in the presence of H_2O_2 and in 0.1 M NaOH [92].

For the measurement of clorsulon, albendazole, triclabendazole, and ivermectin utilising monolithic columns, Rashed et al. devised a straightforward, quick, environmentally friendly, and highly sensitive micellar liquid chromatographic approach. With a MP made up of 120 mM sodium dodecyl sulphate, 15% propanol, &15 mM phosphate buffer (pH 5.5), separation was carried out on an Anonyx monolithic C18 column (100×4.6 mm) at 40 °C using UV detection at 225 nm. The average recoveries varied from 99.2 to 101.2%. Linearity of the method was verified in the range from 0.625 to 25 µg/mL for clorsulon, albendazole, triclabendazole and 30–300 µg/mL for ivermectin. LOD are 0.16, 0.18, 0.18 and 6.15 µg/mL and LOQ are 0.54, 0.60, 0.60 and 20.50 µg/mL for clorsulon, albendazole, triclabendazole and ivermectin, respectively. The recommended method's analytical Eco Scale value was determined, and it received a score of 75, which is very near to being an exceptional green analysis [93].

Magdy et al. devised a unique and environmentally friendly reversed-phase HPLC technique with fluorescence detection, as well as an analytical QBD approach, for the simultaneous quantification of lesinurad &febuxostat (FBX) with diflunisal (DIF). On the Hypersil BDS C18 column, the separation via chromatography is carried out using isocratic elution at 40 °C. ACN: potassium phosphate buffer (30.0 mM; pH 5.5, 32.2:67.8% v/v), pumped at 1.0 mL/min with an injection volume of 20.0 µL, was the MP. Fluorescence detector (FLD) detection was carried out at 280/370 nm. The ternary mixture may be separated using the suggested procedure in about 10 min. The Rt was determined to be 6.599, 7.641, and 9.155 min for DIF, lesinurad, and FBX, respectively. Linear concentration was found in range of 50–500 ng/mL, 50–700 ng/mL and 20–700 ng/mL, respectively, for DIF, lesinurad and FBX. The recoveries for DIF, lesinurad, and FBX were 99.32%, 98.8%, and 99.65%, respectively. The relative standard deviation was found to be less than 2. The recommended method's analytical Eco Scale value was computed, and a score of 87 was discovered [94].

By combining the concepts of GAC, Saroj et al. established a reliable &environmentally friendly RP-HPLC technique for determination of fenoverine. With a mobile phase of methanol and ammonium acetate buffer 20 mM (81:19% v/v), on a flow rate of 1.0 mL/min, and a column oven temperature of 33ºC, while employing UV detection at 262 nm, separation was accomplished on a Spherisorb C18 column (150×4.6 mm, 3 µm). The peak of fenoverine in the unstressed condition was seen in the chromatogram at 7.8 min. According to a forced degradation research, considerable degradation occurs under 10% H_2O_2 and hydrolytic conditions. Linear concentration was found in range of 0.5–160 µg/mL with a limit of detection and limit of quantitation of 0.1 and 0.3 µg/mL, respectively. The % recovery was found to be 99.7%. The developed HPLC method had an efficiency analysis trees (EAT) value of 41.82, while the literature method had a score of 44.01, which concluded that the approach that was created had a smaller effect on the nature because it was developed entirely without using ACN [95].

A brand-new, straightforward liquid chromatographic method for brivaracetam detection together with piracetam and carbamazepine was devised and validated by Mansour et al. On a Promosil C18 column (100 mm × 4.6 mm, 5 µm particle size), separation was accomplished using a MP of ACN: H_2O containing 0.1% triethylamine at a ratio of 30:70%v/v at pH 6.5 corrected with orthophosphoric acid with a column temperature of 25 °C. The flow rate is 0.6 mL/min, the run period was around 9 min, and the UV detector used a 215 nm wavelength for detection. Piracetam, brivaracetam, and carbamazepine were shown to have retention times of 1.4, 4 and 8 min, respectively. The recovery rates were found to be between 94.8 and 101.05%. Values of the limit of quantification were 3.7, 2.3 and 1.8 µg/mL for the piracetam, the brivaracetam and the carbamazepine, respectively. The recommended method's analytical Eco-Score was discovered to be 85[96].

For the simultaneous detection of amlodipine (AML) &metoprolol (MET), Mabrouk et al. devised and validated a rapid, sensitive, and accurate green micellar liquid chromatographic technique. The XBridge ODS column (1150 × 4.6 mm, 5 µm particle size) was used for separation. The mobile phase was composed of SDS and sodium dihydrogen phosphate in water, while the pH was adjusted to pH 3.0 using phosphoric acid. The injection volume was 50 µL, and the flow rate was 1.5 mL/min at 40 °C. For MET and AML, the fluorescence detector was adjusted to emit light at 275/303 nm and excite light at 364/455 nm, respectively. The MET Rt was 3.46 min, and AML was at 6.35 min. Linearity of the method was verified in the range from 0.1 to 10 µg/mL for MET and 0.2–2 µg/mL for AML. The recovery was close to 100.156%. RSD values were below 2%, which demonstrates adequate precision. LOD was 20 ng/mL and 50 ng/mL for MET and AML while LOQ was 61 ng/mL and 81 ng/mL for MET and AML. The developed method was found to have an analytical Eco Scale value of 80 indicating an excellent green HPLC method [97].

A quick, secure, and ecologically conscious analytical technique for determining daptomycin in lyophilized powder was developed by Totoli et al. Using a MP of EtOH-H_2O (55:45%v/v) around pH 4.5, pumped at a flow rate of 0.6 mL/min for an 8-min run period, and UV detection at 221 nm with a DAD detector, separation was accomplished on an Agilent Zorbax C18 analytical column (4.6 × 150 mm, 5 µm). Daptomycin had a retention period of 5.8 min. Linearity of the method was verified in the range from 20.0 to 70.0 µg/mL. The recovery was close to 100%. RSD values were below 2%, which demonstrates adequate precision. LOD was 1.87 µg/mL and the LOQ was 5.68 µg/mL. According to a study on force degradation, the sample was less stable under basic circumstances [98].

Bhukya et al., had developed and validated stability indicating HPLC method for separation and identification of Panobinostat and its degradant product. The analysis was done using a column Waters X bridge C18 3.0 µm (50 × 4.6 mm) was used with mobile phase A as 10 mM NH_4COOH buffer adjusted to pH 3.0 with HCOOH and Ethanol as mobile phase B with gradient elution mode. The mobile phase flow rate is 0.5 mL/min, injection volume are 3 µL and at 277 nm as UV wavelength. The method found linear from 12 to 300 µg/mL with $R^2 \geq 0.998$. The % recovery for analyte was in between 99.28 and 100.36 with 0.60% RSD. The %RSD for the analyte in Method precision and intermediate precision is below 1.0. According to the AGREE, the method's greenness was assessed, and the result was a score of 0.74 [99].

Hammad et al., had developed a solvent free, robust, sensitive, selective and fast chromatographic method for determination of metronidazole (MTR) and ciprofloxacin (CIP). The analysis was done using a X-Bridge (150 × 4.6 mm, 5 µm) column. The separation was achieve using 0.13 M sodium dodecyl sulphate and 0.02 M polyoxyethylene lauryl ether (Brij-35) solution to pH 2.5 using phosphoric acid at a flow rate of 1.3 mL/min and 280 nm wavelength in UV detector. The method was said to be greener as it eliminates the use of harmful organic solvent as well as it minimises the run time (8 min) to reduce cost and energy consumption. The method found linear from 0.5 to 50 µg/mL with $R^2 \geq 0.9998$ for MTR and 0.9997 for CIP. The % recovery for MTR and CIP was to be

99.45 and 100.13%, respectively. The %RSD for the analyte in Method precision and intermediate precision is below 2.0. The AGREE software was employed to evaluate the technique's greenness, and the resultant score of 0.81 [100].

Michael et al., had developed green, accurate, selective and stability-indicating method for determination of levetiracetam using HPLC. The analysis was done using Lichrosorb RP-18 (250×4.6 mm i.d., 5 µm particle size) column. The separation was achieve using phosphate buffer (pH 3.1) and acetonitrile (87:13%v/v) mobile phase with the flow rate of 1.0 mL/min, and UV detection was carried out at 210 nm. The Rt of drug was found to be at 5.6 min. The AGREE software was employed to evaluate the technique's greenness, and the resultant score of 0.82 [101].

Yabre, M., et al., developed an easy, green, and stable RP-HPLC methodology for measuring contaminants in artesunate and amodiaquine using a Quality by Design (QbD) methodology. It effectively handled the difficulty of evaluating nine compounds under a single chromatographic condition by using a gradient elution with EtOH, resulting in a 95% confidence level for identifying the method's operational domain region. To achieve greenness, EtOH and 10 mM acetic acid were used as the mobile phase, which was tested using accuracy profiles and successfully used to raw materials and fixed-dose combination tablets. The technique used an Xbridge BEH C18 column (150 mm×3 mm, 5 µm) with a flow rate of 0.4 mL/min. [102]

Megahed et al.; described an experimental approach to establish a green, gradient chromatographic technique for simultaneously analysing metronidazole (MTR) and spiramycin (SPR). The optimal chromatographic conditions involved a mobile phase of ethanol and 20 mM sodium dihydrogen phosphate solution (pH adjusted to 2.5) in a 2:98 (%v/v) ratio for 2 min, followed by a change to 30:70 (%v/v). The flow rate was 1.3 mL/min, and the separation and analysis were done on an X-bridge C18 column (150 mm×4.6 mm×3.5 µm). The detection wavelength was 230 nm, and the column oven temperature was set at 40 °C. The approach showed a linear response for both drugs in the range of 5–125 µg/mL. [103]

Duan et al.; developed and validated a green HPLC technique for the simultaneous measurement of nine sulphonamides utilizing EtOH as the green alternative solvent, and it was effectively applied to beef and milk samples. The Venusil XBP C18 column (Lanzhou Acetch Technologies Co., Ltd., Lanzhou, China) consisting of the following features: 250 mm, 4.6 mm in diameter, 5 µm particle size was used. The pH of the mobile phase was around 3. Furthermore, no more than 30 mL of trash was created each sample. The four quadrants of the greenness profile are represented by the following criteria: persistent, bio accumulative and toxic (PBT), hazardous, corrosive, and waste. The score of the analytical Eco Scale was 86, indicating an excellent value for the proposed method [104].

Habib et al.; used quality by design principles and green analytical chemistry which aided in the creation of a green micellar HPLC technique for assessing atorvastatin calcium and amlodipine besylate in binary combinations and tablet dosage forms in 8 min. The optimal conditions were a mobile phase of 0.17 M sodium dodecyl sulphate solution (pH 2.9) with 10%v/v n-butanol, a flow rate of 1.5 mL/min, and a column temperature of 45 °C utilizing an X-Bridge™ (150 mm×4.6 mm, 5 µm). Fluorescence detection was set at 276/378 nm for atorvastatin and 366/442 nm for amlodipine. The approach showed linear responses for both medicines in the range of 0.2–25 µg/mL and was verified for tablets. [105]

Elmansi et al.; developed the method for separation of three BDZs (diazepam, clonazepam, and bromazepam) utilizing a green micellar mobile phase. Brij-35, a non-ionic surfactant, substitutes organic solvents, resulted in much shorter retention times and more ecologically friendly separation. The procedure, was carried out on a monolithic C18 column, uses a 50:50% v/v mixture of sodium dodecyl sulphate (SDS) and Brij-35 as the mobile phase. Using UV detection at 240 nm and a flow rate of 1.0 mL/min, separation was accomplished in less than ten minutes, even

without an organic modifier. Furthermore, the method's greenness was evaluated using the analytical eco scale, demonstrating its suitability for testing the three medications. It was found that the developed micellar HPLC method, had an Eco scale value of 95 [106].

Kokilambigai et al.; used analytical quality by design (AQbD) and greener solvent technologies to improve a High-Performance Liquid Chromatographic (HPLC) method for detecting atorvastatin calcium in bulk and pharmaceutical dose forms. A rotating central composite design was used, with EtOH volume and flow rate as essential method variables that influenced analytical characteristics. Using a Zorbax Eclipse plus C18 column (150×4.6 mm, 5 µm), optimum separation was achieved using a mobile phase of 0.5% v/v aqueous acetic acid: EtOH (42.5:57.5%v/v) at 0.91 mL/min. Atorvastatin was detected at 246 nm, resulting in a retention time of 6.27 min and a total run duration of 12 min. The technique demonstrated linearity from 10 to 150 µg/mL, and validation trials produced good findings. The method's greenness and ecological effect were assessed using a variety of indicators, which validated its great environmental profile. When evaluated using the analytical eco scale, the recommended HPLC method received a score of 90 [73].

Stability-indicating techniques for modafinil (MDF) and the by-product of its acid-induced deterioration have been devised and confirmed by Elsheikh et al. The procedure was an environmentally conscious (HPLC) procedure that used an XTERRA MS C-18 column (100 mm×4.6 mm, 5 µm id), EtOH-H_2O (30:70, %v/v) as the MP at 40 °C at a flow of 1 mL/min, and UV scanning at 220 nm. With a lowest time to retention of 3.6 min, the HPLC chromatogram of MDF at 50 g/mL has a Rt of 3.628 while that of its degradation product at 10 g/mL has a Rt of 1.129. Linearity was in ranges of 2–10 µg/mL. Accuracy was found to be 100.01%. LOD and LOQ was 0.127 and 0.384 µg/mL. The created HPLC Eco Scale procedures yield scores of 90 [119] (Table 4).

Table 4. Summary of applications of green solvent in HPLC

Drug	Approach	Greenness	ECO Scale/AGREE Score	References
Zonisamide	HPLC	EtOH: H_2O MP	91 and 84	[72]
Atorvastatin calcium	HPLC	0.5% v/v aqueous acetic acid: EtOH MP	90	[73]
Escitalopram and Etizolam	HPLC	EtOH and phosphate buffer MP	0.78 (AGREE)	[74]
Lamivudine, Zidovudine, and Nevirapine	HPLC	EtOH as MP, reducing column diameter to3mm	75	[75]
Benidipine hydrochloride &Chlorthalidone	HPLC	EtOH and potassium dihydrogen orthophosphate MP	93	[76]
Atorvastatin, Ezetimibe, and Fenofibrate	RP-HPLC	Buffer (0.1% triethanolamine in H_2O) and EtOH MP	91	[77]

Molnupiravir and its breakdown products	UV spectrophotometric and HPLC	EtOH and phosphate buffer MP	94	[78]
Betamethasone and Calcipotriene	RP-HPLC	EtOH and phosphate buffer MP	0.89(AGREE)	[79]
Apremilast, its enantiomer and its seven impurities	RP-HPLC	Green mobile phase buffer (0.01 M NH_4HCO_3, PH 8.0) along with ACN	0.66(AGREE)	[80]
Olopatadine hydrochloride	LC method	Boston green C8 column along with sodium dihydrogen phosphate buffer (pH 3.5) with ACN as MP	77	[81]
Ondansetron hydrochloride	HPLC	Phosphate buffer pH 5.7 and ACN MP	–	[82]
Metformin hydrochloride, Pioglitazone hydrochloride, and Glibenclamide	HPLC–UV	Short run time and less environmental risks	0.76(AGREE)	[83]
Tamsulosin HCl, Tadalafil, Alfuzosin HCl, and Solifenacin succinate	HPLC–DAD	EtOH and phosphate buffer MP and effective use of monolithic-based columns by enable analysis with just 4 millilitres of EtOH	94	[84]
Ketoconazole and Beclomethasone	RP-HPLC &UV spectrophotometric	EtOH: 0.1 M potassium dihydrogen phosphate buffer MP	–	[85]
Clonazepam and its associated compounds	RP-HPLC	2% sodium dodecyl sulphate, 0.05 M sodium acetate buffer pH 3.5, and isopropanol as MP	–	[86]
Sofosbuvir and Ledipasvir	RP-HPLC–UV-Fluorescence	–	–	[87]
Favipiravir	RP-HPLC	MeOH, EtOH, and water MP	92	[88]
Vitamin D3 and calcium levels in atorvastatin	HPLC	0.1% orthophosphoric acid and EtOH	0.75(AGREE)	[89]
5-fluorouracil (5-FU)	HPLC	Formic acid solution and EtOH MP	–	[90]
Aspirin and Domperidone	HPLC	KH_2PO_4: Acetonitrile	–	[91]
Rosuvastatin calcium	HPLC	MeOH, EtOH and ethyl acetate MP	–	[92]

Clorsulon, Albendazole, Triclabendazole, and Ivermectin	Micellar liquid chromatographic	Sodium dodecyl sulphate, 15% propanol, and 15 mM phosphate buffer	75	[93]
Lesinurad and Febuxostat	RP-HPLC	ACN: potassium phosphate buffer MP	87	[94]
Fenoverine	Reversed-phase liquid chromatographic	MeOH and ammonium acetate buffer 20 mM	41.82(EAT value)	[95]
Brivaracetam detection together with Piracetam and Carbamazepine	LC	ACN: H_2O containing 0.1% triethylamine	85	[96]
Metoprolol and Amlodipine	Micellar liquid chromatographic	SDS and sodium dihydrogen phosphate in H_2O MP and technique	80	[97]
Daptomycin	HPLC	EtOH- H2O MP	–	[98]
Panobinostat	HPLC	NH_4COOH buffer-EtOH	0.74 (AGREE)	[99]
Metronidazole and Ciprofloxacin	HPLC	0.13 M sodium dodecyl sulphate and 0.02 M Brij-35 solution	0.81 (AGREE)	[100]
Levetiracetam	HPLC	Phosphate buffer and ACN (87:13%v/v)	0.82 (AGREE)	[101]
Artesunate and Amodiaquine	RP-HPLC	Solvent EtOH and 10 mM CH_3COOH	–	[102]
Metronidazole (MTR) and Spiramycin (SPR)	HPLC	EtOH and 20 mM sodium dihydrogen phosphate solution	–	[103]
Nine sulphonamides	HPLC	EtOH	86	[104]
Atorvastatin calcium and Amlodipine	HPLC	0.17 M sodium dodecyl sulphate solution (pH 2.9) with 10%v/v n-butanol	–	[105]
Three BDZs (diazepam, clonazepam, and bromazepam)	HPLC	50:50% v/v mixture of sodium dodecyl sulphate (SDS) and polyoxyethylene lauryl ether (Brij-35)	95	[106]
Atorvastatin	HPLC	EtOH	90	[73]

Modafinil	HPLC	EtOH-H_2O	90	[119]

By minimising solvent consumption

1. UHPLC (Ultra high-performance liquid chromatography)

A QbD-compliant simple, quick, robust, sensitive, efficient, economical, and ecologically conscious UHPLC approach for chrysin quantification has been developed by Sharma et al. Utilising Box Behnken Design, essential parameter optimisation was completed. The best technique conditions are a C8 column with an ACN and H_2O mobile phase that flow at a rate 0.5 mL/min by injecting volume of 5 µL at a maximum wavelength of 267 nm via a PDA detector. Here, ethanol is not used as the mobile phase because it produces high pressure, which can be reduced by raising the column temperature, but this was avoided because doing so would increase energy requirement, which is in contradiction of the GAC principles, so ACN along with water were chosen as the mobile phases instead. Additionally, the UHPLC method is referred to as a “greener” method because it minimised the amount of waste generated and operator and ecological safety risks associated with exposure to organic solvents. Other benefits of the method include increased method effective; decreased back pressure, and low solvent consumption. Chrysin had a retention time of 4.802 min. The accuracy testing revealed that the percent recovery ranged from 98.34 to 104.80%, proving that the procedure is very accurate. The method linearity for chrysin concentration ranging from 0.1 to 50 µg/mL. The method showed 0.028 µg/mL as LOD and 0.075 µg/mL as LOQ. The Analytical Eco Scale employed to evaluate the technique's greenness, and the resultant score of 81 [107].
An environmentally friendly AQbD based UHPLC technique has been proposed by Chanduluru et al. for the environmentally friendly measurement of isosorbide dinitrate (ISDN) and hydralazine hydrochloride (HHC). On a Phenomenex C18 (50×2.1 mm, 2 µm) column with EtOH and 0.1% trifluoroacetic acid (60:40% v/v) at a flow rate of 0.5 mL/min, separation was carried out. The devised approach discovered a runtime of just 3.5 min and an excellent resolution of 5.4 between the two medications. The recovery rate falls between 98.4 and 101.9%. Linearity ranges from 10–60 µg/mL and 18.75–112.5 µg/mL, with R^2 of 0.9998 and 0.9992 for ISDN and HHC, respectively. LOD was found to be 0.923 µg/mL and 0.549 µg/mL while LOQ was found to be 2.797 µg/mL and 1.666 µg/mL for ISDN and HHC, respectively. When the technique's greenness was evaluated through the ECO Scale tool, the score was discovered to be 96, which is very excellent [108].
Kannaiah et al. suggested an environmentally conscious, simple, and reliable technique for estimating Crotamiton (CTM) and Hydrocortisone (HCT) by combining GAC principles with an AQbD-rotatable CCD methodology employing RP-UHPLC. The Waters X-Bridge (C18 50×2.5 mm i.d, 1.7 µm) column were utilisd for estimation, and the MP composition was ethanol: 0.01 M ammonium acetate buffer (pH 3.0) 30:70%v/v with the flow of 0.3 ml/min. Linearity concentration was made in range of 70–130 µg/mL for CTM and 1.75–3.75 µg/mL for HCT. Here, UHPLC was chosen over HPLC because it requires less energy as well as solvent, and analytical time. Using the AGREE tool, the method's greenness was evaluated, and the analytical score came out to be 0.83[109].
The UHPLC technique was proposed by Chanduluru et al. to measure pitavastatin and ezetimibe (EZB). Rotatable central composite design, which is modelled after the Ishikawa fishbone diagram, was utilised for optimisation. The satisfactory chromatographic estimation was done on Agilent UHPLC-PDA system (1290 infinity II LC system), alongside Kinetex phenyl hexyl (50×4.6 mm, 2.6 µm) column and MP of 72: 28% v/v EtOH and 0.1% orthophosphoric acid (pH 3.5), at a 0.31 mL/min flow rate with detection on 240 nm wavelength through photodiode array (PDA) detector. Rt for pitavastatin was 0.85 and for EZB was 1.91 min. Recovery for pitavastatin and EZB was determined to be 99.1%-100.94% and 99.9%-101.52%, respectively. Linearity ranging from 2–30 and 10–150 µg/mL

with an R^2 of 0.9999 and 0.9997, respectively, for pitavastatin and EZB. LOQ for pitavastatin and EZB was 0.0584 µg/mL and 0.0233 µg/mL, respectively, while LOD was 0.0192 µg/mL and 0.0076 µg/mL, respectively. Studies on forced deterioration have revealed that whereas EZB was hydrolysed under basic conditions, pitavastatin was vulnerable to acid hydrolysis. The result of the ECO Scale was found to be 97 [110].

Muzaffar et al. presented a UHPLC-MS/MS approach for fast measurement of umifenovir in plasma samples and measured greenness. Using the ACQUITY UPLC BEH C18 column (2.1 × 100; 1.7 m) and a MP made up of 15 mM ammonium acetate and ACN in an 80:20 (%v/v) ratio while being pumped at 0.3 mL/min, umifenovir and the IS were separated in under 2.5 min. The auto-sampler and column oven were each set to a temperature of 10 and 40 °C, respectively. The material was ionised using positive electrospray ionisation. The developed method showed excellent linearity in the concentration range of 1.32–625 ng/mL. Accuracy was in the ranges of 90.5–105.8%. The score, which ranges from 0.75 to 1.00 and indicates an environmentally favourable procedure, was determined to be 0.77 [111].

A unique UHPLC-MS/MS assay was created by Muzaffar et al. for the quick measurement of delafloxacin. Delafloxacin (DFX) and the internal standard (losartan) were separated on a UHPLC BEH C18 column (50 × 2.1 mm; 1.7 m) using gradient programming of an MP containing 0.1% formic acid in acetonitrile and 0.1% formic acid in water, with a flow rate of 0.3 mL/min, injection volume of 5 µL (partial loop mode), column oven temperature at 35 °C. A positive mode triple quadrupole mass detector was used for the quantification at an electrospray ionisation interface. The Rt of DFX and IS were, respectively, 1.72 and 1.79 min. Linearity was between concentration ranges of 2.92–6666 ng/mL with an acceptable correlation coefficient of $R^2 \geq 0.995$. The accuracy values ranged between 94.4 and 106.1%. The approach's greenness evaluation was evaluated by using AGREE software having a score of 0.78, confirming excellent greenness of the approach [112].

Kamal et al.; developed method using The Waters Acquity UHPLC BEH C18 column (100 × 2.1 mm, 1.7 µm) which efficiently removed Meropenem MPM, contaminants, and peaks from the sample matrix. Mobile phase A was a 25 mM monobasic potassium phosphate buffer adjusted to pH 4.05 using orthophosphoric acid (OPA) solution, while mobile phase B was a 30:70 (%v/v) combination of water and ACN. A simple binary gradient program (0.0–12.0 min, 87%→0% A, 13%→100% B) with a flow rate of 0.4 mL/min allowed for component separation in 15 min. The method's greenness was assessed with GAPI, AGREE, and analytical eco scale methods. Each sample preparation used 40.0 mL of ACN, resulting in a total consumption of <50 mL per sample analysis and a penalty point score of 15. The approach achieves an eco scale score of 85, indicating exceptional greenness. [113]

Muchakayala et al. devised a green, robust, and speedy stability indicating chromatographic approach for the simultaneous measurement of fluorescein sodium, benoxinate hydrochloride, and their degradation products within 4 min. Fractional factorial and Box-Behnken designs were used for screening and optimization, respectively. The ideal chromatographic conditions included a mobile phase of isopropanol and 20 mM potassium dihydrogen phosphate solution (pH 3.0) in a 27:73%v/v, a flow rate of 1.5 mL/min, and a column oven temperature of 40 °C. The analysis was done on an Eclipse plus C18 column (100 mm × 4.6 mm × 3.5 µm) with a DAD detector tuned to 220 nm. Linear responses were obtained between 2.5–60 µg/mL for benoxinate and 1–50 µg/mL for fluorescein. The approach proved successful in quantifying pharmaceuticals in ophthalmic solution, with mean %recovery ± SD of 99.21 ± 0.74 for benoxinate and 99.88 ± 0.58 for fluorescein. Compared to previously described approaches, the suggested method is quicker and more environmentally friendly. Its greenness was proven by a high analytical eco scale score of 90 and a low EAT score of 4.21 [114] (Table 5).

Table 5. Summary of green technique by reducing solvent consumptions using UHPLC

Drug	Approach	Greenness	ECO Scale/AGREE Score	References
Chrysin	UHPLC	ACN with water MP and UHPLC technique minimised the amount of waste generated	81	[107]
Isosorbide dinitrate and hydralazine hydrochloride	UHPLC	EtOH and 0.1% trifluoroacetic acid MP	96	[108]
Crotamiton and Hydrocortisone	RP-UHPLC	EtOH: 0.01 M ammonium acetate buffer	0.83(AGREE)	[109]
Pitavastatin and Ezetimibe	UHPLC	EtOH and 0.1% orthophosphoric acid MP	97	[110]
Umifenovir	UHPLC-MS/MS	Technique as well as 15 mM ammonium acetate and acetonitrile MP	0.77(AGREE)	[111]
Delafloxacin	UHPLC-MS/MS	Technique as well as 0.1% formic acid in acetonitrile and 0.1% formic acid in H_2O MP	0.78(AGREE)	[112]
MPM	UHPLC	Potassium phosphate buffer	85	[113]
Fluorescein sodium &Benoxinate hydrochloride	UHPLC	Isopropanol and 20 mM potassium dihydrogen phosphate) in a 27:73%v/v	90 &4.21(EAT)	[114]

1. HPTLC (High-performance thin layer chromatography)

Using the AQbD methodology, Prajapati et al. developed a reliable and ecological conscious HPTLC approach for the measurement of thiocolchicoside (THC) in its medicinal dose forms. Utilising Box Behnken Design, essential parameter optimisation has been accomplished. In contrast to HPLC, HPTLC uses a little quantity of MP to analyse several samples at once, decreasing the quantity of time and money required for each analysis. Chromatographic separation was carried out using toluene-acetone–water (1.5:7.5:1.0, %v/v/v) as the MP and 10 cm × 10 cm aluminium plates pre-coated using 250 µm of silica gel 60 F254 at 25 °C, 35% relative humidity, 15 min chamber saturation time, and 90 mm displacement distance. According to the degradation research, thiocolchicoside is more susceptible to oxidative degradation and acidic-alkaline hydrolysis, but less susceptible to photolysis, dry-heat, and water hydrolysis. thiocolchicoside, acidic deteriorated product DP1, and acidic deteriorated product DP2 have spots at retardation factor, R_f = 0.53, 0.65, and 0.80, respectively. The recovery rate falls between 99.39 and 101.65%. Linearity ranges from 100 to 500 ng/spot with R^2 of 0.9979. LOD was found to be 4.03 µg/band while LOQ was

found to be 12.21 µg/band [115].

In order to determine a novel blend of mebendazole (MBZ) &quinfamide formulations, Ibrahim et al. devised a simple, quick, inexpensive, sensitive, selectivity, broader linearity ranges, ecological, and short analytical time technique. The first approach is HPTLC, in which at 254 nm, distinct bands were scanned. After being separated employing silica gel HPTLC F254 plates &a simple MP made of MeOH: toluene (2:6, %v/v). It was discovered that the values of the R_f for MEB and quinfamide were 0.45 and 0.75, respectively. Linearity was in ranges of 0.2–2.5 and 0.1–2 µg/band for quinfamide and MEB, respectively. Accuracy was found to be 99.62% and 100.10% for QF and MBZ, respectively. LOD and LOQ for quinfamide was 0.055 and 0.168 µg/band, for MBZ was 0.031 and 0.094 µg/band. The second technique used RP-HPLC and involved isocratic separation of both pharmaceuticals on a Phenomenex C18 column with a green MP made of double distilled H_2O: MeOH (30:70%v/v) with a flow rate of 0.8 mL/min and a run duration of 4 min and UV detection at 254 nm. The volume of trash was reduced to 3.2 mL/run using a short column (100 mm) having tiny particle size (3.5 µm), which is thought to be a significant indicator of greenness of process. MBZ and quinfamide had retention times of 2.69 and 3.43, respectively, Linearity was in ranges of 1–60 and 2–80 µg/band for QF and MBZ, respectively. Accuracy was found to be 100.04% and 99.87% for QF and MBZ, respectively. LOD and LOQ for quinfamide was 0.323 and 0.979 µg/band, for MBZ was 0.643 and 1.948 µg/band [116].

A novel technique for the estimation of furosemide (FRS), spironolactone (SPL), &canrenone (CAN) is being researched by Ibrahim et al. Alumina plates (20 × 20 cm) coated by 0.25 mm silica gel 60 F254 plates were utilised for Method 1's HPTLC separation, with ethyl acetate, triethylamine, and acetic acid (9: 0.7: 0.5, by volume) serving as the forming system &UV detection at 254 nm serving as the detection wavelength. For the three distinct components, FRS, SPL, and CAN have the Rf values of 0.320.02, 0.640.02, and 0.790.02, respectively. Linearity was in ranges of 0.2–2, 0.05–2.6 and 0.05–2 µg/band for FRS, SPL and CAN, respectively. Accuracy was found to be 100.11%, 99.65% and 99.98% for FR, SP and CN, respectively. LOD and LOQ for FRS was 0.059 µg/band and 0.195 µg/band, for SPL was 0.015 µg/band and 0.048 µg/band and for CAN was 0.014 and 0.045. Using a ZOBRAX Eclipse Plus C18 (4.6 × 100 mm) column and a MP made up of EtOH and deionized water (45:55%v/v), Method 2 was developed that uses green isocratic RP-HPLC with UV estimation at 254 nm. The flow rate was adjusted to 1 ml/min and the pH to 3.5 using glacial acetic acid. Within 5 min, the three chemicals had been successfully eluted with satisfactory separation. The duration of retention values for SPL, FRS, and CAN were determined to be 3.36, 1.64, and 4.42 min, respectively. Linearity was in ranges of 5–60, 2–60 and 2–60 µg/mL for FRS, SPL and CAN, respectively. Accuracy was found to be 100.10%, 100.03% and 100.01% for FRS, SPL and CAN, respectively. LOD and LOQ for FRS was 1.333 µg/mL and 4.00 µg/mL, for SPL was 0.485 µg/mL and 1.60 µg/mL and for CAN was 0.60 µg/mL and 1.80 µg/mL [117].

Bang et al., had developed and validated green HPTLC technique for estimation of Lenvatinib. He had developed two green methods, i.e. RP-HPTLC and NP-HPTLC, mobile phase used here are ethanol and water (60:40, %v/v), and 50:50%v/v of ethanol and ethyl acetate, respectively. The detection was carried out at 243 nm. Analytical greenness (AGREE) scores were estimated as 0.88 and 0.82, respectively, for the RP and NP [118] (Table 6).

Table 6. Summary of green technique by reducing solvent consumptions using HPTLC

Drug	Approach	Greenness	ECO Scale/AGREE Score	References

Thiocolchicoside	HPTLC	HPTLC uses a minimal amount of mobile phase to analyse	–	[115]
Quinfamide and Mebendazole	HPTLC and RP-HPLC	Short analytical time technique and water: methanol	–	[116]

Lenvatinib	RP-HPTLC, NP-HPTLC	ethanol and water (60:40, %v/v), and 50:50%v/v of ethanol and ethyl acetate	0.88 &0.82 (AGREE)	[118]

1. TLC (Thin layer chromatography)

Stability-indicating techniques for modafinil and the by-product of its acid-induced deterioration have been devised and confirmed by Elsheikh et al. using TLC-Densitometric, which uses plates that are precoated with silica gel G60 F254 and are 10 × 20 cm in size and 0.25 mm thick. Dichloromethane-methanol (90:10, %v/v) was employed as the growing solution, and the chromatograms are scanned at 254 nm afterwards. Modafinil had a R_f of 0.48 and its degradation product had an R_f of 0.77. Linearity was in ranges of 1–10 µg/band. Accuracy was found to be 100.11%. LOD and LOQ was 0.110 and 0.335 µg/band. The created TLC-densitometry analytical Eco Scale procedures yield scores of 80 [119].

Elsheikh et al. have developed and optimised straightforward, accurate, and reliable stability-indicating TLC-densitometric technique for zonisamide (ZNS) in the presence of its breakdown product, which was carried out using aluminium plates covered with silica gel 60F254 as a SP, while chloroform, MeOH, and acetic acid (80:15:5%v/v/v) as a growing solution, and detection at 240 nm under a UV lamp. ZNS had an R_f value of 0.76 and its degradation product had an R_f value of 0.11. The newly developed TLC-densitometry procedures have ECO Scale scores of 84, with modest green colours which shows that the method is eco-friendly [72].

Green spectroscopy methods

An eco-sustainable spectrophotometric simultaneous equation approach was suggested by Kokilambigai et al. for the measurement of paracetamol (PCM), aceclofenac (ACF), and thiocolchicoside (THC) pharmaceuticals in their combined dose form. Instead of methanol, the diluent phosphate buffer with pH 7.8 was employed as an ecological solvent since it has no effect on the medicines' UV spectral properties. PCM, ACF, and THC all had maximum absorptions (λ_{max}) at wavelengths of 243, 274, and 259 nm, respectively. The devised procedure was accurate since the recovery amount varied from 99.56 to 100.99% w/w. The linear range was established between 5 and 15 µg/mL for paracetamol, 1–5 µg/mL for aceclofenac, and 1–5 µg/mL thiocolchicoside. The LOD values for PCM, ACF and THC were in the ranges of 0.24 µg/mL, 0.33 µg/mL and 0.32 µg/mL, respectively. The LOQ value were in the ranges of 0.78 µg/mL, 1.01 µg/mL and 0.95 µg/mL, respectively. The ECO Scale tool was used to assess the greenness profile score, and it revealed a greenness score of 100 [120].

For the simultaneous quantification of Paracetamol (PCM), Aceclofenac (ACF), and Eperisone Hydrochloride (ES) Rathinam et al. have devised an environmentally safe, user-friendly, quick, sensitive, and affordable UV spectrophotometric approach. The diluent phosphate buffer pH 7.8 is employed as a green solvent since it has no effect on the medicines' UV spectral properties. When the wavelengths of the PCM, ACF, and ES were scanned across 200–400 nm with phosphate buffer pH 7.80 serving as the reference, their λ_{max} were 243, 272, and 262 nm,

respectively. Linearity concentration ranges between 12 and 18 µg/mL for paracetamol, 3.69–5.53 µg/mL for Aceclofenac, and 2.76–4.15 µg/mL Eperisone hydrochloride, and the LOD values were in the ranges of 0.48 µg/mL, 0.20 µg/mL and 0.13 µg/mL, respectively. The LOQ value were in the ranges of 1.44 µg/mL, 0.61 µg/mL and 0.38 µg/mL, respectively. The %recovery for PCM, ACF and ES was 100.48%, 100.33 and 100.07%. Software called ECO Scale determined that the simultaneous equation score was 96 [121].

Using Ultra-Violet (UV) spectrophotometric techniques, Chanduluru et al. have presented a straightforward, distinctive, economical, environmentally conscious, stability-indicating test approach to evaluate Chlorthalidone (CTD) and Cilnidipine (CIL). This approach uses propylene carbonate rather than methanol as a green solvent for CIL and CTD analyses because propylene carbonate is harmless in terms of influence on water, air, health risks, combustibility, stability. According to area under curve approaches, the absorbance ranges for CTD and CIL were 218–227 nm and 224–232 nm, respectively. Linearity concentration range of 7–13 µg/mL for CTD and 8.75–16.25 µg/mL for CIL. According to the agree programme, the simultaneous equation score was 0.91[122].

By utilising spectrophotometric techniques, Fawzy et al. produced accurate, eclectic, affordable, simple, and sensitive spectrophotometric tactics for the simultaneous estimation of saxagliptin hydrochloride and dapagliflozin propanediol monohydrate. The initial strategy, known as the induced dual-wavelength approach (IDW), mainly depended upon employment of substitute equality factors (*F*) to exclude the influence of dapagliflozin propanediol monohydrate while determining saxagliptin hydrochloride and vice versa. The second approach, known as the ratio difference method (RDM), determined the amplitude difference on the ratio spectrum of saxagliptin hydrochloride and DAG, respectively, using divisors of 25 µg/mL of dapagliflozin propanediol monohydrate and 20 µg/mL of saxagliptin hydrochloride. The third approach, plateau subtraction followed by multiplication by the division of dapagliflozin propanediol monohydrate 25 µg/mL, was used to compute SAG at λ_{max} 221 nm. The ECO Scale score for given technique was 88[123].

Fawzy et al. develop ecologically sustainable, easy, and reliable spectrophotometric and chemometric approaches for the simultaneous quantification of Fluticasone propionate and Azelastine. Although methanol is used as a diluent, the procedure is ecologically favourable in terms of a number of other aspects, including the utilization of instruments, chemicals, and disposal of waste. For both medications, the absorbance is at 258 nm (λiso). This approach received an ECO Scale score of 88[124].

For the measurement of ramipril as well as temisartan both coupled with hydrochoryhiazide (HCTZ), Elsonbaty et al. have presented a specific, quick, green, exact, and simple analytical methodology employing a reconstituted FSD aided UV spectrophotometric technique. HCTZ is measured at 276 nm, which is the zero-crossing point for temisartan, whereas temisartan was measured at 257 nm, which was the no contribution point of HCTZ. HCTZ was concurrently measured at 244 nm and ramipril was calculated at 231 nm for ramipril /HCTZ, which is the zero-crossing point of both HCTZ and ramipril. The linear ranges for telmisartan, ramipril, and hydrochlorothiazide were 1–25 µg/mL, 5–35 µg/mL, and 1–10 µg/mL, respectively, and the LOD values were in the ranges of 0.067–0.747 µg/mL. The %recovery for about drugs was 100.82, 99.10, 99.55, respectively. The ease of use, speed, lack of demand for complex software, and increased sensitivity of the new technology over the conventional deconvolution-curve fitting are its advantages. The analytical eco scale's overall score is 88, which is very good [125].

Lofty et al. devised a straightforward, inexpensive, quick, efficient, and environmentally friendly approach for evaluating single-tablet regimens of atenolol (Ate), amiloride (AMD), and chlortalidone (CTD). Zero order spectra, which serve as spectral profiles or fingerprints for pharmaceuticals, were recovered using the Parent Spectrum Restoration Technique (PSRT). This approach used three computing approaches: the well-known smart method

spectrum subtraction (SS), the derivative ratio transformation utilising normalised spectra or any other divisor, and the dual amplitude difference (DAD) through factorised spectra. Utilising methanol as both a blank and a solvent, the λ_{max} for Ate, AMD, and CTD were discovered to be 226 nm, 362 nm, and 230 nm, respectively. Linearity for each drug was ranging between 4.0 and 40.0 µg/mL for Ate, 3.0–20.0 µg/mL for both AMD and CTD. The %recovery for AMD, CTD, Ate was 99.61%, 99.92%, and 99.82%, respectively. The UV-methods obtained a better score for greenness 89 due to their use of less energy and solvent than the HPLC described approach, which received a middling score of 84[126].

Kannaiah et al. suggested a simple, sustainable, inexpensive, sturdy, specific, and successful extraction technique, as well as a multivariant green analytical approach, for estimating ketoconazole using UV spectroscopy. The diluent is made by combining water and ethanol (99.9%) in 80:20%v/v. The drug's λ_{max} at 226 nm over a diluent in blank solution was discovered. The linearity was found at concentration of 12.8–19.2 µg/mL with R^2 value of 0.9992. LOD and LOQ was found to be 0.338 and 1.026 µg/mL, respectively. The %recovery was 100.31%. Through the ECO Scale tool, the analytical value was discovered to be 96 [127].

Salicylic acid (SA) &Mometasone furoate (MF) were analysed concurrently using a green capillary zone electrophoretic technique (CZE) that was developed &validated by Amira et al. Agilent CE instrument 7100 series along with a Diode Array Detector was utilised for separation. Agilent Technologies provided a capillary made of fused silica with an effective length of 50 cm and an internal diameter (id) of 50 m. Measurements were made in the hydrodynamic mode at a temperature of 25 °C. MF and SA showed good linearity in the series of 0.2–40 µg/mL and 0.1–80 µg/mL, respectively. The detection and quantification limits for the assay of MF were 0.04 and 0.13 µg/mL, and of SA were 0.03 µg/mL and 0.1 µg/mL, respectively. The% recovery was 99.60% and 99.35%, respectively. The discovered approach has various benefits, including little solvent use, low operating expenses, minimal sample time for analysis requirements, and no need for sample preparation. The recommended method's analytical Eco Scale value was computed, and its score of 86 was discovered [128].

For the estimation of remogliflozin (REM) &metformin (MET), Attimarad et al. devised and validated straightforward, precise, sensitive, affordable, and green UV spectrophotometric techniques. The diluent is ethanol. For REM and MET, the peak amplitudes were at 233.0 nm &252.2 nm, respectively. The assay was found to be in the range of 98.16–101.37% for REM and 98.10–101.76% for MET. REM and MET showed good linearity in the series of 1–20 µg/mL and 2.5–35 µg/mL, respectively, with correlation coefficient of 0.998. The %RSD for the analyte in Method precision and intermediate precision is below 1.0. The recovery rate was shown to be between 98.4 and 101.5%. The new spectroscopic techniques scored 94 on the eco scale, showing their greenness [129].

Megahed et al., had developed a simple, rapid, robust, selective, green and sensitive spectrofluorimetric method for determination of favipiravir. The stock solution of FAV was prepared in distilled water then transfer FAV stock solution followed by 2.5 mL of 0.2 M borate buffer pH 8.0 to make a range of 40–280 ng/mL. The solutions were measured at 432 nm after excitation at 361 nm. The% recovery was found to be 100%. The %RSD for the analyte in Method precision and intermediate precision is below 1.0. The eco scale was found to be 92 [130].

Abdelazim et al., had developed an eco-friendly spectrophotometric method for the determination of Molnupiravir. A standard stock solution of molnupiravir was prepared in ethanol then 0.5 mL of hydrochloric acid [0.5 M] and 0.5 mL sodium nitrite was added for diazotization of molnupiravir. After that 1 mL of 8-hydroxyquinoline [0.35%] was added. Then 0.5 mL sodium hydroxide [2 M] was added and the prepared solutions were allowed to stand for 5 min. Finally, the volume was made with ethanol. The absorbance of the red-coloured azo dye complexes was measured at 515 nm against a blank. The method found linear from 1.0 to 12.0 µg/mL with $R^2 \geq 0.9996$. The %recovery was 99.82%. The %RSD for the analyte in Method precision and intermediate precision is below 1.0. The AGREE

software was employed to evaluate the technique's greenness, and the resultant score of 0.81 [131] (Table 7).

Table 7. Summary of Green Spectroscopy techniques

Drug	Approach	Greenness	ECO Scale/AGREE Score	References
Paracetamol, Aceclofenac, and Thiocolchicoside	Spectrophotometric	Diluent phosphate buffer pH 7.8	100	[120]
Paracetamol, Aceclofenac, and Eperisone Hydrochloride	UV spectrophotometric	Diluent phosphate buffer pH 7.8	96	[121]
Chlorthalidone and Cilnidipine	Ultra-Violet (UV) spectrophotometric	Propylene carbonate as diluent	0.91(AGREE)	[122]
Saxagliptin hydrochloride and Dapagliflozin propanediol monohydrate	Spectrophotometric	Favourable use of instruments, reagents, and the disposal of waste	88	[123]
Fluticasone propionate and Azelastine	Ultra-Violet (UV) spectrophotometric	Favourable use of instruments, reagents, and the disposal of waste	88	[124]
Ramipril as well as Temisartan coupled with Hydrochoryhiazide	FSD aided UV spectrophotometric	Technique	88	[125]
Atenolol, Amiloride, and Chlortalidone	UV-methods	Less solvent consumption	89	[126]
Ketoconazole	UV-methods	$H_2O$and EtOH diluent	96	[127]
Mometasone furoate and salicylic acid	Capillary zone electrophoretic	Technique itself	86	[128]
Metformin and Remogliflozin	UV spectrophotometric	Technique	94	[129]
Favipiravir	Spectrofluorimetric	0.2 M borate buffer	92	[130]
Molnupiravir	UV spectrophotometric	EtOH	0.81(AGREE)	[131]

Bold value indicates score that has been obtained from analytical eco-scale's tool that suggests that the method is greener compared to traditional method

Conclusion

The insights provided in this review article on green analytical techniques incorporating examples of GAC using

HPLC, HPTLC, UHPLC, and TLC lay the groundwork for several future advancements and applications. Firstly, it serves as a comprehensive reference for researchers, analysts, and industry professionals seeking to adopt more sustainable, novel, cost-effective, efficient, and ecologically practices in their analytical workflows. By highlighting the benefits and feasibility of green analytical techniques, this review facilitates the widespread adoption of environmentally friendly methodologies across various sectors, including pharmaceuticals, food analysis, environmental monitoring, and beyond.

Liquid chromatographic equipment is extensively used in pharmaceutical quality control globally, often consuming large quantities of organic solvents and leading to unsustainable waste generation. This has driven considerable interest in greening liquid chromatographic techniques, aiming to protect both analysts and the environment. Solvent use is a significant contributor to waste and poses toxicity concerns, which can be addressed by integrating green analytical chemistry principles into method development. Various tools for assessing the environmental impact of liquid chromatography methods play a crucial role in developing environmentally friendly methods with minimal adverse effects. It's advisable to incorporate suitable green evaluation tools into method design to ensure better environmental consideration. Common aspects considered across assessment tools include evaluating a method's environmental impact in terms of solvents, energy consumption, and waste generation. Incorporating green solvents like Sodium dodecyl sulphate and propylene carbonate into methods can help address environmental concerns. Additionally, adopting miniaturised techniques like UHPLC may reduce energy consumption and waste generation during analysis. This shift towards greener practices in pharmaceutical analysis is essential for minimising adverse impacts while maintaining analytical performance standards.

Additionally, this review fosters ongoing innovation in the field of analytical chemistry by identifying areas for further research and development. It encourages the exploration of new green solvents, alternative separation techniques, and novel instrumentation to enhance the eco-efficiency and analytical performance of green analytical methods. Moreover, the examples provided offer inspiration for the design and implementation of customized green analytical protocols tailored to specific analytical challenges and applications.

Furthermore, this review contributes to the global sustainability agenda by promoting awareness and advocacy for greener practices within the scientific community and beyond. By emphasizing the societal and environmental benefits of adopting green analytical techniques, it encourages policymakers, regulatory agencies, and industry stakeholders to prioritise sustainability in chemical analysis and decision-making processes.

In essence, the future usefulness of this review lies in its ability to catalyse positive change, inspire innovation, and promote collaboration towards a more sustainable and environmentally conscious approach to analytical chemistry. This review includes developing methodologies, unique technology, and creative approaches that have not garnered much attention. Green extraction technologies, solid-phase microextraction, and supercritical fluid extraction are all revolutionary procedures that utilise fewer organic solvents and generate less waste. The review also examines the use of sophisticated technologies such as microfluidics, nanotechnology, and spectroscopic approaches to create more efficient and environmentally friendly analytical procedures.

Our evaluation provides a unique viewpoint or focus on certain parts of green analytical methodologies. We have prioritised conversations about the application of green chemistry concepts, the use of greener solvents, and the assessment of environmental effect using diverse methodologies. We have included the most recent advances in green analytical approaches, including data from recent research publications.

Acknowledgements

We are very grateful to the Faculty of Pharmacy, The Maharaja Sayajirao University of Baroda. This review article is based on used green analytical techniques such as, HPLC with green solvents, UPLC, HTLC, HPTLC, and TLC, to

develop a novel, cost-effective, efficient, and ecologically sustainable approach. Also, vast research is going on to creating novel Green Analytical Chemistry approaches to address these environmental problems and create an ecologically preferable replacement.

Short-cut route validated for monitoring fentanyl and its metabolite in urine using LC–MS/MS, in a wide concentration range

Cavus Yonar, Fatma1 ; Anılanmert, Beril1 ; Acikkol, Munevver1 1 Istanbul University-Cerrahpasa, Institute of Forensic Sciences and Legal Medicine, Buyukcekmece Campus, Istanbul, Turkey (GRID:grid.506076.2) (ISNI:0000 0004 1797 5496)

ABSTRACT (ENGLISH)

Background

Fentanyl is a highly potent analgesic, used in surgery, frequently abused or used in drug-facilitated crimes (DFC) and in military activities. It is also increasingly used in the treatment of chronic pain (especially in cancer patients). The improper use of transdermal patch forms can cause toxicity and deaths, related to overdose or combined use with other drug substances. Methods are needed for fast, reliable and inexpensive fentanyl detection and we aimed to develop such a method in urine using LC–MS/MS, especially for toxic and fatal concentrations which lack in the literature.

Results

An LC–MS/MS method has been presented for the co-determination of fentanyl and its main metabolite, norfentanyl in urine. The recoveries of the extraction method were 95(±6)% and 70(±9)% for fentanyl and norfentanyl, respectively. LOD and LOQ values are 1.7 and 14.0 ng/mL for fentanyl, while they were 20.6 ng/mL and 42.0 ng/mL for norfentanyl.

Conclusion

A rapid, sensitive, very practical, inexpensive and a high-recovery analysis method is developed and validated. This is the only fentanyl monitoring LC–MS/MS method in urine having a linearity over a wide range up to 500.0 ng/mL and its success is demonstrated on real samples in the therapeutic drug monitoring of fentanyl and is expected to contribute to clarify intoxications/deaths related to its use.

FULL TEXT

Background

Fentanyl is a potent, synthetic, narcotic, analgesic opioid with an analgesic activity that is approximately 80 times more effective than morphine and 500 times more potent than meperidine, with fewer side effects [1, 2]. 85% of the fentanyl taken into the body is excreted in the first 72 h; 7% is excreted unchanged (6% urine, 1% feces), 78% is metabolized in the liver (70% urine, 8% feces) [3]. Its main metabolite is norfentanyl. Studies conducted in countries where polydrug use is common, show that a significant group of these individuals who lost their lives due to overdose, combined one or more drugs with the active substance fentanyl [4, 5]. The transdermal route is superior to both oral and parenteral routes in terms of ease of administration in therapy [6]. Dose-related poisoning occurs frequently, as a result of simultaneous use of several transdermal fentanyl bands in home treatment to increase analgesic effect, or in misuse [7]. There are many case reports regarding inappropriate use or misuse of fentanyl skin patch content via intravenous, oral, rectal and inhalation [8, 9]. Defective patches are one of the causes of intoxication [10].

Fentanyl has forensic importance as a drug of abuse, which can also be used for suicidal and criminal purposes,

besides having toxicological and clinical importance in environmental and occupational exposure, regarding healthcare personnel while administering [11]. Environmental exposure might occur via inhalation of powders/aerosols, ingestion, fentanyl patches or items contaminated with fentanyl (which may be present in powder, tablet or liquid forms). Its production and consumption is increasing day by day [12]. In recent years, deaths due to fentanyl overdose have been detected among patients hospitalized for chronic pain [6].

In cases of polymorphisms seen in the CYP3A4 gene which metabolizes fentanyl, serious toxicological effects may occur related to fentanyl use [13, 14]. Therefore, drug monitoring is important for fentanyl. To monitor the levels of fentanyl and its metabolite norfentanyl or to clarify the cases of toxicity/death due to the use of fentanyl transdermal patches in people who use or misuse the patch or in their relatives or health personnel who are exposed to them; a simple and rapid method in urine, with low detection limit, higher recovery, having a wide linearity range, was developed using LC–MS/MS. Although the extraction method was modified from study of Coopman et al. [15], differently here, steps were reduced using undiluted urine; recovery for norfentanyl was increased twice; linearity range was increased up to a very high amount as 500 ng/mL; and a 2.5 times enrichment was performed, while a lower injection volume was used. Papaverine hydrochloride was chosen as the internal standard (IS) and a 2.5-min ultra-fast LC–MS/MS analysis was performed using C_{18} poroshell column. The whole validated method is for quantitative purposes with given LOD and LOQ values. This method is the first short-cut fentanyl monitoring method in the literature with the widest concentration range, requiring no dilution at toxic concentrations.

Material and methods

Reagents and chemicals

Acetonitrile (HPLC-Grade) and formic acid (99–100%) were used in mobile phase (Merck, Germany). Ethylacetate, *n*-hexane and potassium carbonate were of analytical grade (Sigma-Aldrich, UK). Fentanyl and norfentanyl standard (both %99.9) were purchased from Lipomed (Germany). Preliminary investigations were performed using fentanyl from Janssen-Clag (Bulgaria). Papaverine hydrochloride was provided from Sopharma (Bulgaria). All standard solutions were prepared using HPLC grade methanol (Merck, Germany).

Instrumentation

A QQQ Tandem Gold ESI-LC–MS/MS (Zivak, Turkey) was used. Chromatographic elution was performed at 60 °C, using Poroshell 120 2.7 µm, $C_{18,}$ 100 × 3.0 mm analytical column (Agilent, USA) fitted to a guard cartridge of 4.0 mm × 2.0 mm (Phenomenex, USA). Autosampler temperature was 4 °C. Multiple reaction monitoring (MRM) channels for the analytes and IS were determined after the optimization of the capillary voltage and collision energies (Table 1). During the optimization, 0.1% formic acid (pH: 2.6)/acetonitrile (50:50, v/v) mobile phase composition was used. MS parameters for needle, shield voltage, nebulizer gas pressure and drying gas pressure, drying gas temperature were: + 5500.0 V, + 600.0 V, 55.0 psi, 30.0 psi and 400 °C, respectively. Single ion monitoring (SIM) width was 1.5 amu. Atmospheric pressure ionization (API) housing was kept at 65.0 °C and argon pressure at 2.40 mTorr. An accurate analysis was performed in an ultra-short elution time (2.5 min) with an isocratic elution via 0.1% formic acid/acetonitrile (50:50, v/v) composition (flow rate: 0.3 mL/min). Injection volumes were 10.0 µL.

Table 1. MRM table of the instrument

ANALYTE	Q_1	Q_3	Capillary voltage (V)	Collision energy (V)	Dwell time (s)
Fentanyl	337.0	188.0	+ 90.0	20.0	0.15
Norfentanyl	233.2	150.1	+ 60.0	13.0	0.15
Papaverine HCl (IS)	340.1	202.0	+ 92.0	22.5	0.15

Sample collection

Urine samples were collected from five healthy individuals (between ages 24 and 36 years old) with no drug use and

with no known chronic disease, and mixed in a pot to form a blank urine pool for method development and validation. To test the method in real cases, approximately 50 mL of urine samples was obtained from three inpatients (aged between 54 and 66), two of whom were female, in cooperation with Istanbul University-Cerrahpasa Medical Faculty, Department of Algology, for analysis. Two of the participants had diagnosed with servix cancer (body weight: 42 and 65 kg) and one of them with soft tissue cancer (body weight: 73 kg) in the last 2 years and all were treated with transdermal fentanyl patches to overcome violent pain. None had tobacco or alcohol use and all were unrelated from the point of kinship and did not use any other medication. The daily doses of the amount of fentanyl used by patients varied between 50 and 100 µg/h. All collected urine samples were placed in sterile, plastic urine containers and were stored at + 4 °C until analysis. Standard solutions were spiked to these urine samples, extracted and analyzed.

Preparation of the standard solutions and urine samples

Analyte and IS solutions were prepared using methanol at final concentrations of 500.0, 5000.0, 12,500.0, 50,000.0 ng/mL and added freshly to blind urine samples in predetermined volumes, not exceeding 20.0 µL. A 20.0 µL IS solution of 20.0 µg/mL was also added. Finally, methanol in varying amounts was added to each sample in order to standardize the spiking volume as 40.0 µL. Blind urine samples were also studied. All stock and test solutions were prepared freshly.

Optimization of the extraction method

The extraction method was modified from the liquid–liquid extraction (LLE) method of Coopman et al. [15] and optimized. In the modification and optimization studies; the effect of mixing time, sample volume and the number of extraction steps on the recovery efficiency were investigated. Unlike the former study, undiluted urine was used for extraction. The effect of salt on extraction efficiency was investigated through testing NaF, Na_2SO_4 and K_2CO_3 in the extraction with 7.00 mL of n-hexane/ethylacetate (7:3, v:v). When NaF and Na_2SO_4 were used, the phase separation was not clear, and K_2CO_3 provided the best phase separation. Since fentanyl and norfentanyl were weak bases, the nonionized fractions of the analytes and the recovery were increased after the added urine was alkalized (to pH = 11.50–12.00) with K_2CO_3 solution. The effect of mixing time on the recovery of fentanyl in LLE was also investigated; trying 3, 5 and 7 min extraction times. 7 min was observed to give much higher recovery than the Coopman's method. Sample volumes of 1.00 and 2.00 mL were tried and the best recovery was obtained with 1.00 mL sample volume. Also a two-step extraction method was tried with a total of 7.00 mL extraction solvent. Since no significant difference was observed between the one-step and two-step extraction methods, a single-step extraction was preferred. Unlike the former study, a mild block temperature of 35 °C was chosen for evaporation under nitrogen, in order not to degrade the analytes.

The optimized sample preparation method below had higher precision and higher analytically acceptable recoveries than the unmodified form:

1.00 mL of urine was placed in a polypropylene test tube, 0.363 M K_2CO_3 was added till a pH between 11.5 and 12.0 was obtained. After 30 s vortexing, 7.00 mL of n-hexane/ethylacetate (7:3, v:v) mixture was added and vortexed for 7 min. After 5 min centrifugation at 5000 rpm, the upper phase was evaporated to dryness at 35 °C under nitrogen, reconstituted in 400.0 µL methanol and transferred to vials for analysis in LC–MS/MS.

All measurements were performed, wherever possible, at low temperatures (autosampler: at 4 °C, evaporation: at 35 °C) and in a short period of time.

Validation

The chromatograms of solvent, extracted blank and spiked samples ($n \geq 6$) were compared to determine the specificity of the method. It was checked whether there was any interference from the solvent and the matrix, at the ion channels and retention times of the peaks of fentanyl and norfentanyl. In addition, in order to provide the selectivity, characteristic MRM ion channels specific to each of the analytes and IS were created. Each standard was injected one by one to monitor whether their peaks interfere with each other's ion channels to demonstrate the selectivity. Data evaluation and calculations of validation parameters were performed using Microsoft Excel. A matrix-matched calibration technique was used for the compensation of matrix effects: Spiked matrix samples were

prepared in increasing concentrations between 1.0 and 1250.0 ng/mL for construction of the calibration curves. Least squares method was used to create the calibration curves. Standard deviations obtained from at least two injections of each of three samples ($n \geq 6$) for each concentration level were calculated. The relative standard deviation (RSD%) values for each calibration level were used in LOQ estimation via Eurachem method [16], which is the most strict method utilizing the reasonable and a gradual decrease of the repeatabilities in the y-axis of the Eurachem graph versus increasing concentration and regarding 15% RSD as the LOQ. This was estimated through plotting RSD% values versus concentrations of the spiked samples analyzed during the matrix-matched calibration. LOD was calculated using Eq. 1 [17]:

1

LOD=3.3sslopeofthecalibrationcurves: standard deviations of the analyte area/IS area ratios.

Recovery studies were performed at low, medium and high concentrations of the linear range of fentanyl and norfentanyl for urine samples, each with at least six replicates. Average recovery rates along with their precision values were calculated from Eq. 2 [18]:

2

RE%=pre - extractionspikepost - extractionspike×100

The matrix effect was evaluated by comparing spiked matrices with the standard solutions in methanol ($n \geq 6$) and was studied for full concentration scale in the calibration graph (Eq. 3) [19]:

Results

In this study, a fast and simple LC–MS/MS method for fentanyl and its metabolite norfentanyl in urine is developed and validated. The sample preparation method was modified from Coopman et al. [15] and optimized. In the method developed for screening and confirmation, the analytes were determined in 1.00 mL urine sample, with a very fast (2.5 min) isocratic elution in LC–MS/MS, following a 30–35 min LLE. LLE was performed at a pH between 11.5 and 12.0 (K_2CO_3) using 7.00 mL of n-hexane/ethylacetate solution, in 7 min and the organic phase was enriched 2.5 times for analysis in LC–MS/MS.

The retention times for fentanyl and norfentanyl were 1.73(±0.00) and 1.38(±0.01) minutes. MRM transitions were 337.0>188.0 m/*z* for fentanyl and 233.2>150.1 m/*z* for norfentanyl. The retention time for IS was 1.73(±0.00) minutes, while its MRM transition was 340.1>202.0 m/*z*. The validation was performed by means of specificity, selectivity, linearity, linear range, recovery, LOD, LOQ and matrix effect.

Validation of the optimized method

In the validation of the optimized method, the selectivity was confirmed by the determination of the analytes in their characteristic ion channels. As a result of the comparison of the chromatograms of the analytes in urine extracts, with the methanol and blank urine chromatograms; it was observed that no interference from the solvent and the blank urine existed in the retention times of the analytes, so the specificity was also confirmed (Fig. 1).

Fig. 1 [Images not available. See PDF.]

MRM Chromatograms of **a** fentanyl and **b** norfentanyl, added to the blind urine matrix before extraction at concentrations of 250.0 ng/mL and **c** Papaverine (IS) at 5.0 ng/mL

Calibration of the whole method, including sample preparation and instrumental method, was performed with matrix-matched calibration technique at five different concentrations. The equations of the calibration curves, linear ranges, regression limit value, LOD and LOQ values of the instrumental method regarding standard fentanyl and norfentanyl in solutions and in urine matrix are shown in Table 2. Calibration curves of the standard solutions as well as the matrix-matched calibration curves for fentanyl and norfentanyl, along with their r^2 values are demonstrated in Fig. 2. Matrix effect calculated for each analyte ($n \geq 6$) was found as 6.25% for fentanyl showing an ion enhancement and -20% for norfentanyl indicating anion suppression. The validation results obtained in standard solutions and sample

extracts fit for the purpose for analysis in tablet and injectable solutions and drug monitoring/toxicological analysis in urine, respectively.

Table 2. Linearity, linear ranges, calibration equations, LOD and LOQ values for fentanyl and norfentanyl regarding the whole method

Analyte	Calibration with standard solution				Matrix-matched calibration			
Linear Range[a]	Equation	LOD[a]	LOQ [a]	Linear Range[a]	Equation	LOD[a]	LOQ [a]	Fentanyl
2.5–1250.0	$y=0.0032x-0.0130$	0.7	2.5	14.0–500.0	$y=0.0034x+0.0354$	1.7	14.0	Norfentanyl

Calibration curves of fentanyl (**a**), norfentanyl in neat solutions (**b**) and matrix-matched calibration curves for fentanyl (**c**) and norfentanyl (**d**) in urine

An average recovery of 95(±6) % was obtained for fentanyl and 70(±9) % for norfentanyl, regarding low, mid and high concentrations (Table 3). Recovery findings were found to be within acceptable limits.

Table 3. Recovery and precision values for fentanyl and norfentanyl regarding the whole method at low, mid and high concentrations

Analyte	Spiked concentration (ng/mL)	Recovery%	%RSD
	10.00	92	6
	50.0	98	6
Fentanyl	250.0	94	8
	500.0	96	5
	50.0	69	16
Norfentanyl	250.0	71	4
	500.0	70	8

Number of analyses n≥6

Real examples

The method was applied to urine samples of three patients treated with fentanyl in Istanbul University-Cerrahpasa Medical Faculty, Department of Algology. The analysis results obtained using LC–MS/MS are shown in Table 4. Since the amount of substance in the urine of the patients is variable, blank methanol was analyzed between

samples, in order to prevent contamination. The chromatograms obtained after each blank methanol analysis were examined and it was seen that there was no carry over between the analyses. Fentanyl and norfentanyl concentrations were calculated using calibration graphs. The lowest amount of fentanyl detected was 32.6 ng/mL and the highest amount was 111.3 ng/mL.

Table 4. Concentrations of fentanyl and its metabolite found in the urine of the patients after the given doses ($n \geq 3$)

Sample No	1	2	3
Given dose for fentanyl (μg/h)	100 μg/h	100 μg/h	50 μg/h
Last fentanyl intake (before urine collection)	5 days before	2 days before	1 day before
Fentanyl concentration found (ng/mL)	32.6 (±0.5)[a]	111.3 (±4.4)[a]	44.9 (±2.7)[a]
Norfentanyl concentration found (ng/mL)	267.2 (±28.1)[b]	183.0 (±19.5)[b]	151.3 (±18.9)[b]

[a]RSD % for fentanyl ≤ 6

[b]RSD % for norfentanyl ≤ 12

Discussion

In the literature, deaths due to fentanyl absorption in high doses have been detected in patients treated with fentanyl transdermal patches for chronic pain [6]. Various LC–MS/MS methods have been developed for the determination of fentanyl and norfentanyl, in urine and other biological materials, as well as in formulations [15, 20]. Although our basic extraction method was modified from Coopman's work [15], the recovery obtained here is almost doubled for norfentanyl (raised from 40 to 70%). Wider linearity range up to 500 ng/mL was provided (so that no dilution will be required in higher concentrations), which does not exist in any of the studies encountered. Since it is important to see higher concentrations in serious toxicities, wider linearity range will provide immediate results without dilution steps and without any change of matrix effect. Also, in our method, urine was used without dilution (number of steps were decreased), mixing time, sample volume and elution and drying temperatures were optimized, papaverine hydrochloride was chosen as the IS, and a 2.5 times enrichment was performed, while a lower injection volume was used. In this study, a quantitative method was validated by calculating LOQ values in standard solutions and in urine. The effect of different salts was also examined. Furthermore, this method is very fast compared to the literature methods, especially when the 2.5 min chromatographic elution is considered. An average of 95(±6)% recovery was obtained for fentanyl and all RSD% values were <15.0%.

Also, our modified extraction method is simpler, faster [21–23] and 2.5 min LC–MS/MS method is shorter than all the equivalent literature methods regarding fentanyl and norfentanyl, except the method of Mahlke et al., where fentanyl was eluted in 1.68 min (1.73 in our study) and norfentanyl was eluted in 1.56 min (1.38 in our study). However, the linear range in most of the studies including Mahlke et al. were in maximum up to 10.0 or 50.0 ng/mL, while our method can detect higher and toxic concentrations without any dilution [10, 23–27].

Verplaetse and Tytgat [17] have used solid phase extraction (SPE) for determination of fentanyl and norfentanyl in urine and have given a linearity up to 5 ng/mL and 10 ng/mL, respectively [11]. They also developed another SPE method with excellent recoveries for nine narcotic analgesics and metabolites including fentanyl and norfentanyl, with a 7.2 min elution time for fentanyl and 10 and 40 ng/mL as the highest levels of given linearity range, for the drug and its metabolite [12]. Cunha et al. [28] have performed a microextraction by packed sorbent, with a chromatographic run of 10.3 min. Recovery was at least 27% for all analytes and 13% for norfentanyl. Eckart et al. [29] have developed an automated SPE method for a wide range of opioids with a highest calibration level 10 ng/mL, where the recovery for fentanyl and norfentanyl was between 62 and 78% and the elution times were 21.3 min and 10 min. As a result, the calibration range of our study is wider than the published equivalent studies,

and our method is faster, easier, besides presenting high recoveries.

Fentanyl test strips are also used for testing the presence of fentanyls in illicit drug products. However, most fentanyl test strips are based on competitive lateral flow immunoassays on simple paper-based devices [30] and there is a considerable lack of knowledge about the selectivity and sensitivity of testing with urine fentanyl strips [31]. Since the test results are highly concentration-dependent, detection of lower concentrations can be problematic [30]. The fentanyl test strips do not measure the exact fentanyl concentration and do not provide results that differentiate between or among fentanyl and any of the analogs present in a sample [32]. Most of the strips give only qualitative results, but with a validated fast chromatographic method, exact concentration can be determined quantitatively and sensitively. An additive effect would occur in case of presence of acetylfentanyl, acrylfentanyl, furanylfentanyl and butyrfentanyl at low concentrations of fentanyl (10 ng/mL), thus false positive results may be obtained. It was only demonstrated on the Nal van Minden test, but this additive effect is expected to be a general principle for all test strip brands (false positive). Four brands of fentanyl test strips (Rapid Response, One Step, Nal van Minden and Rapid Self Test) were examined using single-component drug solutions [30]. 21–24 of the 28 fentanyl analogues were tested. The effect of co-presence of heroin or ascorbic acid on test results was also examined and one of the test strip brands gave false positive results in the presence of ascorbic acid. With strip, fentanyl and norfentanyl cannot be distinguished from other fentanyl analogues, but a chromatographic analysis can selectively determine fentanyl. Since a clean-up step is applied in this method, the selectivity is much more higher than testing with fentanyl strips.

Different amounts of fentanyl and norfentanyl found with this method in the urine samples of patients who were treated with patches containing the same dose, arouse the conviction that individual characteristics (gender, age, enzyme polymorphism, foodstuffs, other drugs taken together with fentanyl, urine concentration, etc.) or periodical/non-periodical applications might be the reasons. Besides these inter-individual differences, from time to time, differences within individuals are reported during the treatment [33]. The patient with the highest value has received the last fentanyl dose (100 µg/hour) two days before the urine sample was taken, and the drug administration was continued at 72-h intervals. The lowest amount of norfentanyl detected was 151.3 ng/mL and the highest amount was 267.2 ng/mL. According to the information of the patient with the lowest level of norfentanyl; a dose of 50 µg/hour was administered, and it was not repeated at 72-h intervals due to the patient's disrupting the medication.

Conclusion

Considering the risk of intoxication/death that may be encountered during treatment or because of misuse of fentanyl, a fast (30–35 min sample preparation + 5 min elution time in total), validated, sensitive LC–MS/MS analysis method with high recovery is presented here for the simultaneous determination of fentanyl and its metabolite in urine; to benefit in therapeutic drug monitoring, emergency toxicology and in forensic cases as toxicity/death caused by this drug and in supporting the presence of polymorphism of CYP3A4 gene (metabolizing fentanyl). The recovery obtained by the modified extraction method is almost doubled for norfentanyl and the upper linearity range was increased to at least10 times that of the former methods. Since this method has the widest linearity range in the literature, it is employable in a wide concentration range and no dilution will be required in higher concentrations. Especially, overdilution of the matrices will change the matrix intensity and errors may arise in the results. We suggest that this analysis method should be tested in future studies for the determination of new and more potent fentanyl derivatives in the market. Since it is important to determine higher concentrations in serious toxicities, wider linearity range will be useful in reaching the results immediately. This study fills this gap along with its high accuracy, speed and simplicity.

Comparative study of UV spectroscopy, RP-HPLC and HPTLC methods for quantification of antiviral drug lamivudine in tablet formulation

Somkuwar, Komal1 ; Sabale, Prafulla1; Sawale, Vaibhav1; Rahangdale, Priya11 R. T. M. Nagpur University, Department of Pharmaceutical Sciences, Nagpur, India (GRID:grid.411997.3) (ISNI:0000 0001 1177 8457)

ABSTRACT (ENGLISH)

Background

In the current study, estimation of lamivudine (LMU) by UV spectroscopy, reverse-phase HPLC (RP-HPLC) and HPTLC methods in tablet formulation was developed, and comparative studies between the methods were investigated by analytical results and statistical test analysis of variance (ANOVA) to find out best method. In the UV spectral method, LMU was quantified at 271 nm absorption maxima using methanol as the solvent. In the RP-HPLC method, the Shimadzu C18 column (250 mm × 4.6 mm i.d., 5 µm particle size) was employed for chromatographic separation. The mobile phase used consists of methanol: water (70:30 v/v) in an isocratic mode with a 1.0 mL/min flow rate. In the HPTLC method, the chromatogram was developed on a pre-coated plate of silica gel 60 F254 with a mobile phase composition of chloroform: methanol (8:2 v/v). The quantification was performed at an absorbance mode of 271 nm by densitometry. The methods were validated according to the International Conference on Harmonization (ICH) guideline Q2 (R1). The degradation conditions were employed as per ICH guidelines Q1A(R2) and Q1B which include acid, alkaline, neutral, thermal and photostability to determine the intrinsic stability of the drug in varied environmental conditions.

Results

LMU absorption maxima was found to be 271 nm. The retention time of LMU was 3.125 min, and the total analysis time was 5 min. The R_f value of LMU was 0.49–0.62. The methods were linear within 2–12 µg/mL range. The correlation coefficient (r^2) for UV, HPLC and HPTLC was 0.9980, 0.9993 and 0.9988, and percent recoveries were calculated as 98.40–100.52%, 99.27–101.18% and 98.01–100.30%, respectively, with percentage relative standard deviation (RSD) less than 2% showing that methods were precise and accurate.

Conclusion

Developed UV, RP-HPLC and HPTLC methods are free from intervention caused by excipients present in tablets and thus can be used for regular quantitative analysis of LMU in tablet formulation. Based on analytical results and statistical tests, ANOVA, it is inferred that the HPLC method is best for LMU quantification tablet formulation due to its high reproducibility, good retention time and sensitivity; it has a higher percent recovery and has less analysis time, i.e., 5 min. The degradation peaks were well separated from the LMU peak indicating stability of the HPLC method.

FULL TEXT

Background

Lamivudine, Fig. 1, (4-amino-1-[(2R, 5S)-2-(hydroxyethyl)-1, 3-oxathiolan-5-yl] pyrimidin-2-one) is a reverse transcriptase inhibitor. It is used for HIV (human immunodeficiency virus) and hepatitis B infections. It is used for both HIV-1 and HIV-2. LMU is a synthetic nucleoside analogue of cytidine. Lamivudine triphosphate (L-TP) was formed by going through intracellular phosphorylation. An active 5′-triphosphate metabolite that competes with it is incorporated into the DNA of the virus. They impede reverse transcriptase enzymes competitively. The inserted nucleoside analogue has a 3′-OH group missing which functions as a chain breaker of DNA synthesis, which is necessary for the production of the 5′ to 3′ phosphodiester linkage needed for DNA chain extension. LMU is marketed under the brand name Lamivir 150-mg film-coated tablet [1–3].

Fig. 1 [Images not available. See PDF.]

LMU Chemical Structure

An extensive literature survey disclosed that LMU has been determined independently or in combination with other drugs by UV spectroscopy [4, 5], RP-HPLC [6–13] and HPTLC [14–16]; however, there was not a single research work that has been done reporting that LMU individually was determined simultaneously by all three methods, i.e., UV spectrophotometry, RP-HPLC and HPTLC, and investigating the best method among them. Further to carry out

stability indicating study of the selected superior method for separating the active analyte present in the pharmaceutical dosage is carried out, which makes the present research work unique and novel. Hence, we have strived to develop precise, accurate, sensitive and inexpensive methods and compare them based on analytical results such as sensitivity, % recovery and % assay of the drug. Validation of the method was performed according to Q2 (R1) ICH guidelines [17].

Methods

Materials

LMU was procured from *Cipla Ltd, Kurkumbh*, Maharashtra, India, as a gift sample. The marketed pharmaceutical tablets of Lamivir 150 mg (manufactured by Cipla Ltd) were purchased from a nearby pharmacy. Double distilled water was obtained from the Millipore unit. HPLC-grade chloroform and methanol were acquired from *Sisco Research Laboratories Pvt. Ltd, Mumbai, India*.

Instrumentation

A double-beam UV-1800 Shimadzu UV spectrophotometer along with a pair of matched quartz cells 10 mm is used. The HPLC system was a Shimadzu model no. DGU-20A5R which consists of a PDA detector. HPTLC was carried out on a pre-coated silica gel 60 F254 TLC Merck plate using a sample syringe of Camag 100 µl with an applicator of Linomat 5 and a twin-trough chamber; densitometry was executed with a CAMAG TLC Scanner 3 with Visioncats software. Shimadzu ATX224 digital analytical balance and PCi analytics ultrasonic bath were employed for weighing the samples and for sonication, respectively.

Sample preparation for UV, RP-HPLC and HPTLC method development

Standard solution preparation

Five milligrams of LMU was precisely weighed and poured into a 50-mL volumetric flask. Methanol was used as a solvent to make up the volume. 1 mL of stock solution was poured into a 10-mL volumetric flask, and the volume was raised to have a final concentration of 10 µg/mL.

Sample solution preparation

Approximately 20 tablets were weighed, and an average weight was determined for each tablet. A powder equal to five milligrams was weighed and poured into a 50-mL volumetric flask, consequently adding 15 mL of methanol and sonicating for 30 min. Later on, the volume was raised to the mark and filtered from the Whatman filter paper No. 41. Appropriately the solution was diluted to get a concentration of 10 µg/mL.

UV method development

Determination of LMU maximum absorbance (λmax)

The standard solution of LMU in the region of 200–400 nm is scanned. An absorption maximum was determined to be 271 nm, which was selected as the analytical wavelength for further analysis. The spectrum was recorded as shown in Fig. 2.

Fig. 2 [Images not available. See PDF.]

UV spectrum of LMU standard solution. The λmax was determined to be 271 nm

HPLC method development

Optimization of HPLC method

To achieve optimized chromatographic conditions, the below parameters were modified in each trial. The trial runs are shown in Table 1 (Additional file 1).

Table 1. Trial run for optimization of chromatographic conditions

Mobile phase	Flow rate (mL/min)	Retention time (min)	Comment

Methanol:Water (50:50)	0.8	4.135	Sharp peak appears, but retention time was more
Methanol:Water (60:40)	0.8	3.795	Sharp peak appears, but retention time was more
Methanol:Water (60:40)	1.0	3.534	Sharp peak appears, but retention time was more
Methanol:Water (65:35)	1.0	3.351	Sharp peak appears, but retention time was more
Methanol:Water (70:30)	1.0	3.125	Sharp peaks appear with less retention time

From the trial, the best possible chromatographic condition was selected based on peak shape that is sharp evaluated by theoretical plates and tailing factor which were within specified limit, and retention time is 3.125 min which is much less. Therefore, separation of LMU was performed on a Shimadzu C_{18} (250 mm × 4.6 mm i.d., 5 µm particle size) consisting of methanol: water (70:30) as a mobile phase; by using a membrane filter it was filtered and degassed. The flow rate was retained at 1.0 mL/min. The injection volume was kept at 10 µl at a column oven temperature of 30 °C, and effluents were checked at 271 nm. The mode of separation was isocratic. The chromatogram of LMU and its 3D image are shown in Figs. 3 and 4, respectively.

Fig. 3 [Images not available. See PDF.]

Chromatogram showing the separation of LMU

Fig. 4 [Images not available. See PDF.]

3D image of LMU chromatogram

Peak purity

The peak purity of the LMU peak was examined in a degradation solution using a photodiode array detector. Peak purity for each solution was passed at the threshold level. The peak purity report is depicted in Table 2, and peak purity spectra and profile are depicted in Figs. 5 and 6.

Fig. 5 [Images not available. See PDF.]

Peak purity spectra of LMU

Fig. 6 [Images not available. See PDF.]

Peak profile of LMU

Table 2. Peak purity description

Impurity	Not detected
Peak purity index	0.284

Single-point threshold	1.00

HPTLC method development

Optimization of mobile phase by TLC

Different compositions of the mobile phase were tried first on the TLC plate. The trial runs are presented in Table 3. From the trial data, chloroform: methanol (8:2) is selected as a suitable mobile phase since it shows a detectable significant spot of LMU (Additional file 1). This optimized mobile phase is used for HPTLC method development.

Table 3. Trial run for optimization of mobile phase for HPTLC

Trial run	Volume of toluene (mL)	The volume of ethyl acetic acid (mL)	Volume of methanol (mL)	Volume of glacial acetic acid (mL)	Volume of chloroform (mL)	Rf value	Comment
1	4	4	1.5	0.5	–	0.46	Spot shows tailing
2	6	2	2	–	–	0.71	Spot shows tailing
3	4	2	4	–	–	–	No spot appears
4	5	2	3	–	–	–	No spot appears
5	–	–	2	–	8	0.60	Significant spot appears without tailing

The LMU standard solution of 2 µl was employed as spot bands of 4 mm to the HPTLC plates under the stream of nitrogen using LINOMAT V. Application locations were at least 15 mm from the edges and 10 mm from the foot of the plate. The development chamber was kept for saturation with chloroform: methanol (8:2 v/v) before each run for 20 min. Development of the plate was performed to migrate a distance of 7 cm by the ascending technique. The analyses were performed in a temperature-controlled laboratory (20–24 °C). Densitometry scanning was carried out using a deuterium lamp in absorbance mode at 271 nm. The chromatogram is depicted in Fig. 7.

Fig. 7 [Images not available. See PDF.]

HPTLC chromatogram of LMU. Rf value 0.49–0.62

Forced degradation studies by the HPLC method

Forced degradation includes the degradation of active substances and drug products which results in degradation products that are studied to evaluate the intrinsic stability of the molecule. Degradation conditions such as acidic, alkaline, thermal, neutral and photostability were represented by ICH guidelines Q1A, Q1B [18, 19] and Q2 (R2). In a stability-indicating method, the acceptable degradation percentage should not exceed 20% .

Results

Method validation

System suitability parameters

After equilibrating the column with the mobile phase, the standard solution was autoinjected five times and the chromatograms were noted. The data are presented in Table 4.

Table 4. System suitability results (RP-HPLC)

Sr. No	Peak area	Tailing factor	Theoretical plates
1	2,413,422	1.162	2860
2	2,431,570	1.147	2908
3	2,459,066	1.142	2846
4	2,467,969	1.140	2884
5	2,431,480	1.146	2870
% RSD	0.91	0.75	0.83
Limit	NMT 2%	NMT 1.5	NLT 2000

Linearity

The standard stock solution of LMU was serially diluted to yield 6 distinct concentrations, i.e., 2, 4, 6, 8, 10 and 12 µg/mL. At 271 nm, their absorbance was measured against a blank. For HPLC, similar dilutions were performed and these solutions were autoinjected with optimized chromatographic conditions. For HPTLC, a volume of 2 µl of each serially diluted solution was employed on the HPTLC plate to carry 2, 4, 6, 8, 10 and 12 µg/mL of LMU per spot. The UV, HPLC and HPTLC methods confirmed linearity in the 2–12 µg/mL range, and the linearity equations were $y = 0.0421x - 0.0016$, $y = 33177x - 534$ and $y = 0.001x + 0.0018$ with r^2 of 0.9980, 0.9993 and 0.9988, respectively. Table 5 shows the results. The calibration plots for UV, HPLC and HPTLC are depicted in Figs. 8, 9 and 10, respectively.

r^2	0.9980	r^2	0.9993	r^2	0.9988

Accuracy

Accuracy was measured at 50%, 100% and 150% by spiking a standard solution of LMU (0.5, 1.0, 1.5 µg/mL) into the sample solution. The recoveries were ascertained in the range of 98.40–100.52%, 99.27–101.18% and 98.01–100.30% by UV, HPLC and HPTLC, respectively. The % RSD was found to be less than 2, indicating that there was no interference of the excipients while determining LMU. Therefore, the method is accurate. The accuracy data are depicted in Table 6.

Precision

For this study, six standard solutions of LMU were analyzed by UV, HPLC and HPTLC methods. The % RSD was less than 2, which significantly assures the precision of the proposed methods. Intraday and interday data are reported in Table 7.

Table 7. Precision data

Robustness

LMU's six working standard solutions were used for analysis. In the proposed UV method, to validate the robustness parameter, slight variation was employed in wavelength (±2 nm); for HPLC robustness was assessed by introducing little, variation in the percent of methanol (±2%), flow rate (±0.2 mL/min), sonication time (±5 min) and using different Whatman filter no. (40, 42). Similarly, for HPTLC, there was a small change in chamber saturation time (± 5 min) and the mobile phase composition (±0.5). The data are presented in Table 8. The % RSD was not more than 2, hence significantly representing methods to be robust (Table 9).

Table 8. Robustness data

Results of analysis of tablet formulation of LMU by UV, HPLC and HPTLC methods

LMU standard and sample solutions absorbance was measured at 271 nm. In HPLC, both standard and sample solutions were autoinjected into the HPLC system, similarly for HPTLC 2 µl of standard, and sample solutions were employed as bands 4 mm on the HPTLC plate. The amount of LMU present per tablet was determined by UV, HPLC and HPTLC by comparing the absorbance and peak area of the sample with that of the standard, respectively. The obtained results of % labeled claim are reported in Table 10. Percent content obtained by UV HPLC and HPTLC was statistically compared by ANOVA, as depicted in Table 11.

Table 10. Results of analysis of tablet formulations

Method	Brand name	Label claim	Manufacturer name	Batch No	% Label claim estimated (% content)	Mean	% RSD
UV	Lamivir 150	150 mg Lamivudine	Cipla	SA12696	98.76	99.02	0.36

99.34	98.53	99.38	98.82	99.01	HPLC	Lamivir 150	150 mg Lamivudine
Cipla	SA12696	99.97	99.90	0.83	98.79	100.87	99.16
100.77	99.85	HPTLC	Lamivir 150	150 mg Lamivudine	Cipla	SA12696	99.24

Statistical comparison between UV, HPLC and HPTLC methods for % contents

ANOVA test

Table 11. Observations and results of ANOVA test for % contents study

Parameter	Variance			*F* Value	*P* Value	F critical
UV	HPLC	HPTLC	% Content	0.1133	0.6970	0.0504

From the statistical data, it could be inferred that the F value is greater than the F critical value indicating there is a remarkable differentiation between the mean % content determined by UV, HPLC and HPTLC methods, and hence, the null hypothesis is rejected.

Table 12. Comparative study of UV, HPLC and HPTLC methods

Parameters	UV method	HPLC method	HPTLC method
Linearity equation	y=0.0421x – 0.0016	y=33177x – 534	y=0.001x+0.0018

% label claim	99.02	99.90	99.54

Forced degradation study

For this study, drug was given treatment with various degradation conditions. 1 mL from stock solutions (1000 µg/mL) was treated separately with 1 mL of 1N hydrochloric acid (heated in a water bath for 2 h at 60 °C), 1 mL of sodium hydroxide (heated in a water bath for 2 h at 60 °C), neutral degradation (refluxing with water for 6 h at 60 °C), dry heat degradation (exposure of drug powder in the oven at 60 °C for 10 days) and photostability

degradation (exposure of drug powder in sunlight for 10 days). Samples were taken at regular intervals to monitor degradations. There is no interaction of the degradation peak with that of the LMU peak. Hence, the proposed HPLC method was stability indicating and specific (Figs. 11, 12, 13, 14 and 15). The peak purity index values of LMU peak and degradation peaks were found to be within acceptable limits, Table 13.

Discussion

The present research work aims to compare all three developed methods UV, RP-HPLC and HPTLC on grounds of sensitivity, accuracy, percent recovery and percent purity and to evaluate the best method among them, since to our knowledge, no such venture had been made earlier. The inference from the study could be briefed as the UV method could be implemented in laboratories that lack high-tech analytical instruments, in developing countries where affording expensive instruments is a big deal along with the availability of highly skilled person so UV spectroscopy is a method of choice, which is cheapest and does not require so-skilled person in comparing with HPLC and HPTLC methods which are complicated, expensive and time-consuming. The HPTLC method utilized not more than 30 mL of mobile phase thus reducing mobile phase consumption when compared with HPLC method, also less mobile phase consumption indicate the eco-friendly nature of the method. After optimization of the method by TLC to develop that new method on HPTLC it takes an average of 1 h which is much less relative to HPLC but HPTLC shows less sensitivity as per analysis data reported in Table 12. Handling HPTLC requires a skilled person

and is expensive. The RP-HPLC method is more sensitive at 0.33 µg/mL and has a high % recovery of 99.27–101.18% and a % label claim of 99.90% in comparison with the other two methods as depicted in the analysis data of Table 12. Complex samples having many ingredients can be separated easily via HPLC showing high separation capacity, since being autosampler enables batch analysis of multiple components; it is an extremely precise and reliable technique. It is an expensive method that requires a large amount of expensive organic solvents and needs regular maintenance of the system. Also, the current research work provides an alternative method to the Anbazhagan S et al. approach [5] where the simultaneous quantification of three drugs was carried out by all three methods while in the present research work the focus is on LMU alone which was never quantified individually by all three methods before as per literature review. Therefore, in comparison with the Anbazhagan S et al. research work, the current research work requires less consumption of solvents for dilutions, chemicals and glassware thus promising the cost-efficiency of the present method, also total analysis time for HPLC is just 5 min with a retention time of LMU 3.125 min while in Anbazhagan S et al. research work it was 10.81 min with retention time of LMU 4.330 min indicating shorter period of analysis, and hence, rapid analysis of more number of samples could be done. ANOVA was applied to validate the information that there is a remarkable differentiation between mean % content determined by UV, HPLC and HPTLC methods. The *P* value (0.0280) is smaller than the alpha value ($\alpha = 0.05$), i.e., significance level therefore rejecting the null hypothesis, and the proposed null hypothesis was there is no remarkable difference. From the forced degradation studies, it could be inferred that all the degradant peaks and LMU peaks were well separated from each other. Peak purity for each solution was passed at the threshold level. Therefore, the proposed HPLC method is confirmed to be stability indicating (Table 13).

Conclusions

The proposed UV, RP-HPLC and HPTLC methods for the quantification of LMU in tablet formulation were linear having a concentration range (2–12 µg/mL) and had perfect accuracy ranging from 98 to 102%, precision with sensitivity and robust in nature. The % RSD was less than 2% thus compliance with ICH guidelines. The proposed methods are free from intervention due to excipients in tablets and thus could be used for regular determination of LMU in tablets. In conclusion, as per the aim of the study comparison between the methods was carried out, and based on analytical results and statistical tests, ANOVA shows that HPLC is the best method for the quantification of LMU in tablets due to its high reproducibility, sensitivity, good retention time; it has a higher percent recovery and has less analysis time, i.e., 5 min. Hence, forced degradation study by RP-HPLC was carried out by employing many stress conditions to assess the method's stability. The developed RP-HPLC method successfully separates the drug and its degradation products with good resolution so the method is proved to be stability indicating. The present research work is going to be extended to perform the impurity profile of LMU and to detect the pathway of degradation for the same.

ABSTRACT (ENGLISH)

Background

In this work, we represent synthesis, in silico analysis and biological activity of 1,4 diazepine linked piperidine derivatives (6a–6o). All the derivatives were screened for their anti-microbial activity against gram-positive (*Staphylococcus aureus, Bacillus Subtills, Bacillus megaterium*) and gram-negative (*Escherichia coli, Pseudonymous, Shigella sp.)* bacteria. Compounds were synthesized from reaction of tert-butyl 1,4-diazepane-1-carboxylic, butyryl chloride and varied aromatic aldehyde, further characterized by ^{1}H NMR and LCMS spectral techniques.

Result

Using ampicillin as a positive control, the synthetic compounds 6a–6o were tested for their in-silico study and experimental anti-microbial activity against gram-positive (*Staphylococcus aureus, Bacillus Subtills, Bacillus megaterium*) and gram-negative (*Escherichia coli, Pseudonymous, Shigella sp.)* bacteria. According to in vitro assay compound 6a, compound 6c, compound 6d, compound 6m and compound 6l showed higher activity against all the tested strains. Molecule 6i, compound 6j, compound 6k, compound 6f has good to moderate antibacterial activity. DFT computations were used to optimize the molecular geometry at the B3LYP/6-31G (d, p) theoretical level. The corresponding energy values of molecular orbitals were visualized using optimized geometries. Moreover, Auto Dock Vina 1.2.0 is used to assess molecular docking against two target proteins, Bacillus subtilis (PDB ID: 6UF6) and Protease Vulgaris (PDB ID: 5HXW). The target molecule 6b displayed the best binding energies for both. Additionally, we calculated the ADME for each molecule (6a–6o).

Conclusion

All fifteen synthesized compounds were screened for their in vitro and in silico analysis. In vitro analysis for anti-microbial activity was carried out against gram-positive (*Staphylococcus aureus, Bacillus Subtills, Bacillus megaterium*) and gram-negative (*Escherichia coli, Pseudonymous, Shigella sp.)* bacteria and compound 6a, compound 6c, compound 6d, compound 6m and compound 6l exhibits more potent activity towards all tested strains. Molecular docking is performed against target proteins, L-amino acid deaminase from *Proteus Vulgaris* and LcpA ligase from *Bacillus subtilis*, representing the Gram-negative bacterium and Gram-positive bacterium, respectively. Compound 6b showed the highest no. of interaction with protein according to molecular docking. With the advent of innovative techniques like ADME, we select their hit compounds early on and anticipate future pharmacokinetic and pharmacodynamic benefits and drawbacks of these promising therapeutic candidates.

FULL TEXT

Background

Heterocycles are crucial chemicals their applications in many domains, including medicinal, agrochemical, and veterinary [1]. Several seven membered heterocyclic rings, with 2 hetero atoms, have shown wide range of

medicinal activity. Among these, 1,4-diazepine,1,4-diazepane, and azepinone have been studied in detail. 1,4-diazepanes, also known as homopiperazine, hexahydyro-1,4 diazepine, were first identified as a fundamental heterocyclic molecule in 1899. Later, a simple method was developed to manufacture these at industrial scale [2]. Molecular formula of 1,4 diazepane is $C_5H_{12}N_2$ and M.P. is 42 °C [3]. 1,4-diazepane is seven membered heterocyclic ring with nitrogen atoms at position 1 and position 4 of diazepan ring [4]. These molecules have been extensively studied owing to their versatile nature, and potential application in medicines, agrochemicals, and materials science [5]. Moreover, the 1,4-diazepane (homopiperazine) ring is prevalent among the various substitutions, linkers, as well as scaffolds used in pharmaceutical hit-to-lead optimization, particularly as a crucial component of optimized lead compounds [6]. Further, as 1,4-diazepane is hydrophobic, facilitate the organotin complex to permeate the cell and enhance the compound's biological activity [7]. In medicinal chemistry, 1,4-diazepane moiety has shown extensive pharmaceutical properties (Fig. 1) as anti-HIV [8, 9], anti-dengue [10], anti-Alzheimer [11], anti-tubercular [12], anti-fungal [13], anti-oxidant [14, 15], anti-bacterial [16], anti-cancer [17], anti-microbial [13, 18], Histamine receptor [19], anti-tumour [7, 20], and as Kinase inhibitor [21].

Fig. 1 [Images not available. See PDF.]

Different medicinal activity of 1,4 diazepane

Further, piperidine is a fundamental heterocyclic part of medical chemistry. Piperidine core compounds exhibit pharmaceutical properties like anti-HIV, anti-cancer. A.R. Zala and colleagues developed piperidine-containing molecules as antibacterial drugs in 2023 [22]. Mahmat Yildiz and colleagues developed piperidine derivatives that act as antimicrobial agents [23]. In contrast, Enrico Casalone and colleagues developed 1,4-diazepane derivatives as antimicrobial agents in 2020 [24]. Since, both piperidine and 1,4 diazepane show potent antimicrobial activities, in this study we created 1,4 diazepane linked piperidine derivatives and have characterize their antimicrobial efficacy. The derivative molecules have also been investigated using a series of computational chemistry tools, such as the Density Functional Theory, Molecular docking and ADME analysis. Here, we aim to facilitate the current research in designing innovative strategies for the discovery and development of good antimicrobial agents.

Methods

All the compounds and solvents were purchased from Sigma Aldrich and used without any additional purification. The gradient of MeOH in MDC was created using the elutes and was used for the thin layer chromatography (TLC) method on silica gel plates (60F254, 0.2 mm thick, Merck). In this study, we used a Bruker Advance II 400 NMR spectrometer, used with the internal standard tetra methyl silane (TMS) as a ^{1}H NMR spectrometer, to perform ^{1}H NMR spectra in $CDCl_3$ solution at 400 MHz. Parts per million, or ppm, are used to compute the value in ^{1}H NMR. As the mobile phase of the LCMS equipment, which used WATERS to record data, 0.15% formic acid in acetonitrile was used as a mobile phase for the LCMS equipment.

Chemistry

The five-step synthesis process outlined in Scheme 1 was created to produce the desired anti-microbial active ingredient. Commercially available tert-butyl 1,4-diazepane-1-carboxylic **(1)** intrigues the production route when it is coupled with butyryl chloride in the presence of triethanolamine (TEA) and methylene chloride (DCM) to produce compound **2** [25]. Compound **3** is produced by carbamate hydrolysis using compound **2** and 6 N HCl in dioxane to remove the boc protecting group [26]. In the presence of TEA, $ZnCl_2$, and MeOH, compound **4** was produced by treating compound **3** with commercially available tert-butyl-4-oxopiperidine-1-carboxylate[27]. Once more, carbamate hydrolysis is performed to remove the boc protecting group in preparation for the transition from compound **4** to compound **5** [26]. With the addition of DIPEA, the carboxylic acid in DMF was reacted with compound **5** in the presence of HATU and generated a high quality desired derivative (**6a-o**).[28, 29]. All the used aldehydes and properties of desired derivatives shown in Table 1.

Scheme 1 [Images not available. See PDF.]

Synthetic route of 1,4 diazepane linked piperidine derivative

Table 1. Properties of compounds

In vitro assay

For the investigation of in vitro anti-microbial activity, the cup plate method [30, 31], which is very popular, was used. Gram-positive (*Staphylococcus aureus, Bacillus Subtills, Bacillus megaterium* and gram-negative (*Escherichia coli, Pseudonymous, Shigella* sp.) microorganisms, as well as Staphylococcus aureus (Gram+), were used to test in-vitro anti-microbial activity. To carry out this approach, all bacterial cultures were first kept in nutrient broth and then incubated overnight at a temperature of 37 °C. A full hour was given for the incubated molten agar to set and solidify before it was transferred to the sterilized petri plates. Bacterial culture was evenly swabbed on the sterile plates using a cotton swab. On agar media, 6 mm broad bores were constructed using sterilized cork. Each bore was filled with the test compound solution, which had a measured concentration of 1000 µg/ml, using a sterile tip and micropipette. A plate was similarly prepared for the positive control ampicillin, which is taken as standard. The prepared plates were incubated for 24 h at 37 °C. Every bore had a clear zone encircling it after the incubation process, demonstrating that the 1,4-diazepane linked piperidine derivative under test had anti-microbial efficacy. The average diameter of these formed clear zones of inhibition was determined and used to report activity in millimeters. A value for the MIC (minimum inhibitory concentration) was obtained using the liquid dilution method [32], All derivatives MIC values were established for *Staphylococcus aureus* (Gram+) bacterium. The investigated substances were dissolved in a suitable solvent at a concentration of 50 mg/ml. Similar to this, a conventional ampicillin solution was made at a 50 mg/ml concentration. Bacterial culture inoculum preparation was carried out. In a series of test tubes, 0.2 ml of inoculum is inserted along with a 1 ml solution of the test substance at a specified concentration. In each test tube, 3.8 ml of sterile water was also added. All these test tubes were maintained under observation and incubated for a day in order to detect the existence of turbidity. A similar process was used to screen ampicillin, which is a commonly used medication. MIC values are those where bacterial growth was not seen to occur.

Computational methods

The electronic structures of all 1,4 diazepane linked piperidine derivative molecules (**6a–6o**) were studied using quantum mechanical calculations. Each molecule was constructed using GaussView 5 software [33] and was subjected to geometry optimization using DFT calculations at the B3LYP/6-31G(d,p) level of theory as implemented in Gaussian 09 quantum chemistry package [34]. The calculations were performed in an implicit PCM water solvent model. No symmetrical constraints were imposed during the optimization. Optimized geometries were used to visualize molecular orbitals and their associated energy values using GaussView 5. In particular, the nature and energetics of the lowest unoccupied molecular orbital (LUMO) and highest occupied molecular orbital (HOMO) were characterized. Several other molecular properties were calculated from the HOMO and LUMO energies, namely, the global hardness (η), softness (σ), electronegativity (χ), and electrophilicity index (ω). The following equations are used to compute these properties:

1

$$\chi=12EHOMO+ELUMO$$

2

$$\eta=-12EHOMO-ELUMO$$

3

$$\sigma=1\eta$$

4

$$\omega=\mu22\eta$$

Next, the optimized geometry of each derivative molecule was used to perform molecular docking against two target proteins corresponding to the *Protease Vulgaris* (PDB ID: 5HXW) [35] and *Bacillus subtilis* (PDB ID: 6UF6) [36]. The starting structure for the target proteins were based on their crystal structure deposited in the RCSB protein data bank. Both proteins were prepared for molecular docking by removing any existing ligand and water molecules, followed by charge assignment using MGL Tools 1.5.7. [37] The grid box corresponding to the whole protein was defined for each target. Each derivative molecule was prepared for docking using MGL Tools 1.5.7.

AutoDock Vina 1.2.0 [38] was used for docking the derivate molecules against the two target proteins. Ten conformations were generated for each derivative molecule and the most favorable conformation, based on the binding affinity, was selected for further structural analysis. The non-covalent interactions between the protein and docked ligand were analysed and visualized using LigPlot software [39].

Further, the Absorption, Distribution, Metabolism, and Excretion (ADME) analysis was carried out for each derivatized molecule using the SwissADME server [40] The ADME analysis provides determines various physiochemical properties to assess the pharmacodynamic properties of a potential ligand molecule. Various relevant parameters, such as the Lipinski's rule of five violations, number of hydrogen donors, hydrogen acceptors, rotatable bonds, total polar surface area, skin permeability (Log Kp), molar refractivity, gastro-intestinal absorption (GI), blood brain barrier (BBB), inhibition of cytochromes P450 isoforms (CYP1A2, CYP2C19, CYP2C9, CYP2D6) were estimated.

Next, we carried out Quantitative Structure–activity relationships (QSAR) to determine the quantitative relationship between the biological activity and the molecule properties of the derivatives. We constructed the QSAR models by performing multiple linear regression analysis, which links selected independent variables with the dependent variable using the following equation:

Where X i are the molecular descriptors, Y is the biological activity, n is number of descriptors, a 0 is the constant and a i are the respective coefficients.

Result

By observing structural alterations brought on by the attachment of various substitutions and their placement on the heterocyclic ring in the generated derivative, the link between structure and activity was investigated (Fig. 2). Because of the varied positions of the aryl group and heterocyclic ring, biological activity was changing. In this study, different substituted phenyl rings linked to piperidine and piperidine directly coupled to 1,4-diazepane were found to have different anti-microbial activities. Distinct substitutions have distinct electrical properties, and these differences are shown in their anti-microbial effectiveness. According to research on SAR, anti-microbial activity can vary depending on the heterocyclic or aryl ring. The heterocyclic ring substitutions of manufactured compounds could either donate electrons or draw them out. When substitutions such halogenated groups at various positions on a heterocyclic ring are made, the anti-microbial action increases. According to Table 2, when phenyl rings are substituted in compounds with different halogenated groups, the chloro group exhibits more activity than the bromo group. The enhanced antimicrobial activity was found to be more in both **6c** and **6h**, due to the heterocyclic moiety in the synthetic derivatives with alkoxy phenyl ring in **6h** and the heterocyclic moiety on the heterocyclic ring with –Br and –F in **6c**. Higher antibacterial inhibitory action was demonstrated in **6m** by the phenyl ring with the chloro group in the ortho position. As opposed to the meta-substituted **6e** and the amine-aryl ring with a bromine substitution in **6g**, the phenyl ring with a bromine and methyl group in **6f** shown stronger inhibitory activity. Higher antibacterial inhibitory action was demonstrated by compound **6a**'s phenyl ring with the nitro group in the ortho position as compared to compound **6d**'s phenyl ring with the electron-donating and withdrawing groups replaced. In contrast, **6l** had reduced activity due to the presence of an electron releasing group at the o-position. The methoxy group, a weak electron donor, was shown to be less active than other groups in position 4 of the phenyl ring in compound **6k**. Other substituted derivatives **6i**, **6b**, and **6j** displayed modest activity, while **6o** was found to be more effective than regular ampicillin against *Staphylococcus aureus* and *E. coli*.

Fig. 2 [Images not available. See PDF.]

Structure activity relationship study

Table 2. Antibacterial activity of tested compounds as a zone of inhibition in MIC(μg/mL) of synthesized compound

Compound number	*Staphylococcus aureus* (Gram+	*Bacillus Subtills* (Gram+)	*Bacillus megaterium* (Gram+)	*Escherichia coli* (Gram−)	*Pseudonymous spp.* (Gram−)	*Shigella sp.* (Gram−)
6a	46	42	44	37	39	20
6b	45	32	38	20	15	–
6c	59	54	48	50	51	33
6d	47	41	40	37	34	18
6e	51	46	45	42	29	22
6f	53	47	49	47	34	26
6g	51	45	45	41	35	21
6h	57	53	50	52	40	31
6i	47	36	40	23	19	8
6j	35	28	–	20	16	–
6k	40	34	37	25	21	11
6l	45	40	41	32	29	18
6m	58	50	52	47	39	28
6n	40	38	34	31	28	16
6o	30	–	–	17	–	–
Ampicilin	48	39	29	40	32	21

Table 2 shows that the majority of the substances tested had varying inhibitory effects on the growth of the bacterial strains that were put to the test, according to the results of the study. Because the compound **6a**, the compound **6d**, and the compound **6m**, compound **6l** both possess electron withdrawing and electron releasing groups, these compounds showed a high level of inhibitory activity against the tested microbial strains. Comparatively to the reference drug Ampicillin, compound **6c** substituted with –Br and –F on its heterocyclic ring as well as compound **6h** containing heterocyclic rings attached to methoxybenzene were found to exhibit superior activity against all Gram-positive and Gram-negative microbial strains. Even though compound **6o** showed no effect against *B. subtilis, Bacilius magneterium, Pseudomonas spp., and Shigella spp.*, compound **6j** lost its antibacterial efficacy due to the absence of an aryl ring substitution. Due to the presence of an electron releasing group and a phenyl ring, **6i**, **6k** demonstrated a modest amount of inhibitory action against the investigated strains of *Pseudomonas spp., B. subtilis,*

E. coli, and *Staphylococcus aureus*. Figure 3 depicts the graphical representation of antibacterial activity.

Fig. 3 [Images not available. See PDF.]

Statistical diagram of antimicrobial activity

DFT calculations

All 1,4 diazepane linked piperidine derivative molecules were optimized using the DFT methods at the B3LYP/6-31G(d,p) level of theory. The optimized geometries are shown in Fig. 4 and the various electronic properties are presented in Table 3. First, we compared the energy gap (E_{HOMO}-E_{LUMO}), which is an important parameter to assess the thermal stability and the chemical reactivity of a molecule. The E_{HOMO} and E_{LUMO} energy gap were computed to be negative for all derivative molecules, indicating their stability and in the following order: **6b>6k>6l>6j>6f>6e>6m>6a>6c>6g>6n>6o>6i>6h>6d**. Further, Frontier Molecular Orbital analysis illustrate that for all molecules, the lowest occupied molecular orbital (LUMO) orbital is localized on the π orbitals of the phenyl ring (Fig. 5). Whereas the highest occupied molecular orbital (HOMO) orbital is localized on the diazepane and piperidine binding site. We also computed additional electronic and structural parameters, such as electronegativity (χ), global hardness (η), global softness (σ) and global electrophilicity index (ω), to ascertain the biological activity of the derivative molecules (Table 3). The large χ and ω for all compounds indicate their excellent bioactivity.

The HOMO and LUMO orbitals for selected derivative molecules (**6b** and **6c**) as calculated at the B3LYP/6-31G(d,p) level of theory

Molecular docking

The derivative molecules were next subjected to molecular docking to assess their antibacterial potential. To this end, we used the geometry optimized derivative molecules to perform molecular docking against two target proteins, L-amino acid deaminase from *Proteus Vulgaris* and LcpA ligase from *Bacillus subtilis*, representing the Gram-negative bacterium and Gram-positive bacterium, respectively. The relative stability of the target protein – ligand complex was determined by their binding affinities Table 4 and their intermolecular interactions with the target proteins (Additional file 1: Figures S21–S22). Molecules **6b** showed the largest binding affinity for both target proteins (Fig. 6). Further analysis of the protein–ligand complex revealed a higher number of interactions in the case of **6b** (Fig. 7). The derivate **6b** formed H-bonds involving residues Tyr286 and Tyr284 of the L-amino acid deaminase from *Proteus Vulgaris*. Similarly, it formed H-bonds with Asn353 and Gln350 residues of LcpA ligase from *Bacillus subtilis*. These H-bonds, together with several hydrophobic interactions, provide higher binding strength to the complex of **6b** with target proteins.

Table 4. Calculated docking affinities (in kcal/mol) of the derivative molecules and ampicillin against the target proteins from *Bacillus subtilis* (PDB ID: 6UF6), and *Proteus Vulgaris* (PDB ID: 5HXW)

No	5HXW	6UF6
6a	−8.7	−7.7
6b	−9.4	−8.2
6c	−8.8	−7.4
6d	−8.3	−7.2

Comparison of the calculated docking affinities (in kcal/mol) of all derivative molecules and ampicillin against the target proteins from *Bacillus subtilis* (PDB ID: 6UF6), and *Proteus Vulgaris* (PDB ID: 5HXW)

Fig. 7 [Images not available. See PDF.]

Overlay of the protein-derivative molecule 6b complexes as obtained from their docking with *Bacillus subtilis* (PDB ID: 6UF6) and *Proteus Vulgaris* (PDB ID: 5HXW) proteins. The docked poses were chosen based on their binding affinities and geometric similarities. Intermolecular interactions between the derivation molecules and the target proteins are shown. The hydrogen bond interactions are highlighted

ADME calculations

Next, we performed the ADME calculations for the derivative molecules using the SwissADME server to characterize their drug-likeness and bioavailability. The ADME analysis showed that none of the molecules violated any of the five Lipinski rule. (Table 5) Therefore, these molecules have good potential to be developed as orally active drugs. The TPSA value, closely related to the bioavailability, for the molecules were observed in the range of 56 $Å^2$ to 102 $Å^2$, which is well below the limit of 140 $Å^2$. Similarly, the number of rotatable bonds (NRB) for all molecules is less than the limit of 10, except for **6i**, suggesting that the molecules are conformationally stable.

Table 5. Drug-likeness predictions for the derivative molecules as computed using SwissADME

C	MW	NRB	NHA	NHD	TPSA	LogP	LV	MR
6a	405.45	7	7	0	102.15	0.98	0	123.03
6b	473.57	9	7	0	85.87	1.28	0	144.39
6c	458.33	6	7	0	69.22	1.87	0	119.66

6d	419.47	7	7	0	102.15	1.31	0	127.99
6e	439.35	6	5	0	56.33	2.18	0	121.9
6f	453.37	6	5	0	56.33	2.5	0	126.87
6g	454.36	6	5	1	82.35	1.78	0	126.31
6h	475.58	8	9	2	89.98	1.18	0	145.88
6i	445.6	10	5	0	59.57	2.25	0	142.45
6j	360.45	6	5	0	56.33	1.56	0	114.2
6k	390.48	7	6	0	65.56	1.57	0	120.7
6l	390.48	7	6	0	65.56	1.35	0	120.7
6m	394.9	6	5	0	56.33	2.07	0	119.21
6n	385.46	6	6	0	80.12	1.33	0	118.92
6o	366.5	6	5	0	56.33	1.76	0	116.22

The number of rotatable bonds (NRB), number of hydrogen donors (NHD), number of hydrogen acceptors (NHA), total polar surface area (TPSA) in $Å^2$, LogP value and Lipinski's rule of five violation (LV), and Molar Refractivity (MR) are reported

Moreover, the low skin permeability value (Log K_p) for all molecules indicates low level of skin permeation (Table 6). All derivative molecules showed high level of gastrointestinal (GI) absorption. The molecule's hazardous or adverse effects also depend on its suppression of cytochromes P450 isoforms (CYP1A2, CYP2C19, CYP2C9, and CYP2D6). SwissADME predictions showed that all the derivative molecules show inhibition propensity against one or more of these isoforms.

Table 6. Absorption, Distribution, Metabolism, and Excretion (ADME) analysis for the derivative molecules as computed using SwissADME

	Log K_p	GI Absorption	BBB Absorption	Inhibitor interaction			
CYP1A2	CYP2C19	CYP2C9	CYP2D6	**6a**	−7.6	High	No
No	Yes	No	No	**6b**	−8.27	High	No
No	Yes	No	No	**6c**	−7.53	High	No
No	Yes	No	No	**6d**	−7.42	High	No

No	Yes	Yes	No	**6e**	−7.19	High	Yes
No	Yes	No	Yes	**6f**	−7.02	High	Yes
No	Yes	No	Yes	**6g**	−7.37	High	No
No	Yes	No	Yes	**6h**	−8.19	High	No
No	No	No	Yes	**6i**	−6.99	High	Yes
No	No	No	Yes	**6j**	−7.21	High	No
No	Yes	No	No	**6k**	−7.4	High	No
No	Yes	No	No	**6l**	−8.03	High	No
No	No	No	No	**6m**	−6.97	High	Yes
No	Yes	No	Yes	**6n**	−7.56	High	No
No	Yes	No	No	**6o**	−6.94	High	No

Skin permeability (Log K_p), gastro-intestinal absorption (GI), blood brain barrier (BBB), and inhibition of cytochrome-P isoforms are reported

Considering all the ADME predictions as well as the binding affinities, molecule **6b** appear as the most effective lead as an antibacterial agent. While it is noted that other derivative molecules, such as 6n, showed high binding affinity and similar binding mode as 6b, the latter is more favourable owing to its higher tendency to form H-bonds with the nearby receptor residues.

Among the 15 molecular descriptors, seven were selected for the regression analysis based on their correlation coefficient values. The seven descriptors are the following: Log P, Log S, NHA, η, molecular weight (MW), TPSA, and Log Kp. The resulting QSAR model based on the regression analysis is given by the following equation:

Where N = 15, R = 0.87, determination coefficient (R^2) = 0.77, mean square error (MSE) = 1.77, statistical confidence degree (F) = 5.68.

The high values of R2 and F indicate that the derived QSAR model is acceptable, and that the biological activity is linear correlated with these descriptors (Additional file 1: Figure S23). These descriptors can be used to predict inhibitory activity of new compounds based on the structure of 1,4 diazepane linked piperidine derivatives.

Discussion

Preparation of tert-butyl 4-butyryl-1,4-diazepane-1-carboxylate (2)

Tert-butyl 1,4-diazepane-1-carboxylate **(1)** (1.0 g, 4.99 mmol), TEA (1.04 mL, 7.48 mmol), and DCM (10 mL) were dissolved at 0 °C in a reaction jar. After then, the solution received a dropwise addition of butyryl chloride (798.0 mg, 7.48 mmol). The mixture was then mixed at room temperature for 30 min. The reaction mixture was then split equally between 100 mL of H_2O and 100 mL of EtOAc. EtOAc (2 × 50 mL) was used to extract the aqueous layer further. Na_2SO_4 was used to mix and dry the organic layers. Tert-butyl 4-Butyryl-1,4-diazepane-1-carboxylate **(2)** (1.2 g, 88.88%) was obtained as the crude product after the solvent was removed under vacuum. The next stage didn't require any purification because the crude product was used immediately.

Preparation of 1-(1,4-diazepan-1-yl)butan-1-one hydrochloride salt (3)

The reaction mixture was agitated at room temperature for 16 h with tert-butyl 4-butyryl-1,4-diazepane-1-carboxylate **(2)** (1.0 g, 3.70 mmol) in 6N HCl-dioxane (10.0 mL). To produce the crude product, 1-(1,4-diazepan-1-yl)butan-1-one hydrochloride salt **(3)** (550 mg), the reaction mixture was then concentrated under vacuum. The crude product was utilized right away in the subsequent step of the reaction without going through any purifying procedures.

Preparation of ethyl 4-(1-(tert-butoxycarbonyl)piperidin-4-yl)-1,4-diazepane-1-carboxylate (4)

Tert-butyl 4-oxopiperidine-1-carboxylate (578 mg, 2.90 mmol), 1-(1,4-diazepan-1-yl)butan-1-one hydrochloride salt **(3)** (500 mg, 2.90 mmol), TEA (1.2 mL, 8.70 mmol), $ZnCl_2$ (8.0 mg, 0.1 mmol), and MeOH (7 mL) were mixed in an RBF. The mixture for the reaction was heated to 60 °C and given 4 h to react. The reaction mixture was then cooled to zero degrees Celsius. $NaCNBH_3$ (540 mg, 8.70 mmol) was added to the reaction mixture at 0 °C, and the mixture was stirred for 16 h as it warmed to room temperature. A residue was produced after the reaction mixture was concentrated under a vacuum. The aqueous layer was extracted with EtOAc (250 mL) after the residue was divided between 500 mL of H_2O and 500 mL of EtOAc. Na_2SO_4 was used to mix and dry the organic layers. A crude product was produced after the solvent was subsequently extracted under a vacuum. Column chromatography was used to purify the crude product. Ethyl 4-(1-(tert-butoxy carbonyl)piperidin-4-yl)-1,4-diazepane was the pure product that was produced.400 mg of −1-carboxylate **(4)**, 38.76% yield.

Ethyl 4-(piperidin-4-yl)-1,4-diazepane-1-carboxylate hydrochloride salt (5)

The reaction mixture was agitated at room temperature for 16 h with ethyl 4-(1-(tert-butoxycarbonyl)piperidin-4-yl)-1,4-diazepane-1-carboxylate **(4)** (400 mg, 3.70 mmol) in 6N HCl-dioxane (4 mL). A crude product of ethyl 4-(piperidin-4-yl)-1,4-diazepane-1-carboxylate hydrochloride salt **(5)** (250 mg, 76.13% yield) was produced when the mixture was concentrated under vacuum. The crude product was utilized right away in the subsequent step of the reaction without going through any purifying procedures.

General procedure of compound (6a–o)

The carboxylic acid (1 equivalent) was mixed in DMF (10 volumes) in a reaction vessel. Next, the resulting mixture was cooled to absolute zero. After adding HATU (1.5 equivalents), the reaction mixture was stirred at 0 °C for 10 min. Ethyl 4-(piperidin-4-yl)-1,4-diazepane-1-carboxylate hydrochloride salt **(5)** (1.1 equivalents) and DIPEA (3 equivalents) were then added to the reaction mixture. The end product was stirred at room temperature for six hours. The reaction mixture was then dumped into ice-cold water after it had finished. The resultant residue was divided between 500 mL of H_2O and 500 mL of EtOAc. EtOAc (250 mL) was used to extract the aqueous layer further. Na_2SO_4 was used to mix and dry the organic layers. The crude product was then produced after the solvent was removed under vacuum. To produce the final chemicals **6a-o**, column chromatography was used to purify the crude product. (Supplementary File).

Ethyl 4-(1-(2-nitrobenzoyl)piperidin-4-yl)-1,4-diazepane-1-carboxylate (6a)

^{1}H NMR (400 MHz, DMSO) δ 1.25–1.29 (3H, t), 1.81 (4H, m), 2.77 (6H, m), 3.06 (2H, m), 3.49 (5H, m), 4.12–4.18 (2H, q), 4.77–4.88 (2H, m), 7.3 (1H, m), 7.57–7.61 (1H, m), 7.72 (1H, m), 8.21–8.23 (2H, d, *J*=8 Hz). LCMS m/z Cal. $[M+H]^+$ 404.21 found $[M+H]^+$405.21.

LCMS m/z Cal. $[M+H]^+$ 442.29 found $[M+H]^+$442.60.

Ethyl 4-(1-benzoylpiperidin-4-yl)-1,4-diazepane-1-carboxylate (6j)

^{1}H NMR (400 MHz, DMSO) δ 1.29–1.33 (3H, t, *J* = 12 Hz), 1.47–1.72 (2H, m), 2.23–2.26 (3H, d, *J* = 12 Hz), 2.43 (3H, s), 3.15–3.25 (3H, m), 3.62 (4H, s), 3.93 (3H, s), 4.19–4.22 (2H, t, *J* = 12 Hz), 7.31–7.45 (6H, m). LCMS m/z Cal. $[M+H]^+$ 359.22 found $[M+H]^+$359.47.

Conclusion

In this research study, synthesis, characterization, in silico and anti-microbial activity been done on a series of 1,4-diazepane linked piperidine derivatives. In vitro assay for anti-microbial activity done with Gram-positive (*Staphylococcus aureus, Bacillus Subtills, Bacillus megaterium*) and gram-negative (*Escherichia coli, Pseudonymous, Shigella* sp.) bacterial strains of synthesized compounds were compared to that of standard drug ampicillin and found to have good activity. The geometry optimization in gas phase at the B3LYP/6-31G (d,p) level of theory as implemented in Gaussian 05 DFT study. The negative values of EHOMO and ELUMO calculations for all derivative indicate their stability which favors for the chemical reactivity. The molecular docking against target proteins, L-amino acid deaminase from *Proteus Vulgaris* and LcpA ligase from *Bacillus subtilis* in identifying the relative stability of the target protein—ligand complex. Molecules **6b** showed the largest binding affinity for both target proteins. Also, the ADME predictions for each derivatized molecule favors for the highest binding affinity. Additional electronic properties, such as electronegativity (χ), global hardness (η), global softness (σ) and global electrophilicity index (ω), was computed to ascertain the biological activity of the derivative.

Acknowledgements

The authors are thankful to Prof (Dr.) Keyur Shah of Shri M M Patel College of Sciences and Research, Department of Chemistry, Kadi Sarva Vishwavidyalaya, India for providing necessary facilities. We'd like to express our gratitude for their intellectual, technical, and logistical assistance during the evaluation process.

ABSTRACT (ENGLISH)

Background

Phellinus fastuosus is a wood-eating medicinal fungus from Western Ghats of India. Therefore, we investigated hypoglycemic and hepatoprotective effects of *P. fastuosus* aqueous extract on streptozotocin-induced diabetic and carbon tetrachloride (CCl_4) induced hepatotoxicity in rats, respectively.

Result

As compared to the diabetic control group, a 400 mg/kg dose had significant hypoglycemic effects, including a reduction in blood glucose (24.44%) and gain in body weight. Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) activity reduced by 31.81% and 32.84%, respectively, were also noted, along with decreases in triglycerides (24.32%) and cholesterol (25.89%) levels. The albumin, bilirubin and creatinine levels were also significantly reduced after administration of *P. fastuosus* extract in diabetic rats. Administration of *P. fastuosus* extract showed a substantial decrease in the activity of ALT, AST, alkaline phosphatase (ALP), catalase (CAT) and superoxide dismutase (SOD) in addition a decrease in the level of lipid peroxidation (LPO) as compared to CCl_4-intoxicated rats. The cumulative effect of CCl_4 increased the erythrocyte membrane peroxidation, whereas *P. fastuosus* extract reduced the cholesterol and increased phospholipid, thus preventing the alteration of membrane fluidity as compared to CCl_4-intoxicated rats. FTIR and HR-LC-MS-based metabolic profiling revealed the presence of various functional groups and bioactive metabolites.

Conclusion

The extract showed the hypoglycemic and hepatoprotective effects due to the presence of various bioactive

metabolites. Exploration of therapeutic potential of *P. fastuosus* using bioassay-guided fractionation is needed.

FULL TEXT

Background

Medicinal mushrooms are higher fungi with additional qualities including low-fat content and a trans-isomer of unsaturated fatty acids, followed by high fiber, terpenes, phenolics, sterols, etc. [1]. Owing to this, they are widely used in pharmaceutical and nutraceutical industries, particularly for their bioactive potential such as anticancer, immunomodulatory, antibacterial, hypoglycemic and hepatoprotection [2, 3]. Among medicinal mushrooms, the *Phellinus* spp. possess great variability in chemical composition within individual species, hence, are widely used in traditional medication and exploited to evaluate their bioactive potential against cancer, cardiovascular diseases, and diabetes [4–6]. Though some species are explored for their bioactive potential, many of them still required scientific evaluation, for instance, *Phellinus fastuosus*, which also forms a part of folk medicine.

Diabetes mellitus is an endocrine metabolic disorder that disturbs the metabolism of proteins, carbohydrates, and fats. Worldwide more than 425 million individuals are affected by this chronic disorder, which can turn fatal in comorbid conditions [7]. Further, it is a major cause of blindness, kidney failure, cardiac arrest, and lower limb amputation. Numerous traditional remedies have been developed to treat diabetes. Among them, mushrooms are widely used as a natural source of biomolecules for treating ailments, including diabetes [7]. Studies have demonstrated that medicinal mushrooms particularly *Phellinus* spp. has beneficial effects with regards to diabetes. For instance, The *P. badius*, *P. linteus*, and *P. rimosus* showed hypoglycemic activity in experimental diabetic rat/mice models [6, 8, 9].

Liver is a large complex organ in the human body that is vital for detoxification, which is also involved in fat metabolism, protein synthesis and secretion of important enzymes. Drugs, toxic chemicals, or bacterial infections that might affect the liver's normal function are the most common causes of liver damage. Carbon tetrachloride (CCl_4) is a hepatotoxic agent widely used as a toxin to induce liver fibrosis in laboratory investigations [10]. Endoplasmic reticulum structural modifications result from the metabolic activation of CCl_4 by cytochrome P450-dependent mixed oxidases, which further results in the loss of enzymatic machinery, thus impairing normal functioning of liver. Mushroom extracts are reported to prevent CCl_4-induced hepatotoxicity in rats [11].

P. fastuosus is a wood-eating fungus (Fig. 1A), used in traditional formulations to treat ailments such as diabetes, diarrhea, and stomachache as well as to boost the immune system and promote health. It is found across continents, such as Asia and Australia, and is also studied for anti-cariogenic activity [12], plausible use in food preservation [13], and physiochemical characteristics [14]. However, there is no scientific evidence for its bio-prospects, for instance to treat hypoglycemia as well as hepatotoxicity. Therefore, as supported by the traditional knowledge and scientific literature, here we seek to explore the hypoglycemic and hepatoprotective activity of *Phellinus fastuosus* mushroom from Western Ghats of India. The hypoglycemic and hepatoprotective activity of *P. fastuosus* aqueous extract was tested in streptozotocin (STZ) induced diabetic rats and carbon tetrachloride induced erythrocyte-/liver-damaged wistar rats, respectively. Based on the folklore of India's Western Ghats, the aqueous extract was created to resemble the conventional way of administration of medicine (Fig. 1B and C).

Fig. 1 [Images not available. See PDF.]

*Phellinus fastuosus***A** fruiting body, acquired from Devgad **B**, is located in the Western Ghats of India **C**. [Source: https://www.google.com/maps]

Methods

P. fastuosus (Kii 19) basidiocarps were gathered from Western Ghats of Maharashtra, India. The samples were authenticated (SPPU/Bot/42) from Mycology Laboratory, Savitribai Phule Pune University. Further the samples were washed, oven dried at 40 ± 2 °C and grounded using a commercial grinder (Restsch Ultra Centrifugal Mill and Sieving Machine, Germany) and stored in sterile reagent bottles (Borosil®, India).

Extract preparation

Hundred grams powder of *P. fastuosus* fruit body was suspended in distilled water at 90 ºC for four hours and filtered with the help of Whatmann no. 1 paper. The procedure was carried out twice. Combining and filtering the filtrates via Whatmann no. 1 paper. The filtrate was concentrated in vacuum followed by addition of 90% ethanol (4:1 of filtrate) and stirred vigorously. The mixture was allowed to stand overnight at 4 ºC. Next day, centrifuged the mixture at 10,000 rpm for 20 min. Subsequently, equal volume of 10% trichloroacetic acid was added and kept overnight. Next day, centrifuged the sample at 7000 rpm for 5 min and precipitate was wash with chilled 80% ethanol, dissolved in distilled water, and dialyzed for three days against running tap water and one day against distilled water, then centrifuge at 7000 rpm for 15 min. Obtained precipitate was lyophilized and used for bioactivity studies [11, 15].

Hypoglycemic study

Test animals and experimental conditions

Male wistar rats (NTC, Pune, India) of approximately 200 g housed at National Toxicology Center (NTC) were used for animal studies. The rats were housed in a room with stainless steel cages in a controlled environment. Throughout the trial, the rats were fed a commercial pellet meal and given unlimited access to water.

Diabetes was artificially induced by the administration of diabetogenic agent. After a week of acclimatization, the rats had a 16-h fast. Streptozotocin (STZ, or a diabetogenic drug) was injected intraperitoneally at a dosage of 50 mg/kg body weight, diluted in a buffer solution of sodium citrate buffer (pH 4.5) from Sigma, India. The determination of fasting blood glucose was made two days after injecting STZ [16, 17]. When their fasting blood glucose level exceeded 300 mg/dL, the rats were deemed to have diabetes. Rats were divided into six groups, Normal control (NC); Diabetes control (DC); Standard Glibenclamide (STND) (10 mg/kg) [18]; STZ + doses of 100 mg/kg (Kii 19 100); STZ + doses of 200 mg/kg (Kii 19 200); STZ + doses of 400 mg/kg (Kii 19 400) [11, 15, 19]. A single oral dosage of extracts was administered to diabetic rats every day for 14 days. The animal study was conducted at National Toxicology Center (NTC), Pune, India and overall experimental protocol was approved by the institution animal ethical committee (IAEC 805).

Body and organ weight

The change in body weight was measured by calculating the initial and final body weight of the animals. The weight of body organs such as heart, liver, spleen, kidney, pancreas, and lungs were measured after sacrificing the animals.

Biochemical analysis

To estimate glucose level, the tail vein was pricked and followed by blood collection and monitoring using glucometer (Contour®TS, India). In heparinized tubes, blood was drawn, and the plasma was separated by centrifugation at 10,000 rpm for 10 min. An enzymatic colorimetric test kit (Merck Bioline, India) was used to assess the levels of triglycerides and cholesterol. Enzyme kits were used to measure the activity of alanine aminotransferase and aspartate aminotransferase (Merck Bioline, India) based on Reitman-Frankel method [20]. Albumin, bilirubin, creatinine and urea levels were measured using diagnostic kits (Crest Biosystems, India).

Hepatoprotective study

Test animals and experimental conditions

Male wistar rats (150–200 g) were selected and maintained in environmentally controlled conditions. Prior to the experiment, the animals were kept in wire-meshed cages for a week to acclimatize and were given access to regular food and deionized distilled water. Hepatoprotective and erythrocyte protective activity.

Rats were divided into four groups, with ten in each group. Group I (served as control), which received olive oil p.o. three times a week for 14 days. Group II were administered silymarin 200 mg/kg. Group III received CCl_4 1 mL/kg body weight (BW), intraperitoneal (CCl_4 control), three times a week for 14 days. Group IV animals were administered with 400 mg/kg BW along with CCl_4 (Kii19 + CCl_4) for 14 days.

The rats were terminated via cervical dislocation 14 days into the experiment. Blood samples were drawn from the jugular vein, placed in heparinized tubes, and centrifuged for 15 min at 3000 rpm.

The packed cells were rinsed three times with physiological saline (0.9% w/v NaCl), suspended in cold distilled

water (2–5 °C), then centrifuged at 7000 rpm for 30 min to lyse them. The particle that resulted represented the hemolysate, while the supernatant represented the erythrocyte membrane. Aspartate aminotransferase, alanine aminotransferase, and alkaline phosphatase were tested in the plasma that was left over after the initial centrifugation in order to measure lipid peroxidation [20]. Using standardized kits, the enzyme levels were determined.

Catalase [21] and superoxide dismutase [22] activity were estimated using the hemolysate. Using a procedure previously described [23], the lipids from the erythrocyte membrane were extracted, and the amounts of cholesterol and phospholipids were measured [24, 25]. The ratio of cholesterol to phospholipids was then determined.

Histological examination

After the animal was sacrificed, the liver was taken out and washed in ice-cold saline. Before sectioning, the tissue samples were embedded in paraffin wax, treated with 10% formaldehyde, and dehydrated in a graduated series of ethanol. After cutting the paraffin slices, they were dewaxed and rehydrated. Light microscopy was used to examine the sections after they had been stained with hematoxylin and eosin [11].

Fourier transformed infrared spectroscopy (FTIR)

The aqueous extract of *P. fastuosus* was analyzed with FTIR. The FTIR spectra was obtained in the range of 4000–450 cm^{-1}using a Bruker, 3000 Hyperion Microscope with Vertex 80 FTIR System (Bruker, Germany).

HR-LC–MS-based metabolic profiling

The aqueous extract of the *P. fastuosus* was characterized using LC–MS at Indian Institute of Technology, Mumbai (IIT-Powai), India. TOF/Q-TOF mass spectrometer (Model—G6550A; Agilent Technologies) with dual AJS ESI as ion source was used. The details of are: Column—Hypersil GOLD C18 100 × 2.1 mm—3 µM, injection volume: 3 µl, flow rate: 0.3 ml/min, mobile phase A (0.1% formic acid) and mobile phase B (90% Acetonitrile + 10% H_2O + 0.1% formic acid), minimum range: 125 m/z and maximum range 1000 m/z, scan rate 1.00spectra/sec. The peaks were identified using inbuilt mass library.

Statistical analysis

Using the statistical package of the Social Science (SPSS) programmed, one-way analysis of variance (ANOVA) test was used to determine the results' statistical significance. Standard Deviation (SD) was used to represent all data as mean ± SD. A one-way analysis of variance and Duncan's multiple range tests were used to compare the group means. At $p<0.05$, statistical differences were considered significant.

Results

Hypoglycemic activity

Phellinus fastuosus sample's hypoglycemic impact was tested for 14 days in diabetic rats induced by STZ.

Body and organ weight

Figure 2 depicts the effect of *P. fastuosus* administration on the body (Fig. 2A) and organ weight (Fig. 2B) in STZ-induced diabetic rats. When compared to diabetic groups, Kii- 19 400 showed a considerable gain in body weight. Further, body organ weight, i.e., heart, liver, kidney, pancreas and lungs significantly increased at a dose of 200 mg/kg, whereas when compared to the diabetic control group, the 400 mg/kg dosage revealed a substantial change in the weight of the liver and heart.

Fig. 2 [Images not available. See PDF.]

Effect of *P. fastuosus* aqueous extract on **A** body, and **B** organ weight of extract fed and control rats after 14 days. Values are mean ± SD (n = 6), and small letters on the bars denote the significant difference between treatments at $p<0.05$

Blood glucose

Figure 3A shows the activity of *P. fastuosus* samples on the blood glucose level in STZ-induced diabetic rats over a period of 14 days. In the diabetic control group (STZ), the blood glucose level showed continuous increase throughout the experiment, finally reaching a level of 454 mg/dL. In contrast, the administration of *P. fastuosus* extract significantly lowered the blood glucose level compared to that of the diabetic control group. Doses of

400 mg/kg of Kii 19 showed reduction in glucose level by 24.44%. Kii 19 shown a decrease in glucose level of 23.05% when compared to the diabetic control group at a dosage of 200 mg/kg.

Fig. 3 [Images not available. See PDF.]

Effect of *P. fastuosus* aqueous extract on the **A** blood glucose, **B** triglycerides and cholesterol, **C** Alanine aminotransferase (ALAT) and Aspartate aminotransferase (AST), **D** Bilirubin and albumin, **E** Creatinine, **F** Urea and, **G** Alkaline phosphatase in streptozotocin-induced diabetic rats for 14 days. Values are mean ± SD (n = 6), and small letters on the bars denote the significant difference between treatments at $p<0.05$

Studies on lipid metabolism

The level of triglyceride was markedly reduced after the administration of *P. fastuosus* extract compared to diabetic control (Fig. 3B). Dose of 400 mg/kg of Kii 19 showed significant reduction of triglycerides level, i.e., 24.32% as compared to diabetes control group. As shown in Fig. 3B, the administration of *P. fastuosus* extract showed significant reduction in total cholesterol level. Kii 19 dose at 400 mg/kg reduced cholesterol by 25.89% as compared to diabetic control. Throughout the investigation, there was no discernible difference in the total cholesterol levels between the Kii 19 100 mg/kg and Kii 19 200 mg/kg groups.

Aspartate aminotransferase (AST) and Alanine aminotransferase level (ALT)

The plasma AST and ALT activity in the STZ group were higher than those in the NC group. Therefore, the remarkable reduction in levels of AST after oral administration of Kii 19 by 31.81% at a dose of 400 mg/kg which revealed a remedial role in liver function (Fig. 3C). The ALT activity was significantly reduced under the influence of *P. fastuosus* samples. The maximum reduction of 32.84% was observed in 400 mg/kg dose.

Bilirubin and Albumin

The level of bilirubin in diabetic rats were increased as compared to normal control rats (Fig. 3D). Administration of the *P. fastuosus* extracts signifciantly lowered the bilirubin level at a dose of 400 mg/kg by 25.13%. Albumin level was also significantly decreased in all groups as compared to diabetic control group. among all groups Kii-19 sample showed significant effect after 14 days.

Creatinine, urea and alkaline phosphatase activity

Figure 3E and F shows that the significant decreased in creatinine level and urea in 400 mg/kg *P. fastuosus* extract fed rats compared to diabetic control.

Hepatoprotective and erythrocyte protective activity

After CCl_4 intoxication, the levels of plasma hepatic enzymes significantly increased. After administration of *P. fastuosus* extract to animals, significantly reduced the elevated levels plasma ALT, AST and ALP (Fig. 4A).

Fig. 4 [Images not available. See PDF.]

Effect of *P. fastuosus* extract on **A** Plasma ALT, AST and ALP and **B** lipid peroxidation products and primary antioxidant enzymes of the erythrocytes of carbon tetrachloride-intoxicated rats in rats after 14 days of treatment. Values are means ± SD for ten rats per group. Means in the same column having different superscript are significantly different ($p<0.05$)

The increased lipid peroxidation products, superoxide dismutase and catalase activity, and decreases in membrane fluidity were evidence of carbon tetrachloride damage to erythrocytes. The accumulation of hydrogen peroxide caused by the elevated superoxide dismutase activity prompted an increase in catalase activity.

In comparison to the control group, the concentration of lipid peroxidation increased in the carbon tetrachloride-treated animals, indicating higher activity of lipid peroxidation. SOD activity increased significantly in carbon tetrachloride-treated animals compared to the normal group (Fig. 4B). CAT activity also increased significantly after administration of carbon tetrachloride (Fig. 4B). The accumulation of lipid peroxidation products in the plasma was dramatically reduced during treatments with the extracts. Superoxide dismutase and catalase activities significantly increased in the rats after carbon tetrachloride intoxication; however, these activities diminished when carbon tetrachloride was administered concurrently with the extracts (Fig. 4B).

Carbon tetrachloride intoxication increased the ratio of cholesterol to phospholipid, decreased membrane phospholipid, and increased membrane cholesterol (Table 1). The findings of this investigation show that the membranes are stiff. The administration of *P. fastuosus* extracts stopped alterations in membrane fluidity and lipid composition.

Table 1. Effect of *P. fastuosus* extract on erythrocyte membrane lipids and cholesterol/phospholipid ratio of carbon tetrachloride-intoxicated rats

Groups	Cholesterol (mg/100 µL)	Phospholipid (mg/100 µL)	Cholesterol /Phospholipid
Group I (Control)	0.58 ± 0.01^{c}	1.12 ± 0.03^{a}	0.58 ± 0.02^{c}
Group II (Kii19)	0.58 ± 0.03^{c}	1.15 ± 0.05^{a}	0.58 ± 0.06^{c}
GroupIII (CCl_4)	0.74 ± 0.05^{a}	0.80 ± 0.02^{c}	0.92 ± 0.05^{a}
GroupIV (CCl_4 + Kii19)	0.62 ± 0.01^{b}	0.92 ± 0.01^{b}	0.70 ± 0.04^{b}

Values are means ± SD for ten rats per group. Means with different superscripts in the same column are substantially different ($p<0.05$)

Histopathology

The histological examination (Fig. 5) reveals cellular damage compared to the CCl_4-intoxicated rats (Fig. 5C), for instance, administration of *P. fastuosus* extract (Fig. 5D) preserved the architecture of hepatocytes and sinusoidal spaces, which is similar to that of the controls (Fig. 5A and B), whereas CCl_4-intoxicated rats showed moderate parenchymal cell hypertrophy, dilatation of sinusoidal spaces (Fig. 5C).

Fig. 5 [Images not available. See PDF.]

The liver histopathological sections **A** control group; **B** animals treated with silymarin 200 mg/kg; **C** CCl_4 control; **D** Kii19 + CCl_4

Fourier transformed infrared spectroscopy

The FTIR spectra (Fig. 6) reported the range of 990–1200 cm^{-1}, indicating the presence of polysaccharide, while the peaks at 1150–1160 cm^{-1} indicate stretching of glycosidic bond. Furthermore, other peaks at 1384 cm^{-1} indicate presence of β-D glucan. The peak at 1628 cm^{-1} represents vibration of proteins. Other peaks at 2851, 2920 cm^{-1} are C–H stretching vibration and hydroxyl stretching vibration, respectively. However, the peaks for N–H stretching vibration were found between 3194 and 3448 cm^{-1}, whereas amide A (N–H stretching) was found at 3282 cm^{-1} and amide N–H stretch at 3441 cm^{-1}, respectively, indicating the presence of polysaccharide bound proteins.

FTIR study of *P. fastuosus* aqueous extract

HR-LC–MS-based metabolite profiling

The aqueous extract of the *P. fastuosus* subjected to HR-LC-MS profiling which showed the presence of bioactive compounds like acronidine, flaccidine, pongamoside A, epoxyfumitremorgin C, dihydrodeoxystreptomycin, tetradecylamine, hexadecylamine, docosanedioic acid, 4-keto myristic acid,meta 1-hexadecylamine, N-isovalerylglycine, 2-amino-2-norbornanecarboxylic acid, etc. with potential bioactivities were reported (Table 2). Many unknown compounds were present in the metabolite profiling of *P. fastuosus* extract shown in the chromatogram (Figure S1).

Table 2. List of metabolites identified using HR-LC-MS-based metabolic profiling and their biological activities as mentioned in the literature

Metabolite	RT	Mass	*m/z*	Formula	Biological activity	References
TPPU	1.031	359.14	360.1484	C16H20F3N3O3	Antidepressant effect	[26]
N-isovalerylglycine	1.031	159.0886	160.0959	C7H13NO3	ROS inhibitor	[27]
2-Amino-2-Norbornanecarboxylic acid	1.112	155.0936	156.1008	C8H13NO2	Anti-obesity	[28]
Acronidine	5.6	311.1148	312.122	C18H17NO4	Antimicrobial and anticancer	[29]
2'-Hydroxyfurano[2",3":4',3']chalcone	5.631	264.0777	265.0849	C17H12O3	Antimicrobial	[30]
Pyridine-2-azo-pdimethylaniline	5.697	226.1219	249.1111	C13H14N4	Chromogenic reagent	[31]
Flaccidine	6.421	442.1269	465.1162	C23H22O9	Antimicrobial	[32]
Epoxyfumitremorgin C	7.327	393.1671	465.1163	C22H23N3O4	Anticancer	[33]
Pongamoside A	7.942	440.1117	394.1744	C23H20O9	Antihyperlipidemic *Activity*	[34]
Dubamine	8.081	249.0777	250.085	C16H11NO2	Cytotoxicity	[35]
Dihydrodeoxystreptomycin	9.158	567.2865	568.2937	C21H41N7O11	Antifungal	[36]
Tetradecylamine	10.449	213.2447	214.2521	C14H31N	Hypolipidemic	[37]
1-Hexadecylamine	11.88	241.2759	242.2832	C16H35N	Antimicrobial activity	[38]
Docosanedioic acid	19.671	370.3067	371.314	C22H42O4	Antibacterial activity	[39]

Vitamin E Succinate (tocopherol succinate)	21.325	530.3977	531.4055	C33H54O5	Antitumour activity	[40]
4-keto myristic acid	26.666	242.1866	265.1759	C14H26O3	Anxiolytic-Like Effects	[41]
1-Hexadecylamine	26.713	241.2759	242.2831	C16H35N	Anticancer activity	[42]

Discussion

Phellinus spp. (family: Hymenochaetaceae) gained attention due to their potent medicinal properties [6, 43, 44]. *P. fastuosus*, a member of this family is used as folk medicine, and is reported to be an important source of drosophilin A and drosophilin A methyl ether [45, 46]. Therefore present work demonstrates the hypoglycemic and hepatoprotective potential of *P. fastuosus* aqueous extract on Streptozotocin-induced diabetic and carbon tetrachloride-intoxicated rats, respectively.

Streptozotocin treatment affected the secretion of insulin by the pancreas through selective destruction of β-cells of islets of Langerhans. This induced hyperglycemia in rats leading to type-1 diabetes mellitus [6]. The significant increase in body weight and decrease in blood glucose level observed in *P. fastuosus* extract administered rats compared to diabetic control group demonstrates its glucose-lowering property. It can be hypothesized that the blood glucose-lowering effect of extract is due to increased glucose utilization in diabetic rats as a result of insulin secretion [47]. Consequently, the increase in glucose utilization positively correlated with digestion, which resulted in body weight gain. Similar hypoglycemic activity and increased in body weight was reported in rats administered with different medicinal mushroom extract [6, 15, 17].

Most drugs designed to treat diabetes mellitus focuses on controlling and lowering blood glucose levels [47]. Moreover, the various studied mushroom species prove their hypoglycemic property [15] and emerged as an ideal food for the prevention of hyperglycemia [47].

The increased in cholesterol and triglyceride level and AST and ALT in diabetic control group may be due to streptozotocin-induced liver and metabolic malfunction [47]. However, significant reduction in cholesterol and triglyceride level and AST and ALT level after extracting administration as compared to diabetic control group can be attributed to the reduction in fat emission by liver. Bilirubin and albumin levels serve as possible indicators of liver damage as well as normal liver, gallbladder, and bile duct function [15]. There was not much variation recorded in bilirubin content but albumin level significantly decreased in extract administered rats. Elevated blood levels of urea and creatinine, which are important indicators of renal impairment, are brought on by diabetic hyperglycemia [48]. The result demonstrated that there is no significant variation in animal groups for creatinine level. However, after administration extract, significant decrease in the urea level was observed in comparison with diabetic control group, which it a clear indication of improved liver and kidney function. Further alkaline phosphatase is a membrane bound important enzyme mainly found in liver and bone as well as few other tissues. In diabetes, the level of alkaline phosphatase increases due to ruptured of cell membrane followed by leakage [49]. The *P. fastuosus* extract significantly reduced the alkaline phosphatase activity in a concentration dependent manner. The increase in organ weight such as kidney, heart, liver and lungs indicates that the *P. fastuosus* extract strongly promotes growth of organ tissue irrespective of hyperglycemic condition. This finding suggests that along with hypoglycemic effect there are few components which promote tissue growth, which may act via other protective mechanism such as hepatoprotection, antioxidation and anti-inflammation. However, change in oragn weight is one of the important and indirect diabetes diagnosis markers [47]. The findings presented for hypoglycemic activity of *P. fastuosus* are similar to the recent reports on *Phellinus* spp. including *P. baumii, P. pini* [50] and *P. linteus* [51].

ALT, AST and ALP are important liver enzymes that are responsible for efficient functioning of liver and also act as important markers for hepatocellular damage [52]. CCl_4 is one of the most commonly used hepatotoxins to

experimentally induce liver damage [53]. Lipid peroxidative degradation of bio-membrane is one of the principal causes of hepatotoxicity caused by CCl_4 [54].

A popular herbal remedy for antiaging is *P. fastuosus* extract use [8]. Using CCl_4 to cause lipid peroxidation in rat plasma, we were able to demonstrate that *P. fastuosus* aqueous extract greatly reduced the levels of lipid peroxidation and further substantiated the extract's antilipid peroxidation function. The delivery of CCl_4 to the rats causes the liver and other tissues to produce free radicals such CCl_3, CClO, or C_2H_3O, which induce lipid peroxidation, cell death, and tissue damage, which result in severe liver disorders [55]. The degree of lipid peroxidation was represented in the levels of chain reactions that free radicals caused on the cell membrane to produce lipid peroxidation. This measure could offer an easy way to test for lipid peroxidation and damage to cellular membranes. The findings of this investigation showed that administration of *P. fastuosus* extract had an antilipid peroxidative effect and shielded red blood cells from damage brought on by carbon tetrachloride. According to the findings, *P. fastuosus* extract had an antilipid peroxidation impact on normal rats since it somewhat (not significant) lowered the levels of lipid peroxidation in non-toxication rats.

Low levels of lipid peroxidation products are present in tissues and cells under typical physiological conditions. More products from lipid peroxidation are produced as a result of cell damage when there is oxidative stress [55]. Superoxide dismutase, glutathione peroxidase, and catalase are examples of cellular antioxidant enzymes that typically fight oxidative stress [56]. Increases in lipid peroxidation products, superoxide dismutase and catalase activity, and decreases in membrane fluidity in this study's erythrocytes were evidence of carbon tetrachloride damage. The buildup of hydrogen peroxide caused by the elevated superoxide dismutase activity prompted an increase in catalase activity [55].

Superoxide, i.e., O_2^- is harmful to the body and can become one of the primer reasons to induce inflammation, aging and terminally to cancer [57]. SOD is an important enzyme that catalyzes the elimination of reactive oxygen species (ROS). SOD protects human erythrocyte membrane from ROS, which can elevate the fluidity of membranes by decreasing the cross-linking between the membrane proteins. Similarly, catalase are involved in the conversion of hydrogen peroxide to molecular oxygen and water molecules [55]. Due to CCl_4 cumulative impact, erythrocyte membrane peroxidation is increased, which may potentially result in hemolytic alterations [57]. The elevated level of CAT and SOD after the administration of extract provides reliable evidence to its protective action on the erythrocyte membrane.

The FTIR spectra peak at 1628 cm^{-1} represents vibration of proteins. The peaks at 2851, 2920 cm^{-1} are C–H stretching vibration and hydroxyl stretching vibration, respectively [58–60]. However, the peaks for N–H stretching vibration were found between 3194 and 3448 cm^{-1}, whereas amide A (N–H stretching) was found at 3282 cm^{-1} [61] and amide N–H stretch at 3441 cm^{-1}, respectively, indicating the presence of polysaccharide bound proteins [62].

The HR-LC-MS-based metabolite profiling of *P. fastuosus* aqueous extract reported various compounds like acronidine, pongamoside A, flaccidine, dubamine, dihydrodeoxystreptomycin, docosanedioic acid, etc. (Table 2) have bioactive potential [29, 32, 34–36, 39], which interns support the hypoglycemic and hepatoprotective activity of *P. fastuosus.*

Conclusion

The present study confirmed the hypoglycemic and hepatoprotective activity of *P. fastuosus* aqueous extract on streptozotocin-induced diabetic and carbon tetrachloride-intoxicated rats, respectively. Meanwhile, the metabolites identified through HR-LC-MS-based metabolic profiling of aqueous *P. fastuosus* extract support its bioactivities. The physio-biochemical and metabolic analysis indicate that *P. fastuosus* has the potential to provide hepatoprotective and hypoglycemic compounds; however, further bioassay-guided fractionation followed by molecular docking is warranted to identify the active ingredients for pharmaceutical applicability.

Acknowledgements

Authors dedicated this work to Late Prof. Jitendra G. Vaidya and are thankful to Department of Botany, Savitribai Phule Pune University, Pune, for providing the necessary facilities. Authors are thankful to TARE SERB Department of Science and Technology for financial assistance.

Author contributions

HS, DS and SA conducted the experiment, wrote original draft of manuscript and review the manuscript. VG, BB and SG design the study, supervised the work and finalized the manuscript.

Funding

This work was supported by TARE SERB Department of Science and Technology (TAR/2021/000103).

A critical examination of advanced approaches in green chemistry: microbial bioremediation strategies for sustainable mitigation of plastic pollution

Agarwal, Tushar1; Atray, Neeraj1; Sharma, Jai Gopal21 CSIR-Indian Institute of Petroleum, Dehradun, India (GRID:grid.418362.a) (ISNI:0000 0001 2150 6148)2 Delhi Technological University, Department of Biotechnology, Delhi, India (GRID:grid.440678.9) (ISNI:0000 0001 0674 5044)

ABSTRACT (ENGLISH)

Background

The escalating concern regarding the environmental impact of plastic waste necessitates the adoption of biodegradable methodologies to curtail its adverse effects. A profound comprehension of the intricate interplay between bacteria and polymers becomes imperative for devising effective solutions to address plastic-induced environmental challenges.

Main body of the abstract

Numerous microorganisms have evolved specialized mechanisms for the degradation of plastics, rendering them amenable to application in green chemistry for the elimination of hazardous plastics from the ecosystem. This article offers a comprehensive survey of contemporary microbial bioremediation approaches geared towards augmenting plastic waste management and ameliorating plastic pollution. Emphasis is placed on elucidating the potential of microorganisms in mitigating the deleterious repercussions of plastics on ecosystems and human health, underscoring the significance of advanced strategies in green chemistry for sustainable plastic pollution mitigation.

Short conclusion

Current research emphasizes the effectiveness of naturally occurring soil microorganisms, particularly fungi like *Aspergillus* and bacteria like *Bacillus*, in breaking down plastics. To harness this potential on a broader scale, optimization of microbial activity conditions and pre-treatment with environmentally beneficial compounds are essential.

FULL TEXT

Background

According to recent statistics, the world's industries produce roughly 140 million tonnes of plastic annually, with a more significant proportion of that amount being released into the environment as garbage [1–4]. The use of chemicals, detergents, cosmetics, medicines, and food packaging accounts for thirty percent of these tonnes [5]. Approximately 64% of synthetic plastics are made of polyethylene, which has a high molecular weight and hydrophobicity. A considerable amount of the 500 billion to 1 trillion polythene materials manufactured annually worldwide end up in the natural environment (land and water) [6–9]. This raises serious environmental concerns. Approximately 10% of municipal garbage produced worldwide is attributed to packaging materials like polythene [10–12]. However, only 5% of the trash is recycled, and the remainder is buried underground, where it takes roughly 100 years for the material to decompose naturally without the aid of bacteria [13–15]. This results from their resistance, perseverance, and inability to degrade [16–18]. Humans may be subjected to severe health and ecological stresses as a result of this pollution. Particularly worrying microplastics have been linked to instantaneous mortality when ingested by aquatic creatures [19–22].

Due to the rise in environmental issues caused by plastics, the usage of physical [23, 24], and chemical [25–27] methods to break down plastic garbage has been condemned. The biological destruction (Biodegradation) of plastic using bacteria and fungus [28–30] has gained popularity recently owing to their efficacy, affordability, environmental friendliness, and sustainability. Multiple factors, including substrate accessibility, polymer surface area, shape, and molecular weight, all play a role in the biodegradation process [31, 32]. One may use a variety of metrics to assess this deterioration, including by the amount of carbon dioxide released into the atmosphere, the percentage change in the mechanical characteristics and/or chemical structure of the polymer, and the amount by which the substrate itself degrades. At the beginning of research into microbial biodegradation, scientists looked into how microbes may affect the physical qualities of plastics, such as water absorption, crystallinity, and tensile strength. Plastic waste may be assimilated into carbon sources or degraded into important alkane compounds using microbial biotechnology. This offers a promising possibility to increase plastic recycling and, by extension, to minimize

environmental plastic pollution [33–35].

Microbes may break down plastics by first producing extracellular enzymes, then attaching those enzymes to the surface of the plastic, then hydrolyzing the plastic into short polymer intermediates, and finally ingesting those intermediates as a carbon source in order to produce carbon dioxide (Fig. 1). In recent years, several bacteria capable of degrading these polymers have been found, despite the synthetic nature of these polymers. Together with the bacterial consortia, abiotic factors facilitate the mineralization, assimilation, depolymerization, and fragmentation of environmental plastic wastes into carbon dioxide, nitrogen, methane, and water molecules, monomers, dimers, and oligomers [36–38]. Since the 1970s, certain strains of bacteria from the genera *Aspergillus* [39–41]*, Penicillium* [42–44], *Streptomyces* [45–47], *Pseudomonas* [48–50], and *Bacillus* [51–53] have been utilized to break down plastic trash. Though the microorganisms responsible for plastic breakdown have been narrowed down, further study is required to confirm the identities of the specific causes.

Fig. 1 [Images not available. See PDF.]

Biodegradation process of plastic waste

Global concern has been raised about the enormous amount of poly(ethylene terephthalate) (PET) [54–56], polyvinyl chloride (PVC) [51, 57], polyamide (PA), polyethylene (PE), polypropylene (PP) that appears to take centuries to break down in the environment. Moreover, the COVID-19 pandemic has amplified the already alarming issue of plastic pollution, driving an unprecedented surge in the demand for single-use plastics such as personal protective equipment (PPE) [58]. This surge has further strained an already overwhelmed waste management system and exacerbated the pollution of our natural environments. In response to this, there is a growing emphasis on exploring innovative strategies to tackle plastic pollution. One such strategy gaining traction is plastic bioremediation. As the imperative for sustainable solutions intensifies, the focus on biodegradable methodologies gains prominence, necessitating a nuanced understanding of the intricate symbiosis between bacteria and polymers. This discourse delves into advanced microbial bioremediation strategies grounded in green chemistry, offering a comprehensive exploration of cutting-edge approaches to enhance plastic waste management and alleviate the escalating spectre of plastics pollution.

The primary contributions of this research article are as follows:

1. From the standpoint of developing plastic waste management, the study provides substantial information regarding microbes capable of effectively digesting polymers.
2. The study describes several ways in which bacteria may be used to break down plastic.
3. The study's principal goal is to understand how bacteria are used in the control of trash plastics.
4. The study also seeks to uncover existing developments in the microbial breakdown biodegradation of plastic trash.

The remainder of the study is structured as follows: Section "Research approach" provides specifics on the methodology used, which was derived from best practises for critical literature reviews. In the section titled "Biodegradation of Plastic Waste by Microorganisms," we briefly address the bioremediation by various microbes. The section under "Limitations" describes the restrictions that this study had to operate within. The last section of the paper, "Conclusions," outlines the entire work.

Research approach

The Web of Science, Scopus, PubMed, and Google Scholar were among the databases searched as criteria for including and excluding the study. The search was conducted using key terms related to the microbial bioremediation of plastic waste. Additionally, the "AND" and "OR" Boolean operators were used to construct relevant words. After data source evaluation, all filtered sources were collected and checked for duplication using Mendeley

Desktop Version 2.61.1. Titles and abstracts served as the primary criteria for screening. Full-text screening was also applied to the remaining articles. Studies evaluating incomplete publications (In press) and papers on the auxiliary subject were disregarded. We further excluded correspondence, discussions, editorials, books, systematic reviews, book chapters, conference abstracts, doctoral dissertations, and brief communications. This study included papers that discussed the role of microbial bioremediation in the removal of plastic waste. Additionally, we manually looked through relevant and referenced papers from the research and reviews that were included.

Main text

The process of plastic waste decomposition by microbes is closely linked to the chemical makeup of the polymers, environmental factors, and microbial behaviour. Microorganisms are essential in the process of decomposing plastic polymers into smaller pieces, which eventually results in the transformation of these pieces into innocuous chemicals such as carbon dioxide and water. The degradation of polymers is an intricate process that is affected by both inherent characteristics of the polymer and external environmental influences. The chemical composition of a polymer, which includes its arrangement, presence of different atoms, and other substances, greatly affects its vulnerability to degradation [59]. Polymers consisting only of carbon chains, particularly those containing double bonds, exhibit greater inertness in comparison to polymers including heteroatoms or additives [60]. Their high level of purity reduces their susceptibility to external influences, hence decelerating the process of deterioration.

The length and content of the carbon backbone are significant factors. Polypropylene, which has longer chains, often demonstrates resistance to degradation [61]. However, the inclusion of heteroatoms might potentially undermine this resistance. Moreover, the degradation rates are influenced by the polarity of the polymer, with nonpolar molecules exhibiting lower susceptibility to degradation. The degree of crystallinity of a polymer also impacts its degradation. Crystalline polymers have a higher resistance to degradation compared to amorphous compounds [62]. They require less water and oxygen to start decomposing. The molecular weight of polymers is a significant factor that affects their degradation rate. Polymers with larger molecular weights have smaller relative surface areas, resulting in slower degradation [63].

The degradability of a polymer is further influenced by the production method and the additives employed. Within landfills, the combination of UV radiation and heat can trigger breakdown by auto-oxidation, causing polymers to break down into microplastics [64, 65]. These microplastics are then further degraded by microbes, resulting in the production of carbon dioxide and water. Polymers such as polyethylene, polypropylene, and polystyrene mostly break down in the presence of oxygen and exposure to UV radiation [66]. This process results in the formation of different end products, which vary depending on the kind of polymer.

The process of anaerobic degradation that occurs in landfills leads to the generation of methane and water, which is facilitated by microbial enzymes that aid in the breakdown of polymers [67]. During the process of degradation, petrochemicals undergo changes such as increased brittleness, discoloration, and the formation of new functional groups. Microorganisms have a tendency to attack the shapeless parts of plastics, whereas the structured sections break down at a slower rate.

Bioremediation by *Achromobacter* sp.

Achromobacter (Alcaligenaceae family) is a bacterial genus belonging to the Burkholderiales order. The cells are straight rods motile by one to twenty percent of flagella. They are aerobic and may be found in fresh and saltwater and soil. Also recognized as a contaminant in laboratory cell cultures [68, 69]. In a study published in 2022, to expedite the biodegradation of thermo-oxidatively pretreated PVC and Low-Density Polyethylene (LDPE), researchers have successfully identified *Achromobacter denitrificans* from compost [70]. In bacterial flasks made of PVC and LDPE, the percentage of dry weight lost was 12.3% and 6.5%, respectively, and the amount of

extracellular protein was 326.4 and 112.32 mg/L, respectively. PVC underwent treatment that caused its pH to rise to 5.12, and its thermal stability was enhanced by 29 °C. Fourier Transform Infrared Spectroscopy (FTIR) results show that chain breakage in the major backbone, synthesis of new groups, and oxidation of antioxidants have all altered the chemical composition of LDPE. The carbonyl groups formed as a byproduct of LDPE breakdown are responsible for the appearance of peaks between 1700 and 1850 cm^{-1}. Scanning Electron Microscopy (SEM) verified surface changes in LDPE and PVC.

Another research found that a novel bacterial *Achromobacter xylosoxidans* influences the structure of High-Density Polyethylene (HDPE) [71]. By studying the coding sequences of the 16S ribosomal subunit, a hitherto undiscovered strain of *A. xylosoxidans* known as PE-1 was extracted from the soil and identified. Degradation of the HDPE chemical structure was seen in analyses of foil samples performed using SEM and Attenuated Total Reflectance Fourier Transform Infrared Spectroscopy (ATR-FTIR). As a consequence, HDPE foil was found to lose around 9% of its weight. On the basis of a comparison between the spectrum of the raw material before the bacterial treatment and the range from a database of spectra, it was anticipated that the microorganisms primarily depended on the HDPE for their carbon and energy needs.

Bioremediation by *Aspergillus* sp.

Fungi of the genus *Aspergillus* are often found living as saprophytes in the soil, where they consume dead plants and other organic matter, including seeds and grains. The individuals that belong to this genus can flourish in environments with high osmotic pressure. Because of the high oxygen tension, species of the genus *Aspergillus* may be found in almost all environments rich in oxygen. In these environments, they often take the form of moulds on the surface of the substrate [72–74]. An investigation was carried out on the biodegradation of black LDPE sheets by a fungus isolated from several Egyptian landfills [75]. For 16 weeks, minimum salt medium and LDPE sheets were heated to 30 °C and rotated at 120 rpm in a rotary shaker. The fungal strains *A. fumigatus* MF 276893 and *A. carbonarius* MH 856457.1 were found to be promising LDPE biodegradation agents. The sheet weight loss percentage was much higher in a mixed culture of the two strains compared to a single isolate. Physical and chemical treatments were also used to increase the degradation capacity. By 5.89% (chemical treatment), 17.76% (HNO_3 treatment), and 39.1% (heat treatment), biodegradation was found to be accelerated. New functional groups associated with hydrocarbon biodegradation were validated by FTIR, demonstrating the essential involvement of manganese peroxidase in the process. In addition to surface changes in biodegraded LDPE (as determined by SEM), differences in FTIR spectra of mixed culture biomass before and after biodegradation proved that LDPE was depolymerized. It has been reported that these strains are capable of complete biodegradation of plasticizers such as tributyl acetylcitrate, 1,2-benzenedicarboxylic acid diisooctyl ester, diisssctyl phthalate, and bis(2-ethylhexyl) phthalate, using Gas Chromatography-Mass Spectrometry (GC–MS). Another research determined five fungal isolates, including Brown rot, White rot, *A. flavus*, and *A. Niger* fungi isolated from various landfills in Peshawar, Pakistan [29]. Weight loss percentage analysis after 30 days of incubation was used to determine the biodegradation potential of these isolates against LDPE polymers. white rot, brown rot, *A. flavus*, and *A. niger* fungus all demonstrated biodegradation percentages of 22.7%, 18.4%, 16.1%, and 22.9%, respectively.

Further research used *Fusarium solani*, *A. versicolor*, and *A. flavus*, all of which were retrieved from a municipal waste yard in Chennai, India, to study the biodegradation of LDPE [76]. The polymers were tested for degradation by exposure to microbial cultures for 60 days in the lab. FTIR spectra verified the biodegradation of LDPE, whereas Field Emission Scanning Electron Microscopy (FESEM) micrographs demonstrated that the fungi had colonized the polythene matrix as a result of their metabolic activities. Sturm test results suggest *A. versicolor* strain is a more promising LDPE-degrading option than the *F. solani* and *A. flavus* strains. Under controlled laboratory conditions,

the biodegradation rate of LDPE sheets was measured after being inoculated with bacteria and fungi collected from various locations around the Dandora dumpsite [77]. Researchers incubated the LDPE sheets for 16 weeks at 37 °C for bacteria and 28 °C for fungus. *A.s oryzae* strain A5 showed the greatest fungal degradation activity, decreasing the average weight by 36.42±5.53%. Findings suggest that *Aspergillus*, *Bacillus*, and *Brevibacillus* are promising candidates for biodegrading LDPE. Moreover, a group of researchers extracted fungal candidates from a nearby dumping site. Mushrooms were grown in a broth made of mineral salts and LDPE powder. In broth medium supplemented with LDPE, only two (RH06 and RH03) of the nine isolates showed the maximum growth response. The findings showed that after 45 days of culture, there was a 5.13% drop in the weight of LDPE film when using isolate RH03, and there was a 6.63% decrease when using isolate RH06. In addition to this, the tensile strength of the treated film was found to be reduced by 58% over the board and 40% in each isolate. The LDPE film's surface developed a groove and a roughness, as shown by an electron microscopy analysis. Moreover, DNA sequencing and Polymerase Chain Reaction data confirmed that strains RH06 is *A. nomius and* RH03 is *Trichoderma viride,* with a 96% and 97% degree of similarity, respectively. The ability of *A. clavatus* to degrade LDPE in an aqueous medium was observed for 90 days [78]. PE mass loss, CO_2 evolution measured by the Strum test, FTIR, and SEM/Atomic Force Microscopy (AFM) morphological alterations all corroborated the deterioration. Researchers used enrichment culture and screening processes to identify two strains of *Lysinibacillus* sp. and *Aspergillus* sp. from waste soils in Tehran, which showed outstanding capacities to break down LDPE [79]. UV-irradiated and non-irradiated pure LDPE films without pro-oxidant additives underwent 126 days of biodegradation in soil with and without mixed cultures of selected microorganisms. As seen by carbon dioxide soil measurements taken after 126 days, biodegradation was moderate in the absence of microorganisms; UV-irradiated and non-UV-irradiated LDPE mineralization was only 8.6% and 7.6%, respectively. Biodegradation was much more effective when the targeted microorganisms were present, with biodegradation percentages for UV-irradiated and non-UV-irradiated films being 29.5% and 15.8%, respectively. When UV-irradiated LDPE was biodegraded in soil containing the designated microorganisms, the percentage decline in the carbonyl index was more pronounced. X-ray diffraction (XRD), FTIR, and SEM confirmed that the chosen microorganisms were able to alter and colonize both kinds of PE. An *A. flavus* fungi PEDX3 was identified from the digestive tract of the wax moth, *Galleria mellonella* [41]. The results of a 28-day incubation period demonstrated that strain PEDX3 was capable of breaking down HDPE MPP (microplastic particles) into the MPP with reduced molecular weight. As measured by FTIR, the breakdown of PE was further confirmed by the presence of carbonyl and ether groups of MPP. Additionally, Reverse Transcription-Polymerase Chain Reaction (RT-PCR) was used to look for possible degradation enzymes. At the end of the degradation process, two genes, AFLA 053930 and AFLA 006190, encoding laccase-like multicopper oxidases, were found to have had their expression levels increase, indicating that they encode probable PE-degrading enzymes. In another investigation, *A. flavus* VRKPT2 and *A. tubingensis* VRKPT1 isolated from the PE trash deposited in marine coastal regions were tested under in vitro conditions to be efficient in HDPE breakdown [80]. The isolated fungus was identified based on internal transcribed space (ITS) homology sequence analysis. Even after 1 month of incubation, the biofilm development detected using an epifluorescent microscope revealed the vitality of fungal strains.

Bioremediation by *Bacillus* sp.

Bacillus species are rod-shaped, aerobic, sporulating bacteria abundant in nature. They may be either obligatory aerobes, which are oxygen-dependent, or facultative anaerobes and may thrive without oxygen [81]. A study was set out to determine how effective bacterial isolates were in degrading microplastics in the Vaigai River in Madurai, India [82]. After being properly processed, the isolates were included in the degradation of UV-treated PE and PP. Four

bacterial isolates, including *Bacillus* sp. (BS-2), *Bacillus paramycoides* (BP), *Bacillus cereus* (BC), and *Bacillus* sp. (BS-1), passed the first screening and were evaluated for the 21-day degrading experiment. Bacterial isolates were stuffed into the microplastics, and a shake flask experiment was conducted using two different methods, each with a control. Degradation of the microplastics was demonstrated by a decrease in their weight, an increase in their fragmentation, and a shift in their surface area compared to control studies (microplastics without isolates). Although PP degradation was most significant with BP (78.99 ± 0.005%) and BC (63.08 ± 0.009%) when used separately, the greatest PP and PE degradation were achieved when BC and BP were used together (78.62 ± 2.16% and 72.50 ± 20.53%).

Activated sludge was studied as a potential biocatalyst for the degradation of microplastics in water [83]. It was initially tested for its ability to hydrolyze PET polymers pretreated at 100 °C for an hour. To assess degradation potential, the consortium undertook a typical CO_2 evolution test at pH 7–7.5, 30 °C, 168 days reactor residence time, and 2.63 g/L PET concentration. After being incubated, the group was able to break down 17% of the PET. Surface erosion was responsible for the unaltered molecular weight. Biodegradation was also noticeably accelerated in the presence of abundant oxygen. *Agromyces mediolanus* PNP3 and *B. cereus* SEHD031MH were discovered to be two of the consortium's isolated bacterial strains. Even though growth was optimal for both strains when grown on PET medium alone, only *B. cereus* showed enzyme activity in a clear-zone assay. The bacterial degradation of polyhydroxybutyrate (PHB) was studied in a solid-media culture setting over a range of temperatures and salinities [53]. After 14 days of cultivation on PHB film, studies show that Bacillus sp. JY14 can destroy around 98% of PHB. This species was shown to be able to biodegrade P(3HB-*co*-3HV) and P(3HB-*co*-4HB).

In a study, sixty marine bacteria were tested for their capacity to digest LDPE [84]. When tested using polythene as the only carbon source for growth, only three were discovered to be effective. Positive isolates were identified by comparing their 16S rRNA gene sequences. The researcher determined that they belonged to the genus *Kocuria*, species M16; genus *Bacillus*, species M27; and genus *Bacillus subtilis*, species H1584. During a 30-day incubation period with H1584, M27, and M16 isolates, PE lost 1.7%, 1.5%, and 1% of its weight. Hydrophobicity on the cell surface was highest (32% in M16), then 15% in H1584, and finally 27% in M27. A triphenyltetrazolium chloride reduction assay was used to verify the vitality of the isolates grown on the PE surface. Calculations of the Keto Carbonyl Bond Index, Ester Carbonyl Bond Index, and Vinyl Bond Index from FTIR spectra showed increases consistent with PE biodegradation.

Bioremediation by *Collectotrichum* sp.

Colletotrichum (sexual stage: Glomerella) is a genus of endophytes or phytopathogens that are symbionts to plants. Some species in this genus may have a symbiotic relationship with their host plants [85]. Thirty fungi were tested for biodegradability of LDPE films in mineral salt medium agar [86]. *Stagonosporopsis citrulli*, *Collectotrichum fructicola*, *Thyrostroma jaczewskii*, and *Diaporthe italiana* grew much faster than *Aspergillus niger* when grown on LDPE film as the sole carbon source. For a further 90 days, they were grown in a broth made of mineral salts and LDPE film instead of any other carbon source. CO_2 emissions ranged from 0.45 to 1.45 g/L for *D. italiana*, 0.36 to 1.22 g/L for *T. jaczewskii*, 0.33 to 1.26 g/L for *C. fructicola*, 0.37 to 1.27 g/L for *S. citrulli*, and 0.33 to 1.27 g/L for *A. niger* when they were cultured on LDPE film. Compared to the levels of lignin peroxidase and manganese peroxidase secreted by the same fungus, the quantity of laccase enzyme produced was reported to be much higher. It was further investigated how these fungi degrade LDPE sheets when cultured. Weight loss was recorded as 28.78, 45.12, 48.78, 46.34, and 43.90%; tensile strength as 3.34, 1.86, 0.43, 1.78, and 1.56 MPa for LDPE films cultured with *A. niger*, *S. citrulli*, *C. fructicola*, *T. jaczewskii*, and *D. italiana*, respectively. After incubation with various fungi, especially *C. fructicola*, FTIR measurement revealed an increased carbonyl index in LDPE films. The biodegradation

of LDPE films was validated by SEM analysis, which revealed morphological changes on the film's surface, including cracks, scions, and holes. The Volatile Organic Compounds, 1,1-dimethoxy-decane, 1,3-dimethoxy-5-(1-methylethyl)-benzene, and 1,3-dimethoxy-benzene were found in these fungi. In terms of biodegradation of LDPE, *C. fructicola* shows promise as a resource and may be incorporated in fungal-based plastic degrading systems.

Bioremediation by *Comamonas sp.*

Gram-negative, rod-shaped spirilla (often called “rods”) are found in bacteria of the genus *Comamonas*. These microorganisms are chemoorganotrophic, meaning they feed off of organic matter rather than sugars, and they are aerobic [87]. The breakdown of dimethyl phthalate (DMP) by a *Comamonas testosterone* bacterial strain, DB-7, was investigated in a study [88]. The results indicate that DMP at varying doses was quickly destroyed, with over 99% degradation occurring within 14 h at 450 mg/L. The breakdown rate of DMP was found to be positively proportional to the inoculum volume of the bacteria, with the ideal degradation temperature being 30–35 °C and pH 9.0, respectively. According to HPLC (High-performance liquid chromatography) and LC/MS (Liquid Chromatography-Mass Spectrometry) studies of metabolic products, phthalic acid (PA) and mono-methyl phthalate (MMP) are the primary degrading intermediates formed by DB-7 during the breakdown of DMP.

Bioremediation by *Enterobacter* sp.

The genus *Enterobacter* includes rod-shaped, non spore-forming, gram-negative, facultatively anaerobic bacteria of the Enterobacteriaceae family. The type genus of the family Enterobacterales [89]. A group of researchers conducted research on the breakdown of LDPE by the recently discovered Enterobacter cloacae AKS7 [90]. A progressive rise in Extracellular Polymeric Substance (EPS) production by the organism (AKS7) was also identified, indicating the establishment of an effective biofilm on the LDPE surface. In addition, two AKS7 mutants with significantly reduced cell-surface hydrophobicity compared to their wild type were screened. The results of which contrasted to wild-type AKS7 cells, the mutants exhibited lower levels of LDPE breakdown. Further analysis showed that, in contrast to wild-type cells, AKS7 mutant cells lacked the ability to adhere to LDPE. The findings showed that AKS7's hydrophobic cell surface promotes the growth of microbial biofilm on LDPE, leading to more efficient breakdown of the plastic by the microbe. Given these results, the organism may be evaluated as a bio-remediating agent for the long-term degradation of polythene-based toxic waste.

Bioremediation by *Halomonas sp*.

Halomonas is a genus of salt-tolerant (halophilic) bacteria. They are rod-shaped gram-negative bacteria and develop in the presence of oxygen. However, it has been reported that some may grow without oxygen [91]. Four bacterial strains with the ability to biodegrade LDPE were identified by a research group [92]. The 16S rRNA gene sequencing technique indicated that bacterial isolates H-265, H-256, H-255, and H-237 were closely related to *Alcanivorax* sp., *Exigobacterium* sp., *Halomonas* sp., and *Cobetia* sp., respectively. Researchers used the Bushnell-Haas medium to incubate these bacterial strains separately for 90 days while providing them with LDPE sheets as a carbon source. Bacterial isolates were able to develop a viable biofilm on the surface of LDPE during the biodegradation experiment, reducing the films' thermal stability. After the incubation research, the bacterial isolate H-255 was shown to have caused a maximum LDPE film weight decrease of 1.72%. FESEM and AFM demonstrated that bacterial adhesion to the film altered its physical structure (surface erosion, roughness, and deterioration). When compared to a control LDPE film, the spectra obtained using ATR-FTIR demonstrated a shift in the peaks associated with C–H stretching and C=C bond stretching and the development of additional peaks associated with C–O stretching and –C=C– bond stretching. Furthermore, carbon remineralization and enzymatic activity validated the biodegradation of LDPE film. This research demonstrated that some marine bacteria actively biodegrade LDPE film, and that these bacteria have the potential to lessen marine plastic pollution.

Bioremediation by *Klebsiella sp.*

The gram-negative, encapsulated, non-motile, facultatively anaerobic, lactose-fermenting, rod-shaped bacterium *Klebsiella pneumoniae* is characterized by its unique characteristics. It occurs naturally in the soil, and around 30% of strains are capable of fixing nitrogen under anaerobic environments [93]. *Klebsiella pneumoniae* CH001, a clinical isolate, was screened for bioremediation of HDPE [94]. After 60 days of growth in nutritional broth at 30 °C and 120 rpm, results indicated that this strain could develop a substantial biofilm on HDPE surfaces. The Universal testing machine (UTM) results indicated a considerable drop in HDPE film's tensile strength (60%) and weight (18.4%). In addition, SEM research revealed surface fractures in the HDPE, while AFM findings demonstrated an increase in surface roughness during bacterial incubation. Taken together, findings suggest that *K. pneumoniae* CH001 is a promising option for the environmentally responsible breakdown of HDPE in natural settings.

Bioremediation by *Penicillium* Sp.

Penicillium is a genus of ascomycetous fungus that is an integral component of the mycobiome of several species. Certain species of the genus generate penicillin, an antibiotic chemical that kills or inhibits the development of certain types of bacteria. Other species are used in cheese production. According to the tenth edition of the Dictionary of the Fungi (2008), the broad genus has more than 300 species [95]. Because of its rapid colony development in the screening medium, the isolate *Penicillium citrinum* was chosen for biodegradation research. In a research, 16 plastic-degrading fungi were isolated from plastic-laden landfill soil in Bhopal, India [44]. Fungi capable of decomposing PE were screened for using a mineral salt agar medium spiked with 3% LDPE powder. Untreated LDPE fragments lost 38.82 ± 1.08% of their weight when exposed to *P. citrunum*; however, after being pretreated with nitric acid, biodegradation increased by 47.22 ± 2.04%. New functional groups ascribed to hydrocarbon biodegradation appeared in FTIR spectra, suggesting enzymatic participation in the process. Depolymerization of LDPE was validated by changes in the FTIR spectra and FE-SEM of LDPE samples (both untreated and pretreated) before and after biodegradation. Variations in the rates of thermal breakdown between biodegraded and control samples provide more evidence of biodegradation. The remarkable competence of *P. citrinum* in LDPE degrading without any pre-treatment has been reported for the first time in this work.

To effectively biodegrade polyvinyl alcohol (PVA) in vitro, researchers set out to discover and broadly screen endophytic fungi (from specified plants) [42]. Seventy-six endophytic fungi were cultured in total on a PVA screening agar medium. Using a combination of phenotypic traits, ITS ribosomal gene sequences, and phylogenetic analysis, 10 isolates were found to have a potential biodegrading effect and were subsequently identified. After 10 days of growth at 150 rpm and 28 °C, four strains showed maximal PVA-degradation in the liquid medium. *Penicillium brevicompactum* OVR-5 removed 81% of PVA, *Talaromyces verrucosus* PRL-2 removed 67%, *Penicillium polonicum* BJL-9 removed 52%, and *Aspergillus tubingensis* BJR-6 removed 41%. OVR-5 was found to be the most promising PVA biodegradation isolate, producing laccase, manganese peroxidase, and lipase enzymes at an ideal pH of 7.0 and an optimal temperature of 30 °C. This work hypothesized a possible PVA breakdown mechanism for OVR-5 in light of investigations of its metabolic intermediates, which GC–MS discovered. Both SEM and FTIR verified the biodegradation findings.

The antarctic filamentous fungus was studied for its ability to degrade polyurethane (PU), polystyrene (PS), and PE samples in a liquid solution [96]. Plastic samples were either inoculated with Antarctic fungus (*Mortierella*, *Geomyces*, *Penicillium* species), treated, left untreated, or artificially aged in a UV chamber for 500 h per ASTM G155. All samples were kept in an incubator for 90 days at 18 °C. The rate of weight loss was examined as a function of time to evaluate the physical–chemical and biological degradation of plastics. In the artificial ageing

chamber, polymers suffered an oxidative breakdown, which sped up their biodegradation (seen as morphological and structural alterations). *Penicillium* sp., of the three fungal strains, showed the most significant breakdown at 28.3% in PU, 8.39% in PS, and 3.5% in LDPE.

In a study, the researcher used garbage bags to isolate fungi and their ability to degrade LDPE. In this case, ethanol-treated LDPE was used alongside untreated LDPE [43]. F1 isolation demonstrated the most degradation out of the three fungal isolates, and this isolate damaged the untreated sheet similarly. Areas of degradation were seen in the surface morphology of F1-treated LDPE as analyzed by SEM. FTIR testing revealed that F1 affected the polymer's production of carbonyl and C=C groups. F1 fungus, when grown in the laboratory, was discovered to release the lipase enzyme. Molecular testing confirmed that isolate F1 was indeed *P. simplicissimum* strain Bar2. In another study, *P. simplicissimum* was discovered in a Shivamogga district landfill by a group of researchers [97]. Findings indicate that treated PE (38%) was more easily degraded by *P. simplicissimum* than autoclaved (16%) or surface-sterilized (7.7%) PE. *P. simplicissimum* was tested for enzymes that degrade PE. Laccase and manganese peroxidase were shown to be active enzymes. Based on these findings, *P. simplicissimum* was reported as a potential answer to the world's PE crisis.

A group of investigators evaluated "Bionolle®" polyester-modified PET films biodegradation in comparison with unmodified PET films in terms of time to decompose [98]. The films' weight was recorded before and after being incubated with the filamentous fungus *P. funiculosum* or their extracellular hydrolytic enzymes released by "Bionolle®" for 84 days. FTIR and X-ray Photoelectron Spectroscopy (XPS) studies revealed significant chemical alterations in polymeric chains. In addition to hydrolytic enzymes, oxidative ones were likely involved in the degradation of films by fungi, as shown by the significant decrease in the number of aromatic rings formed from terephthalic acid. Additionally, "Bionolle®" did not accelerate modified film deterioration.

Bioremediation by *Phanerochaete sp.*

Phanerochaete is a crust fungus genus belonging to the Phanerochaetaceae family. It has historically been classified based on the fruit body's general shape and microscopic features, such as the spores, cystidia, and hyphal structure. According to molecular analyses, the genus is polyphyletic, with members scattered over the phlebioid clade of the Polyporales order [99, 100]. A study examined the biodegradability of starch-blended PVC films using controlled laboratory studies utilizing selected fungus isolates and *in-situ* burial in soil [101]. SEM revealed the surface anomalies such as colour change and mild disintegration in PVC films after 90 days. Isolation of fungal strains characterized by robust growth and adhesion to plastic sheets. *Phanerochaete chrysosporium* PV1 was chosen among the strains exhibiting the highest levels of activity and later confirmed to be this species by rDNA sequencing. FTIR and Nuclear Magnetic Resonance (NMR) studies revealed new peaks, suggesting substantial structural changes and transformation in the films. Gel permeation chromatography (GPC) backed this up by showing a considerable reduction in the molecular weight of polymer film from 80,275 to 78,866 Da (treated). The release of more carbon dioxide (7.85 g/l) than the control (2.32 g/l) in the respirometric technique provided further evidence of the biodegradation of starch-blended PVC films. Hence, suggesting *P. chrysosporium* PV1 is a fungal strain with excellent potential for bioremediation of plastic waste.

Bioremediation by *Pseudomonas* sp.

There are 191 different species of the genus *Pseudomonas*, which are all gram-negative gamma-proteobacteria in the family Pseudomonadaceae. Members of this genus exhibit a high degree of metabolic variability, allowing them to colonize a wide variety of habitats [102, 103]. It is suggested by research that the *Pseudomonas* sp. found in the digestive tracts of superworms might effectively biodegrade Polyphenylene sulphide (PPS) [49]. The biodegradation time of the bead form of plastic was drastically reduced due to its superior degradation efficiency compared to the

standard film type of plastic. Therefore, this work employed plastic beads with a diameter of 300 m to assess the *Pseudomonas* sp. mediated PPS biodegradation over 10 days instead of film-type plastics. This technology not only compares and verifies the biodegradation performance of different polymers in 10 days, but it also quickly identifies the best bacteria for plastic biodegradation.

As reported, another research set out to examine the biodegradation capabilities of five bacterial strains against PVC, PS, PP, and PE films under aerobic conditions [51]. A generalised aerobic breakdown mechanism for plastics is shown in Fig. 2. *B. flexus* and *P. citronellolis* were chosen as suitable PVC film degraders after preliminary screening. Biodegradation of PVC films was tested using the two strains in 2-L flasks. Fragmentation of the film was found after 45 days of incubation, indicating PVC biodegradation. PVC incubated with *P. citronellolis* had a 10% decrease in average molecular weight, as determined by GPC, suggesting that PVC polymer chains were attacked. These findings led to the selection of the *P. citronellolis* strain for biodegradation experiments. As determined by chemical evaluation of the films after 30 days of incubation, the waste PVC polymers had biodegraded, resulting in a gravimetric weight loss of up to 19%. In conclusion, this study documents *B. flexus* and *P. citronellolis* ability to biodegrade PVC sheets. Both strains were shown to have a negligible effect on PVC polymer, suggesting that they work primarily against PVC additives.

Fig. 2 [Images not available. See PDF.]

A generalised aerobic breakdown mechanism for plastics

A soil-dwelling bacteria capable of degrading polyester PU was isolated and characterized as strain MZA-85 [104]. It was determined that the bacterium was *Pseudomonas aeruginosa* by 16S rRNA gene sequencing. The strain MZA-85 altered the surface morphology of PU film, as shown in SEM. The FTIR spectrum exhibited an augmentation of the organic acid functional group and a concomitant diminution of the ester functional group. Results from GPC showed a rise in polydispersity, suggesting that microorganisms break down PU polymer chains. After conducting a p-Nitrophenyl acetate hydrolysis experiment, it was discovered that the bacteria produced cell-associated esterases. GC–MS confirmed the synthesis of adipic acid and 1,4-butanediol monomers. Cell growth in the presence of breakdown products and the Sturm test showed that strain MZA-85 mineralized PU into H_2O and CO_2. These results suggest that strain MZA-85 and its enzymes may recycle pure monomers in biochemical monomerization. On the other hand, *Pseudomonas* sp. AKS2 can degrade 5 ± 1% LDPE in 45 days without pre-oxidation, which is much quicker than the degradation rates reported in previous investigations [105]. This could be attributable to agents modifying the hydrophobic contact between the polythene and the microbe, which may affect the breakdown rate. Accordingly, this research links the capacity for biofilm formation among bacteria to their ability to degrade polymers and shows a connection between hydrophobic contact and polymer breakdown.

Bioremediation *by Rhizopus* sp.

The fungus genus *Rhizopus* is well-known for its extensive plant saprophytic and its role as a specialist animal parasite. They are present in several organic things, including mature fruits and vegetables, tobacco, peanuts, bread, leather, syrups, and jellies [95]. A fungal lab isolate, *Rhizopus oryzae* NS5 was studied for the biodegradation of LDPE [106]. One month of incubation in a potato dextrose broth at 120 rpm and 30 °C resulted in the development of fungi on the surface of PE. Approximately 8.4 ± 3% of the weight and 60% of the tensile strength of PE was shown to decrease gravimetrically. The SEM study of the PE surface revealed hyphal penetration and degradation. After fungal isolation, AFM showed increased surface roughness. Fungal hyphae formed a biofilm on PE fragments. This research demonstrates the potential of *R oryzae* NS5 for eco-friendly and sustainable PE breakdown.

Bioremediation by *Streptomyces* sp.

Streptomyces is the most populous genus of Actinomycetota and the type genus of the Streptomycetaceae family. There are around 500 recognized species of *Streptomyces* bacteria. The genomes of streptomycetes are gram-positive. Most streptomycetes generate spores and have a unique “earthy” odour due to the synthesis of the volatile metabolite geosmin, primarily found in soil and decomposing plant matter [107]. As PET trash, drinking bottles were pulverized and categorized into four particle sizes in research work. In their work, they investigated the biodegradation of PET by *Streptomyces* species [47]. Extracted samples totaling 50 mg were divided into four groups based on particle size, each of which was then incubated with a different set of microorganisms in a culture medium at 28 °C for 18 days. Degradation values were then calculated on particular days. The biodegradation percentages for 500, 420, 300, and 212 m PET particle sizes were reported to be 49.2%, 57.4%, 62.4%, and 68.8%, respectively. To further verify the biodegradation process, the byproducts were analysed by GC–MS. Experimental results may be better predicted using the Michaelis–Menten activation or inhibition model, according to the kinetic modelling of biodegradation.

Researchers isolated microorganisms from Andhra Pradesh and Telangana waste soil to prevent plastic buildup and rid the environment of plastic [108]. The degrading activity of these microorganisms is determined using the clear zone approach and polythene powder. Changes in the granules' physical and structural properties occurred over time after microbes had attached to polymer particles. To determine the effectiveness of biodegradation, the weight technique was used in the laboratory for 2, 4, and 6 months. Experimental results demonstrated that *Streptomyces* sp. had the greatest plastic degradation ability, degrading up to 46.7%; this was followed by *A. flavus* (16.45%), *Pseudomonas* sp. (24.22%), and *A. niger* (26.17%) during a 6-month period. The results of this study demonstrate the critical function that Streptomyces sp. plays in the breakdown of polythene powder and polymer granules.

Bioremediation by *Zalerion sp.*

The marine fungus, *Z. maritimum*, was discovered in the waters off the coast of Portugal [109]. The researcher assessed mass changes in the fungus *Zalerion maritimum* and PE pellets after different exposure times in a minimum growing medium [110]. Results indicated that *Z. maritimum* is able to use PE under test circumstances, resulting in a reduction in both pellet mass and size. These results point to a naturally occurring fungus that, with its low food requirements, might play an active role in the biodegradation of microplastics.

Bioremediation by the synergistic effect

Scientists evaluated the PET-associated lipase activity of bacteria isolated from petroleum-contaminated soils [48]. Bacterial strains and consortiums were cultivated on a liquid carbon-free basal medium (LCFBM) using PET as the only carbon source. Consistent with the ATR-FTIR findings, this work found hydrolysis byproducts of PET using ^{1}H NMR analysis. Together, PET and its cleavage product bis(2-hydroxyethyl) terephthalic acid (BHET) supported the growth of five strains of *Bacillus* and *Pseudomonas* species. The consortium's secreted enzymes could completely convert BHET to the biologically functional monomers ethylene glycol and terephthalic acid (TPA). Strains with different enzymatic abilities for the metabolic breakdown of ethylene glycol and TPA, the building components of PET polymers, were discovered in draught genomes, cooperating and cross-feeding in a nutrient-limited environment utilising PET as the primary carbon source.

Two distinctive cultures of *Arthrobacter* and *Streptomyces* sp. were extracted from farming soils and found to thrive solely on PE film [45]. The suspension phase of culture was very fruitful for the growth of *Arthrobacter* sp. Streptomyces sp. produced huge biofilms on the PE film, showing that the two strains had distinct metabolic types and lived in different microenvironments with differing nutritional availability. CO_2 evolution, increased carbonyl index, reduced hydrophobicity, and the biofilm development on the film surface were all indicators that a 90-day

inoculation experiment might deteriorate PE film. However, a combination of the two strains had a far greater effect on these negative characteristics.

Yet another study utilized a synergistic system consisting of *Thermobifida fusca cutinase* (TfC) and *Microbacterium oleivorans* JWG-G2 to decompose a high crystalline PET film and BHET oligomers [111]. Ethylene glycol terephthalate (EGT) has been discovered as the unique degradation product of *M. oleivorans* JWG-G2 alone. The synergy degrees for the degradation of PET film and BHET oligomers with the addition of TfC as a second biocatalyst were determined to be 2.26 and 2.79, respectively. After treating PET film with *M. oleivorans* JWG-G2 at 5×10^3 μL/cm^2 and TfC at 120 g/cm^2, the highest concentrations of TPA (47 nM) and mono(2-hydroxyethyl) terephthalate (MHET) (330 nM) were found. The degree of surface degradation of PET film was higher than that generated by each treatment on its own. Synergistic microbe-enzyme treatment is based on the occurrence of extracellular PET hydrolases, and a whole genome sequencing research of *M. oleivorans* JWG-G2 showed the presence of extracellular PET hydrolases, including three a lipase, an esterase, and carboxylesterases.

Microplastics composed of LDPE and PS were biodegraded using pure bacterial strains *Lysinibacillus massiliensis* and *Bacillus licheniformis*, as well as a mixed bacterial culture of *Bacillus* sp. and *Delftia acidovorans* [112]. The biodegradation of Microplastic-PS and Microplastic-LDPE with particle sizes between 300 and 500 μm was evaluated for 22 days at 25 ± 2 °C, 7.15 pH, and 160 rpm. Microplastic-LDPE and Microplastic-PS were both more efficiently decomposed by mixed bacterial cultures than by pure bacterial cultures, and the biodegradation efficiency of Microplastic-LDPE was found to be larger than that of Microplastic-PS, as evidenced by a greater decrease in peak intensity and spectrum distortion, as well as higher inorganic carbon values and colony forming unit.

In another research breakdown of Linear Low-Density Polyethylene (LLDPE) plastic using a microbial culture comprising *Brevibacterium* sp. and *Pseudomonas aeruginosa* was studied [50]. Pieces of 1 × 1 cm^2 LLDPE plastic weighing 10 g were placed in containers containing Nutrient Broth growing material. Gravimetric test at pH 7.0, 25 °C for 30 days demonstrated that a mixed bacterial culture could degrade LLDPE plastic by 2–7%. The results of this study show that LLDPE plastic may be degraded by mixed bacterial cultures by being used as a carbon source.

Also, novel thermophilic consortiums of *Aneurinibacillus* sp. and *Brevibacillus* sp. isolated from sewer treatment plants and waste management landfills were evaluated for their ability to degrade PP, HDPE, and LDPE films and pellets [113]. Over the course of 140 days, researchers tested the degradation ability of 36 plastic-degrading isolates. To test the efficacy of degradation, multiple combinations of the eight isolating factors that showed the highest percentage of degradation were tested. For the three types of plastic that were selected for further examination of degradation under varying temperature settings, the combination of IS1, IS3, ISA, and ISC revealed the best % weight loss. At 50 °C, the weight reduction percentages for PP, LDPE, and HDPE strips treated with the consortia of four isolates were 56.3 ± 2, 46.6 ± 3, and 58.21 ± 2% and, for pellets treated with the consortia, they were 44.2 ± 3, 37.2 ± 3, and 45.7 ± 3%, respectively ($p \leq 0.05$). After 140 days, new adsorption bands could be seen by FTIR scanning of the plastic sheet. AFM and SEM showed biofilm formation and structural alterations on treated plastic strips, while Energy Dispersive X-ray Spectroscopy (EDS) showed a considerable drop in carbon content. NMR revealed methyl and aldehyde groups, whereas GC–MS showed fatty acid byproducts. Four strains—ISC, ISA, IS3, and IS1—identified as *Brevibacillus brevis* btDSCE04, *Brevibacillus* sp. btDSCE03, *Brevibacillus agri* btDSCE02, and *Aneurinibacillus aneurinilyticus* btDSCE01, respectively were found (Table 1).

Table 1. An overview of microbial bioremediation of plastic waste

Type of plastic	Microorganism	Place of isolation of microorganisms	Degradation temperature	Degradation time	Microorganism isolation media	Reported degradation	Researchers	References

Recent advances and challenges

Reengineering of microbes

New possibilities for developing game-changing biorecycling solutions have emerged as a result of recent developments in biology and biotechnology. First, cutting-edge synthetic biology techniques and metabolic engineering methods have created many potential for reengineering and enhancing bacteria that can successfully digest solid plastic wastes and directly utilise the degraded products for biomanufacturing. Enzyme engineering techniques have been used to improve a number of plastic-degrading enzymes. Also, emerging approaches to protein engineering, such as AI-guided protein design and mutation and direct evolution, may increase the likelihood

of creating novel enzymes with resistance to inhibitors or contaminants, temperature tolerance, stability, specificity, and superior activity. Additional methods employ protein alignment data to compare plastic substrate architectures. Modifying cellulosome structure to create a multi-enzyme complex that can effectively degrade PET is an interesting area of research. Large cellulosomes may be created using modern synthetic biology methods, allowing for increased action toward stubborn cellulose [115]. Similarly, high-crystalline PET might be degraded by microbial cell factories if PETsome were developed. Identifying the substance that might serve as a PET-binding domain is crucial, similar to the cellulose-binding domain [116]. An effective bacterial cell surface expression system has recently been established [117].

Mutagenesis

In addition, site-directed mutagenesis has been widely used for enzyme redesign; nonetheless, the success of this approach is fundamentally tied to the accessibility of three-dimensional protein structures. A carboxylesterase from *Archaeoglobus fulgidus* was modified using in silico site-directed mutagenesis to produce a BTA-hydrolase from *Thermobifida fusca* [118]. Molecular docking analysis was then used to compare the interactions of PET with polypropylene following this study. The findings as a whole suggested that the binding affinity of the mutant carboxylesterase for PET was unaffected by the alterations.

Using the *Is*PETase crystal structure and computational modelling, researchers have performed site-directed mutagenesis on 15 amino acid domains in the enzyme's first contact shell [119]. The enzyme was able to depolymerize 90% of the supplied PET in 10 h after disulfide bridges were added to increase its thermostability, and residues crucial for substrate binding were mutated. When the strain was optimized, it could break down 16.7 g of PET per litre per hour. Enzymatic PET degradation, which takes 10 h and is 90% effective, is comparable to chemical PET degradation, which takes 8 h and is 98% effective [120].

Enzyme modelling and experimental results revealed *I. sakaiensis* PETase's binding pockets and a variety of cutinases [121]. Like *Is*PETase, a cutinase isolated from Thermobifida has its binding pocket residues involved in substrate interaction determined [122]. A study comparing the *Is*PETase enzyme to others, such as Thf42 Cut1, determined that the binding pocket structure of *Is*PETase is responsible for its efficacy. When compared to other cutinases, which can only hydrolyze linear PET molecules, this PETase has a shallower and broader surface, making it possible to attach to aggregated PET molecules [121]. The TfCut2 from *Thermobifida fusca* was analyzed in the same fashion. By using computational modelling to identify critical residues and site-directed mutagenesis to modify these residues on the selected substrates, researchers expanded the disintegration rate of PET film by a factor of 12.7 [123].

Adaptive Laboratory Evolution (ALE)

Initiating and promoting evolutionary adaptation processes, such as ALE, is a potent method for enhancing or creating certain phenotypes in microbial strains [124]. ALE is a powerful strain engineering method for introducing mutations to enhance metabolic pathways and enzymes for fast growth on a range of carbon sources and stress tolerances when combined with omics approaches to characterise the induced changes. Numerous ALE instances have arisen for the better usage of plastic monomers; these monomers are crucial for the construction of plastic-upcycling or -degrading cell factories.

After having its genome sequenced, scientists discovered that *Pseudomonas pseudoalcaligenes* CECT 5344 has the capacity to use furoic acid, furfuryl alcohol, and furfurals as carbon sources. Growth on furfurals, however, was discovered to have a significant delay of many days. The ALE-adapted strain grew better on furfurals and had shorter lag periods [125]. This strain improved due to a point mutation in an AraC family activator gene (BN5 2303) in the HTH protein region (L261R). This mutation regulates the upstream hmfABCDE gene cluster.

In addition, terephthalate-independent *P. putida* KT2440 mutants that were successfully isolated from ALE have been shown to use ethylene glycol, a monomeric component of PET [126]. These mutants have missense mutations and a 15 bp deletion in gclR, a transcriptional regulator of the glyoxylate carboligase pathway (PP 4283). PP 2046- and PP 2662-encoded transcriptional regulators and porins improved ethylene glycol growth in ALE-derived *P. putida* KT2440. Secondary mutations may stabilise flux balances during the first phase of ethylene glycol oxidation to glyoxylate.

Current ALE tactics focus mostly on optimising the use of plastic monomers, but there is enormous potential for ALE to be used in the creation and improvement of plastics depolymerization enzymes. A wide variety of enzymes, including esterase, lipase, and cutinase, have been found to depolymerize PET and PLA but with low selectivity and turnover [127]. Novel plastic depolymerizing enzymes might be developed via ALE or directed evolution, two methods that show promise for acquiring enzymatic activity from promiscuous enzyme families.

Obstacles to overcome

The field of microbial bioremediation for plastic waste management encounters several formidable challenges that necessitate concerted efforts to overcome. One prominent obstacle lies in the substrate specificity exhibited by microorganisms. While certain microbes demonstrate efficacy in degrading specific types of plastics, the vast array of plastic polymers presents a challenge in developing microbial solutions that universally address the diversity of plastic materials. Moreover, the rate of plastic degradation through microbial processes is often sluggish. Accelerating this degradation without compromising efficiency remains a significant research challenge, particularly as the volume of plastic waste continues to escalate. Environmental conditions further complicate matters, with factors such as temperature, pH, and the presence of other chemicals influencing the effectiveness of microbial bioremediation. Optimizing these conditions for widespread applicability and scalability across diverse environments poses a considerable hurdle.

The emergence of biodegradable plastics and biopolymers designed to mimic traditional plastics adds complexity to the field. Microorganisms may struggle to differentiate between these bioplastics and conventional plastics, potentially impacting their effectiveness in degrading target materials. The lack of standardized protocols for assessing and categorizing microbial biodegradation of plastics is another critical challenge. Establishing uniform methodologies and metrics is essential for meaningful comparisons and advancements in the field.

Scaling up microbial bioremediation from laboratory experiments to real-world, large-scale applications presents engineering and logistical challenges. Ensuring the viability of microbial processes on an industrial scale while maintaining cost-effectiveness requires innovative solutions and a thorough understanding of the complexities involved. Additionally, the ecological impact of introducing specific microorganisms into ecosystems needs careful assessment. While microbial bioremediation holds promise, unintended consequences on the environment must be thoroughly evaluated through comprehensive risk assessments.

Furthermore, navigating the evolving regulatory landscape surrounding the use of microorganisms for plastic bioremediation poses challenges. Compliance with regulatory standards and ensuring the safety of processes and end-products are critical considerations for the responsible development and deployment of microbial solutions in plastic waste management. Overcoming these multifaceted challenges demands interdisciplinary collaboration, continuous research and development, and a holistic approach that considers the intricacies of both microbial processes and the environmental contexts in which they are applied.

Limitations

This study has a number of caveats, the first of which is that the search was conducted in a specific segment of the most regularly used libraries. Throughout our search, we skipped to check a few libraries. The decision was made to

restrict attention to studies that appeared in reputable peer-reviewed publications. It was determined not to look through grey publications. Second, only relevant results were obtained since the search terms were restricted to just those most closely associated with the initial query. There is a risk that a manuscript could have been disregarded which may discuss microbial remediation of plastic biodegradation but not using the phrases sought for. By developing a methodology, the authors ensured they would have complete command over the search and selection of papers. Finally, the study only considers the most common microorganisms used in the treatment for plastic biodegradation. The authors have made an attempt to provide bibliographic information for all relevant and well regarded publications.

Conclusion

The annual manufacturing of plastic has topped 300 million tonnes, and recycling has almost failed as a sustainable method for the disposal of plastic trash. With the accumulation of these materials in the environment, particularly in rivers and oceans as macro-, meso-, micro-, and nano-plastics, it is of the utmost significance to discover creative methods to reduce this environmental threat. There have been several efforts to identify and isolate microbes with the ability to use synthetic polymers. Using specific microbial strains for plastic biodegradation has recently been shown to be a viable option.

These findings give fresh insights into LDPE and HDPE biodegradation processes by a consortium of microorganisms with putative metabolic complementarities. Another research found novel bacterial strains that may alter the chemical composition of HDPE. Based on these results, it seems that synergistic microbe-enzyme treatment might be a promising future direction for plastic degradation research. The capability of the microbial strain to digest microplastic particles provides a potential application for the remediation of microplastics. The PET-degrading activity shown by the analyzed bacterial strains holds promise for further study and its application to the successful removal of microplastics from water and wastewater using novel and potent technological approaches. This research also uncovered a thermo- and halo-tolerant bacterium that can degrade PHB in both solid and liquid states. In light of these findings, it seems that this strain of bacteria may be useful for degrading a wide range of PHAs. These methods, when combined, may be used to create a streamlined bioprocessing setup, a microbial system that can effectively break down plastics and upcycle them into high-value compounds. Technological and economic obstacles, such as the toxicity of waste products to degrading enzymes and high operational costs, should be addressed for the benefit of the industry as a whole.

Current research suggests that naturally occurring soil microorganisms, such as bacteria and fungi, are quite effective in breaking down plastic. More often than not, fungi are more potent degraders than bacteria. In the lab, however, fungi and bacteria demonstrated the ability to break down plastic. The maximum degradation capability was found for *Aspergillus* fungi and *Bacillus* bacteria among the studied taxa. For this notion to be utilized commercially and on a wider scale, more work is required to increase its degrading capability by evaluating optimal conditions for microbial activity. Another strategy that might be used to improve plastic biodegradation is the pre-treatment with compounds that are beneficial to the environment.

Diverse pharmacological actions of potential carbazole derivatives by influencing various pathways of molecular signaling

Tiwari, Archita1; Mishra, Bharat2 1 Khwaja Moinuddin Chishti Language University, Lucknow, India2 Dr. Shakuntala Mishra National Rehabilitation University, Lucknow, India (GRID:grid.449145.9) (ISNI:0000 0004 8341 0434)

ABSTRACT (ENGLISH)

Background

Carbazoles are an important class of heterocyclic aromatic compounds that contain nitrogen atom in the ring. They have a large-conjugated system, attractive "electrical and charge-transport properties", and the ability to efficiently incorporate different functional groups into the structurally inflexible carbazolyl ring.

Main text

Carbazole derivative ECCA acts as an anticancer agent by reactivating the P53 molecular signaling pathway; similarly, some other derivatives of carbazole show antifungal activity by acting on the RAS-MAPK pathway. Carbazole derivatives also show their effect on inflammation by inhibiting the p38 mitogen-activated protein kinase signaling pathway by stopping the conversion of DAXX protein into ASK-1. By modifying the AKT molecular

signaling pathway through boosting protein phosphatase activity in the brain, they show anti-Alzheimer's activity and also by translocating the GLUT4 these are effective against diabetes.

Conclusion

After exploring the literature on carbazole, it was found that carbazole has an immeasurably great potential for the treatment of various diseases as the carbazole nucleus leads to various synthesized derivatives which are used for their pharmacological activities. So there is a need to explore carbazole for some newer drugs.

FULL TEXT

Background

Heterocyclic compounds are composed of cyclic rings containing two or more different types of atoms [1, 2]. Throughout nature, heterocyclic compounds are very common and essential. In carbazole, two benzene rings with 6 carbon atoms are fused on either side of a five-membered heterocyclic ring with nitrogen atom showing vast delocalization of electrons [3].

Carbazole and its compounds are useful types of heterocyclic aromatic compounds that show desirable properties of transporting electrons and charges throughout the ring [4]. Also, many polyfunctional groups can be easily added into the carbazolyl ring for the formation of some other novel derivatives [5]. These properties of carbazole-based derivatives result in a wide range of potential applications in the chemistry field (dyes, photoelectrical materials, supramolecular recognition, etc.), and these derivatives also result in various pharmacological activities like antidiabetic [6, 7], antitumor [8–10], anticonvulsant [11], antimicrobial [12–14], antioxidative [15, 16], antifungal [17, 18] antihistaminic [19], anti-inflammatory [20, 21], antitubercular [22], antiviral [23], carbonic anhydrase enzyme activity [24], neuroprotective activity [25] and antidiarrhoel [26], etc.

C-3 and C-6 positions in carbazoles have the highest electron density so in recent years the synthesis of some novel carbazoles has been done by modification in carbazole at C-3 and C-6, and 9th positions of N [27]. If there is no steric hindrance that occurs, the carbazoles along with unblocked 3rd and 6th positions of Carbon in the ring form at least a dimer upon oxidation. Carbazoles undergo electrophilic substitution reaction like sulfonation, nitration, Friedel–Crafts acylation and Friedel–Crafts alkylation forming different derivatives of carbazole. The problem with this substitution is that a mixture of ortho and para positions is obtained but due to high electron density at the 3rd and 6th carbon positions, 75% of the para product formed concerning C-1 and C-8 (ortho position). Formation of mono along with di-, tri-, and tetra-substituted carbazoles is possible due to the reactivity of carbon atoms to the imine group in carbazole. By using appropriate alkylating or acylating agents at room temperature, the N-9 substituted carbazole derivatives are also formed [4].

Main text

Diseases with neurodegeneration

Neurodegenerative diseases (NDs) are a group of disorders (multiple sclerosis, Parkinson's disease, Alzheimer's disease, Huntington's disease, amyotrophic lateral sclerosis, etc.) that cause loss of neuron's structure or function [28–33]. As a result of these changes in the brain anatomy, the logical or functional decline may result in protein misfolding, diminished mitochondrial functions, oxidative stress, impaired neuro-transmission, and loss of neurons which are just a few physiological indicators of NDs [34, 35].

Anticancer potential

Cancer is the major health problem in individuals. Every year approx 18 million peoples are diagnosed with cancer, and it is the prime cause of death worldwide. In developed countries, the age-standardized rate for diagnosis is 296 cases per 1000,000 peoples [36–40]. Cancer is a pathological condition of the body which is due to various genetic mutations which are characterized by uncontrolled proliferation and growth of cells [41–44]. Every cell of the body can become a cancer cell when a genetic mutation occurs [45]. Carcinogenesis process occurs in three stages; in the first stage alteration has already been identified so it is called the initiation stage, in the second promotion stage these altered cells are mutated and form malignant cells, and in the last stage of carcinogenesis which is continuation stage once the tumor has increased in size and cancer cells begin to split in an accelerated irreversible

mode. And in the last stage the cells instead of growing locally start to disseminate to other body parts (metastasis) [46–48].

In human melanoma cells, the p53 pathway is reactivated by the anticancer effect of carbazole derivative ECCA, (9-ethyl-9*H*-carbazole-3-carbaldehyde). In melanoma therapy, about 84% of human melanomas harbor wild-type p53 is thought to be a supreme target for treating melanoma. Carbazole derivatives enhanced the phosphorylation of c-Jun N-terminal kinase (JNK) and p38-MAPK, and either a p38 mitogen-activated protein kinase or c-Jun N-terminal kinase inhibitor reassured cell proliferation inhibition produced by 9-ethyl-9-*H*-carbazole-3-carbaldehyde (ECCA), whose expression was dependent on p53 gene. Carbazole derivatives selectively and significantly depress the expansion of melanoma cells by persuading the programmed cell death of melanoma cells and senescence through p53 activation [49].

Yonghua et al. designated water-soluble carbazole and sulfonamide derivatives which are tested in vivo against human HepG2 (hepatoblastoma liver cancer cell line) xenograft mouse tumor expansion and found that compound 4c (Sodium 6-(*N*-(2,6-dimethoxypyridin-3-yl)sulfamoyl)-9-methyl-9*H*-carbazol-2-yl phosphate) is the most effective tumor inhibitor [50–52].

Huang shows the in vitro cytotoxic activity of different synthesized carbazole derivatives in which compound 7 g (*N*′-(Benzo[d](1,3) dioxol-5-ylmethylene)-1-methyl-9*H*-carbazole-2-carbohydrazide) and compound 7p (*N*′-(4-Chlorobenzylidene)-1,9-dimethyl-9*H*-carbazole-2-carbohydrazide) is the potent inhibitor of cancer cells but do not affect normal cells. 7g Carbazole derivative with acylhydrazone substituted with 1,3-benzodiooxozole displayed significant selective proliferation inhibition activity in vitro with (IC_{50}<12.24 μM). For the in vitro investigation of cytotoxic activity three cell lines, human melanoma (A875), human hepatocellular liver carcinoma (HepG2), and a subclone of the African green monkey cell line (MARC145) were used [53].

Capan, I et al. synthesized a sequence of carbazole derivatives. Result among all the synthesized derivatives showed that compound 9 [(*E*)-2-(9*H*-carbazol-9-yl)-*N*′-(3-(4-chlorophenyl)-4-oxothiazolidin-2-ylidene)acetohydrazide)] and compound 10 [5-((9*H*-carbazol-9-yl)methyl)-1,3,4-oxadiazol-2(3*H*)-one] are found most potent anticancer agent against HepG2, HeLa, and MCF-7 cancer cell lines with IC_{50} values of 7.68, 10.09 μM. Against HeLa, cancer cell lines found that compound 9 is the best antiproliferative agent [54].

Leu et al. synthesized a novel series of carbazole derivatives that are synthesized by imidazole derivatives along with *N*-alkyl bromide substituted carbazole. Compound 61[1-(5-(9*H*-carbazol-9-yl)pentyl)-3-(2-bromobenzyl)-5,6-dimethyl-1*H*-benzo[d]imidazol-3-ium bromide], which was bearing a 2-bromobenzyl substituent at position-3 of the 5,6-dimethyl-benzimidazole, showed powerful inhibitory activities and found to be more selective to human promyelocytic leukemia cell line (HL-60), human hepatocellular carcinoma cell line (SMMC-7721), breast cancer cell line (MCF-7) and human colon adenocarcinoma (SW480) cell lines with IC_{50} values 0.51–2.48 μM. The results of the research indicated that the presence of 5,6-dimethyl-benzimidazole ring and substitution of the imidazolyl-3-position with a 2-bromobenzyl group, as well as for the antitumor activity the length of alkyl chain between carbazole and imidazole ring were important [55] (Fig. 1).

Fig. 1 [Images not available. See PDF.]

Anticancer mechanism of carbazole derivatives. 9-Ethyl-9-*H*-carbazole-3-carbaldehyde (ECCA) re-activates P53 pathway and causes phosphorylation of P38MAPK

Breast and uterine *cancer*

The natural and synthetic carbazole derivatives represent an exciting heterocycle class that has shown several pharmaceutical properties and is also an excellent antitumor tool in preclinical experiments. The antibodies target several cellular key points, such as Topoisomerases I, II and DNA. Several efforts have been made to plan and synthesize some novel carbazole derivatives that have lesser side effects and good potency. The carbazole derivatives without affecting non-tumor cell lines possess antiproliferative activities against uterine and breast cancer cell lines. Carbazole derivatives through the inhibition of Topoisomerase II trigger cancer cells' intrinsic apoptotic pathway.

Antifungal potential

Fungal infections (mycosis) are increasing throughout the world. Although there are several reasons for this higher increase in mycosis, immune modulation of the host is one of the foremost risk factors for intrusive mycosis [56]. Humans suffer from most of the fungal infections due to the setting of iatrogenic immunosuppression. When these factors are absent fungi cause mild, self-limited mucocutaneous surface infections. When this infection develops in a normal host, it causes adaptive immune dysfunction because of genetic defects [56–58].

Tang et al. tested the antifungal activity of all the synthesized compounds against different fungal strains and found that compound 3f (2-(9*H*-carbazol-9-yl)-*N*-(4,5-dihydro-5-(thiophen-2-yl)-1,3,4-thiadiazol-2-yl)acetamide) and 3i (2-(1-chloro-9*H*-carbazol-9-yl)-*N*-(4,5-dihydro-5-*p*-tolyl-1,3,4-thiadiazol-2-yl)acetamide) exhibited the most potent inhibitory activity against C. wilt having inhibition rates 72.40% and 67.65% [59].

Shaikh et al. synthesized two series of carbazole analogues. The first one is 8-methoxy-*N*-substituted-9*H*-carbazole-3-carboxamides, and the second one is carbazolyl-substituted rhodanines. The final compounds were prepared from these two series and were tested for antibacterial activity against *Bacillussubtilis*, *Staphylococcusaureus*, *Pseudomonasaeruginosa*, and *Escherichiacoli* [60–62] and antifungal activity against *Cryptococcus tropicalis*, *Aspergillus niger*, *Cryptococcus neoformans*, and *Candida albicans* [63–65]. Various substituents, nitrogen-containing heterocyclic systems like pyrimidinyl and piperidinyl on carbazole nucleus exerted a significant antifungal activity in the first series of compounds. 2-Methyl piperidinyl carboxamide derivative compound 6f (8-Methoxy-9*H*-carbazol-3-yl)(2-methylpiperidin-1-yl)methanone found as potent antifungal and antibacterial agent. In second series substitution at 3 positions of rhodanines which is conjugated to -methyl carbazole through an acrylidine linkage, the result showed the effect of bioisosteres coumarin present in compound 15i [(5*Z*)-3-(4-methyl-2-oxo-2*H*-chromen-7-yl)-5-((9-methyl-9*H*-carbazol-6-yl)methylene)-2-thioxothiazolidin-4-one]were shown potent inhibitory activity. It was concluded that electron donating groups such as hydroxy, alkoxy, and alkyl groups on the aromatic ring greatly contributed toward the antifungal and antibacterial activity [64].

The morphogenic process came up with the virulency of *Candida albicans*, an opportunistic human fungal pathogen. Ras1-MAPK pathways are crucial to *Candida albicans* virulence through controlling morphogenesis, cell growth, and biofilm formation.

Several carbazole-containing drugs have been prescribed for infections of *Candida albicans*, leading to the expansion of drug-resistant strains. For that reason, it is needed to properly treat fungal infections, and new compounds must be developed. By suppressing Ras/MAPK-related gene protein and RNA levels, carbazole derivatives prevent morphogenesis [66, 67] (Fig. 2).

Fig. 2 [Images not available. See PDF.]

Antifungal mechanism of carbazole derivatives. *N*-(4-methoxybenzyl)-3(9*H*-carbazol-9yl) propan 1-amine inhibits morphogenesis by suppressing protein and RNA levels of Ras/MAPK-related genes

Anti-psoriasis potential

Psoriasis is a chronic autoimmune disease that is associated with systemic manifestation and characterized by keratinocytes and hyperproliferation mediated by T-cells [68–70]. It is an autoimmune disease with a genetic predisposition. In the psoriatic lesions presence of dendritic cells, cytokines and T lymphocytes has prompted the development of biologic therapies [71, 72].

Carbazole present in coal tar is an active antiangiogenic compound along with that antiangiogenic effect carbazole also withdraws the formation of inflammatory IL-15 by human mononuclear cells. It is believed that IL-15, which is increased in psoriasis, contributes to the inflammation of psoriasis [29, 73]. Moreover, carbazole treatment reduced the activity of nitric oxide synthase (iNOS) (a pro-inflammatory enzyme), which is elevated in psoriasis patients. In a study on human psoriasis, carbazole was found to inhibit the activator of stat 3-mediated transcription, which is relevant to psoriasis. iNOS, IL-15, and stat3 activation rely on the small GTPase Rac for optimum activity. As a mechanism for inhibiting downstream inflammatory and angiogenic pathways, carbazole inhibits Rac activation [74]. The mechanism of action of carbazole could involve the inhibition of pro-inflammatory cytokine synthesis, inhibition

of activator protein-1 (AP-1) activity, and inhibition of EGFR activation. Production of IL-15 by mononuclear cells is also inhibited by carbazole, a key cytokine in psoriasis [75–77] (Fig. 3).

Fig. 3 [Images not available. See PDF.]

Anti-psoriasis mechanism of carbazole derivatives. Carbazole present in coal tar inhibits the P38 signaling pathway by inactivation of Rac

Anti-Alzheimer potential

Generally, dementia is caused by Alzheimer's disease, the primary or cellular phase of Alzheimer's disease happens in parallel with accumulating amyloid β, inducing the spread of tau pathology [78]. Pathological characteristics in Alzheimer's disease (AD) are deposition of β-amyloid (Aβ) peptide and hyperphosphorylated tau in the brain, carbazole derivative (9c) *N*(6-(9*H*-carbazol-9-yl)-hexyl)-1benzylpiperidin-4-amine modulated AKT pathway and boosting protein phosphatase 2A activity in the brain. The compound 9c with (IC_{50} = 26.5 μM for AChE and IC_{50} = 0.18 μM for BuChE) results in the highest inhibitory activity against butyrylcholinesterase and acetylcholinesterase. Structure–activity relationship suggested that attachment to the 4-amino-*N*-benzylpiperidine fragment with C5 and C6 alkyl linkers in compound 9c results in the most potent compound among all [79].

Choubdar et al. designated several carbazole derivatives by using some heterocyclic nucleus like quinoline, pyridine, piperidine, benzyl piperidine, and benzyl piperazine, etc., in which compound 3s (9-(5-(quinoline-1 (2*H*)-yl)pentyl)-9*H*-carbazole) linked with quinoline found as the potent drug against BuChE and AChE and also showed the inhibitory activity for AChE induced β-amyloid (Aβ) aggregation. The most potent compound 3s with IC50 = 0.11 μM and 0.02 μM showed the best activity against AChE and BuChE, respectively. The presence of quinoline moiety in compound 3s more actively inhibited Aβ self-aggregation. Docking studies suggested that compound 3s binds effectively to the PAS and anionic binding site of the enzyme with the assistance of π stacking and hydrophobic interactions [80].

Carbazole derivatives regulating Ca2+/CaMKII/CREB signaling pathway. The brain contains CaMKII (Calcium/Calmodulin-dependent Protein Kinase II) which is a specific protein kinase of serine/threonine, which is regulated by Ca2+/calmodulin [81].

Shaikh et al. synthesized a series of α-amino phosphonate-based carbazole derivatives that were in silico and in vitro tested for their cholinesterase activity. All the compounds present better AchE activity [0.475–7.781 μM] than BuChE (3.306–21.32 μM). Against AChE as well as BuChE compound 4j [Diethyl(9-ethyl-9*H*-carbazol-3-yl)amino) (3nhydroxyphenyl)methyl)phosphonate] was the most potent derivative with IC_{50}¼0.475 ± 0.12 mM and IC50¼3.306 ± 0.21 μM, respectively [82] (Fig. 4).

Fig. 4 [Images not available. See PDF.]

Anti-Alzheimer mechanism of carbazole derivatives. AKT pathway regulation by carbazole derivative *N*-(6-(9-*H*-carbazol-9yl) hexyl)-1-benzylpiperidine-4-amine by boosting protein phosphatase activity in brain

Anti-inflammatory potential

Inflammation is a result of a complex biological response that includes inflammatory mediators, sensors, inflammation-inducing factors, and affected target tissues [83, 84]. Physical injuries, toxic chemicals, viruses, fungi, and bacteria are some harmful stimuli under inflammation-inducing factors. Pathogen-associated molecular patterns (PAMs) triggered the inflammatory response [85, 86]. Inflammatory pathways are mediated by some inflammatory mediators like cyclooxygenase (COX), chemokines, vasoactive amines nitric oxide (NO), etc. [87]. The inflammatory responses finally lead to symptoms like heat, pain, redness, and swelling, etc. [88, 89].

Bandgar et al. designated a novel series of carbazole(5a–o) which was tested against the anti-inflammatory activity. Compound 5c via hydrophobic interactions potently binds at the site of COX-II. The oxygen atom of the methoxy group on compound 5c formed two hydrogen bonds with the Asp B:225 and Nag C:671 and the nitrogen atom present in the pyrazoline ring on compound 5c formed two hydrogen bonds with the Leu A:131 [90].

Carbazole derivatives inhibit the lipopolysaccharide-induced inflammatory mediator production in macrophages via

suppression of p38 MAPK (mitogen-activated protein kinase signaling pathway). Carbazole derivatives inhibit the formation of TNF-*α* (tumor necrosis factor *α*), PGE_2 (prostaglandin E_2), and nitric oxide (NO) induced by Lipopolysaccharide (LPS) [91–93] (Fig. 5).

Fig. 5 [Images not available. See PDF.]

Anti-inflammatory mechanism of carbazole derivatives. 3-(3-(2-Methoxy-5-methylphenoxy)-4 5-dihydro-1*H* pyrazole-5yl)-9*H*-Carbazole inhibits the p38 MAPK signaling pathway by stopping the conversion of DAXX protein into ASK-1

Antidiabetic potential

Diabetes is a condition in which due to autoimmune destruction pancreatic β cells slow down the production of insulin results hyperglycemia due to excess availability of glucose [94–98]. α-glucosidase inhibitory activity of compound 7k (1-(5,6-di(furan-2-yl)-1,2,4-triazin-3-ylthio)-3-(3,6-dibromo-9*H*-carbazol-9-yl)propan-2-ol)was found most effective and the result revealed that compound7k is the potent compound with h IC_{50} values of 4.27 ± 0.07 μM among all the synthesized compound by Wang et al. The potent compound with high-density van der Waals contact binds at the bottom of the α-glucosidase pocket, whereas near the entrance of the pocket, furan ring was positioned which made only a few contacts. Detailed analysis showed that the carbazole ring of the potent compound formed arene-cation interactions with Arg-439 and Arg-312 residues, respectively. Furan ring of a potent compound located at the hydrophobic pocket, surrounded by Leu-176, Phe-177, Phe-157, and Pro-240 residues. All these interactions helped 7k to anchor in the binding site of α-glucosidase [99].

Carbazole derivative koenidine translocates the GLUT 4 which is mediated through the AKT-dependent signaling pathway (4) in L6-GLUT-4 myc myotubes [100].

The in vitro testing of separated carbazole alkaloids on uptake of glucose and translocation of GLUT 4 in L6-GLUT-4 myc myotubes was done on streptozotocin-induced diabetic rats for their activities. Therefore, the in vitro study of the koenidine suggested that koenidine, a carbazole derivative, possesses a promising antidiabetic activity through managing diabetes and insulin resistance [6, 101] (Fig. 6).

Fig. 6 [Images not available. See PDF.]

Antidiabetic mechanism of carbazole derivatives. Koenidine 4 translocates GLUT 4 for antidiabetic activity

Conclusion

Carbazole moiety itself is responsible for various types of pharmacological activities; due to high electron delocalization, carbazole shows better physicochemical properties. Derivatives having carbazole pharmacophore are responsible for various therapeutic activities like anti-Alzheimer, antioxidant, antidiabetic, anticancer, anticonvulsant, antimicrobial, and anti-inflammatory, etc., by specifically acting on potential molecular level proteins and factors such as RAS-MAPK, DAXX, ASK-1, AKT, and JNK, either by inhibiting or by activating them by de-phosphorylation or phosphorylation (Fig. 7). Due to all these important activities, the carbazole nucleus has attracted the attention of researchers in the discovery of other novel derivatives of carbazole.

Molecular mechanisms of carbazole derivatives for different pharmacological activities

Acknowledgements

Authors are thankful the Khwaja Moinuddin Chishti Language University, Lucknow, Uttar Pradesh, India, and Dr. Shakuntala Mishra National Rehabilitation University, Lucknow, Uttar Pradesh, India, for providing the necessary facilities to complete this manuscript.

Author contributions

AT has done various works on synthetic chemistry on carbazole derivatives and collected important information from her research and various literature for this review. BM has conceptualized the idea for this review, prepared the outlines and did the refinement of the paper.

Funding

Not applicable.

Availability of data and materials

Present article is a review article, and the authors have not used any material and data.

Declarations

Ethics approval and consent to participate

Not applicable.

Consent for publication

All the authors have read the manuscript and given their consent for publication.

Competing interests

The authors declare that they have no competing interests.

Green analytical chemistry-based spectrophotometric techniques for ternary component analysis of pain relievers

Arunagiri, Thirumalai1; Ganesan, Alagammai1; Ravi Kumaran, Vamsi1; Masilamani, Bharathraj1; Kannaiah, Kanaka Parvathi1 ; Narayanasamy, Damodharan11 SRM Institute of Science and Technology, Department of Pharmaceutical Quality Assurance, SRM College of Pharmacy, Kattankulathur, Chennai, India (GRID:grid.412742.6) (ISNI:0000 0004 0635 5080)

ABSTRACT (ENGLISH)

Background

The management of pain presents a significant challenge in healthcare, particularly in cases where conventional therapies prove inadequate. In response to this need, this study aims to devise two innovative UV spectrophotometric techniques rooted in the principles of green analytical chemistry for the analysis of Aceclofenac (ACE), Paracetamol (PAR), and Tramadol (TRM) in both bulk and tablet forms.

Results

Utilizing advanced mathematical methodologies such as the double divisor ratio spectra method and area under the curve, the concentrations of these drugs were accurately determined. Validation of the developed methods adhered to the guidelines outlined by the International Council for Harmonisation in the Q2 (R1), revealing linear calibration curves for ACE (8–12 µg/mL), PAR (22.75–35.75 µg/mL), and TRM (2.62–4.12 µg/mL). Furthermore, statistical analyses employing Student's *t* test and *F* test were conducted to ensure the robustness of the proposed method. The evaluation of environmental impact through green metric tools confirmed the eco-friendliness of the proposed methodologies.

Conclusion

The assessment performed utilizing green metric tools has substantiated the environmental sustainability of the

proposed approach. Thus, this methodology offers accurate and reliable outcomes for the determination of three drugs, as indicated by the complete overlap observed in the zero-order spectra.

FULL TEXT

Background

Pain is prevalent in today's society, serving both as a valuable warning to prevent harm and as an unwelcome aspect of our lives. Its impact on our quality of life is influenced by its intensity and duration. The opioid crisis has prompted discussions on pain treatment. While opioids are highly effective in suppressing pain signals, they also pose potential harm [1]. Nowadays treatment using a tri-drug therapy has shown a prominent effect over the treatment for pain management rather than using single and dual regimens due to the tolerance effect of the individuals. Among several combinations, two Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) and one opioid have shown effective treatment in the management of pain.

Paracetamol (PAR), chemically N-(4-hydroxyphenyl)acetamide [2] (Fig. 1a), acts as a centrally and peripherally acting non-opioid analgesic and antipyretic [3]. The mechanism of action involves inhibiting prostaglandin synthesis. This inhibition is achieved by targeting COX-1 and COX-2 in conditions with low levels of arachidonic acid and peroxides. Beyond treating headaches, muscular aches, arthritis, backaches, toothaches, and fevers, PAR is frequently used as an over-the-counter medication to alleviate pain and reduce fever. However, a PAR overdose may lead to severe side effects, such as fulminant liver necrosis [4].

Fig. 1 [Images not available. See PDF.]

Structure of **a** PAR, **b** ACE **c** TRM

Aceclofenac (ACE) is an orally administered NSAID, chemically known as 2-[2-[2-[(2,6-dichlorophenyl) amino] phenyl] acetyl] oxyacetic acid (Fig. 1b). It demonstrates a favorable tolerability profile and produces analgesic effects in various painful situations. ACE is employed in the treatment of rheumatic arthritis and soft-tissue injuries [5]. Its potent inhibitory impact on the cyclo-oxygenase (COX) enzyme disrupts the synthesis of prostaglandins, which are inflammation mediators responsible for heat, pain, edema, and inflammation [5–7].

Tramadol (TRM) is chemically (1R, 2R)-2-[(dimethyl amino) methyl]-1-(3-methoxy phenyl) cyclohexanol (Fig. 1c). It acts as an opioid agonist, effectively reducing pain without suppressing prostaglandins or inducing cardiovascular or respiratory depressive effects. Due to its complementary enantiomers, enhancing effectiveness and tolerance, it is utilized as the racemate [5]. The agonistic activity of (+)-tramadol and its main metabolite, (+)-O-desmethyl-tramadol (M1), on the μ opioid receptor (μOR), inhibiting serotonin and norepinephrine reuptake, synergizes to control pain perception and reaction [8]. TRM is efficacious for a broad spectrum of pain, ranging from moderate to severe, including pain during child birth [5].

Misuse of TRM raises concerns about overdose, opiate addiction, and physical dependence. Its connection to addiction in sports athletes is notable, as it is reportedly used in professional sports to endure discomfort and enhance performance, recognized even as a doping substance in cycling. Despite its hazards, TRM is frequently employed to treat injuries and alleviate perceived exertional pain and fatigue, particularly in cycling, as evidenced by the World Anti-Doping Agency (WADA) Monitoring Program [9]. Athletes, coaches, sports physicians, and pharmacists should familiarize themselves with WADA's 2024 Prohibited List, effective from January 1, 2024 [10].

TRM is commonly prescribed in combination with non-opioid analgesics like PAR for the treatment of moderate-to-severe pains. A fixed-dose combination of PAR, ACE, and TRM provides multimodal analgesic effects with an extended half-life and quick onset. Patients experiencing both chronic and moderate to severe pain are often prescribed and taken orally every 4–6 hr, with a maximum daily intake of 400 mg. The instructions were very clear on the label as the drug cannot be used for more than 5 days [11].

The goal of the current research is to develop an ecologically friendly strategy for analyzing this specific medication. Green chemistry, pioneered by Paul Anastas, aims to replace harmful solvents with less or non-toxic alternatives [12, 13]. Sample preparation and separation science in analytical chemistry often involve solvents, leading to the

development of the “3” approach—Reduction, Replacement, and Recycling. This has led to the redesign of instruments, the use of substitute solvents, and economic benefits in large-volume applications [14]. Additionally, environmentally friendly solvents meeting the US Environmental Protection Agency’s (EPA) criteria for reducing hazardous environmental consequences have fueled the growth of green analytical chemistry (GAC). This focus addresses environmental, social, and economic objectives, emphasizing pollution control, sustainable industrial ecology, pollution prevention, and environmental safety [12].

The combination of these three drugs forms a marketed formulation categorized as a Schedule H1 drug. While the literature search indicates the detection of these three drugs as single components or in combination with other medications using UV and other techniques [15–27], this novel medication lacks a valid pharmacopeia method but is purported to effectively reduce inflammation, swelling, and discomfort in conditions such as ankylosing spondylitis, osteoarthritis, and rheumatoid arthritis. It also aids in managing temporary discomfort, including toothache, ear, and throat pain, as well as muscular and back pain, by suppressing substances in the body that cause edema and pain [17].

This work aims to develop two simple UV spectrophotometric methods for estimating drugs in combination. The double divisor ratio spectra method (DDRSM) and area under the curve (AUC) are easy to understand, accurate, precise, and appropriate for regular QC analysis and identification in bulk and tablet pharmaceutical dosage forms.

Theoretical background

Method 1: double divisor ratio spectra method (DDRSM)

In this novel separation technique, spectra containing varying concentrations of mixture ABC are scanned separately, stored, and then subjected to mathematical operations involving standard spectra with double divisors B′ and C′ in case to separate and analyze A. Double divisor was prepared by the addition of standard spectra B′ and C′ which is divided by the mixture spectra. The resulting ratio spectra of A were further multiplied by using the same double divisor to obtain a zero-order spectrum of A which was further utilized for estimating the concentration of A in the ternary mixture; the overall process is illustrated in Eqs. 1–3.

The stored spectra are divided by the standard spectrum, which consists of double divisors such as A′ and C′, to find the concentration of B in the ternary mixture; it is prepared by the addition of standard spectra A′ and C′ which is divided by the mixture spectra yielding the ratio spectra of B, which were further multiplied by using the same double divisor to obtain a zero-order spectrum of B which were further utilized for estimating the concentration of B in the ternary mixture; the process is illustrated in Eqs. 4 and 5. Similarly, to determine the concentration of C in the ternary mixture, the spectra obtained from Eqs. 3 and 5 were combined and subtracted from the initial mixture spectra, as shown in Eqs. 6 and 7.

This approach, utilizing double divisors and ratio spectra, provides a method for analyzing and quantifying the individual components (A, B, and C) within the ternary mixture [28, 29]. The mathematical procedures involved in these calculations contribute to the accurate determination of each component’s concentration in the complex mixture

1

$$A+B+CB'+C'=AB'C'+BB'C'+CB'C'=AB'+C'+\text{constant}$$

2

$$=AB'+C'+\text{constant}-\text{constant}=AB'+C'\times B'+C'$$

3

$$=A$$

The same steps are used to find the standard spectrum of B, by using the double divisor A′+C′

4

$$A+B+CA'+C'=AA'+C'\times BA'+C'\times CA'+C'$$

5

$$=B$$

6

=A+B+C-A+B

7

=C

Method 2: area under the Curve (AUC)

In this method, the area under the curve (AUC) is calculated by determining the integrated absorbance value between two specified wavelengths, denoted as $\lambda 1$ and $\lambda 2$. These wavelengths serve as the starting and ending points of the curve region in the spectra. The AUC is then computed within the wavelength range of ± 20 nm, representing a specific study region. The concentration of each drug in the ternary mixture is determined solely based on its absorption characteristics within this integrated region. This method provides a straightforward approach for quantifying the amount of each drug in the mixture, relying on the cumulative absorbance values over the specified wavelength range [30]. The combination of these two methods will have an advantage over the HPLC methods because Method 1 helps in the separation of the mixture were as Method 2 helps in determining the concentration of the drug based on the area of the spectra.

Experimental

Apparatus

The JASCO UV–visible double monochromator model number V-730 is utilized, sealed, and quartz-coated with Czerny–Turner monochromator optics, providing a wavelength range of 190–900 nm. Its incredibly low stray light percentage (0.00008%) allows for precise measurements across the largest photometric range (up to 8AU). The apparatus also boasts a narrow spectral bandwidth of 0.1 nm and extended photometric linearity up to 8Abs, enabling the measurement of highly absorbing samples. The photomultiplier tube serves as the detector, and data output is facilitated using the software Spectra Manager™ version 2.5.

Materials and chemicals used

Therapeutic pharmaceutical products, namely PAR, ACE, and TRM, were acquired as gift samples from, Shree Icon laboratory, Vijayawada, India, by re-analyze the content of PAR, ACE, and TRM using an official method; the result was obtained as 99.5 ± 1.25. The same products were employed as working standards without any additional treatment. Hayman premium grade ethanol is used for diluent preparation.

Marketed formulation

The commercially available Zerodol-PT, with the batch number of JTZ013011AS containing 325 mg of PAR, 100 mg of ACE, 37.5 mg of TRM, and additional excipients in sufficient quantities, was obtained from the local pharmacy. This medicine is manufactured and marketed by IPCA Laboratories Limited.

Diluent preparation

For analysis, a diluent is prepared by adding 20 ml ethanol (Hayman premium grade ethanol) in distilled water to reach 100 ml.

Procedure

Standard solution

Standard stock solutions for spectrophotometric analyses were prepared by accurately weighing 10 mg of pure ACE, PAR, and TRM, individually, and dissolving each in a 10-mL standard volumetric flask. To achieve complete dissolution, the solutions were prepared up to the mark using a diluent after being sonicated for three to five minutes (Dilution 1). Further, 1 mL of ACE, 3.25 mL of PAR, and 0.375 mL of TRM were taken from the above solution and diluted with 10 ml in the standard volumetric flask were made accordingly to achieve the concentration of working standards to obtain 10, 32.5, and 3.75 + 6.25 µg/mL (standard addition), respectively. Furthermore, 6.25 µg/mL of known concentration of TRM was added because TRM concentration was very less [31–34] when compared to the other two drugs ACE and PAR which is difficult to interpret in the presence of other. So, to achieve a maximum concentration equal to ACE and PAR, a 6.25 µg/mL concentration was raised by standard addition to achieve a nearer concentration of ACE (10–3.25 µg/mL = 6.25 µg/mL) (Dilution 2). From Dilution 2, 1 ml of each solution was taken and made up to 10 mL of the diluent (Dilution 3); these solutions were then scanned in a UV–visible spectrophotometer within the wavelength range of 200–400 nm. For linearity 0.5, 0.75, 1, 1.25, and 1.5 mL of each

solution was taken from Dilution 2 in standard volumetric flask and was made up to mark with 10 mL diluent and these solutions were then scanned in a UV–visible spectrophotometer.

Preparation of sample solutions from marketed formulations

A total of 20 tablets from the marketed formulation were finely ground, and the powder equivalent to 100 mg, 325 mg, and 37.5 mg of ACE, PAR, and TRM, respectively, was accurately weighed. This drug was transferred into a 100 mL standard volumetric flask, and 6.25 mg of TRM was added as a standard addition technique to avoid the hindrance of the other two drugs in determining TRM. To the flask added a small amount of diluent and sonicated the mixture for approximately twenty minutes. Finally, the volume was made up to 100 mL using the diluent. The resulting solutions were further diluted to obtain final concentrations of 10, 32.5, and 3.75 + 6.25 µg/mL of ACE, PAR, and TRM, respectively, and were designated as sample solutions.

Results

After the preparation of the drug solution, UV scanning was conducted over the wavelength range of 200–400 nm. The spectra of all three drugs exhibited absorbance within the challenging range of 240–280 nm, as depicted in the zero-order spectrum (Fig. 2). To distinguish individual drugs within the ternary mixture, specific methods were applied to each D^0 spectra individually. This step is crucial for accurate identification and quantification of the individual components in the complex mixture. According to the reported method, the UV spectrophotometric methods can be divided into different windows as the methods selected in the determination of three drugs fall in Window 1 (W1), which utilizes zero-order absorption spectra, and Window 3 (W3), which is based on ratio spectra.

Fig. 2 [Images not available. See PDF.]

Overlay of three drugs of UV spectra, ACE (10 µg/mL)—red, PAR (32.5 µg/mL)—blue, and TRM (3.75 µg/mL)—green

Method 1: double divisor ratio spectra method (DDRSM)

Determination of ACE

In this method, the first step involves generation of double divisor by adding the standard spectra of PAR′ and TRM′ to obtain a PAR′ TRM′ followed by a constant generation, where the standard spectra of PAR and TRM are divided by the double divisor PAR′ TRM′. The resulting ternary mixture spectrum is divided by the double divisor to obtain a spectrum, which is then subtracted from the constant and subsequently multiplied by the double divisor PAR′ TRM′ to yield a D^0 spectra of ACE at a wavelength of 276 nm. The overall separation process of ACE from the ternary mixture with the help of spectrums is depicted in Fig. 3

Fig. 3 [Images not available. See PDF.]

The process of how the ACE (10 µg/mL) was separated from the ternary mixture

Determination *of PAR*

To determine the D^0 spectra of PAR, the double devisor was prepared by adding the standard spectra of ACE′ with TRM′ to yield ACE′ TRM′ and then constant is prepared by dividing the standard spectra of ACE and TRM by the double divisor (ACE′ TRM′). The mixture spectrum is then divided by the double divisor, subtracted from the constant, and multiplied by the double divisor to obtain a D^0 spectra of PAR at a wavelength of 247 nm. The overall separation process of ACE from the ternary mixture with the help of spectrums is depicted in Fig. 4.

Fig. 4 [Images not available. See PDF.]

The process of how the PAR (32.5 µg/mL) was separated from the ternary mixture

Determination of TRM

This is achieved using spectra manager software. The above-obtained spectra of ACE and PAR are added together which are subtracted from ternary mixture spectra to obtain D^0 spectra of TRM at a wavelength of 270 nm. The overall separation process of ACE from the ternary mixture with the help of spectrums is depicted in Fig. 5.

Fig. 5 [Images not available. See PDF.]

The process of how the TRM (3.75 µg/mL) was separated from the ternary mixture

Method 2: Area under the curve method (AUC)

Determination of ACE

AUC is calculated for the D^0 spectra obtained from the method 1 to determine the concentration of the separated spectra. This can be performed by selecting a wavelength range of approximately 205–225 nm for the D^0 spectra (Fig. 6a).

Fig. 6 [Images not available. See PDF.]

Area under the curve selection for the three drugs **a** ACE (10 µg/mL), **b** PAR (32.5 µg/mL), and **c** TRM (3.75 µg/mL) at different wavelength ranges

Determination of PAR

AUC is calculated by selecting a wavelength range of approximately 235–255 nm for the AUC spectra (Fig. 6b) which is obtained in the above method. Furthermore, the spectra were utilized to calculate the marketed formulation unknown concentration.

Determination of TRM

AUC is determined for the obtained TRM spectra by selecting a wavelength range of approximately 260–280 nm (Fig. 6c).

Method validation

In accordance with ICH recommendations Q2R1, the developed methods underwent thorough validation, and specific parameters were assessed, including linearity, limit of quantification, detection, accuracy, and precision [30, 35–37].

Precision

The ACE, PAR, and TRM weights were measured precisely. Six repetitions of the identical process were carried out to ensure method repeatability, accounting for both intra- and interday fluctuations. Analyzing the drug solution three times in a single day allowed for the determination of intraday precision. By examining solutions with the same concentrations on three distinct days in a week, interday precision is determined in Table 1.

Table 1. Results for ACE, PAR, and TRM in terms of accuracy and precision

Parameter	Double divisor ratio spectra method		Area under the curve			
ACE	PAR	TRM	ACE	PAR	TRM	*Precision*
Interday precision (mean ± SD)	99.64 ± 1.27	99.30 ± 0.95	99.47 ± 0.87	99.33 ± 0.76	99.10 ± 0.93	99.04 ± 1.09
Intraday precision (mean ± SD)	99.62 ± 1.26	99.45 ± 1.00	99.30 ± 0.85	98.87 ± 0.79	98.60 ± 0.87	98.69 ± 1.05
Accuracy (mean ± SD)	97.76 ± 1.32	98.50 ± 0.59	97.26 ± 1.28	97.71 ± 1.00	98.01 ± 0.53	97.92 ± 1.25

Accuracy

Applying the standard addition method to a medication sample containing known concentrations of ACE, PAR, and TRM standard drugs is equal to 50%, 100%, and 150% of the label claim allowed for the assessment of the method's accuracy. The experiment's results are listed in Table 1.

Stability

Working solutions of ACE, PAR, and TRM were stored in tightly sealed containers at approximately 4 °C for three weeks. Volumetric flasks containing these solutions were covered with aluminum foil to ensure protection.

Linearity

The method's linearity was determined by evaluating five different concentrations ranging from ACE (8–12 µg/mL), PAR (22.75–35.75 µg/mL), and TRM (2.62–4.12 µg/mL), respectively. The linearity spectra for each separated drugs are depicted in Fig. 7, and the results are depicted in Table 2. The detection limit (LOD) and quantification limit (LOQ) for ACE, PAR, and TRM were estimated using the calibration curve approach. LOD represents the smallest detectable amount of an analyte, while LOQ is the smallest quantifiable amount with appropriate precision and accuracy. The results are shown in Table 2.

Fig. 7 [Images not available. See PDF.]

Linearity spectra for the three drugs **a** ACE (8–12 µg/mL), **b** PAR (22.75–35.75 µg/mL), **c** TRM (2.62–4.12 µg/mL) at different concentration ranges

Table 2. Linearity data for the proposed method

Parameter	Double divisor ratio spectra method			Area under the curve		
ACE	PAR	TRM	ACE	PAR	TRM	Wavelength (nm)

0.013*x*–0.042	0.040*x*–0.049	0.062*x*–0.132	0.077*x*–0.226	0.042*x*–0.263	0.413*x*–0.883	Slope
0.013	0.04	0.062	0.077	0.042	0.413	R^2
0.999	0.998	0.999	0.999	0.998	0.999	LOD (µg/mL)
0.080	0.859	0.026	0.136	0.745	0.025	LOQ (µg/mL)
0.243	2.603	0.078	0.411	2.259	0.077	Linearity range (µg/mL)
8–12	22.75–35.75	2.62–4.12	8–12	22.75–35.75	2.62–4.12	%RSD

Assay of marketed formulation

The proposed spectrophotometric techniques were applied to analyze a commercially available tablet, Zerodol-PT. The mean drug content ranged from 99.5 ± 1.25. No interference peaks were observed in the spectra, indicating accurate approximation of the medication without considering excipients, and the results are depicted in Table 3.

Table 3. Assay of tablet formulation

Brand	Content	Amount present (µg/mL)	Amount added (µg/mL)	Double divisor ratio spectra method		Area under the curve	
Amt. founded (µg/mL)	Percentage recovered	Amt. founded (µg/mL)	Percentage recovered	Zerodol—PT	ACE		5
5.05	101	5.1	102	10	10	9.95	99.5
10	100		15	15.08	100.53	15.04	100.26

Statistical analysis

A statistical comparison between the proposed method and reported method [38] is suggested for ACE, PAR, and TRM analysis in pharmaceutical dosage form with respect to assay, and the results are depicted in Table 4. The calculated Student's *t* and *F* test with a null hypothesis (H_0) stating no difference observed between the values and an alternative hypothesis (H_a) stating the maximum difference between the values is observed. The values obtained were found to be less than the tabulated ones.

Table 4. Determination by Student *t* test and *F* test for the proposed method and reported method [38]

Reported method	Proposed method	*t* test	*F* test	*t* test critical value	*F* test critical value

DDRSM	AUC	DDRSM	AUC	DDRSM	AUC	97.26	99.45	100.75
0.318	0.95	0.128	0.502	4.303	19	100.49	99.71	99.86

Green assessment for the proposed method

The development of the method was rooted in adherence to the twelve principles of analytical green chemistry. Initially, the solvent selection was done based on the G score; it was found that ethanol has a G score of 6.6 which is near to water (7.3). To assert the eco-friendliness of an analytical approach, substantiation through assessment tools is imperative. In this case, two distinct assessment tools were employed for evaluating the developed method. The first, AES, underwent manual computation for its assessment. Conversely, the GAPI assessment utilized software termed the GAPI chart generator version 1.0 which was employed for crafting the GAPI chart, while AGREE metric calculations were conducted utilizing AGREE calculator version 0.5 beta. This comprehensive approach ensured a thorough evaluation of the method's environmental sustainability [39–44]

Green analytical procedure index (GAPI)

GAPI stands as a qualitative gauge utilized to appraise the ecological soundness of an analytical methodology. Operating as a semi-quantitative instrument, it employs pictorial depictions to gauge the environmental sustainability of analytical procedures. By integrating eco-friendly ethanol solvents into the methodology, a method was developed to symbolize a green emblem, highlighting its environmentally mindful characteristics. The GAPI assessment incorporates a color-coded representation of the GAPI value within the final pictogram, offering a visual indicator of its eco-friendliness. Comprising 15 discernible stages, the GAPI evaluation framework is meticulously structured within the GAPI software interface. The proposed method underwent a comprehensive assessment via the GAPI software, with the outcomes elucidated in Table 5 showcasing its environmental viability.

Table 5. Comparison of green metric tools between developed method and proposed methods

Author name	Instrument	Solvent	GAPI	AGREE	ECO SCALE	Refs.
P. Chouhan	RP-HPLC	Methanol: 0.5% Triethanolamine			6+1+1+3+3=14 100–14=86	[38]
Preeti Chandra et al.	HPLC	40: 60 (v/v); phosphate buffer (pH 6.0): methanol			6+1+3+5=15 100–15=85	[5]
V.V. Vaidya et al.	RP-HPLC	0.02M potassium dihydrogen orthophosphate buffer pH 3.0: acetonitrile in the ratio (40:60) v/v			6+1+3+3=13 100–13=87	[46]
Proposed method	UV–visible spectrophotometer	20% ethanol; 80% distilled water			6+0+0+0+0=6 100–6=94	

Analytical eco-scale (AES)

The AES assessment relies on the assignment of penalty points (PP) to chemicals involved. PP is derived through a graphical representation illustrating the chemicals employed in the process. It encompasses four primary evaluation stages, culminating in the AES computation formula: AES = 100—PP.

In the initial stage, ethanol is depicted with three pictograms, resulting in an overall PP of 3. Proceeding to the second stage, as the quantity of solvent or reagent utilized per sample is less than 10 mL, the PP is calculated as 3 × 2 (pictogram score), yielding 6.

Moving to the third stage, with the UV energy consumption per analysis falling below 0.1 kWh, the PP is set at 0. Subsequently, in the fourth stage, the method's waste of solvents, known to have environmental ramifications, is evaluated based on the employed wastage recycling approach, leading to a PP of 0.

Consequently, with the cumulative PP loss for the devised technique totaling 9, the resulting AES score for the developed method stands at 94.

Analytic GREEnness (AGREE)

AGREE metrics is an innovative tool crafted to gauge how environmentally friendly. It provides a detailed look at how these methods impact the environment. The results from AGREE are displayed as a circular graph split into 12 sections, each reflecting one of the twelve green analytical chemistry principles. Every section gets a score between 0 and 1, where 1 signifies the highest level of eco-friendliness. The average score appears at the center of the graph, and the closer it is to 1, the better it is for the environment. The software is designed to fully integrate the established methodology, ensuring that the outcomes reflect the most environmentally friendly approach possible. You can see a summary of the AGREE findings in Table 5. Application of the present method to the AGREE tool yielded a score of 0.91, indicating its strong alignment with GAC principles and highlighting its environmentally friendly analytical attributes.

The developed method underwent a thorough comparison with established HPLC techniques to evaluate its efficiency. The term "greenness" denotes not only the absence of efficiency drawbacks in the developed method but also its exceptional ecological safety profile. When scrutinized for environmental impact alongside other methods, the developed approach exhibited significantly higher greenness scores [45]. These findings, including the comparative analysis results, are detailed in Table 5.

*ACE and PAR dissolve readily in organic solvents and completely insoluble in water. Based on this aspect, any method which utilized water as a solvent to dissolve these drugs was not considered into account because it is practically not possible [47]. Pharmaceutical formulations typically use organic solvents such as ethanol, methanol, chloroform, and acetone to dissolve active ingredients. Both compounds are more soluble in organic solvents than in water; however, this might vary depending on the solvent and other conditions such as temperature [48].

Discussion

UV spectrophotometry, a widely employed and efficient analytical tool in both industry and academia, forms the basis of this study. The primary focus is on the Multicomponent Analytical Technique, showcasing its ease of transferability. To mitigate environmental and safety concerns associated with the typical solvent methanol, a 20% concentration of biodegradable and environmentally friendly ethanol in water is employed. This approach aims to reduce solvent consumption and enhance affordability for responsible consumption of the solvents which is an US SDG goal 12 [49]. Notably, all three medications demonstrated full solubility in the 20% ethanol solution without any issues.

The application of DDRSM facilitated the accurate determination of individual drug components within the mixture. By carefully manipulating the spectra and utilizing specific wavelengths, we isolated the D^0 spectra of each drug, enabling their quantification. Additionally, AUC provided another avenue for determining the concentration of separated spectra. By selecting appropriate wavelength ranges, we could accurately calculate the concentration of each drug component. One significant advantage of these methods is their ability to estimate overlapping spectra, particularly when utilizing environmentally friendly solvents. This ensures accurate analysis of the ternary mixture in tablet dosage form, contributing to both analytical efficiency and environmental responsibility.

In terms of method validation, precision results were found to be accurate for both the proposed methods at various time intervals. Research has demonstrated that the low percentage RSD value and recovered concentration work synergistically, with %RSD below 2%. There was no significant variation in the accuracy results between the drug's various concentrations, despite six determinations being conducted at each level. Stability studies over a period of three weeks revealed no spectrophotometric alterations in the drug solution. The linearity assessment of the proposed method demonstrates its ability to accurately measure concentrations of ACE, PAR, and TRM over their respective linear ranges. The high correlation coefficients (R^2 values close to 1) indicate excellent linearity between concentration and response for each drug. LOD and LOQ values indicate the method's sensitivity, with low values suggesting its capability to detect and quantify trace amounts of the analytes with good precision and accuracy. The %RSD values, representing the relative standard deviation, reflect the method's precision, with low %RSD values obtained indicating good repeatability and reproducibility of the method. Overall, the linearity results validate the suitability of the proposed method for accurate and precise quantification of ACE, PAR, and TRM in pharmaceutical formulations. Statistical comparison between the proposed methods shows no significant difference in terms of the assay, as evidenced by calculated student *t* and *F* tests with H_0 (no difference observed between the values) accepted. Furthermore, there was no discernible difference seen when comparing the dosage form analysis results using the reported methodologies, hence supporting the acceptance of H_0.

The results of the green assessment for the proposed method demonstrate its eco-friendliness and adherence to GAC principles. The utilization of ethanol solvents and the implementation of efficient waste recycling approaches contributed to the high scores obtained from GAPI, AES, and AGREE assessments. The developed method’s AES score of 94 indicates minimal environmental impact, further supported by its AGREE score of 0.91. These scores signify strong alignment with green analytical chemistry principles and highlight the method's environmentally friendly attributes. Comparative analysis with established HPLC techniques reaffirms the superiority of the proposed method in terms of greenness. The method not only offers efficient analytical performance but also ensures exceptional ecological safety, making it a promising choice for environmentally conscious analytical practices.

Conclusion

After dwelling on the above research, it becomes apparent that the proposed techniques are straightforward and uncomplicated to implement, requiring no specialized methods or tools. These analytical methods were very specific, exact, linear, accurate, and consistent in detecting ACE, PAR and TRM in tablet formulation. In contrast to the organic solvents typically utilized in UV spectroscopy, this approach is environmentally benign. UV–visible spectroscopy proves to be superior, cost-effective, and eco-friendly for determining the three medications. Ethanol serves as the solvent, and both methods have been validated according to ICH requirements, even with varying concentrations of the three drugs without pre-separation. The %RSD value, determined from the results and discussions, is less than 2%. Notably, this method poses no negative environmental impact, making it easily adaptable for the determination of ACE, PAR, and TRM medications. The method underwent additional evaluation utilizing environmentally conscious assessment techniques, yielding notably eco-friendly outcomes, particularly evident when employing ethanol and water as solvents. With negligible adverse environmental impacts, the energy demand for UV–visible spectroscopy instrumentation remains low. Its versatility extends to the analysis of ACE, PAR, and TRM, along with other drug compounds, owing to their solubility in ethanol and water. Consequently, this technique is highly adaptable and favored by pharmaceutical industries and quality control departments for routine research and sustainable development endeavors.

Targeting small druggable compounds against 3RZE histamine H1 receptor as potential of anti-allergic drug applying molecular modeling approach

Akram, Adeel1; Su, Chia-Hung1; Fu, Chun-Chong1 1 Ming Chi University of Technology, Department of Chemical Engineering, New Taipei City, Taiwan, Republic of China (GRID:grid.440372.6) (ISNI:0000 0004 1798 0973)

ABSTRACT (ENGLISH)

Background

Allergic disorders, prevalent global health concerns, afflict a substantial portion of the world's population. These maladies result from an exaggerated immune system response to ordinarily innocuous substances, such as pollen, dust mites, and specific dietary components. Clinical manifestations of this heightened immune response include itching, swelling, and respiratory impairment, often accompanied by releasing mediators like histamine. The pathophysiological mechanisms of allergy disorders are intricate, arising from a complex interplay between genetic and environmental factors. While clinical presentations may vary, all allergy conditions share a common foundation in the dysregulated immune response to allergens.

Result

The current aim of this study was to identify innovative anti-allergic agents capable of inhibiting histamine and effectively mitigating allergic reactions by utilizing the computer-aided drug design approach by discovery studio (DS) 2022 v 23.1.1 package. The overarching aim was identifying potential drug candidates targeting the active site within the histamine H1 receptor complex; therefore, a collection of 4000 small druggable compounds was curated from ZINC, PubChem, and DRUG BANK databases sources. Four compounds appeared as promising candidates after assessing docking scores and binding energies. Notably, Compound ID 34154, recognized as tymazoline, showed the highest affinity for the H1 receptor of 3RZE, suggesting it may be the most promising choice for more research. Further chemoinformatic and ADMET (absorption, distribution, metabolism, excretion, and toxicity) analyses were conducted to assess the drug-like qualities of this chosen molecule. In addition, bioisosteric substitution techniques were employed to enhance tymazoline's ADMET characteristics.

Conclusion

Tymazoline shows strong binding affinity with 3RZE and verified all the drug-likeness criteria to inhibit the allergic disorders. Furthermore, molecular dynamics (MD) studies corroborated tymazoline's potential as an anti-allergic agent, demonstrating contact between the ligand and the receptor that is well defined and stable.

FULL TEXT

Background

Allergic responses are an abnormal and overactive immune reaction triggered by exposure to allergenic substances can lead to tissue damage or dysfunction [1]. Critical actors in this process include IgE antibodies, mast cells, and cytokines, serving as mediators that coordinate immune cells and chemical signals crucial to the allergic response [2]. Estimates write down that these conditions affect 20–30% of the global population, with variations influenced by geographic location, age groups, and other factors, including genetic predisposition, environmental exposures, and changes in dietary and lifestyle choices [3]. Histamine is a significant mediator in localized allergic hypersensitivity reactions [4]. Besides, histamine receptors are found in four distinct types known as H1, H2, H3, and H4, which are

expressed differently on different cell types and regulate many physiological processes. The activation of H1 receptors causes vasodilation, increased vascular permeability, and bronchoconstriction, all defining characteristics of allergic reactions [5]. Allergic reactions are typically categorized into two primary types: one is IgE-mediate, and the other is non-IgE-mediate. The most frequent allergic reactions, known as IgE-mediate reactions, are brought on by the binding of allergen-specific IgE antibodies to basophils and mast cells. This causes the release of histamine and other inflammatory mediators, which lead to the manifestation of allergy symptoms [6, 7]. Current medications and treatments used to manage persistent allergies often show limited effectiveness [8, 9].

This study proposed the most significant anti-allergic small druggable compounds that have undergone comprehensive investigation for their ability to suppress receptor cells [10]. Small druggable compounds that function as druggable ligands hold significant promise for allergy treatment due to their multifaceted properties, which can neutralize allergens and other beneficial effects [11, 12]. A substantial proportion, approximately 60%, of anti-allergy medications trace their origins to these small druggable compounds because these small druggable compounds have mechanisms of alleviating the inflammatory or allergic responses triggered by allergenic substances [13].

To find the most promising drug molecule, four thousand small druggable compounds were collected in this study, which have characteristics related to suppressing the hypersensitivity from diverse databases (ZINC, PubChem, DRUG BANK) to find potential anti-allergic compounds. Molecular modeling investigations of these compounds were performed using the Computer-Aided Drug Design approach, employing the DS 2022 v 23.1.1 package. The molecular modeling study includes the molecular docking, drug assessment, and dynamics simulations of the histamine H1 receptor of PDB ID is 3RZE. Tymazoline, used as an antihistamine to help reduce swelling and inflammation [14], showed the most excellent affinity for the H1 receptor of 3RZE. The good affinity between tymazoline and the 3RZE H1 receptor implies that tymazoline would be the best inhibitor to suppress the allergic response [15]. Comprehensive analyses were performed to evaluate tymazoline’s drug-likeness, ADMET characteristics, and toxicity. A Molecular dynamics (MD) simulation was performed to confirm tymazoline’s anti-allergic potential against the histamine H1 receptor. Molecular dynamics simulation results were analyzed on the base of root mean square deviation (RMSD) and root mean square fluctuation (RMSF) that was kept at a standard value of 2.25 Å, and tymazoline made stable and satisfactory interaction with 3RZE. Tymazoline complex with 3RZE keeps RMSD lower than the standard value, which reveals a more vital acceptable interaction of complex while slight fluctuation of residues during root mean square fluctuation (RMSF), which confirms that the compound tymazoline gave more promising results than the reference co-crystal inhibitor compound. To our knowledge, tymazoline was first revealed to potentially have the function of an anti-allergic drug by inhibiting the 3RZE H1 receptor cell based on the in silico study.

Material

Bioactive compounds

Since the 3RZE H1 receptor is selected as the target protein and the binding site, 4000 small druggable compounds are collected from various databases (ZINC, PubChem, DRUG BANK) to find potential anti-allergic compounds. These anti-allergic compounds were investigated to check their inhibitory capabilities against the hydrolase enzyme associated with the histamine receptor, explicitly targeting the protein structure represented by PDB ID 3RZE.

Preparation of 3RZE H1 receptor structure

The histamine H1 receptor 3RZE complex’s three-dimensional structure with the ligand doxepin was obtained from Protein Data Bank (www.rcsb.org) and then downloaded file open into DS 2022 v 23.1.1 for further analysis. To enhance the accuracy and relevance of the structural information, computational procedures were applied, including energy minimization, 3D protonation, water molecule removal, and chiral gradient with a resolution of 0.05 Å [16]. By the DS 2022 v 23.1.1 package, the amino acid (THR 112, TYR 108, PHE 432, ILE 454, ASP 107, TRP 158, SER 111) in the 3RZE protein's active site was identified. Computational analyses were conducted using the DS 2022 v 23.1.1 package in an HP laptop 348 G7 with a 1.6 GHz frequency, up to 4.2.1 GHz with intel turbo technology, 8 GB RAM, and 250 GB hard disk.

Molecular docking

After the mentioned protein 3RZE and ligands were prepared by DS 2022 v 23.1.1, molecular docking is ready for processing. The compounds' 3D structures were created, and CHARMM (Chemistry at Harvard Molecular Mechanics) energy minimization was applied within DS 2022 v 23.1.1 using standard smart minimizer protocol [17]. The cleaning water content and energy minimization by CHARMM method within DS 2022 v 23.1.1 are necessary steps taken to prepare the protein molecules by following the standard protocol of smart minimizer in 2000 steps associated with gradient threshold 0.01 kcal/mol [18]. The binding cavity, or active sites, of the energy-minimized protein molecule was surrounded by a receptor grid. This was accomplished by locating important residues of amino acids. These amino acid residues were defined by the choice of the co-crystal ligand, or active inhibitor, linked to the corresponding protein molecule. This process helped to aid in the prediction of binding locations. For the protein structure appointed as 3RZE, the receptor grid boxes that were created were set up with a binding site sphere that had a radius of 2.90 Å and dimensions of 10.858743, 12.558267, and 85.699954 along the *x*, *y*, and *z* axes, respectively [19].

A standard protocol of CDOCKER in DS 2022 v 23.1.1, a molecular docking method based on CHARMM's position, provides highly exact docking results; it is used to find the precise position of drugs inside the active site of a target protein. Some default values, such as simulated annealing and forcefield for all docking and scoring-related parameters, were kept to efficiently generate the docked conformations for the compound of interest [20]. The prediction of binding affinities for the docked compounds was achieved [21]. Furthermore, the interaction types corresponding to the highest docked position were scrutinized in the context of the three-dimensional complex of ligand and receptor. Various non-bonding interplay, including hydrophobic and hydrogen bonding interactions, were assessed using two-dimensional diagrams depicting the receptor–ligand complexes. Each ligand was subjected to generating ten distinct poses within the active site of the receptor molecule, and those ligand molecules showing higher binding affinities were selected as potential drugs for further analysis and consideration.

Drug-likeness properties

Drug-likeness properties and drug-related factors were evaluated using theoretical methods in DS 2022 v 23.1.1. These drug-likeness characteristics included the LogP, molecular polar surface area, molecular weight, number of hydrogen bond donors, and number of hydrogen bond acceptors, all essential elements of Lipinski's rule of five (RO5) [22]. The number of rotatable bonds, aromatic rings, and other physicochemical characteristics were also estimated. The drug-likeness score was used to recognize and confirm the criteria for evaluating pharmaceutical compounds.

ADMET analysis

The ADME-toxicity parameters are figured out by ADMET descriptor tool within DS 2022 v 23.1.1. Distinct types of mathematical modules are used to determine the drug properties, which help to predict drug molecules' pharmacokinetics (pk) and ADMET characteristics. These models encompass plasma protein binding (PPB), cytochrome P450(CYP)2D6 inhibition, aqueous solubility, intestine solubility, blood–brain barrier (BBB), and hepatotoxicity. The mentioned six valuable indices insights into the compound's behavior about safety and pharmacokinetics within biological systems.

Toxicity assessment

Toxicity analysis is virtually assessed by the TOPKAT tool of the DS 2022 v 23.1.1. package. The following toxicity parameters computed to assess carcinogenicity and mutagenicity include rat female or male NTP(National toxicology program potential), mouse female or male FDA (Food and Drug Administration), rat female or male NTP, Ames test prediction, mouse female and male FDA, and rat oral LD50. These toxicity parameters provide valuable information on the compound's safety profile, particularly concerning its potential to cause cancer or mutagenic effects.

Molecular dynamics simulation

Since tymazoline exhibited the most favorable bonding with the H1R target molecule; therefore, it underwent further investigation for MD simulations by DS 2022 v 23.1.1. The target proteins' first crystal structures bound to co-crystal

inhibitors, as well as the complexes of 3RZE and tymazoline, were chosen for inclusion in the MD simulation. The necessary preparations, such as solvent environment using explicit periodic boundary conditions within an orthorhombic box filled with water molecules, were made to ensure the integrity and accuracy of protein and ligand complex by using standard protocol within DS 2022 v 23.1.1 [23]. CHARMM-based smart minimizer, which executes 2000 steps of steepest descent followed by conjugate gradient algorithm with RMSD gradient of 0.01 kcal/, was used to minimize the energy. The distance between the solute molecules and the box boundary was set to 5 Å to create a sufficient buffer zone, as well as 0.15 M sodium chloride was applied to the system during solvation to keep charge neutrality and physiological ion concentration. The stability of complex molecules associated with energy minimization was confirmed by default. MD simulation of ligand and receptor molecule complex was gradually started over a heating period of 10 picoseconds and equilibrated for 10 picoseconds at 300 K temperature using the standard dynamics cascade in DS 2022 v 23.1.1. The main molecular dynamics production run was conducted for 500 picoseconds in the NPT ensemble, and snapshots of the system were saved at regular intervals of 2 picoseconds throughout this process.

RMSD and RMSF

The root mean square deviation (RMSD) calculates the average distance between a molecule's atoms at various simulation time periods in relation to a ligand structure. To calculate RMSD during MD simulation, the initial structure of molecule coordinates is compared with the coordinates of ligand structure, and the distance between the atoms is calculated. RMSD is computed in DS 2022 v 23.1.1 by tool trajectory analysis, which indicates how much the molecule shows deviation from initial conformation during simulation periods.

The root mean square fluctuations (RMSF) calculate the individual atoms' fluctuation or flexibility throughout the course of a simulation in a molecule. The average deviation of each atom's position from its mean position during the simulation is used to calculate it. Which areas of the molecule are more flexible or rigid can be determined using RMSF. High RMSF values denote highly flexible areas, while low RMSF values point to more rigid or lowly flexible areas. After simulation, a trajectory analysis tool was used within DS 2022 v 23.1.1 to calculate the values [24].

Binding free energy calculation

The free binding energy of each protein–ligand complex was determined using the Binding Free Energy Single Trajectory Tool in DS 2022 v 23.1.1 after molecular dynamic simulation. The average binding free energy of each ligand complex is determined by calculating the binding free energy of all the produced conformations during the analysis.

Redocking of selected compound

Once the MD simulation was finished, tymazoline was chosen, and it was rocked with 3RZE to examine the stability of the ligand molecule, which showed signs of new hydrogen bonds and other hydrophobic interactions. In DS 2022 v 23.1.1, the CDOCKER default protocol was used. Additionally, all grid generation and docking analysis settings were left at their default values, as stated in the previously reported technique was used for docking analysis.

Results

Molecular docking analysis

Histamine receptor 3RZE underwent thorough validation procedures to ensure its suitability for later docking studies. Before the commencement of the docking experiments, a receptor grid model was generated, and binding site spheres were optimized to enhance the predictive accuracy of affinities between the ligand and receptor molecule, as the figure indicates the generation of the binding site/active site Sphere around the H1R protein molecule for protein–ligand docking.

All ligand compounds docked in DS 2022 v 23.1.1 by default, CDOCKER protocol, and total binding energies were calculated based on CDOCKER binding energy and ligand and receptor molecule interaction energy. After the docking process, four compounds out of 4000 were selected based on the docking score and interaction between the receptor and ligand molecules. Among four selected compounds, the compound tymazoline, known as PUB CHEM ID 34154, showed the most vital binding energy with the receptor, which is − 66 kcal/mol, and interaction energy of − 12 kcal/mol with the receptor active site, and the last compound is referred as reference compound as

shown in Table 1. In contrast, other ligand molecules show weak binding energies and positive interaction energies, which is incompatible with further analysis. Tymazoline was chosen as a potential candidate against receptor molecule 3RZE (Fig. 1).

Table 1. CDOCKER Binding energy and interaction energy of ligand molecules with H1R

Protein (3RZE) histamine receptor 1	Bioactive compound	CDOCKER binding energy(kcal/mol)	CDOCKER interaction energy(kcal/mol)
H1R	Tymazoline compound CID: 34154	−66.2616	−12.1047
H1R	Cyanidin compound CID:128861	−46.0177	−8.9929
H1R	Theogallin compound CID:442988	−43.2617	+4.26146
H1R	1-Propanamine, 3-dibenz(*b*,*e*)oxepin-11(6H)-ylidene-*N*,*N*-dimethyl-(Reference compound)	−32.8309	−2.04392

Fig. 1 [Images not available. See PDF.]

Receptor grid model of histamine receptor 1 (3RZE); the figure indicates the generation of binding site/active site sphere around the H1R protein molecule for protein–ligand docking

The interaction between the ligand and the residues of the receptor binding site that interacts with the ligand molecule was checked by a 2D interaction diagram. Hydrogen bonding and hydrophobic interactions, known as secondary interactions, displayed a well-defined pattern, displaying the compatibility between the ligand atom and residues of the receptor molecule. Some other interactions, such as hydrophobic bonds and non-bonded interactions, were also checked. Still, these interactions are less critical than hydrogen bonding interactions, as shown in Fig. 2.

Fig. 2 [Images not available. See PDF.]

Docking analysis of selected compound with protein 3RZE

The specific molecular interaction in the active site of the protein 3RZE with the tymazoline molecule is meticulously documented in the first row of Table 2. To mitigate the tymazoline toxicity, a series of modifications were performed through fragment-based design using a built-in function in DS 2022 v 23.1.1. This approach helps to increase drug molecules' alkaline properties and to decrease tymazoline's toxicity. Interactional changes and the position of interacting ligands within the binding site of receptor molecules were analyzed in 2D and 3D diagrams, as depicted in Fig. 3.

Fig. 3 [Images not available. See PDF.]

A 2D interaction of selected compound tymazoline interaction after fragment base implementation with H1R, **B** 3D structure represents the interaction of residues with H1R active site or hydrophobic cloud around the ligand molecule In particular, the square box colors in Fig. 3 delineate the specific interactions between individual residues and the

drug within the protein's active site.

Drug-likeness

To analyze the drug-like properties of the ligands that showed the highest docking scores for the target molecule, we employed RO5 (Lipinski's rule of five). According to RO5, the molecular weight of the ligands should be equal to or less than 500 Da, have less than ten hydrogen bond acceptors, less than five hydrogen bond donors and miLogP value should not exceed five. Tymazoline shows the same result as having two hydrogen bond acceptors and one hydrogen bond donor, 232.32 g/mol molecular weight, and miLogP value 2.39, as shown in Table 3. Consequently, it received a drug-likeness score of 0.55 according to RO5, which falls within the acceptable range of 0–1.

Table 3. Prediction of RO5 (Lipinski's rule five) of promising drug candidate tymazoline

Compound	MW g/mol	HBA	HBD	Mi Log Value	Lipinski's rule violation
Tymazoline	232.32	2	1	2.39	0

ADMET analysis

ADMET analysis and structural modifications were employed in DS 2022 v 23.1.1 to mitigate the potential toxicity of tymazoline, which exhibited notably poor blood–brain barrier permeability (BBB) and less aqueous solubility (AS), producing no central nervous system (CNS) toxicity. The cytochrome P450 2D6 (CYP 2D6) enzyme is pivotal in drug metabolism, which shows the positive effect of tymazoline and acts as an inhibitor. At the same time, predictive assessments revealed a considerable potential for hepatotoxicity associated with tymazoline, as shown in Table 4.

Table 4. Predicted ADMET properties of tymazoline AS (high), BBB4 (very low), HEPTOX (true, toxic), PPB (true, highly bounded), CYP P450 2D6 (yes, inhibitor)

Pharmacokinetics properties	Effect
AS	High
BBB	4
HEPTOX	True
IA	0
PPB	True
Log Kp	−6.01 cm/s
CYP1A2 inhibitor	No
CYP2C19 inhibitor	No
CYP2C9 inhibitor	No
CYP3A4 inhibitor	No

CYP P450 2D6	Yes

Furthermore, assessments of intestinal absorption (IA) indicated a favorable level, which is 0, ranging from good to better, and plasma protein binding studies unveiled high protein binding for tymazoline.

Toxicity prediction

Toxicity analysis elucidates that the target compound tymazoline demonstrated non-carcinogenic and non-mutagenic properties. The specific toxicity parameters computed for tymazoline include mouse female NTP non-carcinogenic or male NTP carcinogenic, mouse female or male FDA non-carcinogenic, rat female or male NTP non-carcinogenic, Ames prediction (test of mutation in DNA) non-mutagenic, and the Bayesian score (Bs) which represent the dosage activity is less than 1 in all the computed animal except mouse male NTP as shown in Table 5. In-depth analysis using diverse in silico models for non-ruminant animals substantiated their safety and non-toxic nature.

Table 5. TOPKAT toxicity data and Bayesian score of the selected compound tymazoline

Compound (tymazoline)	Effect	BS
Mouse male NTP	Carcinogen	0.68
Mouse female NTP	Non-carcinogen	−1.45
Rat male NTP	Non-carcinogen	−1.36
Rat female NTP	Non-carcinogen	−454
Mouse male FDA	Non-carcinogen	−2.59
Mouse female FDA	Non-carcinogen	−6.55
Rat male FDA	Non-carcinogen	−2.24
Rat female FDA	Non-carcinogen	−3.39
Ames prediction	Non-mutagen	−9.93

Molecular dynamics simulation

MD simulations were meticulously conducted for the compound showing the highest binding affinity, namely tymazoline, with the 3RZE. Simulation of the 3RZE complex was executed under solvated 0.145 NaCl salt concentration for 500 picoseconds by the standard dynamics cascade module integrated within the DS 2022 v 23.1.1. Subsequently, the trajectory of the simulated outcomes was subjected to an exhaustive analysis employing the DS 2022 v 23.1.1 tool, precisely the "Analyze Trajectory" function. Trajectory analysis primarily centered on assessing two critical parameters, focusing on RMSD and RMSF as crucial metrics to identify the stability of ligand molecules within the active site of 3RZE.

Root means square deviation

MD simulations were performed on the protein complexed with tymazoline alongside the reference molecule as co-crystal inhibitor doxepin inside the protein binding site to investigate alterations in protein dynamics and the compliance stability of ligand–protein complexes. During simulations, RMSD was used as a critical parameter to

gauge the conformational changes of ligands within the active site of the 3RZE complex, which showed initial oscillations in the beginning simulation. Also, free protein is supplied to check the comparison between the complex of ligand-bounded protein and reference ligand-bonded protein, while in the free state, it shows more fluctuation throughout time. Still, the stabilization phase in ligand-bonded protein was achieved after approximately 42 picoseconds, as shown in Fig. 4.

Fig. 4 [Images not available. See PDF.]

MD simulation indication of RMSD, the blue line represents the selected ligand bounded within H1R, gray line represents the protein H1R, and the orange line represents the reference ligand bonded within H1R

Subsequently, there was a progressive decrease in RMSD values as the simulation progressed, with only minor fluctuations seen toward the end. The protein complex bound with co-crystal inhibitors displayed a more substantial and persistent fluctuation throughout the simulation trajectory, which manifested higher RMSD values. In contrast, a lower RMSD value in the tymazoline with the 3RZE protein structure implies enhanced stability and satisfaction within the binding site of 3RZE than the co-crystal inhibitor.

Root means square fluctuation

Root means square fluctuation analysis was conducted by considering the backbone atoms of each amino acid residue, and the resulting RMSF plot was employed to visualize residue-level fluctuations. The RMSF plot for the tymazoline complex revealed a consistent pattern of stability within the binding site, with no significant impact on the overall protein flexibility observed throughout the simulation also free protein is supplied to check the stability of the complex molecules. While the in contrast to the reference inhibitor show more fluctuations during the simulation period, as shown in Fig. 5.

Fig. 5 [Images not available. See PDF.]

MD simulation indication of RMSF, the blue line represents the selected ligand bounded within H1R, the gray line represents the protein H1R, and the orange line represents the reference ligand determined within H1R

A notable observation is the heightened residue fluctuation within the loop region spanning from residues ILE148 to LYS191, shown in Fig. 5. Notably, the RMSF values for the protein complex with the ligand remained within the acceptable range (below 2.25 Å), indicating stability in this complex. Conversely, the residues binding the reference drug exhibited fluctuations exceeding the specified threshold.

Molecular dynamics studies reinforced tymazoline's potential as an anti-allergic agent, displaying stable interactions with the 3RZE. The findings suggest a promising avenue for developing novel anti-allergic drugs, with tymazoline warranting further exploration and clinical investigation. Future outcomes may include refining tymazoline's properties, potential synthesis of derivatives, and eventual translation into effective therapeutic interventions for allergic disorders.

Binding free energy calculation

After the completion of the MD simulation, the binding free energy of each ligand complex molecule was calculated for all the generated conformations. The binding free energy is shown in Fig. 6, in which the blue line represents the tymazoline complex molecule's binding energy is − 240059 kcal/mol, the gray line represents the free protein binding free energy is − 264847 kcal/mol while the orange line represents the binding free energy of reference molecule is − 292443 kcal/mol. This shows that the ligand tymazoline complex molecule binding free energy is thermodynamically stable or near to the free protein total binding energy as compared to the reference molecule complex which shows huge gap of energy.

Fig. 6 [Images not available. See PDF.]

Binding free energy calculation of ligand complexes, the blue line represents the ligand-bonded protein, the gray line represents the free protein 3RZE, and the orange line represents the reference-bonded protein

Redocking of selected compound

The detailed intermolecular interactions after redocking the tymazoline with 3RZE active are shown in Fig. 7. We can identify that three hydrogen bonds (LYS179, THR194, ASN198), five hydrophobic bonds(ALA 195, LYS191, SER111, ASP107, TYR108) and some alkyl interactions (PHE435, TRP103, PHE432, TYR431) were found which involve in the stability of tymazoline in active site of protein to make it more stable, which indicate it as promising candidate to consider it as anti-allergic drug.

Fig. 7 [Images not available. See PDF.]

2D interaction diagram of tymazoline with H1R intermolecular interactions, the green dotted line represents the H-bonds, light green dotted lines represent hydrophobic interactions, while pink dotted line represents the alkyl interaction between the tymazoline and H1R(3RZE)

Discussion

Histamine, a pivotal mediator in histamine receptor production (H1R), is crucial in allergic responses. This study leveraged the crystal structure of H1R with the co-crystal inhibitor molecule to identify an inhibitor for allergic reactions. This study aimed to conduct an in silico analysis of small druggable compounds to find an optimal molecule inhibiting histamine for treating allergic symptoms. Docking studies involved 4000 small compounds against the 3RZE histamine receptor 1 protein, with tymazoline selected as the final drug compound based on the least CDOCKER docking and interaction energies. Druggable characteristics of tymazoline were further confirmed through drug analysis, including the Rule of 5 (RO5), ADMET, and MD simulation.

Docking studies revealed that tymazoline binds to TYR 108, ASN 198, and THR 112 amino acid residues with the least binding energies compared to others. MD simulation of 500 ps on the 3RZE-tymazoline complex, alongside the reference co-crystal inhibitor, demonstrated strong and stable confirmations in their interactions. Trajectory analysis based on RMSD and RMSF indexes indicated that the docked complex-maintained stability, with slight fluctuations in RMSD at 42 ps, remaining below 2.4 Å thereafter. In contrast, the co-crystal inhibitor fluctuated from the start, indicating poorer stability than tymazoline. RMSF interpretation suggested normal residue fluctuation for tymazoline compared to the reference molecule. Molecular dynamics studies reinforced tymazoline's potential as an anti-allergic agent, displaying stable interactions with 3RZE. Following MD simulation, the redocking of tymazoline with 3RZE and the computation of binding energy revealed that tymazoline interacted more with the 3RZE active site or formed a more thermodynamically stable complex than the reference molecule.

From our work, we could confirm that Drug assessment of tymazoline, including RO5, showed no violations, and ADMET analysis confirmed its inhibition against H1R without carcinogenicity and mutagenicity effects. The less energy complex indicated greater stability, suggesting improved drug efficacy by binding to the protein for an extended duration. These findings propose a promising avenue for developing novel anti-allergic drugs, with tymazoline warranting further exploration and clinical investigation. Future efforts may involve refining tymazoline's properties, potential synthesis of derivatives, and eventual translation into effective clinical applications.

Conclusion

Allergic mediator 3RZE receptor with a library of 4000 small druggable compounds was investigated by molecular modeling studies, including molecular docking, drug-likeness, ADMET, toxicity assessment, and molecular dynamic simulation studies. Among the library of small druggable compounds, tymazoline was selected, which showed binding solid affinities against the 3RZE regarding CDOCKER interaction energy and binding energy. Tymazoline exhibited satisfactory in silico drug-likeness, ADMET, and toxicity properties. Tymazoline did not violate any RO5 rule, and the drug-likeness score of the compound was within an acceptable range. MD simulation further confirms the anti-allergic potential of the compound tymazoline with the formation of well-defined and stable receptor–ligand interaction. Furthermore, the compound tymazoline exhibited superior scoring values compared to the reference co-crystal inhibitor and maintained standard RMSD values below 2.25 Å throughout the simulation, which confirms that tymazoline is a promising candidate for anti-allergic reactions. These findings underscore the potential of tymazoline as a favorable drug candidate for the targeted medicaments of allergic diseases, demonstrating its good molecular properties, stability, and adherence to established drug development guidelines.

A simple method for the determination of acyclovir concentrations in human plasma using high-

performance liquid chromatography

Aboelezz, Asma1; Kharouba, Maged1; Mahmoud, Sherif Hanafy1 1 University of Alberta, Faculty of Pharmacy and Pharmaceutical Sciences, College of Health Sciences, 2-142G Katz Group Centre for Pharmacy and Health Research, Edmonton, Canada (GRID:grid.17089.37)

ABSTRACT (ENGLISH)

Background

Acyclovir is an anti-viral medication given to treat herpes simplex and herpes zoster infection. In some severe conditions such as herpes encephalitis, acyclovir is administered intravenously. However, high acyclovir doses may cause acute kidney injury and low acyclovir dose may predispose the patient to inadequate exposure to acyclovir which could be fatal in some conditions. In such cases, the acyclovir plasma concentrations will potentially guide the diagnosis and management of the kidney injury. In this study, we provide a simple and time-efficient method for analyzing acyclovir in human plasma using high-performance liquid chromatography (HPLC).

Results

The process starts with a single protein precipitation step by adding acetonitrile to deproteinize 300 µL of plasma. The chromatographic separation conditions consist of a mobile phase of water: methanol (97:3, *v/v*), a flow rate of 1 mL/min, a run time of 17 min, and a detection wavelength of 254 nm. The calibration curve was linear over the range of (0.70–60 mg/L) ($r^2 > 0.99$). The retention times of acyclovir and the internal standard were around 15 and 12 min, respectively. The intra-day and inter-day analysis of acyclovir in plasma using this method exhibited accuracy and precision of less than 7%, which lies within the acceptable range. Different greenness assessment tools confirmed that the proposed method is eco-friendly.

Conclusion

The proposed method of analysis of acyclovir in the plasma using HPLC is simple, green and accurate method. This method could be applied in clinical settings where monitoring acyclovir concentrations is essential as it has wide range of the concentrations that could be detected.

FULL TEXT

Background

Acyclovir (9-[2-hydroxyethoxymethyl]-9H-guanine) (Fig. 1) is a synthetic nucleoside analog that has an anti-viral activity against herpes simplex and varicella zoster virus [1]. Patients with severe infections such as herpes encephalitis may require careful monitoring of the plasma acyclovir level. High acyclovir concentrations could predispose the patient to acyclovir nephrotoxicity and neurotoxicity. On the other hand, low acyclovir concentration that is below the 50% inhibitory concentration (0.56 mg/L for herpes simplex virus and 1.125 mg/L for varicella zoster virus) could lead to treatment failure and worsen the patient's condition [2–4].

Fig. 1 [Images not available. See PDF.]

Acyclovir chemical structure

Acyclovir follows a two-compartment model with first-order elimination kinetics [5]. The primary elimination pathway for acyclovir is through the renal route, making it significantly influenced by kidney function [6]. Impaired kidney function could result in acyclovir accumulation in the body and the development of either nephrotoxicity, neurotoxicity, or both, while enhanced kidney function could lead to subtherapeutic concentrations of acyclovir and subsequently treatment failure [7, 8].

The most common reported methods for the detection of acyclovir in the plasma were high-performance liquid chromatography (HPLC) and liquid chromatography–mass spectrometry (LC–MS) [9–12]. Most of these methods

used a mobile phase with very low acidic pH [13, 14], which by time could degrade the stationary phase of the column.

Green analytical chemistry (GAC) is an area of activity that ensures that the analytical practices are environmentally friendly [15]. The assessment of greenness is crucial to ensure that analytical methods produce the least threats to the environment [16]. There are different developed tools to assess the greenness of the analytical methods such as analytical method GREEnness score (AMGS) [17], analytical eco-scale [18], and analytical GREEnness (AGREE) [19].

This method aimed to develop a simple, sensitive, and time-efficient method for analyzing acyclovir in plasma. The advantages of our method over the previously developed method are that it utilizes a single protein denaturation step, does not include buffers for the preparation of the mobile phase and it provides higher range of concentrations that could detect acyclovir toxicity. The development of buffer-free HPLC method offers a greener, more efficient, and more versatile approach to chemical analysis which protects the column for a longer time and avoids time-consuming cleaning process and waste generated. Furthermore, the absence of buffers allows for a simplified and more cost-effective analytical process. To our knowledge, this is the first acyclovir analysis method using the HPLC that used the greenness assessment tools to ensure that the method is environmentally friendly.

Methods

Reagents and chemicals

Acyclovir with a purity of (95.8% ± 0.9) and the internal standard (IS) ganciclovir with a purity of (99.3% ± 0.2) were obtained from Sigma-Aldrich (Oakville, ON, Canada). HPLC-grade acetonitrile, water, and methanol were purchased from Fisher Scientific (Edmonton, AB, Canada). Drug-free human plasma was acquired from Cedarlane Laboratories (Burlington, ON, Canada).

Instruments

HPLC–UV system (Shimadzu, Kyoto, Japan) was used to perform the analysis. It consisted of a system controller (SCL-10Avp), an autosampler (SIL-HTC), two pumps (LC-10 AD), and a UV–vis detector (SPD-10AV). The chromatographic separation was achieved by using a C18 reverse phase Supleco Discovery® C18 column (5 µm, 250 × 4.6 mm) (Supleco Inc., Mississauga, ON, Canada) protected by a Discovery® C18 Supelguard™ guard column (5 µm, 20 × 4 mm) (Supleco Inc., Mississauga, ON, Canada). Clarity® software version 8.7 (DataApex, Prague, The Czech Republic) was utilized for data collection and analysis.

Chromatographic conditions

The chromatographic separation was conducted through isocratic elution of a mobile phase mixture consisting of water and methanol (97:3, *v/v*). The flow rate was maintained at 1 mL/min for a total run time of 17 min for elution, and the detection wavelength was set at 254 nm. All the steps were conducted at room temperature.

System suitability

The system suitability was tested through the calculation of the tailing factor (symmetry factor), resolution, capacity factor and the height of theoretical plate (HETP) of five replicates. The results were compared with the guidelines to ensure that the chromatographic condition in optimal conditions, and the method is suitable for its intended purpose.

Preparation of stock and working solutions

Acyclovir and ganciclovir were dissolved in HPLC-grade water to prepare stock solutions of 400 mg/L and 500 mg/L, respectively. Working solutions of 50 mg/L and 100 mg/L of acyclovir as well as 100 mg/L ganciclovir were prepared by further diluting the stock solutions. All solutions were prepared fresh daily.

Preparation of calibration concentrations and quality control samples

Serial dilutions of acyclovir in blank human plasma were prepared to obtain the calibration concentrations of (0.7, 2, 5, 15, 25, 60 mg/L) of acyclovir. Four quality control (QC) concentrations were prepared for the method validation. The quality control samples were the lower limit of quantification (LLOQ, 0.7 mg/L), low-level QC (2 mg/L), middle-level QC (25 mg/L), and high-level QC (45 mg/L).

Sample preparation

Sixty µL of 100 mg/L IS were added to 300 µL of blank plasma spiked with acyclovir and vortex mixed for 30 s.

Then, 2 mL of acetonitrile were added to the prepared plasma spiked with acyclovir and ganciclovir and vortex mixed for 1 min for the purpose of the plasma proteins denaturation. Then, the prepared samples were centrifuged (Eppendorf centrifuge 5804, Eppendorf SE, Barkhausenweg, Hamburg, Germany) at 5000 rpm for 20 min. The obtained supernatant was then transferred to clean tubes and concentrated using SpeedVac® Vacuum Concentrator (Thermo Fisher Scientific, Waltham, MA, USA). Reconstitution was performed by the addition of 200 µL of the mobile phase (water: methanol, 97:3, *v/v*) and vortex mixed for 15 s. A volume of 50 µL of the prepared samples was injected into the HPLC for the chromatographic separation.

Method validation

The validation was done following the Guideline on bioanalytical method validation guidelines developed by the European Medicines Agency (EMA, 2011) [20]. The method validation included linearity, selectivity and sensitivity, precision and accuracy, carry-over, stability, and recovery.

Linearity

The linearity of the method was determined by plotting the calibration curves of the peak height ratios (acyclovir /ganciclovir) vs. the calibration concentrations. Linear regression was performed to obtain the slope, intercept, and coefficient of determination (r^2) of the calibration curve.

Selectivity and sensitivity

The selectivity of the developed method was assured by the absence of any plasma peaks interfering with acyclovir and ganciclovir peaks when comparing chromatograms obtained from blank plasma with those obtained from acyclovir-containing samples. The sensitivity was determined in terms of the LLOQ, in which its response must be at least 5 times higher than the plasma response.

Precision and accuracy

The intra-day and inter-day precision and accuracy of the developed method were tested by injecting five replicates of each of the four QC samples mentioned earlier on three consecutive days. The method's precision was presented as the coefficient of variation (CV, %), and the accuracy was expressed as a percentage error.

Carry-over

Carry-over was assessed by injecting drug-free plasma after the injection of the upper limit of quantification (60 mg/L). Based on the EMA guidelines, the blank plasma response must not exceed ± 20% of acyclovir LLOQ response and 5% of the internal standard response.

Stability

The stability of the method was assessed in either plasma spiked with acyclovir or final prepared samples for HPLC injection (e.g., concentrated and reconstituted) over two weeks of three replicates of two QC samples (2 and 55 mg/L). The stability of the plasma spiked with acyclovir was determined at the preparation time and after three hours and 24 h at room temperature. Furthermore, the stability after 1 and 2 weeks stored at 4–8, − 20, and – 80 °C was also assessed. Moreover, the stability of the final prepared samples was examined over one week and stored at room temperature (autosampler), 4–8, − 20, and − 80 °C. Also, the freeze and thaw stability of acyclovir in plasma was assessed by initially freezing the three replicates of the two QC samples at − 80 °C for 24 h followed by thawing them at room temperature. This cycle was repeated for three days before preparing the samples to be injected into the HPLC. In addition, the stability of stock and working solutions kept in the fridge were tested after 2 months by preparing a working solution from the stock solution stored at 2-8° C and comparing the results of samples prepared from these working solutions.

Recovery

The average extraction recovery of acyclovir was measured by injecting three replicates of three QC samples (5, 15, 25 mg/L) and comparing their chromatographic peaks with those of plasma samples spiked with equivalent concentrations of acyclovir after protein precipitation and sample concentration.

Assessment of greenness

The eco-friendliness of the proposed method was tested using different greenness assessment tools. Three were used to evaluate the greenness which are analytical method GREEnness score (AMGS) [17], analytical eco-scale

[18], and analytical GREEnness (AGREE) [19].

Results

Method development

Preliminary experiments were done to optimize the chromatographic conditions of acyclovir analysis. Various solvents and different compositions were tested to obtain the optimum mobile phase composition to run the analysis. Different compositions of acetonitrile and water as well as different compositions of methanol and water were tested as mobile phases, and it was found that the composition of 97% water and 3% methanol gave the best chromatograms of acyclovir samples. The selected mobile phase composition resulted in increasing the retention time compared to more methanol percentage in the mobile phase. Nevertheless, it had the advantages of better peak separation, decreasing the cost of the analysis and reducing the environmental impact of methanol. Moreover, different wavelengths over the range of 200–800 nm were tested to select the wavelength that provides maximum acyclovir UV absorbance and less plasma absorbance which was found to be 254 nm. The effect of different flow rates was studied, and a flow rate of 1 mL/min was chosen for the method. Using flow rates of more than 1 mL/min resulted in increasing the pressure, while using flow rate of less than 1 mL/min resulted in increasing the retention time and hence the run time. Furthermore, acetonitrile and methanol were tested as protein precipitation solvents, and acetonitrile gave better results. The retention times of acyclovir and ganciclovir using the optimum conditions were around 15 and 12 min, respectively. The ratios of the peak heights of acyclovir to ganciclovir were used in all the calculations as they gave more accurate results than the peak area ratios. Although column temperature affects the resolution of the samples, it was not used to make the study applicable to different systems, and the measurements were all in the room temperature.

System suitability

The results of the system suitability (Table 1) were obtained and compared to the reference ranges. All of the obtained values are within the acceptable ranges.

Table 1. System suitability parameters of the proposed method

Parameter	Obtained value	Reference value [21, 22]
Resolution (R_s)	2.03	≥2
Tailing factor (T)	1.35	0.8–1.8
Height of theoretical plate (HETP)	0.0018	The smaller the value, the better the system suitability
Capacity Factor	3.2	>2

Method validation

Linearity

The calibration curves of the plasma samples of acyclovir were done to test the linearity of the developed method. The peak height ratios of acyclovir to ganciclovir showed linearity over the range of 0.7–60 mg/L with r^2>0.99 (Fig. 2).

Fig. 2 [Images not available. See PDF.]

Calibration curve of peak height ratios of acyclovir to the internal standard versus acyclovir concentrations

Selectivity and sensitivity

There were no interfering plasma peaks with the acyclovir or the ganciclovir as shown in Fig. 3. The lower limit of quantification of acyclovir that gives accurate and precise results was 0.70 mg/L.

Fig. 3 [Images not available. See PDF.]

Different chromatograms of **a** Blank plasma; **b** Plasma containing internal standard (20 mg/L)-retention time 12.1 min; **c** Plasma containing acyclovir (25 mg/L) and internal standard (20 mg/L) retention times 15 and 12.2 min, respectively

Precision and accuracy

To assess the intra-day and inter-day precision and accuracy, we prepared five replicates of four quality control samples and analyzed their concentrations in three different days. The method is precise and accurate as shown in Table 2. The intra-day coefficient of variation was less than 2.2%, and the percentage of error was less than 7%. On the other hand, the inter-day coefficient of variation was less than 4.6%, and the percentage of error was less than 6%.

Table 2. Intra-day and inter-day precision and accuracy

Concentration(mg/L) ($n=5$)	Observed concentration(mg/L) (mean ± S.D)	CV%	Error percentage
Intra-day precision and accuracy			
0.7	0.73 ± 0.01	1.30	− 3.67
2	2.07 ± 0.04	1.96	− 3.57
25	24.67 ± 0.20	0.34	1.36
45	41.87 ± 0.90	2.15	6.96
Inter-day precision and accuracy			
0.7	0.74 ± 0.06	7.38	− 5.99
2	2.07 ± 0.04	1.90	− 3.42
25	25.40 ± 1.16	4.57	− 1.61
45	43.86 ± 1.92	4.37	2.54

S.D standard deviation; *CV*% Coefficient of variation (percentage)

Carry-over

There were no peaks appearing in the blank plasma chromatogram after injecting the upper limit of quantification either in the retention time of acyclovir or ganciclovir. This indicates that there were no carry-over effects of high acyclovir concentrations.

Stability

Plasma samples spiked with acyclovir were stable for 2 weeks at different temperatures. Also, the finally prepared samples for injection showed stability for one week stored at different temperatures. Acyclovir showed stability after three freeze and thaw cycles. All the % remaining of the acyclovir in samples compared with the initial samples (zero time) ranges from 88 to 113% (Table 3) which lies within ± 15% indicating the stability of acyclovir samples. Moreover, the stock and working solutions were stable for 2 months.

Table 3. Stability of acyclovir in plasma and in the finally prepared samples for HPLC injection

Concentration (mg/L) (*n*=3)	Time (storage temperature)	Mean concentration(mg/L)± S.D	% Remaining

S.D standard deviation; % remaining, percentage of drug remaining compared to the initial concentrations

Recovery

The mean percentages recovery of the three QC of 5, 15, 25 mg/L ($n=3$) concentrations is in Table 4. It ranged from 88 to 90%.

Table 4. Mean percent recovery of acyclovir

Concentration (mg/L) ($n=3$)	Recovery %, mean ± S.D	CV%
5	88.40 ± 5.68	6.43
15	90.22 ± 1.07	1.18
25	88.43 ± 4.74	5.36

S.D standard deviation; *CV*%, Coefficient of variation (percentage)

Assessment of greenness

The web application version of the AGREE tool provided the result based on the 12 criteria of green analytical chemistry. The score was 0.64 which indicates that the method is green. The AMGS score, which calculates the instrument energy score, solvent energy score and solvent EHS score were 216.34 which also indicates the greenness of the method. The analytical eco-scale resulted in a score of (100-16) = 84 of which means that the

method is green.

Discussion

Acyclovir is the anti-viral nucleoside analog drug used for the treatment of herpes infections. Acyclovir is given intravenously to patients suffering from herpes encephalitis at a dose of 10 mg/kg/dose every 8 h [23]. High concentrations of acyclovir in plasma above 25 mg/L could highly predispose the patient to nephrotoxicity and neurotoxicity [24]. This paper describes a simple, rapid, accurate, and precise method for the quantifying of acyclovir in human plasma.

This method utilizes a small volume of the plasma 0.3 mL compared to other methods which use larger volumes (0.5–1 mL) [9, 13, 14, 25]. The run time was 17 min which could aid in the analysis of large numbers of samples in a short time. The wavelength that showed the best chromatograms was 254 nm after scanning the UV range (200–800 nm). Although the mobile phase composition was 97% water and 3% methanol which resulted in increasing the retention time compared to more methanol percentage in the mobile phase, it has the advantages of better peak separation, decreasing the cost of the analysis and reducing the environmental impact of methanol. The mobile phase used to elute acyclovir did not contain buffers, which provides the advantages of the simplicity of the method and protection of the column without affecting the results' selectivity and sensitivity.

The greenness of the developed method was assessed using different tools. The AGREE tool was first developed in 2020 by Pena-Pereira, et al. [19]. It involves the 12 concepts of green analytical chemistry in its evaluation [15]. The analytical eco-scale is also an interesting tool to assess if the method is environmentally safe, and it has a score of hundred and good results expected to be >75 [18]. Analytical method GREEnness score (AMGS) is a semi-quantitative user-friendly tool to evaluate the greenness of the analytical methods [17]. The proposed study is determined as green and environmentally safe based on the results obtained from this tool. This was the first acyclovir HPLC analysis study that evaluated the greenness of the proposed method.

It has the advantage of a single protein precipitation step which also reinforces the uncomplicatedness of the developed method compared to other methods [14]. Moreover, the stability of the developed method was assessed, and acyclovir showed stability in stock and working solutions kept for two months in the fridge. In addition, it showed stability in the plasma over two weeks and finally prepared samples over one week in different storage conditions. The validation of the developed method showed precision and accuracy results within the acceptable range (± 15%) as reported by the EMA guidelines [20].

The linearity range of the method (0.70–60 mg/L) covers a wider range than previous study, including high acyclovir concentrations, which are known to be associated with potential adverse effects [14, 26, 27]. Acyclovir levels in herpes encephalitis should be maintained above the 50% inhibitory concentration which is 0.56 mg/L for herpes simplex virus and 1.125 mg/L for varicella zoster virus. On the other hand, high acyclovir concentrations above 25 mg/L could cause acyclovir adverse effects [2, 4, 28]. These concentrations could be readily measured in patients experiencing adverse effects, such as acute kidney failure, neurotoxicity, or worsening symptoms, using this method.

Conclusion

This article represents a quantitative method that is fully validated based on the EMA guidelines for the analysis of acyclovir in the plasma. It has a linearity range of (0.7–60 mg/L) which make it applicable in the clinical practice. The method has undergone evaluation for its eco-friendliness using diverse green assessment tools, positioning it as a novel method of acyclovir detection in the plasma assigned to be green. The developed method is simple and utilizes a single protein precipitation step and excludes the use of the buffered mobile phase. Overall, it is a rapid, selective, accurate, and precise method that could be used widely in clinical settings.

ABSTRACT (ENGLISH)

Background

Hepatic cancer endures a major health scourge as the consequence of a high incidence of >1 million cases by 2025. Plant-based products are typically effective in ameliorating health conditions. Pomegranate peel extract (PE) with its high polyphenolic content has anticancer effects against different types of cancer. Herein, we aimed to maximize the

PE chemotherapeutic efficacy by loading it in a suitable delivery system to overcome the limitations of PE, to control its release and to achieve liver targeting.

Method

A nanoprecipitation procedure was adopted to incorporate PE into biodegradable and biocompatible natural polymeric zein (ZN)-based nanoparticles (NPs) (PE-ZN NPs). A full factorial design ($2^2 \times 3^1$) was developed to study the effects of the formulation variables, namely pH of dispersion, PE-to-ZN ratio and surfactant concentration.

Results

The optimization revealed a surfactant-free stable PE-ZN NPs formula with a small particle size of 99.5 ± 6.43 nm, high PE encapsulation efficiency % of 99.31% ± 3.64 (w/w) and controlled release of PE over 24 h.

Conclusion

Moreover, the cytotoxicity of the optimum formula against hepatic cancer HepG2 cell lines was assessed and attained about a 2.5-fold reduction in the inhibitory concentration (IC_{50}) values compared to the free PE affording a promising green platform to combat hepatic cancer.

FULL TEXT

Background

Cancer is considered one of the main causes of mortality worldwide as a consequence of millions of new reported cases yearly. Hepatic cancer is the sixth most common cancer globally, ranking the fifth in men and the ninth most commonly occurring cancer in women [16]. The prognosis for hepatic cancer is poor, and there are many challenges for its cure. Liver resection and liver transplantation are the best options of cure for only 5–15% of early-stage patients; however, the high postoperative recurrence and the severe shortage of organ donors limit this option. In more advanced stages patients, chemotherapy is the only available treatment option; however, the traditional cytotoxic drugs affect both cancer and normal cells causing numerous side effects, including gastrointestinal tract ulcers, bone marrow depression, nausea, and hair loss [8]. As a result, neither current ablation therapies nor chemotherapy is appreciably effective in improving outcomes of this devastating disease. Considerable attention is needed for better therapy alternatives for hepatic cancer patients. A European study showed that prevention, development, progression, and treatment of cancers is associated with the diet of patients and a higher dietary intake of fruits and vegetables is associated with a lower risk of cancer development [7, 33]. There is always an increase in researchers' interest and efforts to identify new anticancer treatments with a scope of less toxic, more potent, more selective, and hence a more effective approach than other traditional ones [25].

Nature has been the best source of drugs since ancient ages; natural products are highly considered for their anticancer properties that do not only protect against cellular damage and disease but also have vital roles in the treatment of many diseases such as cancer [4, 17]. As a result of the aforementioned facts, it became necessary to explore natural and plant-based products as a good substitute for chemotherapeutics to overwhelm the major adverse effects of chemotherapeutics, in addition to exhibiting improvements in therapeutic indices.

Punica granatum L. plant (Pomegranate) has been known for its nutritional values, medicinal properties and anticancer activities. Pomegranate parts such as peel, bark, root, and flower encompass various active phytochemicals. Among these parts, the pomegranate peel corresponds to around 50% of the fruit weight which is abundant in high molecular weight polyphenols including flavonoids, ellagic acids, gallotannins and ellagitannins (ETs) [50, 55]. ETs are the most bioactive components in pomegranates. Punicalagin (PU) is considered the most valuable and abundant ET in pomegranates [48]. The anticancer activity of pomegranate can be exerted in a chemo-preventive and/or chemotherapeutic approach. This activity is accountable for its anti-inflammatory, anti-invasive, anti-proliferative and pro-apoptotic activities in different types of cell lines such as skin, breast, prostate, colon and lung cancers [9]. Moreover, Bishayee et al. highlighted the remarkable chemo-preventive effect of PE against liver cancer using a chemical-induced and clinically relevant two-stage rat liver carcinogenesis model and ascribed this activity to the potent antioxidant and anticancer effects of PE extract [14].

Despite these promising characteristics and the intense therapeutic potency of PE extract, its poor solubility, instability and consequently its low bioavailability may hinder its applications. Nanotechnology has the unraveling

ability to shield the PE extract inside the nanoparticles' (NPs) matrix and accordingly prevent additional degradation, and augment the bioavailability [13], in addition to its radical impact in achieving size-dependent passive targeting to specific organs relying on the enhanced permeability and retention (EPR) concept. To achieve this purpose, the particle size of NPs should be controlled to avoid the recognition by the reticuloendothelial system (RES) and to attain an efficient biodistribution pattern [34].

The employment of natural polymers for NPs preparation facilitates the accomplishment of safe dosage forms with low toxicity, high biocompatibility and biodegradability [26]. Many natural polymers such as collagen, zein and chitosan were extensively studied in previous research works [39]. Zein (ZN), a vegetable protein, is auspicious for the preparation of NPs due to its distinctive properties, including biocompatibility, biodegradability and reproducibility [45]. Its structure promotes the encapsulation of different bioactive compounds with hydrophobic, hydrophilic and amphiphilic characteristics, in addition to its desirable slow digestibility that imparts the formed NPs with long stability in the gastrointestinal tract before being degraded. In this regard, NPs that formed from zein have the suitability and ability to control the release of the encapsulated bioactive and to improve its bioavailability [5].

Hence, our aim is to incorporate PE peel extract into the natural biodegradable and biocompatible ZN NPs to provide an amenable green platform with a surfactant-free strategy able to deliver PE extract and ameliorate its activity against hepatic cancer. Utilization of such controlled system not only would result in augmenting the activity of PE but also would aid in the efficient liver targeting potential by the passive delivery in the future applications. The design and optimization were done using a $2^2 \times 3^1$ full factorial design to study the effect of the different variables on PE-ZN NPs characteristics. The physical properties of the developed NPs and the in vitro PE release from the NPs were investigated. Moreover, the ex vivo permeation of the PE-ZN NPs was examined as a prediction of the bioavailability of the investigated formula for the oral administration. Besides, the anti-proliferative activity (MTT assay) of the optimized formulation was studied in HepG-2 cancer cell lines in comparison with free PE.

Materials and methods

Materials

Pomegranate was purchased from Cairo Farms (Cairo, Egypt). Zein protein was generously obtained by FLO CHEMICAL CORPORATION (Wisconsin, USA) as a kind gift. Methanol was purchased from Sigma-Aldrich (St. Louis, USA). All other used chemicals were of analytical grade.

Cells

Human liver (HepG2) cells (VACSERA Company, Egypt) were cultured in Dulbecco's modified Eagle's medium (Invitrogen, CA, USA) including 10% fetal bovine serum (Gibco, NY, USA), 100 U/mL penicillin, and 100 µg/mL streptomycin at 5% CO_2 atmosphere and temperature of 37 °C.

Preparation of pomegranate peel extract

Pomegranate fruits were cleaned up and washed with tap water; then dried and peeled. The peels were separated from the rind and cut into small pieces then dried at 50 °C in a drying oven (Heraeus, Germany) to dryness. The dried peels were ground to coarse powder of approximately 1 mm size. To prepare PE extract, 100 gm of ground pomegranate peel was soaked in 500 mL methanol and subjected to regular mixing for 6 h; followed by maceration for 48 h at 37 °C with intermittent shaking. The extraction procedure was repeated three times to extract the maximum components from the pomegranate peel. Subsequently, the pooled extracts were filtered on Whatman No.1, UK filter paper. The filtrate was concentrated under vacuum using a rotary evaporator (Heidolph, Germany) at 50 °C to obtain 25 ml (mL). The concentrated extract was stored in a refrigerator at 4 °C [38, 40, 43].

Preliminary screening of surfactants

Surfactants of different hydrophilic-lipophilic balance (HLB), as shown in Fig. 1, were examined to investigate their effects on the PE encapsulation and the physical characteristics of the formed PE-ZN NPs. An amount of 50 mg of the surfactant was sonicated in 5 mL ethanolic dispersion of ZN in case of lipophilic surfactants (HLB<7). For hydrophilic surfactants (HLB>7), they were stirred in 10 mL preheated distilled water until complete dissolution with a magnetic stirrer (Stuart US150, USA). The PE-ZN NPs were prepared by the nanoprecipitation technique reported by [34]. Homogeneity of the formed dispersion and PE encapsulation efficiency were the two screening criteria for

selecting the surfactant.

Fig. 1 [Images not available. See PDF.]

Screened surfactants in the preliminary studies arranged according to their HLB

Quality target product profile (QTPP) and critical quality attributes (CQA)

As a prospective strategy to achieve the aim of the study effectively, a quality target product profile has been determined and is summarized in Fig. 2 with the desired quality attributes that will guarantee the achievement of the appropriate formula. The main target is to develop a green and safe dosage form against hepatic target. The employment of natural extract and natural polymer will be examined. The necessity of use of surfactant will be examined. The appropriate method of preparation that will yield the desired particle size for liver targeting and the adequate encapsulation efficiency with a controlled release, augmented ex vivo permeability and optimum activity will be studied. In addition the critical quality attributes that have a substantial role such as method of preparation, residual methanol, particle size, encapsulation efficiency, zeta potential, ex vivo permeability and in vitro cytotoxicity have been determined and justified as demonstrated in Fig. 2.

Fig. 2 [Images not available. See PDF.]

Quality target product profile (QTPP) and critical quality attributes (CQA)

Factorial design

A $2^2 \times 3^1$ full factorial design was implemented to determine the effects of the selected variables using Minitab® 16.1.0 (Minitab Inc., USA). The three variables were: the dispersion pH (X1), PE: ZN ratio (w/w) (X2), and the surfactant concentration (mg/mL) (X3) using the selected surfactant from the preliminary study. The analysis of variance (ANOVA) was used to estimate the significant effects of the selected variables on the following responses; PE encapsulation efficiency (Y1), particle size (Y2), polydispersity index (PDI) (Y3) and zeta potential (Y4) of the PE-ZN NPs.

Preparation and characterization of PE-loaded ZN NPs

Preparation of PE-loaded ZN NPs

The nanoprecipitation procedure was utilized to prepare PE-ZN NPs; the steps are summarized in Fig. 3 with an asterisk on the critical process parameters (CPP). Separately, amounts of ZN and span 40 according to Table 1 were dissolved in 70% v/v ethanolic aqueous solution (5 mL) and PE extract was dissolved in methanol. After that, the two solutions were mixed and added drop wisely into a pH-adjusted aqueous phase (10 mL) (with either 0.1 N HCl or 0.1 N NaOH) under stirring with a magnetic stirrer (AccuPlate™ Analog Hot Plate Stirrer, UK) at room temperature and 2000 rpm for 1 h until the evaporation of alcoholic solvents.

Fig. 3 [Images not available. See PDF.]

Flowchart of preparation and characterization of PE ZN NPs

Table 1. Full factorial design independent and dependent variables and their levels

Independent variables	Levels		
−1	0	1	X1: pH
2	7	9	X2: PE: ZN ratio (% W/W)

0.2		0.6	X3: Conc. of surfactant (mg/mL)

Dependent variable	Constraints
Y1: encapsulation efficiency	Maximize
Y2: particle size	Minimize
Y3: PDI	Minimize
Y4: zeta potential	Maximize

Characterization of PE-loaded ZN NPs

Differential scanning calorimetry (DSC)

A differential scanning calorimeter (Setline DSC+, Setaram, Switzerland) was utilized to scan the prospective physical incompatibilities between PE and the polymer or the surfactant in the dispersion. PE, physical mixtures of (PE and ZN) and (PE and the selected surfactant) were weighed in 30 µL Al-crucibles and measured in a range of 25–300 °C with heating rate of 10 °C/min. under nitrogen atmosphere [37].

Fourier transform infrared (FTIR) spectroscopy

FTIR spectrophotometer (IR Affinity-1, Shimadzu, Japan) was used to evaluate the possible chemical interaction between PE and the polymer or the surfactant in the dispersion. Potassium bromide was physically mixed with the freeze-dried (Lyovapor L-200, Buchi, Switzerland) PE in addition to the physical mixture of ((PE and ZN) and (PE and the selected surfactant). Then a hydraulic pressing machine was used to compress these mixtures into thin discs. After that, the spectra were performed in the wavelength range from 400 to 4000 cm^{-1} [32].

Particle size (PS), polydispersity index (PDI) and Zeta potential (ZP)

The average particle size accompanied by the polydispersity index (PDI) and zeta potential were evaluated by Zetasizer (Malvern Instruments Ltd, Malvern, UK). Samples were appropriately diluted with deionized water and all values were reported as the mean value ± standard deviation (SD) of three different measurements [1].

Encapsulation efficiency

The centrifugation method was used to separate the free drug from PE-ZN NPs; the prepared dispersion of PE-ZN NPs was centrifuged at 10,000 rpm for 1 h at 4 °C using cooling microfuge (Remi CM-12 Plus, Remi laboratory instruments, India). Then, the supernatant was diluted with methanol and measured spectrophotometrically at the wavelength of maximum absorbance (λmax) 265 nm using an ultraviolet–visible spectrophotometer (V-630, Jasco, Tokyo, Japan) in correspondence to a calibration curve of PE in methanol ($n=3$; $R^2=0.999$). PE encapsulation efficiency (EE%) was calculated by the following equation [9, 11]:

1

PEencapsulationefficiency=InitialamountofPE-amountoffreePE×100InitialamountofPE

Determination of residual solvents (methanol)

Testing should be performed for residual solvents when production or purification processes are known to result in the presence of such solvents. As methanol (Class 2 Solvent) was used in the extraction of bioactive compounds from pomegranate peels, therefore the residual methanol was tested in the PE extract and the final optimum formula. The USP<467>protocol for determination of class 1 and class 2 residual solvents was utilized.

Morphological examination by transmission electron microscope (TEM)

The morphology of the optimum NP formula was studied by TEM (JEM-2100, Japan). Each sample was negatively stained with phosphotungstic acid; the excess stain was removed by filter paper and then left to be air dried for

15 min. Consequently, a drop of the stained NPs was placed on a 200-mesh carbon-coated copper grid and the microscope was operated at an acceleration voltage of 200 kV [10].

In vitro drug release

The dialysis membrane method was used to determine the PE release from the selected formulation and was compared to that of the free PE. Initially, the dialysis bags (MW cutoff of 12,000–14,000 Da) (Spectrum Medica, CA, USA) were soaked overnight in phosphate buffer solution (PBS) pH 7.4. The experiment was carried out using the USP dissolution (Hanson Research Corporation, CA, USA), apparatus II (paddle), at 37 °C, 100 rpm, and in 100 mL PBS pH 7.4 as a dissolution medium [9, 34]. A volume of 2 mL of the formula containing an amount of PE equivalent to 20 mg was placed in the dialysis bag and 2 mL aliquots were taken at predetermined time intervals and restored with fresh buffer to retain the sink condition. The same experiment was followed, but in this case 20 mg free PE/2 mL dissolution medium was placed in the dialysis membrane. A preliminary study was done to ensure that the above conditions provide a sink medium for PE at this dose level. PE concentration in the samples was assessed spectrophotometrically at 265 nm in correspondence to a calibration curve of PE in PBS pH 7.4 ($n=3$; $R^2=0.999$).

Determination of release kinetics

To determine the release of PE extract from the optimized NP preparation, (zero order, first order and Higuchi) mathematical kinetic models have been employed for the in vitro drug release results. The coefficients of determination (R^2) results of the three models for the optimum preparation were calculated [28].

Ex vivo permeability study

Ex vivo permeability of the investigated formula was done to investigate the permeability parameters of pure free PE extract and optimized PE-ZN NPs (Z12) formulation. Small intestines of rabbits that were allowed to fast overnight were used. The duodenal parts were isolated and their contents were removed by flushing with normal saline. Subsequently, they were divided into segment sacs of 5 cm and a volume of 2 mL of the optimum formula containing an amount of PE equivalent to 20 mg was placed in each sac which their ends were tied carefully with sutures [36]. The same was done for free PE and blank ZN NPs (free from PE) to act as a blank. A USP dissolution with amber mini-vessels (Hanson Research Corporation, CA, USA), was used and each sac was tied onto apparatus II (paddle), at 37 °C, 75 rpm, and in 100 mL PBS pH 7.4 as a dissolution medium. Samples of 1 mL were withdrawn at time intervals of (0.5, 1, 2, 3, 4, 6, 8, 10 and 24 h) and replaced with an equivalent amount of the fresh buffer solution. The samples were assayed spectrophotometrically at 265 nm [52] with a calibration curve of PE in PBS pH 7.4 ($n=3$; $R^2=0.998$), and the experiment was repeated in triplicate.

In vitro cytotoxicity study

The cytotoxic effect of both the optimized PE-ZN NPs formula and the free PE on HepG2 cancer cell lines (ATCC® HB-8065™) was studied. Samples of free PE and optimized formulae were diluted on pre-cultured cell lines for 48 h treatment at 37 °C post-decanting growth medium. Treated cell lines were microscopically examined for detection of morphological changes and detached cells. Dead cells were washed-out using phosphate buffer saline (PBS), pH 7.2 ± 0.2 (with 0.05% Tween 20). Residual live cells were treated with 0.5% MTT stain as 25 µL/well. Plates were incubated for 3–4 h at 37 °C. Developed intra-cytoplasmic MTT formazan crystals were dissolved using 0.05 mL DMSO for 30 min on a plate shaker. Optical densities (OD) were read using an ELISA plate reader (Anthos-Elisa-reader 2001, Labtec, Heerhugowaard, Netherlands). The 50% inhibitory concentration (IC_{50}) of both the PE extract and the optimized PE-ZN NPs formula were determined using the Master–plex-2010 program (Hitachi Software Engineering America, Ltd). Data were recorded for three independent experiments. The viability percentage was calculated as follows [6, 54]:

2

$$\text{Cellviability percentage} = \text{OD of treated cells} / \text{OD of untreated cells} \times 100.$$

Results

Preliminary screening of surfactants

The screened surfactants were subjected initially to physical inspection. Only formulations prepared with Tween® 40, Cremophor® RH 40, and Span® 40 displayed homogeneous dispersions, while those formulated with other

surfactants showed precipitates. Afterward, the homogenous formulations were exposed to another screening step of estimation of the PE encapsulation efficiency. As shown in Fig. 1 Span® 40 formula revealed a remarkably higher PE encapsulation efficiency of 70.3% ± 2.3 in comparison with 45.7% ± 1.9 for Cremophor® RH 40 formula and 37.5% ± 3.8 in case of Tween® 40. This may be attributed to that zein is a polymer having three-fourths lipophilic and one-fourth hydrophilic amino acids residues, thus acting as a water barrier, and helping in attaining higher encapsulation efficiency values of PE in NPs, especially those including Span® 40. That verifies that there is a reversible relationship between the PE encapsulation and the HLB values of the used surfactant during ZN NPs formation Therefore, Span 40 was selected to be utilized in further studies [12, 23].

Characterization of PE-loaded ZN NPs

Differential scanning calorimetry (DSC)

As shown in Fig. 4 and supplemental Fig. 1A, B and C, the DSC thermogram of the PE showed a sharp endothermic peak at a temperature of 142.791 °C that can be related to the melting point of polyphenols present in PE [56]. The physical mixture of PE: ZN thermogram had the same peak with a slight shift to 146.047 °C with no other peaks for ZN similar to that reported in previous study [45]. It is worth noting that the mixture with polymers could enhance the thermal stability of PE resulting in this slight higher melting temperature [30]. On the other hand, it is depicted from the thermogram of the physical mixture of PE: Span® 40 the appearance of two endothermic peaks at 56.394 °C and 115.666 °C. The first endothermic peak could be attributed to the melting point of Span® 40 as reported in literature [47]. The another peak could be assigned to the melting of PE and this shift to lower temperature can be justified to the result of the partial dissolution of PE in the physical mixture of PE and Span® 40 when the latter is heated [42].

Fig. 4 [Images not available. See PDF.]

DSC thermograms of PE and the physical mixtures of PE with ZN and span 40

Fourier transform infrared (FTIR) spectroscopy

The FTIR spectra of the freeze-dried PE and the two physical mixtures of PE with ZN and Span 40 as shown in Fig. 5 revealed the wide band recorded at 3346 cm^{-1} corresponding to the stretching vibration of N–H and O–H groups and the peaks between 1046 to 1800 cm^{-1} belonged to the aromatic and aliphatic functional groups of the polyphenolic content of PE including CH, C=O, –C=C–C=O, –C=C– and –C–C–. The investigated spectra showed an insignificant shift in the peaks of PE in the physical mixtures relative to the peaks in the spectrum of the pure extract, indicating the absence of any interactions between PE and the other used excipients. The reduction of the peak intensity of PE in the physical mixture may be due to the dilution effect of the mixing process [51]. Therefore, PE and all the used excipients are compatible to be used collectively.

Fig. 5 [Images not available. See PDF.]

Fourier transform infrared spectra of freeze-dried PE and the physical mixtures of PE with ZN and span 40, respectively

Particle size (PS), polydispersity index (PDI) and Zeta potential (ZP)

The average particle size (PS) values of the obtained PE-ZN NPs ranged from 99.5 ± 6.43 nm (Z12) to 1335.0 ± 1.31 nm (Z4) as shown in Table 2 and supplemental Fig. 5. The ANOVA analysis showed a significant effect of the 2 variables (X1; pH and X2; surfactant concentration) (*p*-values of 0.015 and 0.023, respectively) on the PS, while PE: ZN ratio showed a non-significant effect (*p*-value > 0.05). PS was noticed to be high at the pH of the dispersion near the isoelectric point (PI) of ZN which might be attributed to the aggregation of the colloidal dispersion when the pH gets close to the PI of ZN polymer. Accordingly, the PS was shown to be reduced apart from PI at both pH 2 and pH 9 as shown in Fig. 6A. The incorporation of a surfactant led to an increase in PS. This was ascribed to the fact that surfactants with high and low HLB values are not able to be adsorbed on hydrophobic surfaces of drug particles which led to the aggregation of these particles to agglomerate rapidly increasing the particle size [46]. The PDI values of the obtained PE-ZN NPs alternated from 0.096 to 0.869, indicating a narrow size distribution, since all values were less than 1. The concentration of the surfactant (X3) showed a significant effect on PDI (*p*-value < 0.05).

Formulations free of surfactants showed more homogenous distribution than those containing a surfactant. On the contrary, the other two factors (PE: ZN ratio and pH) showed a non-significant effect on PDI. In the present study, the zeta potential of PE-ZN NPs showed a relatively high zeta potential except Z1 which showed the lowest zeta potential (−8.8±0.7) as shown in Table 2. This may be attributed to the PS observed of Z1 (973.1±89.2 nm) where the attraction between particles may exceed the electrostatic repulsive forces, so the zeta potential decreased and the PS increased [31]. Zeta potential at pH lower than ZN PI (pH 6.8) exhibited a positive charge. However, at PI, the dispersion showed a zeta potential of negative value in the presence of nonionic surfactant (Span® 40). It was stated that at a neutral pH, many nonionic surfactants granted a negative charge on the NPs as a result of the differential adsorption of the produced ions (H_3O^+ and OH^-) on their surfaces [2, 31]. On the other side, Podaralla and Peruma indicated that at high alkaline pH, a very high variation in the zeta potential of the ZN NPs is expected. This variation was observed in formulations prepared at pH 9 [44].

Table 2. Preparations and characterization of PE-ZN NPs

#	pH	PM: ZN (% W/W)	Surfactant (mg/mL)	EE (%)	PS (nm)	PDI	ZP (mV)
Z1	7	0.6	50	64.46±1.23	973.1±9.61	0.869±0.001	−8.8±0.7
Z2	7	0.6	0	80.84±3.56	206.7±7.80	0.129±0.003	32.5±1.2
Z3	7	0.2	0	73.4±0.89	185.0±8.90	0.314±0.002	43.3±2.3
Z4	7	0.2	50	68.36±5.62	1335.0±1.31	0.593±0.002	−22.4±0.6
Z5	9	0.2	0	99.12±2.89	175.0±6.77	0.103±0.001	−37.9±1.5
Z6	9	0.6	50	99.57±1.78	116.2±14.60	0.411±0.001	17.2±2.4
Z7	9	0.2	50	99.05±6.59	152.9±10.31	0.497±0.002	17.6±0.8
Z8	9	0.6	0	99.14±0.23	173.8±9.55	0.096±0.001	−41.4±0.2
Z9	2	0.6	50	99.3±4.23	177.2±5.67	0.101±0.003	46.5±1.7
Z10	2	0.2	50	99.32±1.56	278.1±7.37	0.408±0.001	44.9±2.6
Z11	2	0.6	0	99.29±0.56	131.0±2.54	0.149±0.002	24.8±0.1
Z12	2	0.2	0	99.31±3.64	99.5±6.34	0.237±0.001	37.8±1.3

Dependent variables are reported as average values (n=3)±SD

Fig. 6 [Images not available. See PDF.]

Response surface plot of effect of **A** dispersion pH and **B** conc. of surfactant on particle size

Encapsulation efficiency

EE% was determined by measuring the amount of unencapsulated extract in the aqueous phase after centrifugation

of the developed dispersion systems as displayed in Table 2. It was observed that ZN-NPs entrapped a significant amount of PE (64.46–99.57%). pH significantly affected the PE encapsulation efficiency (p value < 0.05). pH apart from the isoelectric point (PI) of ZN protein polymer, such as pH 2 and pH 9 showed a high amount of encapsulated extract in contrast to pH 7 (isoelectric point of ZN) which showed a lower amount of PE entrapped. McTigue and Perry observed an increase in the encapsulation efficiency of the investigated protein (Hen Egg White Lysozyme) while using a pH away from its PI [15]. On the other side, the other two factors (PE-ZN ratio and surfactant concentration) showed a non-significant effect on the EE as displayed in Fig. 6B.

Selection of the optimum ZN NP preparation

Selection of the optimum preparation was based on studying the effects of the different preparation variables on the four essential investigated responses (EE%, PS, PDI and ZP). According to the ANOVA analysis, pH and surfactant concentration have a principal significant effect on EE% and PS, respectively. It is inferred that pH apart from the PI of ZN was favorable to obtain high EE% and small PS. In addition, increasing the surfactant concentration from zero to 50 mg/mL had a negative effect on PS. Therefore, preparations with a surfactant concentration level of 50 mg/mL were excluded. On the other hand, the priority was attained to NP preparations of pH 2. Basically for two reasons: first, to avoid the obtained variations in ZP at pH 9 and second, to obtain NP with a positively charged surface for the favorable interaction with the negatively charged cell membrane. By the examination of the NP preparations of pH 2 level, the preparation of the maximum EE%, minimum PS and highest positive ZP was obtained by Z12. Therefore, Z12 was selected as the optimized NP preparation and subjected to further characterization.

Determination of residual solvents (methanol)

The determination of methanol as a residual solvent in pharmaceuticals is an important quality control measure. Methanol is classified as a Class 2 solvent which should be limited due to potential toxicity. The compendial method for determination of residual solvents USP <467> was capable to determine the residual methanol in both pure PE extract and the optimized formulation of PE-ZN NPs (Z12). The results were 812 ppm and 237 ppm for the pure PE extract and the optimized formulation (Z12), respectively. According to ICH Q3C (R8) option 1, the acceptable amount of methanol as a residual solvent in the final product should be not more than 3000 ppm based on 30 mg/day permitted daily exposure (PDE) and daily dose does not exceed 10 g. The two results were below the limit indicating the safety of the formula and the compliance with global regulatory requirements.

Morphological examination by transmission electron microscope (TEM)

The examination of the morphology of the optimized formulation of PE-ZN NPs (Z12) under transmission electron microscope showed that the ZN-NPs had a spherical uniform shape and a smooth surface. There was no aggregation, and the size of the particles was in the nanosize, matching the results obtained by the Zetasizer as shown in Fig. 7.

Fig. 7 [Images not available. See PDF.]

TEM image of the optimized PE ZN NP

In vitro drug release

The optimized ZN NP preparation (Z12) was selected to study its release profile in comparison with free PE extract. The free extract showed a rapid release pattern of more than 75% of PE within 2 h as inferred from Fig. 8, while the release pattern of PE from the optimum preparation was relatively slow. This slow release pattern was confirmed by the significant difference (p value < 0.0001) in release between free PE extract and Z12 at 2 h. Moreover, it achieves a controlled release over 24 h with higher stability of the encapsulated PE in Z12 comparable to the obvious decline in the release of PE (p value < 0.0011) in the period between 10 and 24 h which most probably might be justified by the degradation of the released free PE in the release medium [9].

Fig. 8 [Images not available. See PDF.]

In vitro release of pomegranate from PE ZN NPs compared to PE

Determination of release kinetics

The results of the estimation of (R^2) of the utilized three mathematical models revealed that the highest (R^2) was for the Higuchi model pointing to a diffusion-controlled release of the encapsulated PE extract from the hydrophobic matrix of the formed ZN NPs to the external aqueous phase.

Ex vivo permeability study

As illustrated in Fig. 9, the ex vivo cumulative permeation percentages of PE through the rabbit intestine from both optimized PE-ZN NPs (Z12) and free PE extract over 24 h were plotted. It was noticeable that the permeation percentages from both optimized PE-ZN NPs (Z12) and free PE were comparable till the first hour. Thereafter, the permeation rate of free PE was relatively slower than the optimized PE-ZN NPs (Z12) and reached the maximum at 6 h with cumulative percentage of (56.96% ± 1.72) and significant difference (p value < 0.0133) from the optimized Z12 formula that had permeation percentage of (63.62 ± 3.54). Conversely, the permeation of PE from the optimized PE-ZN NPs (Z12) was continuous after 6 h and reached the maximum at 24 h with cumulative permeation percentage of (89.02% ± 4.58). This relative increment in PE permeation in case of PE-ZN NPs could be attributed to several factors. For instance, the small nanosized of the particles and the high positive charge of the NPs surface that aid to increase the interaction with the cell membrane and consequently augment the flux and permeation of the extract. In addition, the hydrophobic properties of the zein molecules due to the γ-zein N-terminal repetitive part promote the extract permeation through interaction with the cell membranes components. Similar finding were reported by [21, 24].

Fig. 9 [Images not available. See PDF.]

Ex vivo permeation of pomegranate from PE ZN NPs compared to PE

In vitro cytotoxicity study

To examine the effect of nanoencapsulation on the biological activity of PE, the cytotoxic effect of the optimized preparation of PE-ZN NPs (Z12) and the free PE on HepG2 cancer cells were compared. It was found that the optimized formula (Z12) had a superior anti-proliferative effect on the HepG2 liver cell line with a 50% inhibitory concentration (IC50) of 266.68 µg/mL ± 23.11 relative to 657.47 µg/mL ± 13.84 in case of free PE extract. As demonstrated in Fig. 10, the optimized PE-ZN NP preparation (Z12) increased the potency of the cytotoxic activity on HepG2 hepatic cancer cells by reducing the IC50 values by about 2.5-fold than the free PE (p value < 0.0001). This finding may be attributed to the more interaction between the negatively charged cell membranes and the positive charge of the optimized preparation [3]. Furthermore, the augmented cytotoxic activity might be due to the high ability of PE NP in internalization of PE into the cells relative to the free extract [36].

IC50 values of the PE extract and PE ZN NPs (Z12)

Discussion

To sum up, hepatic cancer with its high morbidity and lethality increases the emergence of developing promising platforms to combat it. Nature is a precious source of natural products that have proven their medicinal properties. Considerable anticancer therapeutics have originated from natural sources. Phytochemicals and their valuable constituents always pave the way to handle chronic health threats. Pomegranate is an ancient fruit with auspicious antioxidant and anticancer properties and is considered an effective remedy for different cancer diseases. Punicalagin is one of the most valuable polyphenols in pomegranates which is not absorbed in its intact form but hydrolyzed into moieties of ellagic acid and rapidly metabolized into short-lived metabolites of ellagic acid [48].These compounds possess many biological activities in the prevention and treatment of cancer [29, 53] because of their free radical scavenging activities [22] as well as their anticancer effects [48].

Accordingly, our goal in this study is to make a formula that stands out for the therapeutic significance of pomegranate and overcome any challenges that may affect the physicochemical properties, bioavailability and stability of pomegranate. Many attempts have been made to augment its biological activities and studies have been performed to assess the safety and efficacy. For example, Shirode et al. [48] have developed poly (d,l-lactic-*co*-

glycolic acid)–poly(ethylene glycol) NPs encapsulated with PE extract with efficient cellular uptake and anti-proliferative activity against different breast cancer cell lines. Another study obtained by Badawi et al. [9] who optimized solid lipid nanoparticles loaded with PE extract and improved its cytotoxic activity against different cancer cell lines relative to the free PE extract. Finally, Soltanzadeh et al. [49] encapsulated the PE extract in chitosan NPs aiming to protect its sensitive constituents but a limitation to encapsulation has been observed when increasing the PE concentration.

In our study, we focused on increasing the encapsulation efficiency, controlling the release of PE extract and achieving a qualified platform suitable for targeted delivery to hepatic cancers. Zein natural polymer was utilized to load PE extract by carrying on a $2^2 \times 3^1$ full factorial design to study the effect of different variables on the properties of the formed NPs.

The screening of the potential physical or chemical incompatibilities as a prerequisite for selection of the most suitable excipients in the dosage form was done by implementing two concomitantly and complementary analytical techniques, namely DSC and FTIR [18]. The FTIR analysis showed the chemical compatibility between the PE extract and the selected polymer and surfactant and the DSC analysis indicated the presence of the sharp melting peak of PE in the DSC of the physical mixtures of both zein polymer and span® 40 with a forward shift in case of zein due to the thermal stability and a backward shift in case of span® 40 on account of the partial dissolution of PE in the melted surfactant.

The pH of dispersion at three levels, namely 2, 7 and 9, parallel with two levels of Span 40 as surfactant concentrations, namely zero and 50 mg/mL were selected to demonstrate the feasibility to rely on tuning the pH of the dispersion and passing up the use of surfactants. The ANOVA analysis revealed the significant effect of pH on PS (being high at pH 7 near the isoelectric point (PI) of ZN and low at pH apart from PI at both pH 2&9), EE% (pH 2&9 showed a high amount of encapsulated extract in contrast to pH 7) and ZP. While the surfactant concentration had a significant effect on PS and PDI, the change of PE: ZN ratio had no significance on any of the investigated responses. The observed effects on each response were in harmony with literature. In detail, the observed effect of pH on PS has been reported by many authors such as [44] that reported that the decrease in PS of ZN NPs is due to the existence of zein polymer in in the monomeric form at pH>PI. On the other hand, [19] attributed the low PS and high porosity of ZN NPs at low pH to the more solubility of zein in acidic pH. For the encapsulation efficiency, the attained EE% at pH apart from the PI was remarkably high around 99%, on the other hand, a noticeable decrease in the EE% at pH 7 (near the PI) from 64.46 ± 1.23 to 80.84 ± 3.56%. This could be appropriately attributed to the refolding behavior of proteins at the PI which could result in the escape of the encapsulated extract leading to less encapsulation efficiency than that obtained at pH far from the PI as reported by [35]. In case of the ZP, the effect of pH on the ZP of the prepared ZN NPs was in agreement with [27] who attributed the obtained change in the ZP of the uncoated ZN NPs from highly positive at low pH to highly negative at high pH to the electrical characteristics dominated by the zein molecules at particles' surfaces, which are cationic at low pH due to protonation of amino and carboxyl groups ($–NH_3^+$ and –COOH) and anionic at high pH due to de-protonation of these groups ($–NH_2$ and $–COO^-$). Finally, the surfactant concentration effect was negative on both PS and PDI with observable increase in PS and less homogeneity with relatively higher PDI values than the surfactant-free formulations. Based on these findings, it is inferable that the integral positive effect of changing the pH of the dispersion medium in comparison of the incorporation of surfactant and the adequacy of the hypothesis of the reliance on tuning the dispersion pH is deduced.

As per the predetermined QTPP and the above ANOVA analysis, the optimization resulted in an optimized ZN NP preparation having a small PS of 99.5 ± 6.43 nm (<100 nm) that a prerequisite for size-dependent passive targeting to liver as reported by [34] who studied the distribution of 5-fluorouracil zein nanoparticles and discussed the optimum average size required for accumulation in liver after IV administration taking into consideration the fenestrae size and the necessity of the unrecognition by RES and high EE% of 99.31 ± 3.64. In addition, a PDI value of 0.237 ± 0.001 indicates narrow size distribution and a high positive ZP charge of 37.8 ± 1.3 that imports good physical stability and ability to interact efficiently with negatively charged cell membranes. Then the performed in-

vitro study on the optimized ZN NP preparation showed a distinguishable and stable in vitro release pattern comparable to the free PE extract in a controlled manner for 24 h achieving sustained release profile. Additionally, as the methanol which is a class 2 solvent was used in the PE extract preparation and it is known that residual solvents have no therapeutic value and may affect physicochemical properties of the active constituents and have potential toxicity [20]. Taking into consideration exceeded quantities of such solvents can consequently result in risks for patients. Methanol (Permissible Daily Exposure 30 mg/day) can be used in the pharmaceutical products with permissible limit of 3000 ppm as a residual solvent in the final products according to ICH guideline for Residual Solvents Q3C (R9). GC analysis was performed to detect the quantity of the residual solvent in both the PE extract and the optimized NPs. The obtained results showed that both the extract and the formula were below the permissible limit indicating the safety of the formula and the compliance with global regulatory requirements. Nanosized formulations exhibit a large loading capacity together with a larger surface on which the loaded drug can conjugate with targeting organs with a controlled permeation pattern [41].This was exhibited through the ex vivo permeability study that has revealed an enhancement of 1.5 folds of the cumulative PE permeation from the optimized ZN NP over 24 h in comparison with PE extract that delivered its content through only 6 h.
Oxidative stress is one of the main causes of the development of human hepatic cancer. Bishayee et al. [14] demonstrated the potential effect of using pomegranate products in the chemoprevention and treatment of hepatic cancer through overcoming the oxidative damage trough modulation of Nrf2 signaling. In our study, the anti-proliferative activity (MTT assay) of the optimized formulation was studied in HepG-2 cancer cell lines in comparison with free PE. The potential of the optimized preparation to enhance the cytotoxic activity of PE extract was evidenced by an in vitro cytotoxicity study that revealed the superiority of PE-loaded ZN NP over Free PE extract on HepG2 liver cell line by significantly decreasing the IC50 by 2.5 fold than the free PE which in turn proves our endeavor and presents a promising platform for future utilization in preclinical and clinical studies against hepatic cancer.

Conclusion

Successful treatment for hepatic cancer was aimed in this study by loading pomegranate peel extract in nanosized particles with the aid of zein polymer which achieves high drug encapsulation efficiency with small particle size. This developed system attained more effective and more retardation of pomegranate extract release than the free extract. The in vitro drug release study demonstrated that the free extract showed a high percentage of release of about 80% within 2 h, while the optimized preparation exhibited more retardation till 24 h. The in vitro cytotoxicity study showed that PE-ZN NPs attained reduced IC_{50} values by 2.5-fold than the free PE; thus, formulated pomegranate extract in zein nanoparticles has a more effective and cytotoxic effect than free extract. The study demonstrated that the pomegranate zein nanoparticles could be a promising green drug delivery system, where both the active ingredient and the carrier polymer are derived from plants with a surfactant-free strategy, thus protecting the liver against toxins and can be safely and effectively used to treat hepatic cancer. Finally, future stability studies, more in vitro tests to understand the underlying mechanisms of the hepatic anticancer properties of prepared NPs of the optimum formula and in vivo experiments are required to validate PE-ZN NPs efficacy and bioavailability. Consequently, the approach may be worth considering for scale-up to expand its applications in clinical studies against hepatic cancer.

ABSTRACT (ENGLISH)

Background

The infamous multidrug-resistant (MDR) bacterium *Acinetobacter baumannii* is becoming a nightmare in intensive care units across the globe. Since there are now very few effective antimicrobial agents, it is necessary to explore unconventional resources for novel antimicrobials. This study investigated the potential antimicrobial activity of *Origanum majorana* L. against *A. baumannii* employing multiple approaches including antimicrobial susceptibility, fractionation, ultra-performance liquid chromatography–high-resolution mass spectrometry (UPLC-HRMS) dereplication, and in silico analysis for target/ligand identification.

Results

On the extremely pathogenic MDR strain *A. baumannii* AB5075, *O. majorana* L. has shown a significant growth inhibitory effect (MIC = 0.675 mg/mL). The polar 50% methanol fraction was the most active (MIC = 0.5 mg/mL). The UPLC-HRMS dereplication of the bioactive fraction detected 29 metabolites belonging to different chemical classes. Justicidin B, one of the identified metabolites, was projected by preliminary in silico analysis to be the most highly

scoring metabolite for binding with molecular targets in *A. baumannii* with a Fit score = 8.56 for enoyl-ACP reductase (FabI) (PDB ID: 6AHE), suggesting it to be its potential target. Additionally, docking, molecular dynamics simulation, and bioinformatics analysis suggested that this interaction is similar to a well-known FabI inhibitor. The amino acids involved in the interaction are conserved among different MDR *A. baumannii* strains and the effectiveness could extend to Gram-negative pathogens within the ESKAPE group.

Conclusions

Origanum majorana L. extract exhibits antimicrobial activity against *A. baumannii* using one or more metabolites in its 50% methanol fraction. The characterized active metabolite is hypothesized to be justicidin B which inhibits the growth of *A. baumannii* AB5075 via targeting its fatty acid synthesis.

FULL TEXT

Background

Healthcare practitioners everywhere give careful consideration to *Acinetobacter baumannii* as it is a major cause of nosocomial infections. *A. baumannii* is frequently responsible for outbreaks in intensive care units that show up as urinary tract infections, surgical site infections, pneumonia linked to ventilator use, and sepsis [1]. Based on pooled data from various regions globally, *A. baumannii* was found to produce approximately 25 hospital-acquired infection cases per 1000 patients; in intensive care units, this ratio rose to 54 cases per 1000 patients [2]. Furthermore, the problem has gotten worse due to its resistance to several antimicrobial agents that are currently available, as well as, its acquired resistance to their alternatives.

Multidrug-resistant (MDR) *A. baumannii* are increasingly reported worldwide reaching 45% of *A. baumannii* infections, exceeding the MDR rates reported for all other common nosocomial pathogens [3]. This has placed *A. baumannii* among the ESKAPE pathogens (*Enterococcus faecium, Staphylococcus aureus*, *Klebsiella pneumoniae, A. baumannii, Pseudomonas aeruginosa,* and *Enterobacter* spp.) [4–6]. For multidrug-resistant Gram-negative bacteria, including *A. baumannii*, colistin and carbapenems like doripenem, imipenem, and meropenem, are typically regarded as the last resort treatments [7–9]. Nevertheless, the administration of colistin has been restricted due to its toxicity, including nephrotoxicity and neurotoxicity [10, 11]. The frequency of isolation of carbapenem-resistant *A. baumannii* (CRAB) is increasing with currently few alternatives for treatment. The Centres for Disease Control and Prevention (CDC) has listed CRAB as an “urgent threat” to human health [12, 13]. In a developing country like Egypt, the rate of isolating CRAB from patients reached 80% and higher [14]. After the COVID-19 pandemic, the reported infections by CRAB increased by 78%, which is highly alarming [13].

The development of novel antibiotics is essential due to the high mortality rates associated with CRAB infections [15, 16]. This has warranted WHO to include *A. baumannii,* along with other carbapenem-resistant pathogens, *P. aeruginosa* and Enterobacteriaceae*,* to be critically prioritized in the research and development of new antibiotics [17].

Plant-produced secondary metabolites, sometimes referred to as phytochemicals, may offer chemical resistance against infectious agents. The abundance of these metabolites, some with efficacies comparable to that of synthetic antibiotics, provides a repertoire of chemicals that could be used to successfully create and deploy new antimicrobial agents against MDR-ESKAPE pathogens [18–20].

Origanum majorana L. commonly referred to as Sahtar, Zaatar or sweet marjoram is a photoautotrophic medicinal perennial herb of the *Origanum* genus, which belongs to the Lamiaceae family [21]. This plant is found broadly all around the Mediterranean region, but especially in Morocco, Algeria, Egypt, Spain, and Portugal [22]. Traditional medicine makes extensive use of it, as a possible treatment for a wide range of illnesses including allergies, respiratory infections, hypertension, diabetes, and stomach pain, as well as, an intestinal antispasmodic, [23]. Pharmacological research revealed that this plant’s essential oils and extracts possessed a variety of biological qualities, including hepatoprotective, antimutagenic, anticancer, antiparasitic, antibacterial, antifungal, antidiabetic, antioxidant, anti-inflammatory, and analgesic effects [24]. The plant extracts’ safety and therapeutic advantages have been verified by a toxicological evaluation [25]. In rats, *O. majorana* L. extracts did not result in any fatalities,

which further confirms their safety [26, 27]. *O. majorana* L. has previously been found to contain a wide range of bioactive compounds from various chemical classes, including hydroquinone, sterols, terpenoids, tannins, phenolic acids (arbutin and methyl arbutin), fatty alcohols, and flavonoids (diosmetin, orientin, luteolin, apigenin, vitexin, and thymonin) [28]. Thymol, carvacrol, cis-sabinene hydrate, limonene, terpinene, and camphene are among the plant's abundant volatile oil constituents [28]. It is important to bear in mind that different plant organs, growth stages, and even harvesting techniques can have different effects on the amount and composition of the aforementioned metabolites and volatile oil components within the same species [29]. Antibacterial activity has been demonstrated by the plant against a variety of pathogenic bacteria, including *E. faecalis*, *Bacillus subtilis*, *Escherichia coli*, *K. pneumoniae*, *Serratia* sp. and *Salmonella choleraesuis* [30–32].

In search of prospective treatments for MDR *A. baumannii*, this study aimed to investigate the antibacterial activity of *O. majorana* L. extract and its fractions. UPLC-HRMS was used to analyse the chemical profile of the active 50% methanol fraction (50% MF) in order to establish a relationship between the antibacterial activity and the bioactive secondary plant metabolites. Justicidin B, a secondary metabolite identified in *O. majorana* L. bioactive fraction, has been identified as a potential novel antimicrobial agent against *A. baumannii* and other ESKAPE pathogens, which targets the essential FAS-II fatty acid biosynthesis pathway component FabI.

Methods

Bacterial strains and culture conditions

The multidrug-resistant highly virulent *A. baumannii* strain AB5075 [33] was obtained from Prof. Dr. Lory, Harvard University, USA as a gift, and was used as the test microorganism in all the experiments. The bacterial strain was typically grown in tryptic soy broth (TSB) with shaking at 180 rpm at 37 °C or plated on tryptic soy agar (TSA) and incubated at 37 °C.

Preparation, extraction and fractionation of *O. majorana* L. aerial parts

Origanum majorana L. aerial parts were collected from the Experimental Station of the Faculty of Pharmacy, Cairo University, Giza, Egypt. Mrs Therese Labib, Consultant at Orman Botanic Garden, Dokki, Giza, Egypt, kindly authenticated the plant material. Air-dried powder of *O. majorana* L. aerial parts (0.5 kg) was exhaustively extracted with methanol (5 × 7 L) and evaporated on a rotary evaporator to yield the total methanolic extract (ME, 75 g). Part of the residue (45 g) was suspended in 350 mL of distilled water and then fractionated using dichloromethane (3 × 750 mL), which was then evaporated to get DCM-F (25 g). The mother liquor (ML) was applied on the Diaion-HP20 column and eluted firstly with distilled water (1L, discarded), followed by 50% methanol (1 L), and then 100% methanol (1 L). The fractions were evaporated to yield 50% MF (4 g) and 100% MF (6 g), respectively.

Preliminary screening of *O. majorana* L. extract for antimicrobial activity

An overnight culture of *A. baumannii* AB5075 was grown in TSB at 37 °C and 180 rpm. The culture was diluted in TSB to OD600 = 0.1 arbitrary units, then diluted 1:1000 in TSA which was prewarmed to 50 °C. The inoculated TSA (50 mL) was distributed in a 15-cm-wide petri dish. After agar solidification, 10 µL of the extract, or the fraction, were spotted on the agar surface, the spots were dried in a laminar flow cabinet, and the plates were incubated at 37 °C. After 24 h, the plates were inspected visually, and the diameters of the growth inhibition zones were measured using a ruler.

Determination of the minimum inhibitory concentration (MIC)

Following the criteria of the Clinical and Laboratory Standards Institute (CLSI), the MIC was ascertained using the broth microdilution method [34]. The dried extract or fraction was dissolved in DMSO to a final concentration of 100 mg/mL. Then, it was diluted in Muëller-Hinton broth to yield a series of twofold dilutions ranging from 0.001 to 2 mg/mL. One hundred µL aliquots from each concentration were distributed in a 96-well plate. Each well was inoculated with 10 µL (~10^5 CFU as determined spectrophotometrically by measuring absorbance at 600 nm and verified by viable count) of a freshly prepared bacterial suspension. The plates were incubated for 24 h at 37 °C. The MIC was the minimum concentration of the tested crude extract or its fractions that inhibited visible bacterial growth. Muëller-Hinton broth containing the equivalent of DMSO served as a negative control and the experiment was performed in triplicate.

UPLC-HRMS analysis of the active fraction

The *O. majorana* L. active subfraction (50% MF) was subjected to UPLC-HRMS analysis followed by dereplication (identification of the secondary metabolites present in the extract) using the Dictionary of Natural Products and Reaxys online databases. The dereplication depended on the HRMS isotope profiles, MS/MS fragmentation, and the databases were filtered to include only the plant genus or family.

A Bruker MAXIS II Q-ToF mass spectrometer connected to an Agilent 1290 UHPLC system was used to analyse the samples. The column used was a Phenomenex Kinetex XB-C18 (2.6 mM, 100 × 2.1 mm). The following LC gradient profile was used to achieve separation: 5% MeCN + 0.1% formic acid to 100% MeCN + 0.1% formic acid in 15 min at a flow rate of 0.1 mL/min. MS parameters were: mass range *m/z* 100–2000, capillary voltage 4.5 kV, nebulizer gas 4.0 bar, dry gas 9.0 L/min, and dry temperature of 250 °C. MS/MS experiments with a step collision energy of 80–200% were carried out using the Auto MS/MS scan mode.

Virtual target identification

PharmMapper was used to characterize potential target(s) of justicidin B [35]. This platform uses an extracted pharmacophore model and stores it as a library ligand dataset in mol2 format. Then, it rates each molecule in the PDB according to how well it fits the model. This approach yields a pure Fit score that is far more reliable and significant than chance pharmacophore matching. The query structure was submitted to the platform in the pdb format, and the results were sorted based on the Fit scores.

Docking study

Using an AutoDock Vina docking machine, the crystal structures of FabI (PDB ID: 6AHE) were utilized for the docking study [36]. The co-crystallized ligand AFN-1252 was used to determine the binding site and the docking grid-box. The coordinates of the grid-box were set to be x = −36.404, y = −8.512, z = −3.293.

A criterion of 2.0 Å was established for the ligand to binding site shape matching root-mean-square deviation (RMSD). The Charmm force field (v.1.02) with a distance-dependent dielectric and a non-bonded cut-off distance of 10.0 was used to obtain the interaction energies. Then, an energy grid was set at 5.0 Å from the binding site [36]. Inside the chosen binding pocket, the studied compound, justicidin B, was energy-minimized. Pymol software was used to edit and visualize the generated binding poses [37].

Molecular dynamics simulation (MDS)

NAMD 3.0.0. software was used to perform MDS [38, 39]. Protein systems were constructed with the VMD software's QwikMD toolkit [39, 40], and the protonation states of the amino acid residues were set (pH 7.4). The protein structure was examined for any missing hydrogens, and the co-crystalized water molecules were then removed. Following that, the entire structure was immersed in an orthorhombic box of TIP3P water together with 0.15 M Na^+ and Cl^- ions in a 20 Å solvent buffer. The systems were then energy-minimized and allowed to equilibrate for five nanoseconds. With the help of the VMD plugin Force Field Toolkit (ffTK), the ligand topologies and properties were determined. Afterwards, the produced parameters and topology files were loaded into VMD so that the simulation steps could be carried out and the protein–ligand complexes could be interpreted without errors.

Binding free energy calculations

The molecular mechanics Poisson–Boltzmann surface area (MM-PBSA) method from the AMBER18's MMPBSA.py module was used to calculate the docked complex's binding free energy by applying the following equation complex $\Delta G_{Binding} = \Delta G_{Complex} - \Delta G_{Receptor} - \Delta G_{Inhibitor}$ [41].

Conservation of the FabI sequences

The amino acid sequence of the FabI (PDB ID: 6AHE) enzyme, which showed the best-Fit score with justicidin B, was retrieved from the NCBI database. To confirm the conservation of FabI in different strains of *A. baumannii* and different strains of ESKAPE pathogens, the protein sequence of FabI was analysed by the BlastP tool (https://blast.ncbi.nlm.nih.gov/Blast.cgi?PAGE=Proteins) [42], using a nonredundant protein sequences database against each organism (*A. baumannii*, *E. faecium*, *S. aureus*, *K. pneumoniae*, *P. aeruginosa* and *Enterobacter* spp.) with an expect threshold of 0.001. Proteins were considered conserved if they had a max alignment score of more than 200.

The conservation of amino acids in the predicted binding site for justicidin B was further confirmed by the alignment of the sequences of representative proteins from MDR *A. baumannii* strains (including those from *A. baumannii* ATCC 19606 (PDB ID:6AHE) and *A. baumannii* AB5075) and from representative strains of different ESKAPE pathogens. The sequences of the target proteins were retrieved from the NCBI database. The protein sequences were aligned using the multiple sequence alignment Clustal Omega tool with default settings (https://www.ebi.ac.uk/Tools/msa/clustalo/) [43].

Results

O. majorana L. total methanolic extract and its fractions have potent growth inhibitory effects against *A. baumannii*

The *O. majorana* L. total methanolic extract was spotted on the trypticase soy (TS) agar seed inoculated with *A. baumannii* AB5075. It showed a 14-mm zone of growth inhibition after 24-h incubation (Fig. 1A). Using the broth microdilution method, the minimum inhibitory concentration (MIC) of the total methanolic extract of *O. majorana* L. was determined at 0.675 mg/mL. Chromatographic techniques were used to prepare subfractions by partitioning with solvents of different polarities and applying them on a Diaion column. The 50% methanol fraction showed considerable antimicrobial activity (Fig. 1B). Upon measuring the MIC for this fraction, it showed a value of 0.5 mg/mL. On the other hand, the non-polar dichloromethane fraction had a higher MIC value of 0.875 mg/mL.

Fig. 1 [Images not available. See PDF.]

Growth-inhibitory effects of *O. majorana* L and its fractions against *A. baumannii*. Ten µl of the total methanolic (TM) extract (**A**) of *O. majorana* L or the 50% methanol fraction from Diaion-HP20 (50% MF) (**B**) were spotted on TSA plates inoculated with *A. baumannii* AB5075 and the plates were incubated overnight at 37 °C. In both cases, equivalent amounts of the solvent (DMSO) were spotted on the same plates. The experiment was repeated three times, and representative images were presented

UPLC-HRMS analysis of *O. majorana* L. active fraction reveals multiple metabolites.

To unlock the chemical diversity of the active fraction of the *O. majorana* L., UPLC-HRMS profiling revealed the presence of 29 metabolites belonging to different structural classes, comprising two terpenes, two alkaloids, one lignan, nine flavonoid aglycones, four flavonoid glycosides, seven phenolic acid derivatives, and two alicyclic derivatives. Moreover, three hits were not identified, indicating new compounds or compounds that were not reported before in the family Lamiaceae (Table 1).

Table 1. LC-HRMS analysis of the 50% methanol fraction (50% MF) of *Origanum majorana* L

HRMS m/z	Mol. formula	Tentative identification	Compound structure
165.0911	$C_{10}H_{12}O_2$	Eugenol	
181.04954	$C_9H_8O_4$	Caffeic acid	
227.1279	$C_{12}H_{18}O_4$	12-hydroxyjasmonic acid	
271.0603	$C_{15}H_{10}O_5$	Apigenin	
273.0758	$C_{15}H_{12}O_5$	Naringenin	
283.0812	$C_{13}H_{14}O_7$	No hit from the family	
285.0757	$C_{16}H_{12}O_5$	Genkwanin	

289.0706	$C_{15}H_{12}O_6$	Aromadendrin; dihydrokaempferol	
299.2005	$C_{20}H_{26}O_2$	Majoradiol	
303.0499	$C_{15}H_{10}O_7$	Quercitrin; sophoretin; flavin

315.0865	$C_{17}H_{14}O_6$	Salvigenin; cirsimaritin	
329.1019	$C_{18}H_{16}O_6$	5-Hydroxy-4',6,7-trimethoxyflavone	
331.0812	$C_{17}H_{14}O_7$	5,6,4'-Trihydroxy-7,3'-dimethoxyflavone	
342.0608	$C_{17}H_{11}NO_7$	Aristolochic acid I; aristolochic acid	
355.1023	$C_{16}H_{18}O_9$	Chlorogenic acid; 5-*O*-caffeoylquinic acid	
359.1125	$C_{19}H_{18}O_7$	Gardenin B	
361.0917	$C_{18}H_{16}O_8$	(R)-(+)-rosmarinic acid	
365.1032	$C_{21}H_{16}O_6$	Justicidin B	
375.1074	$C_{19}H_{18}O_8$	Rosmarinic acid methyl ester	
379.1023	$C_{18}H_{18}O_9$	No hits from the family	
389.1806	$C_{18}H_{28}O_9$	12-Hydroxyjasmonic acid 12-*O*-hexoside	
407.0972	$C_{19}H_{18}O_{10}$	No hits from the family	
423.1285	$C_{20}H_{22}O_{10}$	Amburoside A	
439.1235	$C_{20}H_{22}O_{11}$	Oreganol-A; protocatechuoyl calleryanin	
447.0921	$C_{21}H_{18}O_{11}$	Apigenin-7-*O*- glucuronide	
453.1391	$C_{21}H_{24}O_{11}$	Oreganol-B	
463.0873	$C_{21}H_{18}O_{12}$	Luteolin-7-*O*- glucuronide	
593.1864	$C_{28}H_{32}O_{14}$	Acacetin-7-*O*-rutinoside	
595.1656	$C_{27}H_{30}O_{15}$	Vicenin-2; apigenin 6,8-di-C-hexoside	

Virtual screening-based target characterization

PharmMapper was employed to suggest a suitable protein target for the identified metabolites. The retrieved results were arranged according to their Fit scores. Only bacterial targets related to the *Acinetobacter* genus were considered. A threshold Fit score of 7 was set to select the best-scoring hits. As a result, *A. baumannii*-derived enoyl-ACP reductase (FabI) (PDB ID: 6AHE) was found to be among the top-scoring hits for justicidin B (Fit score = 8.56), where all the remaining bacterial hits were below the cut-off score of 7. Hence, this target (i.e. FabI) was proposed as its potential target, and justicidin B was the only compound among the 29 LC-HRMS-dereplicated metabolites that scored above the threshold Fit score.

Re-docking justicidin B modelled structure into the FabI active site achieved binding mode and docking score comparable to those of the co-crystalized inhibitor AFN-1252 (docking scores = −10.67 and −11.75 kcal/mol, respectively). Justicidin B was able to establish two H-bonds with TYR-149 and TYR-159. In addition, it was involved in multiple hydrophobic interactions with PHE-96, LEU-102, TYR-149, and ILE-203. Similarly, the co-crystallized inhibitor was involved in the same hydrophobic interactions and formed H-bonds with both TYR-159, as seen in justicidin B, and with ALA-97 (Fig. 2A, B).

Fig. 2 [Images not available. See PDF.]

Binding modes of justicidin B (brick red-coloured structure) (**A**) and the co-crystalized inhibitor AFN-1252 (Cyan-coloured structure) (**B**) inside the binding site of FabI (PDB ID: 6AHE). **C** RMSDs of both structures (i.e. Justicidin B and AFN-1252) inside the binding site of FabI throughout 100 ns-long MD simulation. The yellow-coloured structure is the co-factor Nicotinamide Adenine Dinucleotide (NAD)

According to subsequent molecular dynamic simulation (MSD) experiments (100 ns-long), the justicidin B structure was able to achieve stable binding mode throughout the simulation, with an average Root Mean Square Deviation (RMSD) of 1.96 Å, which was similar to that of the co-crystallized inhibitor AFN-1252 (average RMSD = 1.65 Å; Fig. 2C). Such stable bindings of both justicidin B and AFN-1252 were translated into stable and significant interaction energies (electrostatic and van der Waals) inside the enzyme's binding site, where both compounds showed total interaction energies averaged around − 26.16 and − 44.27 kcal/mol, respectively (Fig. 3A, B). Hence, their calculated absolute binding free energies were comparable as well ($\Delta G_{Binding}$ = -8.11 and -9.52 kcal/mol, respectively).

Fig. 3 [Images not available. See PDF.]

Interaction energies (i.e. electrostatic and van der Waals interaction energies) of justicidin B (**A**) and AFN-1252 (**B**), respectively inside the binding site of FabI over the course of 100 ns-long MD simulation

According to the previous modelling and MD simulation findings, it could be hypothesized that *O. majorana* L. extract was able to inhibit the growth of *A. baumannii* via targeting its fatty acid synthesis by one of its metabolites (i.e. justicidin B).

The conservation of the predicted interaction sites of justicidin B and FabI in *A. baumannii* and among members of the ESKAPE group

To check if the predicted interaction of justicidin B and FabI could be extended to other strains of *A. baumannii*, we performed a blast analysis for the enoyl-ACP reductase (FabI) amino acid sequence against *A. baumannii* strains in the National Centre for Biotechnology Information (NCBI) database. The alignment score was >200, indicating a high degree of conservation of the overall amino acid sequence of this protein. Upon performing a multiple sequence alignment of the amino acid sequences of the FabI protein in fifteen MDR and CRAB strains, all five amino acids involved in the interaction were conserved (TYR-149, TYR-159, PHE-96, LEU-102, and ILE-203) (Fig. 4A). Moreover, to determine if this interaction could be extended to other members of the ESKAPE pathogens, the FabI amino acid sequence of representative MDR strains from the members of this group was retrieved when another multiple sequence alignment was performed (Fig. 4B). The results of this alignment indicated that all the five amino acids involved in the interaction between justicidin B and FabI are conserved (TYR-149, TYR-159, PHE-96, LEU-

102, and ILE-203) in the Gram-negative members: *K. pneumoniae, A. baumannii, P. aeruginosa* and *Enterobacter* spp. On the other hand, for the Gram-positive members *S. aureus* and *E. faecium*, all the interaction sites were conserved except the non-polar amino acid ILE-203 which was replaced with another non-polar amino acid, valine, and TYR replaced PHE-96 in *E. faecium*. This change in one amino acid in these two strains could have a minimal impact on justicidin B binding.

Fig. 4 [Images not available. See PDF.]

Alignment of the protein sequences of the enoyl-ACP reductase (FabI) in (**A**) MDR and CRAB *A. baumannii* strains and (**B**) among ESKAPE (*Enterococcus faecium, Staphylococcus aureus, Klebsiella pneumoniae, Acinetobacter baumannii, Pseudomonas aeruginosa* and *Enterobacter* spp.) pathogens. The amino acid sequence of each protein was retrieved from the NCBI database and aligned using Clustal Omega software. The alignment visualization was done using Jalview 2.11.3.1. The amino acids involved in justicidin B binding are highlighted

Discussion

The rise of antibiotic-resistant pathogens and the difficulties in developing antimicrobials have aroused concerns among medical professionals for the well-being of humanity. Plants, a rich source of undiscovered metabolites, offer a solution as a natural source of antimicrobial compounds because they are attainable and generally safe to use. *O. majorana* L. or sweet marjoram is an aromatic, herbaceous, perennial plant in the family Lamiaceae. The plant has been used as a flavouring and herbal spice and is widely reported for its antibacterial activity against multiple pathogens, including *E. coli*, *B. subtilis*, *B. megaterium*, *S. aureus, P. aeruginosa*, and *Proteus vulgaris* [44, 45].

In the current study, the methanolic extract of *O. majorana* L. demonstrated remarkable antimicrobial activity against *A. baumannii* with a MIC of 0.675 mg/mL. The antimicrobial activity of the methanolic and ethanolic extracts and the decoction of *O. majorana* L. was reported previously against many Gram-positive and Gram-negative pathogens and *Candida* spp. [46, 47]. Only one study evaluated and proved its antimicrobial activity against *A. baumannii,* using the disc diffusion method [48]. The MIC of the methanolic extract was reported previously to be >100 µg/mL against *S. aureus* and *E. coli* [49]. A higher MIC (1.56 mg/mL) was determined for the decoction of *O. majorana* L. against *S. aureus* and *K. pneumoniae* [47]. The ethanolic fraction has MIC between 40 and 80 µg/mL, against *E. coli* and *K. pneumoniae* [46]. Additionally, the essential oil fraction of the plant was found to be highly active against different bacteria, fungi and protozoa [31, 49, 50]. However, it was not quantitatively tested against *A. baumannii*.

To pinpoint the active fraction responsible for the antimicrobial activity against *A. baumannii* in this study, the plant was fractionated, where the polar 50% methanol fraction was found to be the most active subfraction (MIC = 0.5 mg/mL). Chemical profiling of the bioactive fraction by UPLC-HRMS analysis revealed 29 metabolites belonging to diverse chemical classes. The dominant metabolites were phenolic acids, flavonoids, and lignans [51]. Phenolic acids such as rosmarinic acid, caffeic acid, and chlorogenic acid were previously reported in *O. majorana* L. [29]. They are beneficial against several chronic diseases such as degenerative diseases, cancer, diabetes, and ageing [52]. However, to the best of our knowledge, no reports are available about the antimicrobial activity of these metabolites from *O. majorana* L. against *A. baumannii*. The antimicrobial activity of many of these metabolites against Gram-positive and Gram-negative pathogens, such as naringenin [53], quercetin [54], and caffeic acid [55], was previously reported.

Two alicyclic derivatives, 12-hydroxy jasmonic acid and its 12-*O*-glucoside, were previously isolated for the first time from *Origanum* species, i.e. polar extracts of *O. vulgare* L [56]. Later, they were isolated from *O. dictamnus* L. Only 12-hydroxy jasmonic acid and not its glucoside exhibited a strong antibacterial effect against *A. hemoliticus* [57]. When screened for its phytotoxic potential against different phytopathogens, bioguided fractionation of the most active *O. majorana* L. fraction led to the isolation of different molecules, including a new compound named majoradiol, a carvacrol dimer, which was characterized but was not tested for its bioactivity due to its scarcity [58]. Aristolochic acid I and aristolochic acid II were isolated from *O. vulgare* and showed potent activity against leukaemia. Additionally, this is the first report to find that aristolochic acid I and aristolochic acid II demonstrated potent antithrombin activity [59]. Justicidin B, an arylnaphthalene lactone, is a plant-derived subclass of lignans

which is distributed in many plants and different families. It is the main active component of *Phyllanthus piscatorum*, exhibiting strong antifungal, antiprotozoal, and anti-proliferative properties [60].
Caffeic acid was isolated from *Origanum dictamnus* L. and demonstrated a good antibacterial effect against *A. hemoliticus* and *P. aeruginosa* [57]. Chlorogenic acid, rosmarinic acid, and rosmarinic acid methyl ester were isolated from the methanol extract of *O. dictamnus* L. and exhibited weak antibacterial activity against *S. aureus* [61]. Amburoside A was previously isolated from *O. micranthum* and exhibited a weak carbonic anhydrase inhibitory effect [62]. Oreganol A and B were isolated from the extract of dried leaves *O. vulgare* and exhibited strong 1,1-dipehnyl-2-picrylhydrazyl (DPPH) radical scavenging activity [63].
Naringenin was previously reported in *O. dictamnus* L. and showed a strong antibacterial effect against *Acinetobacter hemoliticus* [57]. Despite the structural similarity with naringenin, apigenin was also isolated from the same species in the same study by Chatzopoulou and co-workers but did not demonstrate any antibacterial activity [57]. Genkwanin, salvigenin, and 5,6,4'-trihydroxy-7,3'-dimethoxyflavone were isolated from the chloroform extract of glandular hairs of *O. x intercedens* [64]. Genkwanin is known for its potent antiviral activity against African swine fever viral infection in Vero cells in a dose-dependent manner [65]. Gardenin B, quercitrin, 5-hydroxy-4',6,7-trimethoxyflavone, and aromadendrin were isolated from *O. majorana* L. with other flavonoid aglycones [58]. Aromadendrin demonstrated moderate anti-inflammatory activity by the inhibition of COX-1 [66]. Apigenin-7-*O*-glucuronide, luteolin-7-*O*-glucuronide, acacetin-7-*O*-rutinoside, and vicenin-2 were isolated from the methanol extract of *O. dictamnus*. None of them demonstrated antibacterial effects against the Gram-positive or Gram-negative strains tested [61].
It can be challenging to characterize a given molecule's biological target. The success rate of identifying accurate molecular targets has greatly increased due to the ongoing development of in silico methods like virtual screening and molecular modelling. Nowadays, a plethora of ligand-based or structural search methods are employed in various online target identification platforms. PharmMapper is a dependable platform that makes use of its pharmacophore model to screen and propose the most probable protein targets for a query chemical [35]. Pharmacophore-based screening works on the basic premise that pharmacophore maps, which delineate the spatial arrangement of structural features, are the primary determinants of the binding of certain compounds to their protein targets. Therefore, molecules whose shapes match these pharmacophore maps have the best chance of binding to the same protein target.
PharmMapper software was employed to screen the 29 metabolites detected in the 50% methanol fraction for binding with putative protein targets in *A. baumannii*. The metabolite justicidin B recorded the highest Fit score (8.56) with the *A. baumannii*-derived enoyl-ACP reductase (FabI). Justicidin B is an aryl naphthalene lignan previously identified in the Lamiaceae family [67], but it is identified here for the first time in *O. majorana* L. extract. The antimicrobial activity of justicidin B was previously reported against *S. aureus*, *E. coli,* and *P. aeruginosa.* In addition, justicidin B has been proven to have antiviral, antifungal, and antiparasitic properties. It also exhibits anti-inflammatory, antioxidant and anticancer properties [68]. It was originally isolated through the bioactivity-guided fractionation of the dichloromethane extract of *P. piscatorum* and demonstrated non-specific cytotoxicity, in addition to potent in vitro fungicidal and antiprotozoal effects [60]. It recently demonstrated strong antiviral potential against Zika virus [69], an effective inhibitor of the Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) [70], and strong cytotoxic activity against HeLa cervical cancer cells through targeting key proteins involved in apoptosis regulation [71]. It was even isolated from a marine-derived actinomycete, *Nocardia* sp. ALAA 2000 and exhibited a broad-spectrum antimicrobial effect against a panel of Gram-positive and Gram-negative strains as well as different fungi [72].
FabI was predicted as a possible binding target for justicidin B. FabI is a bacterial catalytic enzyme that reduces a carbon–carbon double bond in an enoyl moiety covalently linked to an acyl carrier protein. This is the rate-determining step in the elongation cycle of fatty acids used in lipid metabolism and biotin biosynthesis in bacteria [73, 74]. Being a unique bacterial enzyme, FabI has been considered a potential target for developing new antibacterial therapeutics [75, 76]. It has been discovered that FabI is necessary for bacterial viability. Recently, a

wide range of compounds has been recognized as FabI inhibitors, such as triclosan, imidazoles, indole naphthyridinones, thiopyridine, and 4-pyridone [77].

Lately, there has been a growing recognition of promising antimicrobial targets involved in fatty acids synthesis pathways [78]. Novel FabI inhibitors are considered promising antimicrobial agents against MDR bacteria which could be identified by using molecular docking and virtual screening with the FabI X-ray crystal structures that are currently accessible [79]. Fabimycin is a previously discovered FabI inhibitor and an antibiotic candidate with in vivo activity against Gram-negative pathogens [80]. Our docking studies and MDS suggested justicidin B as a novel inhibitor against *A. baumannii* FabI; it binds the enzyme in a pattern similar to its co-crystalized ligand.

The sequence of FabI enzyme that bound to justicidin B was found to be conserved in *A. baumannii* and ESKAPE pathogens strains available in the NCBI database with alignment scores >200. The conservation of FabI enzyme among different bacterial species was confirmed previously [81]. The conservation of the amino acids involved in justicidin B binding was confirmed. Only in *S. aureus* and *E. faecium*, the amino acid ILE-203 was replaced with valine, and PHE-96 by tyrosine, respectively, which should have minimal impact on justicidin B binding. This predicts justicidin B as a promising antimicrobial agent through FabI inhibition with potential broad-spectrum activity. However, the impact of changes in the amino acid sequence in these two Gram-positive pathogens is yet to be determined.

Finally, the predicted activity of justicidin B (an aryl naphthalene lignan) as a broad-spectrum antimicrobial against *A. baumannii* and other ESKAPE pathogens through FabI inhibition still needs to be confirmed by different phenotypic and genotypic studies in a step towards the introduction of new antimicrobial compounds. By tracing the aryl naphthalene lignans containing metabolites, we could take a substantial step towards discovering plant-based chemicals as prospective inhibitors of conserved protein targets in MDR-ESKAPE pathogens.

Conclusions

O. majorana L. extract offers a promising source of natural antimicrobial extracts that could be successfully used against the troublesome *A. baumannii* infections. With further experimental confirmations, justicidin B can be employed as a lead molecule for the development of novel inhibitors against MDR *A. baumannii* and other ESKAPE pathogens through interaction with its potential target, the FabI, and the subsequent inhibition of lipid metabolism and biotin biosynthesis in bacteria.

Statement regarding plants

Origanum majorana L. aerial parts were collected from the Experimental Station of the Faculty of Pharmacy, Cairo University, Giza, Egypt. Mrs Therese Labib, Consultant at Orman Botanic Garden, Dokki, Giza, Egypt, kindly authenticated the plant material. Voucher specimen No. (PHARM-16.12.2020) was kept at the Herbarium of the Department of Pharmacognosy, Faculty of Pharmacy, Cairo University.

Exploration of different strategies of nanoencapsulation of bioactive compounds and their ensuing approaches

Chowdhury, Sailee1; Kar, Koyel1; Mazumder, Rana21 BCDA College of Pharmacy and Technology, Barasat, Kolkata, India2 Gitanjali College of Pharmacy, Birbhum, India

ABSTRACT (ENGLISH)

Background

Nanotechnology has gained rapid popularity in many fields, such as food science. The labile bioactive is enclosed in a shield that protects it from harmful environmental factors. It also allows for targeted delivery to specific areas. Bioactive compounds in foods are slowly degraded or can change due to external or internal factors such as oxidation. Innovative technologies and novel edible packaging materials can be used to reduce bioavailability. One promising technology for overcoming the problems above is encapsulation.

The main body of the abstract

Nanostructure systems enhances a number of properties, including resistance to degradation and improvements of physicochemical functions like solubility, stability, and bioavailability, among others as the nanosize increases surface area and, consequently, activity. A recently emerged nanoencapsulation technologies, including electro spraying, nano-fluidics, complex coacervation, electrospinning, polymerization, etc. have been briefly discussed. Different bioactive molecules can be nano encapsulated by absorbing, incorporating, chemically interacting, or dispersing substances into nanocarriers. There have also been other characterization techniques and different physico chemical parameters investigated to evaluate the characteristics of encapsulated bioactives. The current article highlights numerous bioactive substances utilized for nanoencapsulation using cutting-edge methods.

Short conclusion

This review examines how different encapsulating bioactive materials can improve encapsulating films or coatings. The advent of nanotechnology has opened up a wide range of possibilities for the development, design, and formulation of innovative pharmaceuticals. The food and pharmaceutical industry can focus its attention on products that have added value through the various enhancements offered by nanoencapsulation.

FULL TEXT

Background

Widespread bioactive substances, also referred to as secondary metabolites, are found in plant matrix, and over the

past few decades, numerous in vitro as well as in vivo researches comprises of epidemiological and cohort designing, have provided the indication that eating plant-based food protects against a number of ailments.
The nanoencapsulation process provides a protective barrier around bioactive substances [1]. It is a system where a suitable nano-carrier, resistant to enzymatic degradation [2], especially in the gastrointestinal tract, including chitosan, zein, and alginate, is widely used to encapsulate bioactive compounds employing several delivery methods [3], including association colloids, nano-particles, nano-emulsions, nano-fibres/nano-tubes, and nano-laminates. Research on innovative formulation methods, particularly the creation of biological capsules, is encouraged by the rising demand for biological products in agriculture [4].This has happened because these bioproducts are more stable and their active components are more reactive, which reduces volatility losses [5].
According to these circumstances, bioactive constituents (volatile oils, metabolites from fungi, different extracts from plants etc.) can be shielded from outside influences and deterioration by being enclosed in food and agricultural zones. The encapsulation enables the products' biological integrity and maintains the environment during storage, maintaining the active ingredients' long-term vitality [6].
Upon UV exposure and high temperatures, for instance, microbial compounds are vulnerable to abiotic and biotic variables that decrease the efficiency of these living things and metabolites of those, results in the loss of toxin integrity and spore viability [7].
Encapsulation functions as a substitute for these difficulties in this way. It enables, among other things, the reduction of volatility-related losses, the improvement of biological integrity, enhancement of efficacy, enhancement ofcommercial viability, and enhancement of stability of different formulations in the agricultural sector [8–10].
Numerous polymers are employed as wall materials for encapsulation in order to safeguard the core, which is typically created by bioactive chemicals. For this, a variety of substances are employed, including chitosan, maltodextrin, gums (such as shellac, gum arabic, gum acacia, and), whey protein, starch, sodium alginate, pectin, cellulose and,sodium caseinate, zein, pullulan, galactomannan [11–15].
Before a new encapsulated product is developed, it is essential to conduct preformulation studies on the materials to be used for encapsulation in order to accommodate the physicochemical behaviour of the active ingredient and produce the desired encapsulation efficiency, as well as the size of the shell or capsule, the surface morphology and functionalities of the capsule, and the behaviour of the encapsulated active ingredient. Encapsulating pharmaceuticals with the appropriate encapsulating material(s) can greatly increase the bioavailability of both currently available and upcoming poorly soluble drugs [16].
For encapsulation, natural polymers are ideal materials. Natural polymers, which are macromolecules with high molecular weights that are derived from nature, are favoured because of their adaptability to change, biodegradability, biocompatibility, renewability, and low toxicity [17].

Main text

Bioactive composites derived from plant

Plants have always been a benediction for maintaining a healthy lifestyle from the dawn of time since them not only offer a safe place to live but also, and perhaps most significantly, food and bioactive components for therapeutic use [18]. Plants and foods derived from them were first employed as a source of food and for its nutritional value; subsequently, their therapeutic properties, which might treat ailments, were discovered and Fig. 1 has shown various types of bioactive compounds from plant for nanoencapsulation [19]. Furthermore, these substances are categorised as follows depending on their clinical and toxicological characteristics:

Fig. 1 [Images not available. See PDF.]

Bioactive compounds from plant

Alkaloids

Alkaloids are heterocyclic chemicals with a small distribution in the plant kingdom that have a bitter taste and can retain nitrogen. Tropane alkaloids having anticholinergic characteristics are found in the Solanaceae family of plants, which also includes *Atropa belladonna*, *Datura spp.*, and *Hyoscyamus niger.* Alkaloids are the focus of research on

plant-based drugs. The investigation of alkaloids from herbal and medicinal plants showed antiproliferative effects and antineoplastic properties in vitro and in *vivo* for a wide range of cancers. The databases that were accessible electronically have been screened for antiproliferative properties in lung cancer treatment [20]. It is frequently employed to lessen muscle pain. Additionally, pyrrolizidine alkaloids are found in Senecio species and other Asteraceae and Boraginaceae plants. With huge application including the treatment of cancer cells, boosting bone marrow leucocyte production, and increasing cardiac contraction. Additionally, *Theobroma cacao* and *Coffee arabica* both contain methylxanthine alkaloids [21].

Glycosides

They are usually attached with a monosaccharides or oligosaccharides or sometimes with uronic acids. Glycone is the portion that is attached to saccharide, while aglycone is the portion that is made up of pentacyclic triterpenoids and tetracyclic steroids. The main subcategories of glycosides are saponins, anthraquinones,cyanogenics, glucosinolates, and cardiac glycosides.

These substances are glycosylated, and the aglycone moieties, which are connected to uronic acid or monosaccharide or oligosaccharide, are constituted of vitamins, terpenoids, alkaloids, polyphenols, steroids, antibiotics, and other substances [22]. The glycosides' glycosidic residue is thought to be the cause of their biological effects [23]. The cardiac glycosides, diterpenoid glycosides, cyanogenic glycosides, and anthraquinone glycosides are among the classes of glycosides that are frequently harmful. Cardiac glycosides are known to produce hyperkalaemia, a disease that results in blood potassium ions that are greater than normal [24].

The Na+/K+-ATPase activity of bio-membranes is inhibited by the cardiac glycoside derivatives digitalis and strophanthus, such as ouabain [25, 26]. Diterpenoid glycoside consumption has been linked to renal proximal tubule necrosis in both humans and animals, as well as centrilobular hepatic necrosis. Adenine nucleoside carriers are hampered by diterpenoid glycosides, which have been connected to the inhibition of oxidative phosphorylation in mitochondria [27].

More than 2,650 plant species produce the cyanogenic glycosides, which are -linked glycosides of -hydroxy nitriles.Plants containing this class of glycosides produce hydrogen cyanide into the bloodstream, which impairs the efficient utilisation of oxygen in the peripheral tissues by reducing the activity of cytochrome oxidase in the mitochondrial electron transport chain. Aside from goitre and congenital hypothyroidism in children, irreversible paralysis, angular stomatitis, damage of the optic nerves, tropical ataxic neuropathy, sensorineural hearing loss, and sensory gait ataxia are further harmful outcomes of cyanide use. Examples of cyanogenic glycosides that can be found in edible plant parts are linamarin and lotaustralin, both of which are present in *M. esculenta* [28].

Tannins

Tannins are bioactive bitter polyphenolic chemicals that bind to and precipitate proteins, alkaloids, and other substances. They are soluble in water. Numerous plant species contain tannins, particularly those in the Polygonaceae and Fagaceae families. Condensed tannins and hydrolysable tannins are the two main categories.Condensed tannin groups are composed of bigger polymers of flavonoids, whereas hydrolysable tannin groups are composed of glucose clusters coupled to various catechin derivatives. Tannin molecules and protein molecules commonly engage in random interactions. Larger groups of tannins are used as drugs to treat skin bleeding, diarrhoea, and transudates [29].

Terpenoids and phenylpropanoids

The isoprenoids, often referred to as terpene derivatives, are made up of numerous combinations of terpene derivatives that are derived from five carbon isoprene units, which are combined together to form terpenoids. Instead of existing as low polar or none terpene aglycones, the majority of terpenoids exist as glycosidic forms [30].

An isoprene with penta carbons is used in the synthesis of terpenoids. Mono-terpenoids contain two isoprene units, whereas sesqui-terpenoids include three isoprene units. They are well-known for having a lower molecular weight and having a large number of groups more than 25,000. Though, phenylpropanoids are a class of compounds having a basic carbon structure that begins at nine and above, strong flavours, and a volatile tendency. These substances are frequently found in the *Lamiacea*e family and are known as volatile oils [31].

It has antibacterial, antiviral, and antitumor properties and is used as a natural medicine. Additionally, it supports gastric stimulation. Diterpenoids are also a cluster of 4 isoprene units with a strong flavour that is a lipophilic non-volatile (odourless) molecule. Since it has antioxidant properties, it is abundantly available in many plants, like coffee arabica [32].

Resins

Resins are the mixtures that include both volatile as well as non-volatile property chemicals, as well as a collection of compounds that are lipid soluble. While volatile resins have mono- and sesquiterpenoids, non-volatile resins are made up of diterpenoid and triterpenoid molecules. The antibacterial and wound-healing abilities of these resins, which are widely distributed in herbaceous plants, are well-known [33].

Proteins

Since proteins are a substantial source of nutrients for both animals and human, plant proteins have grown significantly in favour in the food and pharmaceutical industries. It is commonly known that the Fabaceae family, lentils, and the Euphorbiaceae family all have significant protein content [34].

Categorization of nanoencapsulation schemes

In the area of food science, nanoencapsulation has grown in favour recently. A bioactive substance is used as the core matrix and is encapsulated a wall matrix in inner part that can survive enzymatic and other degradation. Because bioactive substances are very susceptible to heat and the digestive enzymes found in the stomach and GI system of a person, using a substantial wall matrix/nano-carrier protects against them. Encapsulating bioactive compounds has been the subject of increasing research for various reasons. Encapsulations have been achieved using a variety of techniques, including electrospinning and coacervation. These encapsulations are known to enhance the physicochemical characteristics of bioactive compounds, increase bioavailability and stability, control the release, improve bioactivity and disguise flavour. The materials used include lipids and synthetic and natural polymers. They also influence performance and functionality. Additionally, these wall materials aid in sustaining the compound's nutritional activity and aid in disguising some compounds' unpleasant tastes [35]. Depending on how much energy is used to encapsulate these molecules, several methods are used, such as top-down and bottom-down procedures as well as their combination [36].

The top-down method of encapsulation uses equipment like spray-drying, ultrasonication, homogenizers, and many others, which results in high power consumption, as opposed to the bottom-up method, which uses techniques like precipitation, micro-emulsification, conjugation, atom exchange, etc., which use much less energy. Delivery release rate, solubility and stability of the nano-carrier, and manufacturing cost, are significant variables that are crucial in choosing a specific method for nanoencapsulation [37].

Bioactive agents and its encapsulating carriers

Hybrid nano-carriers

Internal (metal and polymer) and exterior (single/multi-lipid layer) networks make up the two main networks that make up hybrid nano-carriers [38]. This nanoparticle's outside coating serves as defence against degradation and water diffusion. These lipid-polymer and organic–inorganic carriers were primarily created for the regulated release of bioactive substances for the treatment of cancer cells.

Seyedabadi et al. reported that when compared to nano-liposomes without chitosan covering, slow-release encapsulated caffeine using chitosan wrapped in nano-liposomes performed better for the encapsulation of caffeine. [39]

Lipid-based nano-carriers

Niosomes, nano-liposomes, particulate carriers are lipid-based nano-carriers, also referred to as vesicular carriers. As a result of the interaction between the surfactant molecule and the aqueous solution, a spherical bilayer is formed. It is employed to encapsulate peptide among other bioactive substances. While liquid and solid lipid are mixed together to create nano-lipid particles, in internal phase solid lipid nanoparticles are created by combining solid lipid [37].

Chaudhari et al. studiedcompritol, a solid lipid, squalene, a liquid lipid, span 80, and tween 80 were used as

emulsifiers and co-emulsifiers to encapsulate the compounds piperine and quercetin. For slow lipid wall matrix erosiveness (12 h), these bioactive chemicals were encapsulated and showed slower release [40].
Another research reported by Abd-Elhakeem et al. demonstrated about employing lipid-based nanoencapsulation to elevate the bioavailability and target delivery of eplerenone orally. After 24 h, rabbit intestinal permeability to eplerenone-loaded nano-lipid capsules were up to two folds higher than that of traditional aqueous medication [41].

Polymeric nano-carriers

They are thought to be an incredibly ideal part for encasing and delivering bioactive chemicals. Currently, natural-based nano-carriers such starch, chitosan, casein, albumin and whey protein are most frequently employed. Ravi et al. in 2018 utilised chitosan as a wall substance to enclose the marine carotenoid named fucoxanthin [42]. The bioactive compound's anticancer activity was improved, and caspase-3 activity was 25.8 times higher as a result. Gagliardi et al. conducted a comparison study for the encapsulation of rutin using natural and synthetic nanoparticles, namely poly (lactic-co-glycolic acid), zein etc. According to the findings, poly release represented slower release (25%) after 60 h in comparison to zein along with 0.8% rutting [43].
Apart from this, in 2021, a research group from Portugal, Costa et al. bioactive extract from grape pomace was encapsulated with nanoparticles of chitosan and alginate, which increased the bioactivity and prevented the bioactive components from being hydrolysed in the gastrointestinal tract [44].

Systems of nanoencapsulation of biologically active composites

Capsulation of Bioactive substances is considereda more difficult technique than microencapsulation. It is broken down into three primary categories: low-energy, high-energy, and a combination of low and high. Low-energy processesinclude precipitation, micro-emulsification, conjugation, etc.[45]. Spray-drying, ultrasonication, homogenization, etc. will fall under the category of high-energyprocesses.
Delivery energy, release rate, solvability, solidity of the nano-carrier, and manufacturingprice are some of the variables that affect the decision of which method to adopt for designing nano-capsules. Several encapsulation methodshave been covered in the current review study [46].

Electro spraying

An alternative to the drying-encapsulation method is the electro-spraying process. At room temperature, it uses high-voltage electric current to operate. The fundamental idea behind electrospinning and electro-spraying is the same, but what sets these two techniques apart is the molecular adhesion of the polymers, which is less for electro-spraying causing the jet to break up into tiny droplets [47]. Due to the surface tension in the air, the jet particles acquire a spherical shape when exposed to it. It has been previously demonstrated that using zein as a wall material during electro spraying increases the permeability and bioactive release characteristics in green tea catechins. Later in 2019, it came to light that resveratrol achieves a 70% encapsulation efficiency when nano-encapsulated with the same wall material [48].

Micro-/nano-fluidics

The fundamental idea behind micro- and nano-fluidics is the interfacial contact between the fluids. It promotes droplet development delaying the emancipation of biologically active substances. Additionally, it aids in the creation of precise nano-droplets of a similar size. It comprises a polydimethylsiloxane glass foundation. This channel helps in transporting the fluid because it is related to all other channels [49]. A syringe is used to inject gas and liquid. This processutilizes nano or microfluidic appliances as emulsion devices. Micro fluidization was used to create a nano-emulsion system under ideal conditions, which included pressures between 40 and 65 MPa and 2–5 cycles. The research suggested that the nano-emulsion included smaller fish oil droplets. After a few years, the system was altered by utilizing micro fluidization and citrus pectin. The results exhibited that the qualities of the nano-emulsion were improved, thus safeguarding cholecalciferol against UV [50] degradation in comparison to the original pectin. Additionally, the modified pectin's molecular weight and hydrodynamic diameter were both decreased to 235 kDa and 420 nm, respectively.

Complex coacervation

In the encapsulation process known as complex coacervation, two polyelectrolytes with opposing charges engage

with one another in an aqueous media. The bioactive substance is encapsulated around a protein or carbohydrate compound [51]. This interaction only occurs at particular parameters like strength, polymeric concentration, biopolymer content, and biopolymer weight. This method enables the creation of particles that have a coating of a capsulating agent thus protecting the biologically active chemicals [52, 53].

Electrospinning

By applying high-voltage electricity to polymeric fluids to process fluids with electric charges, electrospinning creates dry micro- and nanostructures. The instrument essentially consists of three main components: syringe and pump, an electrified needle, and a collection plate [54]. When high-voltage electricity is applied to the nozzle or needle, the liquid is forced inside. The studies were conducted at room temperature, and the nanofibers were stored in a desiccator before being transported after being collected on an electric collector plate [48]. Nano-fibers can be anything between one and many nanometers in diameter [55].

Blend, coaxial, emulsion, high-throughput, and polymer-free are among the five main types of electrospinning techniques. The biologically active component and the solutions of the polymerare assortedtogether using either a blend or emulsion approach, which is effective at managing the release of bioactive substances. Using this method, both hydrophilic and hydrophobic compounds can be easily enclosed [56]. On the other hand, a coaxial electrospinning arrangement utilizesa syringe connected to a single output pump producing enclosed fibers [57]. High-throughput electrospinning, on the other hand, is a pointless process used to create ultra-thin fibers from emulsions. In 2018, a high-throughput process was utilized to create glycoconjugates. In addition to all of these methods, the polymer-free methodutilizes a solution of a polymer having high masswhich is incorporated by a pump to produce a greater yield than the traditional methods [58].

According to Xiao et al. [59], this method can create nanofibers varying from 80 to 50 nm, while Moreira et al. [60] claim that the polymer-free method can widely help the food industry. Additionally, Poornima et al. [61] successfully delivered controlled drug release using this method to capsulate resveratrol with caprolactone and lactic acid. While Zein was used to enclose resveratrol with the best encapsulation effectiveness (96.9%), they are the ideal one according to researchers [62].

Spray chilling

Ascorbic acid, a form of vitamin C, has been shown to have positive benefits in agriculture, including lowering the impact of nickel and cadmium on barley, reducing the stress of drought on sweet pepperand cucumber, and enhancing apple quality [63]. It makes it possible to lessen the effects of salt stress and promote better barley growth. In this regard, spray cooling has been reported as an efficient method for encapsulating ascorbic acid, displaying retentions above 80% [64]. The method entails melting the completely hydrogenated palm oil to 85 °C, mixing in the ascorbic acid, and then letting it instantly flow through the spray drier before being cooled to 4 °C.

Polymerization

In this method of nano-encapsulation, the bioactive ingredient is added after the aqueous fluid's monomers are polymerized to create nano-particles. Additionally, the nano-particles are cleansed during encapsulation by getting rid of excess stabilizer and surfactant that had accumulated on their surface. Typically, this method is used to create poly butyl cyanoacrylate nanoparticles [65].

Supercritical microencapsulation

Modern terminology for supercritical microencapsulation includes "micronization." Mild temperatures are used during supercritical micronization to prevent lowering the quality of bioactive substances. Water and carbon dioxide are the two most common solvents utilized in this method. To microencapsulate bioactive substances of relevance to the food and agricultural industries, carbon dioxide under supercritical circumstances has grown in popularity [53].

It is a different environmentally friendly technique for creating nanoparticles. Since CO_2 is non-toxic, inexpensive, and inflammable, it is frequently utilized as a supercritical fluid. In this procedure, a liquid solvent is used. This liquid solvent isassorted with supercritical liquid (CO_2). Instant precipitation now occurs as a result of the solute's insolubility non the supercritical fluid, which enhances the effect of the produced nanoparticles [66].

According to some studies, depending on the characteristics of the wall matrices and the active components, this

method can be beneficial in a variety of contexts, including the creation of encapsulated products. The processing method employing supercritical CO_2 is chosen according to the main component and polymer to be capsulated. For instance, the way CO_2 reacts with the solvent, the wall material, and the active substance. The contact between CO_2 and the solution of polymer utilized in the biopolymer drug delivery system is crucial to the encapsulation process. While polymers, such as polylactide, are effective for SAS treatment, RESS is challenging to solubilize in supercritical CO_2 [67].

Ultrasonication

The term ultrasound refers to a group of sound waves that are louder than 16 kHz. There are two types of sound waves: low-intensity waves and high-sound waves. Low-intensity waves are utilized for the purpose of detection, butmolecules are modified utilizing high sound waves, including reducing their size and emulsification. It is employed in nanotechnology to create several types of nanostructures [68].

A generator, a transducer, and a titanium horn-shaped sound expeller make up the ultrasound system's components [69]. To create nano-emulsions, nano-liposomes, niosomes, and other types of nano-delivery systems utilizing ultrasound, a variety of nano-delivery strategies have been devised [70].

Homogenization

Homogenization is the process of creating homogeneous-sized nano-fragments at a particularly escalated pressure. It has a pressure range of 100 to 400 MPa, which is 10 to 15 times higher than a typical homogenizer. The study found that the milk and milk product industries frequently use this technique to improve the basic characteristics of the products while also enhancing the anti-microbial quality of certain microbes. At 250 & 350 MPa homogenization pressure and 40 and 50 °C inlet temperatures, a decrease of about 2 and 3 log cycles was found [71].

It also serves as an alternative to thermal processing since it effectively inactivates enzymatic and microbial characteristics [72]. The homogenization technique was also used to create a soy protein emulsion [73]. Figure 2 has shown various types of nanoencapsulation systems for bioactive compounds.

Fig. 2 [Images not available. See PDF.]

Types of nanoencapsulation systems for encapsulation of bioactive composites

Nano encapsulated bioactive agents and its physicochemical features

Encapsulation efficiency and loading capacity

The amount of bioactive compounds encapsulated within the matrix wall is what we call it. Quantifying the amount of mixture in a nanoparticle can be done using UV–Vis spectrum analysis [74]. The perfect nanoparticle has the maximum loading capacity of the compound with minimal wall materials. The incorporation or absorption of bioactive compounds can be done in two ways. Entrapment capacity mainly depends on the solubility and molecular mass of the bioactive compounds encapsulated within the material of the wall [75]. The maximum entrapment capacity is reported for macromolecules and proteins at an isoelectric level.

Particle size

These properties are conscientious for the quality of the nanoparticles, as well as their delivery capability, stability and viscosity [76]. The intracellular capacity of nanoparticles is higher than that of micro-particles due to their relative size and mobility [77].

The size and shape of nanoparticles can be detected using a variety of microscopes. Optical properties of nanoparticles and nano-capsules or micro are determined by laser diffraction &scanning electron microscope techniques. The surface study, which requires extremely powerful analyzers like transmission electron microscopes to determine the quantity of pores, is needed. Mixing fluorescent dyes with the bioactive compounds makes it possible to detect multiple locations using fluorescence or confocal microscopy. The photon correlation spectrum, or dynamic light scattering, is widely used to determine the size of nanoparticles in the 1000 nm range. This helps to determine the particle range and its concentration within a matrix [78]. The charge characteristics of nanoparticles are identified. The electrical properties of nanoparticles can be altered by altering the compounds in the fluid. A nanoparticle with a Zeta Potential greater than (±) 30 mV is stable. It is interesting to note that the Zeta Potential

process can identify whether partition materials are encapsulated within the nano-capsule or if they cover its outer arrangement [64, 79].

Stability

The nanoparticles' stability is the ability to stay intact within the matrix wall until they are released at the time and location desired. The nano-emulsions are more stable caused by the morphological structures of small droplets. The stability of bioactive compounds can also be tested by placing them into various modified environments, such as high/low temperatures, fluids with different ionic charges, and pH levels [80].

Control release

The release of bioactive agents depends on several factors, like as solubility of the mix, the surface binding/adsorption, and the diffusion of the matrix. Other aspects include matrix degradation or a combination of matrix degradation, diffusion, and degradation. The release of nano-spheres containing bioactive compounds in an even distribution is mainly due to erosion of the wall material. Diffusion is the only way to control release if wall degradation occurs slowly. Quick release can lead to poor wall materials or small binding ability [65]. The mixing technique has been reported to play a crucial role in the release profile for nano-capsules, as it slows the release [81]. If the coating is polymer, the release will be by diffusion from the inside of the matrix to the outside. Several other techniques, such as reverse dialysis bags, dialysis bags, and synthetic or artificial membrane diffusion, can release the compound.

Applications of nano-encapsulated compound

The most common encapsulation material is natural or synthetic polymers. Food encapsulation is a technique that has been used for many years in the food industry [82]. Encapsulation is a technique that aims to deliver bioactive compounds directly to target organism tissues. The bioactive compounds are more stable and bioavailable, and their benefits to the body increase [83]. Table 1 shows the various applications of nano-encapsulated compounds in food. Other compounds useful for food encapsulation include dyes and flavors, vitamins, antioxidants, enzymes and bioactive peptides.

Table 1. Applications of nano-encapsulated compound in the food industry

Sl. No	Nano-encapsulated compound	Nanomaterials	Functions	Food materials	References
1	Vitamin D3	Potato proteins	encouragement of human health	beverages solutions	[96]
2	Vitamin E	Edible mustard oil	Health supplement antioxidant	Mango juice	[97]
3	α-Tocopherol	Canola oil and tween 80	Antioxidant agent	Fish sausages	[98]
4	Quinoa peptide	Soyphosphatidylcholine and cholesterol	Natural food preservative	Fresh beef burgers	[99]
5	Pears peel fruit	Sodium alginate-chitosan	Preservative	Guava juice	[100]

6	Olive leaf phenolicsoleuropein	Lecithin cholesterol	Functional food product	Yogurt	[101]
7	Nisin and garlic extract	Phosphatidylcholine and oleic acid	Antimicrobial agent	Whole UHT milk	[102]
8	Nisin and lysozyme	Phosphatidylcholine pectin	Natural antimicrobials	Whole UHT milk	[103]
9	Fish skin peptide	Lecithin	Preservative and vehicle for Entrapping fishy smell	Pork patties	[104]
10	Fish oils	Lecithin sunflower oil	Improvement of the nutritional value	Bread	[105]
11	Chlorogenic acids	β-cyclodextrin	Phenolic compounds Supplementation on aroma volatile profile	Bread, cookies, caramel cottage cheese, nutty filling, and mushroom or meat stuffing	[106, 107]

Other substances, such as those found in essential oils and herbal extracts with insecticidal and antimicrobial properties, are being encapsulated [84]. Biotechnology faces a difficult task in controlling volatile oils and extracts. The essential oil of savoury leaves was combined with natural polymers like apple pectin and gum arabic. All polymers showed a higher efficiency of encapsulation. The herbicidal effect of amaranth, tomato and other plants was subsequently increased [85]. Pepper oil was encapsulated, and its antibacterial activity was tested long-term. Encapsulating this oil with gum arabic/malt dextrin had an inhibitory action against *Pseudomonas aureus, Enterococcus Faecali* and *Staphylococcus aureus.*

The Supercritical Anti-solvent method encapsulated curcumin from turmeric using polymer matrices. This dye contained turmeric extracts. These polymers were Eudragit L100 and Pluronic F127 or mixtures thereof. In this field, economic evaluations were also developed to help boost the application of the technology on a larger scale and to transfer it to an industrial scale.

Gas anti-solvent was used to create poly (caprolactone), containing resveratrol, with heterogeneous properties. The encapsulation process was successful because the resveratrol's chemical structure or antioxidant activity did not change. The microparticles also maintained their release over 48 h [86].

The use of non-hydrolyzed polymers in agriculture has increased due to their accessibility and price. Hydrolyzed starches are the most effective agents for encapsulating pesticides (metabolites made by *Bacillusthuringiensis*) because they protect environmental factors while improving the formulation. Encapsulation is a viable method for formulating biopesticides and/or biofertilizers for agricultural fields. Encapsulation has several uses in agriculture [87] and pharmaceutical, which are shown in Tables 2 and 3

Table 2. Applications of nano-encapsulated compound in the agricultural industry

Sl. No	Nano-encapsulated bioproducts in agriculture	Functions of nano-encapsulated compound

1	Biofertilizer	1. Enhanced formulation stability 2. Better biological properties 3. Slow release of encapsulated bioproducts 4. Reduction of volatility 5. Enhanced in efficiency 6. Increase in commercial viability 7. Protection of encapsulated materials
2	Bioherbicide	3
Biofungicide	4	Bioinsecticide
5	Plant extracts	6

Table 3. Application of nano-encapsulated compound in pharmaceutical industry

Sl. No	Nano-encapsulated bioactive compound	Applications
1	Phenolic compounds	Protection, improvement of their antioxidant and other functional activities, target delivery
2	Carotenoids	Stabilization, efficient controlled release, expansion of their industrial applications
3	Essential fatty acids	Stabilization, better solubility, decrease volatility, use of lower doses, favorable impact on the sensory quality of the final product
4	Vitamins	Protection to oxidation
5	Peptides and enzymes	Improved antimicrobial or antioxidant activity, better absorption
6	Probiotics and prebiotics	Increment of viability, promotion of gastrointestinal health

Trichoderma Harzianum is a very effective biological control agent for agricultural purposes. Its live spores make it highly sensitive to both biotic and non-biotic factors. Encapsulation improves the activity of phytopathog*ens, such as Sclerotinia sclerotiorum. Another study encapsulated spores from the* Trichoderma genus in biologically-based lignin to treat diseases in the vine trunk. In vitro tests showed that the spores remained at rest until the fungus triggered germination at the right time.

The Pickering emulsion microencapsulated *Metarhizium conidia* were found to have a better distribution of cells in the leaves and greater control over the *Spodoptera Littoralis* pest [88]. In a separate study, *Bacillusthuringiensis*

aizawai was encapsulated in Pickering emulsion water-in-oil. It was found that *Spodoptera thuringiensis aizawa* larvae of the first instar were killed with 92% efficiency [89].

Similarly, inoculating potatoes with two strain of *Pseudomonas fluorescens* by an alginate/gelatin capsule led to a larger level of safeguard from harmful soil conditions and a greater establishment in the Rhizosphere. The antifungal effect of salicylic acids containing zinc oxide was shown when the bacteria were encapsulated with sodium alginate. Azadirachtin, a natural insecticide found in neem trees (*Azadirachta indica*), was nano-emulsified with whey isolate. The strategy significantly affected the death of *Spodoptera frugiperda*, a pest caterpillar that attacks soybean crops. The encapsulated orange essential oil also positively affects the mortality of *Spodoptera frugiperda*, affecting soybean crops [90].

Peel inhibits the growth of *Escherichia colitis* and *Staphylococcus aureus* [91]. A study on the encapsulation of biofertilizers showed formulations with *Burkholderia spp*. and Pseudomonas alginate encapsulated in phosphate-alginate provided superior environment for the growth of wheat plants under semi-arid or salt-stressed environments [92]. A study showed that biofertilizers containing *Pseudomonas cepacia* and *Azosprillum brasilense*, encapsulated in polymers made of clay mineral and sodium alginate, led to a higher level of formulation control [93]. The study also showed that the slow release of active compounds positively affected wheat plants' growth, with increased biomass.

Future directions

Nanoencapsulation-based bioactive compounds are unique and current; their operation in both the food and pharmaceutical areas results in new opportunities for commercialization. Their application is primarily the creation of nanostructured ingredients for food and pharmaceutical product, which allows the enhancement of solubility and stability, flavour, texture, and colour of foods. Encapsulation can be used to mask unpleasant aromas or flavours. It also increases the bioavailability of nutrients and allows for controlled release in both food and pharmaceutical products. At the same time, the volatility of compounds encapsulated is reduced. In the near future, food and pharmaceutical industries can gain from incorporating NPs into their new products [94, 95].

Conclusions

It is necessary to strengthen our immune systems to combat the rapid spread of deadly diseases. This can only be achieved by consuming bioactive substances extracted from plants. Nanoencapsulation technologies are unique and recent; their action in both the food and pharmaceutical areas effects in new opportunities for commercialization. The nanoencapsulation with carriers of bioactive compounds is an approach that can be used to improve their bioavailability, stability, and use within the pharmaceutical industry. Nanotechnology used to encapsulate microbial compounds with bioactive properties has many obvious advantages, from packaging to food processing. These include improved bioavailability and stability. The controlled release and defence of bioactive substances also offer safety benefits. To facilitate the safe marketing of health-beneficial new nanotechnology products, global legislation is needed to recognize the safety and toxicology of these nanomaterials. In other words, it is necessary to develop and implement novel extraction and encapsulation technologies for highly effective microbial bioactives that can be used in different industries, such as the food, pharmaceutical and cosmetic industries. Further, it is necessary to understand the safety and toxicology of nanoencapsulation, as well as to implement global legislation to ensure safe marketing and use.

Phytochemical analysis and evaluation of antibacterial activity of various extracts from leaves, stems and roots of Thalictrum foliolosum

Mishra, Manoj Kumar1 1 FET Rama University, Department of Biotechnology, Kanpur, India (GRID:grid.459916.6) (ISNI:0000 0004 1777 2787)

ProQuest document link

ABSTRACT (ENGLISH)

Background

Thalictrum foliolosum, a member of the Ranunculus family, is recognized for its therapeutic potential in addressing gastric issues, dyspepsia, tooth pain, abdominal colic pain, and piles. The diverse array of secondary metabolites present in the plant contributes to these therapeutic applications. This study aims to uncover and quantify the bioactive secondary metabolites found in the unexplored leaves, stems, and roots of *T. foliolosum*. Additionally, we also aimed to evaluate the antibacterial activity and MIC values of these extracts against a panel of pathogenic bacteria, such as pathogenic strains, including *Escherichia coli, Pseudomonas aeruginosa, Streptococcus mutant* and *Staphylococcus aureus*.

Result

HPLC analysis suggested all examined compounds were found significantly more in root parts of plant. To

determine the potential antimicrobial activity of different plant parts result suggested chloroform fraction of root most effective with variable potency against each examined pathogen at 25–100 µg/ml extracts which indicated rich content of berberine in this fraction. Minimum MIC (121.26 µg/mL) of the chloroform fraction of the root was also supported the results. Fatty acid methyl ester analysis by gas chromatography revealed that the stem contained high levels of fatty acids, such as palmitic acid, stearic acid, and linolenic acid, all of which have antibacterial properties.
Conclusion
The potential antimicrobial activity of extracts of various plant parts strongly supports the *T. foliolosum* plant's widespread use in folk medicine for the treatment of various chronic diseases and adulterants with various associated medicinal plant species.

FULL TEXT

Background

In nature, plants are the richest resource of bioactive natural products, such as alkaloids, phenolics, flavonoids, carotenoids, triterpenoids and other secondary metabolites for thousands of years [1]. Extensive studies in ancient pharmaceutical practices and contemporary clinical findings consistently affirm that plant-based medicines exhibit a higher safety profile compared to their synthetic counterparts, maintaining a crucial role in healthcare. Derived from botanical sources, these medicinal compounds serve as chemical entities in traditional medicine systems, modern pharmaceuticals, dietary supplements, pharmaceutical intermediates, and synthetic drug formulations [1, 2]. Thalictrum, a genus encompassing approximately 220 species, exhibits a diverse array of secondary metabolites including flavonoids, alkaloids, steroids, triterpenoids, triterpenoid glycosides, carotenoids, lignins, tannins, cardiac glycosides with high molecular weight, fatty acids, phenolic acids and sterol across its various species, highlighting the pharmacological significance of this genus [3–5]. While there isn't extensive research specifically on *Thalictrum foliolosum's*, although this species has been used in traditional medicine for various purposes. Given the relevance of phytopharmaceuticals in today's society, the current study concentrated on *Thalictrum foliolosum* DC, an endemic herb that has received little attention.

T. foliolosum is a potential medicinal herb belonging to the Ranunculaceae family that is found widely in the Northern Hemisphere region in India and the China Pacific [6–8]. Previous studies have shown that *T. foliolosum* roots are used locally as a tonic, antipyretic, diuretic, laxative, and collyrium for the improvement of eyesight as well as in the treatment of gastric problem, dyspepsia, tooth pain, abdominal colic pain and piles [8, 9]. The combination of the dried root of *T. foliolosum* with *Thymus linearis* was very effective in treating colic and gastric problems [10]. Whole-plant extracts of *T. foliolosum* also showed inhibitory effects against cancer cells as well as the progression of malignant malarial fever [11, 12]. *T. foliolosum* plants may be regarded as belonging to an elite group of medicinal plants due to the presence of benzylisoquinoline alkaloids (BIQ), which include berberine, protoberberine, magnoflorine palmatine, jatrorrhizine, and other considered isoquinoline alkaloids along with several groups of polyphenolic compounds that demonstrated strong bioactivity [13–15]. Previously published reports showed the roots and rhizome parts of *T. foliolosum* have alleviative properties. Therefore, unrestricted collection of roots and rhizome parts resulted in the decline of their population in their habitats [6, 7]. Generally, it is observed that complete knowledge about the chemical composition and potential medicinal uses of various parts of a plant will enable systematic harvesting and conservation of declining plant populations. Considering the therapeutic importance of *T. foliolosum*, there were no more reports of bioactive compounds in aerial parts of this plant. The current study used reverse phase HPLC to identify and quantify four therapeutically important BIQ alkaloids, namely magnoflorine, berberine, palmatine, and thalicarpine, in different parts of the plant (leaves, stem, and roots). Additionally, fatty acids were identified using gas–liquid chromatography. Moreover, a comparative study of antimicrobial activity against human pathogenic bacteria, such as *E. coli*, *Pseudomonas aeruginosa*, *Streptococcus mutans*, and *Staphylococcus aureus*, was conducted using extracts or fractions of various parts of the plant. Thus, the present study was undertaken to analyze the alkaloids content and major fatty acids in *T. foliolosum* leaves, stem and roots and to understand the relation between with antimicrobial activities.

Methods

Sample collection of *T. foliolosum* plants and processing

T. foliolosum, a perennial herb, was obtained in September month from the forest areas of the Nanital district (2290-m asl), Kumaon region of Uttarakhand state in India (Fig. 1). Nanital is located at the GPS coordinates of 29° 22′ 49.0944" N and 79° 27′ 48.8520" E. This region has a humid subtropical climate with an average annual temperature of 17.1 °C (62.7 °F) and 1903 mm (74.9 in) of rainfall. The plants were identified by Dr. Harsh Singh (Taxonomist scholar) and a voucher specimen number 257717(LWG) was deposited at CSIR-National Botanical Research Institute (India). The collected plant materials (leaves, stem and roots) were initially carefully washed with saline water, then the samples were placed under running tap water for further washing. After some time, plant materials are rinsed again with autoclave water for half an hour and then put on blotting paper for 48 h to dry. The plant materials were blotted dry before being chopped into small pieces and dried in the shade for 15–20 days. Finally, the dried plant material was ground into a fine powder using an electric grinder (Mill CT 293 Cyclotec TM) and stored in sterilized glass bottles [5, 6].

Chemicals

All the standards of BIQ alkaloids (Magnoflorine chloride, berberine chloride, palmatine chloride and thalicarpine) were procured from Sigma-Aldrich (USA). Solvent such as methanol, hexane, ethyl acetate, chloroform and acetonitrile and other chemicals were purchased from Merck (India).

Extraction of plant materials for HPLC analysis

For quantitative analysis, fine powders of different plant materials (1 g) were extracted with 25 ml of acidic (1% HCl) methanol using ultrasonication method (Aczet, Ultrasonic cleaner CUB) at room temperature for 40 min. After ultrasonication, plant materials in extracted solvents were kept at room temperature for overnight. The next day, all sonicated extracts were filtered through a Whatman No 1 filter paper in a round bottle flask, and fresh extracted solvent was added to the same plant materials for additional ultra-sonification. Three times, the same procedure was followed. Later all extracted materials were pooled in round bottom flask and evaporated at 50 °C using a rotary evaporator (Buchi, USA) under low pressure. Finally, the dried extracted plant materials were dissolved in methanol and filtered through a 0.45 µm filter and stored at 4 °C for subsequent HPLC analysis [6, 7]. The acidic-methanol extract of *T. foliolosum* had a yield of 27.42%, 21.10% and 16.24% of the extracted root, leaves and stem respectively. Reference standard solutions (i.e. berberine, palmatine, magnoflorine and thalicarpine) (Sigma-Aldrich) were prepared in methanol. All of the extracted solutions as well as the standard solutions were maintained at 4 °C in the refrigerator.

HPLC method

Plant samples were extracted and subjected to further analysis using High-Performance Liquid Chromatography (HPLC) with a gradient method for identifying bioactive compounds, following the protocol established by Mishra et al. [6, 7]. The analysis was performed using a Shimadzu (Japan) HPLC Prominence system comprising a 20 µL sample loop, a PDA SPD M 20 A photodiode array system, an LC-20AD dual pump system, and a SIL-20 AC Autoinjector with a cooler. Compounds were separated on a Shimadzu RP-C18 column (250 × 4.6, 5 µm pore size) with a guard column of the same packing material. A gradient mobile phase was employed consisting of component A (0.3% formic acid + 0.3% triethylamine) and component B (acetonitrile). The mobile phase gradient program was as follows: 0–25 min, 5–25% B; 25–35 min, 25%-35% B; 35–45 min, 35–45% B; 45–60 min, 45–100% B, at a flow rate of 1 mL/min. Data integration and compound identification were performed using Shimadzu Lab Solution software at a wavelength of 265 nm [6]. Results were compared against standards obtained from Sigma-Aldrich, USA. Quantitative analysis was conducted by averaging the results of three independent analyses of the same sample.

Fatty acid analysis using gas liquid chromatography

500 mg dry weight of plant samples (leaf, stem and roots) were used for FAME preparation. Fatty acid methyl esters (FAMES) were prepared as per method followed by Bureau of Indian Standards IS: 548 (Part-III), 1976 reaffirmed 1994. Prepared FAME dissolved in hexane were analyzed using GC system (7890B GC System, Agilent Technologies) equipped with a flame ionization detector (FID). FAMEs were separated on DB-225 column (30 m × 0.25 mm ID × 0.25 µm film thickness). Nitrogen was used as carrier gas and hydrogen and air as ignition gases. The conditions used for GC analysis were: injector temperature of 230 °C, detector (FID) temperature of 260 °C with split mode injection (1:20). The oven temperature program was started from 90 (2 min hold) to 130 °C at ramping rate of 3 °C min^{-1}. Temperature from 130° to 230° (5 min hold) was achieved with ramp of 2 °C min^{-1}. The peaks were identified by comparing with standards and the results are presented as mean of triplicates. Data were integrated by Open LAB CDS Chem Station Edition software. Reference standards of methyl palmitate, methyl stearate, methyl oleate, methyl linoleate, methyl arachidate and methyl behenate, methyl linoleate were procured by M/s Sigma-Aldrich.

Extracts preparation for antimicrobial assay

For antimicrobial activity various plant parts materials (20 g) were extracted in aqueous methanol (50%) by sonication method. Then extracted solvents were further fractionated by various organic solvents, such as ethyl acetate, chloroform and hexane [5]. All extracted samples were filtered using Whatman filter paper No. 1. The filtrate was then dried using a low-pressure rotary evaporator (Buchi, USA) and lyophilized. All samples were stored at 4 °C in an airtight tube until further analysis was completed.

Microorganism used in study

In vitro antimicrobial activity was determined against four different human pathogenic bacteria i.e. *E. coli* (ATCC 25922), *S. mutans* (ATCC 25175), *S. aureus* (ATCC 4944) *and P. aeruginosa* (MTCC 424). *E. coli* is a gram-negative, rod-shaped bacterium that is commonly found in the lower intestine and most of these strains are harmless. However, pathogenic *E. coli* varieties cause serious food poisoning, septic shock, meningitis, or urinary tract infections in humans [16]. *S. mutans* is a gram-positive coccus bacterium, primarily found in mouth, pharynx, and intestine and significantly involved in tooth decay [17]. *Staphylococcus aureus* is a gram positive, round shape, facultative anaerobe bacterium. *S. aureus* are frequently found in the upper respiratory tract and on the skin and being a common cause of respiratory infections including skin infections [18]. *P. aeruginosa* is encapsulated rod-shaped, gram-negative bacterium. The important characteristic of this bacteria is multidrug resistance. Usually, *P. aeruginosa* found in medical equipment's hence these bacteria associated hospital acquired infections, i.e. ventilator associated pneumonia and other sepsis syndrome the general symptoms of these bacteria are inflammation and sepsis but if their colonization occurs in lungs, kidneys and urinary tract it may be fatal [19].

Screening of antimicrobial activity

In vitro antimicrobial activity was determined against four different human pathogenic bacteria using disk-diffusion method with slight modification [20]. In short, 18–24 h old bacteria culture (0.5 OD_{600} nm) was spreading over the entire surface of nutrient agar plates (90 mm size) using autoclaved steel spreader and sterile paper disks (approx. 6 mm diameter) were placed on them. Then different concentrations of test samples (25, 50 and 100 µg) were loaded on disks. Streptomycin (25 µg) was utilized as a positive control and respective solvents to which extract dissolved was used as a negative control. Then, plates were allowed to incubate at 37 ± 1 °C for 18–24 h. The diameter of the inhibition zone (ZOI) was measured after 24 h of incubation to assess antibacterial activity (measured in mm including disk size). All experiments were carried out in triplicate, and the observed ZOI values are expressed as a mean with standard error of the mean (SEM).

Minimum inhibitory concentration (MIC)

MIC was determined of various extract of leaves, stems and roots parts of *T. foliolosum* against the different pathogenic bacteria by using the previously reported serial dilution method using 96-well microtiter plates. In brief, all pathogenic bacteria were grown in nutrient broth for 6 h before being inoculated, followed by 10^6 cells/mL bacterial culture was inoculated in 200 µL nutrient broth containing tube. Now each extract (leaf, stem, and root) has been added separately in bacterial broth with concentrations ranging from 100 to 800 µg/ml. All tubes were incubated at

37 °C for 24 h and further examined for visible turbidity. The minimum inhibitory concentration (MIC) was determined to be the lowest concentration that inhibited visible growth of the tested bacteria. MIC of berberine, magnoflorine and streptomycin were determined with similar procedure.

Results

Identification and quantification of BIQ alkaloids contents in leaves, stems and roots

Chromatographic analysis aimed to quantify biologically active BIQ alkaloids, namely magnoflorine, berberine, palmatine, and thalicarpine, in extracts obtained from leaves, stems, and roots. Identification of all significant peaks in the chromatogram was accomplished using authentic reference standards of the respective alkaloids. (Fig. 2A) (Supplementary Fig. 1). In terms of quantitative analysis, the root extracts of *T. foliolosum* exhibited the highest total alkaloid content (15.03 mg g-1), followed by the leaves (2.75 mg g-1), while the stem extracts contained a comparatively lower amount (Fig. 2B). Examining individual alkaloids in the root part revealed the following order of content: magnoflorine (10.02 mg g-1)>berberine (3.09 mg g-1)>thalicarpine (1.60 mg g-1)>palmatine (0.31 mg g-1). Similar pattern in alkaloid content were observed in the leaves, with stem-derived extracts displaying lower alkaloid levels compared to roots and leaves.

HPLC analysis of antimicrobial responsive alkaloids. **a** Identified BIQ alkaloids i.e. magnoflorine, thalicarpine, palmataine and berberine peaks in HPLC chromatogram of different parts (leaf, stem and root) of *T. foliolosum*. **b** Bar graph represents the comparative observation of identified benzylisoquinoline alkaloids in different plant parts of *Thalictrum foliolosum* plants. The results are expressed as means ± SD of three replicates

Antimicrobial activity of extracted plant materials (leaf root and stem) and standard compounds berberine and magnoflorine

Various extract fractions obtained from different plant parts exhibited a range of antimicrobial activities against the microbial strains employed in the experiment, as detailed in Table 1. The antimicrobial assay indicated that the chloroform fractions of roots and leaves were particularly effective, demonstrating broad-spectrum growth inhibition across all concentration ranges (25–100 µg/ml) against all pathogenic bacteria. The ethyl acetate fractions of leaves and roots displayed remarkable antimicrobial activity at a concentration of 50 µg/ml against all pathogenic bacterial cultures. However, the ethyl acetate fractions from the stem part did not inhibit the growth of gram-negative *P. aeruginosa* (Table 1). Additionally, aqueous methanolic extracts of leaves and roots exhibited impressive growth inhibition against *E. coli*, *P. aeruginosa*, and S. *mutans* at concentrations ≥ 100 µg/ml. Hexane extracts of leaves and stems demonstrated antimicrobial activity against all tested microorganisms except *P. aeruginosa*. However, in our report, hexane root extracts did not exhibit a zone of inhibition against both gram-negative and gram-positive bacteria at concentrations ranging from 25 to 100 µg/ml. Comparatively, when standard compounds berberine chloride and magnoflorine chloride were employed at similar concentrations against the same pathogenic bacterial cultures, berberine emerged as the most effective compound at each concentration. While magnoflorine did not exhibit effective growth inhibition against various pathogens at various concentrations, a slight zone of inhibition was observed against *E. coli* at 100 µg/ml (Fig. 3).

Growth inhibition assay. Antibacterial activity of magnoflorine (M) and berberine (B) reference compounds against human pathogenic bacteria (*E coli, P. aeruginosa, S. mutans and S. aureus*) using 25–100 µg concentration (B). Streptomycin used as standard antibiotic drug 25 µg

Minimum inhibitory concentrations (MIC's) analysis

In our investigation, we determined the Minimum Inhibitory Concentration (MIC) of potent plant extracts using a 96-well microtiter plate. The MIC values for aqueous methanol, ethyl acetate, and chloroform fractions are detailed in Table 2. Notably, the chloroform fraction of the root exhibited the lowest MIC against all tested strains, with a lesser

value of 121.26 µg/ml observed against *S. aureus* (refer to Table 3). The ethyl acetate fraction from various plant parts demonstrated effective MIC values ranging from 158.15 to 448.78 µg/ml against all tested microbial pathogens. Particularly, the ethyl acetate root fraction displayed the minimum MIC against *S. mutans*. Additionally, the aqueous methanolic extracts showed MIC values ranging from 224.78 to 482.67 µg/ml (refer to Table 3). Furthermore, we analyzed the MIC values of reference alkaloid compounds, as presented in Table 4. The findings suggested that berberine chloride showed less MIC values (123.95 µg/ml) compared to magnoflorine chloride against all pathogenic bacterial strains (refer to Table 4).

Table 2. Minimum inhibitory concentration (MIC) analysis of various plant part extracts against pathogenic bacteria

	Plant parts	Extracts	MIC (µg/ml)			
Staphylococcus aureus	*Streptococcus mutans*	*Pseudomonas aeruginosa*	*Escherichia coli*	(a)	Leaf	Aqueous methanol
474.96 ± 3.25 ^{h}	264.91 ± 2.14 ^{f}	324.56 ± 2.42 ^{e}	298.76 ± 3.12 ^{f}	Ethyl acetate	158.15 ± 1.56 ^{d}	250.54 ± 2.43 ^{e}
245.67 ± 2.65 ^{b}	216.25 ± 2.78 ^{c}	Chloroform	121.26 ± 1.01 ^{a}	235.19 ± 2.13 ^{d}	194.54 ± 1.54 ^{a}	209.84 ± 2.87 ^{b}
(b)	Stem	Aqueous methanol	482.67 ± 3.76 ^{i}	350.73 ± 3.65 ^{h}	450.34 ± 3.56 ^{h}	324.54 ± 3.04 ^{g}
Ethyl acetate	146.28 ± 1.23 ^{c}	225 ± 2.24 ^{c}	448.78 ± 3.46 ^{i}	345.12 ± 2.96 ^{h}	Chloroform	168.67 ± 1.76 ^{e}
402.65 ± 3.42 ^{i}	389.45 ± 3.65 ^{g}	399.98 ± 3.78 ^{i}	(c)	Root	Aqueous methanol	400 ± 2.65 ^{g}
279.98 ± 2.45 ^{g}	364.98 ± 3.32 ^{f}	224.78 ± 2.12 ^{d}	Ethyl acetate	345.56 ± 2.34 ^{f}	189.91 ± 1.76 ^{b}	278.14 ± 2.34 ^{d}

The data are presented as the mean ± the standard deviation. The values are presented as the mean of three replicates ± the standard deviation

The data marked with different letters share significance at $p<0.05$ (based on the Duncan test)

Table 3. MIC analysis of Berberine, Magnoflorine and Streptomycin against studied pathogens

		MIC (µg/ml)			
Staphylococcus aureus	*Streptococcus mutans*	*Pseudomonas aeruginosa*	*Escherichia coli*	(a)	Berberine chloride
113.95 ± 1.45	115.45 ± 1.87	140.78 ± 1.21	150.36 ± 1.45	(b)	Magnoflorine
350 ± 2.41	310.25 ± 3.56	325.67 ± 3.87	254.65 ± 2.76	(c)	Streptomycin

The data are presented as the mean ± the standard deviation. The values are presented as the mean of three replicates ± the standard deviation

Table 4. Identification and quantification of fatty acids in *T. foliolosum* by gas liquid chromatography

		Identified fatty acid in *T. foliolosum*	Quantity of FAME in leaf (%)	Quantity of FAME in stem (%)	Structural characteristics
1	Palmitic acid		5.72 ± 0.83	7.81 ± 1.65	Hexadecenoic acid. It is a fatty acid with a 16-carbon chain. It is the most common saturated fatty acid found in animals, plants and microorganisms
2	Stearic acid		0.99 ± 0.06	2.98 ± 0.26	octadecanoic acid, saturated fatty acid with an 18-carbon chain
3	Olic acid		1.81 ± 0.13	3.42 ± 0.19	Long-chain carboxylic acid; its molecule contains one double bond between C9 and C10 with the cis configuration
4	Behenic acid		1.28 ± 0.26	0.76 ± 0.04	Behenic acid (also docosanoic acid) is a carboxylic acid, saturated fatty acid
5	Arachidic acid		0.98 ± 0.025	1.29 ± 0.11	Naturally occur in *Staphisagria macrosperma*, *Dipteryx lacunifera.* saturated long-chain fatty acid with a 20-carbon backbone
6	Linoleic acid		1.30 ± 0.09	2.72 ± 0.12	An octadecadienoic acid in which the two double bonds are at positions 9 and 12 and have cis stereochemistry
7	Linolenic acid		1.42 ± 0.151	3.27 ± 0.09	carboxylic acid with an 18-carbon chain and three cis double bonds

The results are expressed as mean ± SD of two replicates

Fatty acid analysis

Analysis of fatty acids in various parts of the *T. foliolosum* plant (leaves, stems, and roots) revealed higher levels of FAME in the stems compared to other plant parts. Trace amounts of FAME were recorded in root, in our observation. Table 4 provides detailed information on the identified fatty acids and their respective quantities in different plant parts. Notably, fatty acid esters such as palmitic acid (16:0) (7.81%), stearic acid (2.98%), oleic acid (C18:1) (3.42%), linoleic acid (C18:2) (2.72%), and linolenic acid (C18:3) (3.27%) were found in significant amounts in the stem parts.

Discussion

Plant extracts have been used for centuries as natural medicines due to the diverse array of bioactive compounds they contain. These compounds can have therapeutic effects on the human body. Herbal remedies are often passed down through generations and used to treat various ailments. Extracts of various plant, i.e. *Andrographis paniculata* , *Withania somnifera*, *Panax ginseng*, *Panax quinquefolium, Coptis japonica* and *Carica papaya* have been widely

used in natural medicine to treatment of various chronic disorders [5, 21]. Similarly, a lesser explored medicinal herb *T. foliolosum* widely used as traditional medicine in gastric problem, bloating, toothache, abdominal colic pain and piles (hemorrhoids) [7, 22]. Plants contain a variety of bioactive compounds, such as alkaloids, flavonoids, terpenoids, sterols and polyphenols. These compounds possess medicinal properties and can have antioxidant, anti-inflammatory, antiviral, antibacterial, and antifungal effects. Previous reports and contemporary studies have shown that the therapeutic potential of *T. foliolosum* plants may be due to the presence of bioactive BIQ alkaloids and other non-alkaloidal compounds such as flavonoids, saponins, polyphenolic compounds and steroids, etc. [23, 24].

Quantitative and qualitative analysis of BIQ alkaloids—specifically, berberine, magnoflorine, palmatine, and thalicarpine—was conducted using High-Performance Liquid Chromatography (HPLC) across different plant parts of *T. foliolosum*. The order of alkaloid abundance was consistently observed as magnoflorine>berberine>thalicarpine >palmatine in both the underground and leaf components of *T. foliolosum* plants. Magnoflorine is a quaternary aporphine alkaloid with numerous pharmacological properties, including anti-diabetic, anti-inflammatory, neuropsychopharmacology, immunomodulatory, hypotensive, antioxidant, and antifungal properties [25]. Berberine has long history of medicinal use as folk medicine in Chinese, Indian and Native American. Berberine has potential therapeutic use in metabolic syndrome, type 2 diabetes and dyslipidemia as well as antimicrobial activity [26]. The palmatine alkaloids are also used in traditional Asian medicine for the treatment of jaundice, liver infection, high blood pressure, inflammation and dysentery. Palmatine has recently been shown to be beneficial in the treatment of central nervous system problems [27]. Thalicarpine is a hypotensive alkaloid that has been recognized as being involved in the binding of novel antitumor agents [23, 24, 28].

In addition to biochemical analysis, antimicrobial activity showed that the chloroform fractions of root and leaves have significant activity against different pathogenic micro-organism. It was reported that berberine is the most active compound in the chloroform fractions and has been identified as the most important antibacterial component in various Thalictrum species of all the BIQ compounds identified [7, 14, 22, 24]. Similar reports were also found in other species of Thalictrum (*T. delavayi*, *T. minus*, *T. orientale*, *T. fortune* and *T. avanicum)* further supporting the antimicrobial potential of berberine [29]. Furthermore, our antimicrobial assay using berberine and magnoflorine standard compounds against pathogenic bacteria provided valuable insights into the potential bioactivity of these compounds. The observed superior effectiveness of berberine compared to other reference compounds highlights its promising antimicrobial properties (Table 4). The potential mechanisms of berberine antimicrobial activity may be mediated by the suppressing cell adhesion and migration as well as inhibiting the microbial enzymes [22]. Besides, magnoflorine an aporphine BIQ (usually soluble in water, methanol, and ethanol, and insoluble in low polar organic solvents such as petroleum ether and chloroform) was occurred significant amount in root and leaves but this alkaloid has been showed poor antibacterial activity against various pathogenic bacteria (Fig. 3). However, it was reported that magnoflorine had potent antifungal activity against *Penicillium avellaneum* and *Candida* strain, which may account for the potential antifungal activity in *T. foliolosum* [25].

Additionally, ethyl-acetate extracts of leaves were found to have impressive antimicrobial activity than other parts (roots and stem) of ethyl acetate extract against *E. coli*, *S. aureus*, and *S. mutans.* It has been reported the ethyl-acetate fraction contained significant amount of polyphenolic or flavonoids compounds, which have strong antimicrobial activity and antioxidant activity [5, 30]. Moreover, aqueous methanolic extracts (50%) of leaves and roots also shows the effective antibacterial activity against the *E. coli*, *P. aeruginosa* and *S. mutans*. Inhibition activity in aqueous methanolic extract fraction may be due to soluble fraction of alkaloids, phenol and flavonoids compounds [14, 22]. Furthermore, the non-polar hexane fraction, particularly from stem parts, demonstrated effective antimicrobial activity against both gram-negative and gram-positive bacteria. Fatty Acid Methyl Ester (FAME) analysis revealed significant amounts of fatty acid esters including palmitic acid, stearic acid, and linoleic acid in *T. foliolosum* stem parts, contributing to their potential antibacterial activity [31, 32]. The comprehensive analysis of *Thalictrum foliolosum* extracts highlights the presence of various bioactive compounds with significant antimicrobial potential.

Conclusion

In conclusion, our study provides valuable insights into the medicinal properties of *T. foliolosum*, a lesser-explored herb with a rich traditional history of use in treating various ailments. Through quantitative and qualitative analysis, we identified a diverse array of bioactive compounds in different plant parts, particularly BIQ alkaloids such as magnoflorine, berberine, palmatine, and thalicarpine, alongside substantial presence of both unsaturated and saturated fatty acids. Our findings underscore the potential therapeutic significance of *T. foliolosum* extracts, with particular emphasis on their antimicrobial activity against a range of pathogenic microorganisms. Berberine emerged as a key antimicrobial compound, exhibiting potent activity against various bacteria. Additionally, ethyl acetate and aqueous methanolic extracts displayed significant antibacterial effects, likely attributed to their polyphenolic or flavonoid content. Furthermore, our study highlights the importance of understanding the composition and pharmacological properties of medicinal plants to harness their therapeutic potential effectively. *T. foliolosum* shows promise as a natural remedy for combating microbial infections, and further research into its mechanisms of action and clinical applications is needed.

ABSTRACT (ENGLISH)

Background

Cereals have historically played a crucial role in the human diet, serving as a significant natural source of energy and offering various health benefits. Barley (*Hordeum vulgare* L.) has been given significant attention in recent years due to its exceptional nutritional value, surpassing that of other cereals. The objective of this research is to evaluate the antioxidant activity of various solvent extracts obtained from three different barley cultivars.

Results

The G.136 variety's acetone extract exhibited the highest level of antioxidant activity in both the DPPH assay, with an IC_{50} of 55.62 µg/ml, and the FRAP assay, with 447 µM trolox/mg extract. The dominant compounds identified before in the acetone fraction were subjected to an evaluation of their docking scores, along with an assessment of ADMET (Absorption, Distribution, Metabolism, Excretion, and Toxicity) and TOPKAT (Toxicity Prediction by Komputer Assisted Technology) studies. Notably, hordatine A1, prodelphinidin B3, hordatine B1, procyanidin B2, and isovitexin 7-*O*-glucoside were the major compounds with the highest LipDock scores compared to trolox the reference drug with polyphenol oxidase.

Conclusions

The findings indicate that the acetone extract from all three cultivars demonstrates noteworthy results, surpassing the efficacy of other solvent extracts against the antioxidant activity.

FULL TEXT

Background

Cereals have long been closely linked to food and drink, acting as a major natural energy source and providing numerous benefits for human health [1]. Barley is one of the oldest cereal crops that are grown. 10,500 years ago, the ancient Egyptians utilized it for the first time near the Nile River [2]. Barley can be classified according to its grain content into several categories, including normal, waxy (characterized by high-amylose starch content), high-glucan, and proanthocyanidin-free varieties [1]. Among the grains, barley has the highest quantities of β-glucan, followed by rye, wheat, and oats in decreasing order [3]. Oxidative stress, which is associated with the development of several diseases such as cancer, anemia, ischemia, diabetes, and cardiovascular diseases, is known to have a significant impact on the body's cellular processes [4]. Studies have demonstrated that barley grains contain phytochemical substances that have significant antioxidant qualities when evaluated in vitro [5]. The type of solvent employed during the extraction process has been discovered to affect the nature and quantity of secondary metabolites recovered from medicinal plants [6]. The structural dissimilarities of phenolic compounds influence their solubility in liquids of variable polarity. As a result, the solvent used for extraction and separation processes can have a substantial impact on the yield of phytochemicals derived from plant sources [7]. The primary objective of this study was to examine the principal phytochemical constituents within the most potent barley plant extract. The extraction process encompassed the use of various solvents, including 70% ethanol, methanol, water, 80% methanol, and acetone. Additionally, the research evaluated the antioxidant capabilities of the barley extracts, and in silico investigations were conducted to assess the potential binding modes of various phytochemicals as ligands with polyphenol oxidases (PPOs) receptor proteins.

Methods

Plant materials collection and extraction

In August 2019, whole barley grains (*Hordeum vulgare* L.) from three distinct cultivars were gathered from the Agriculture Research Center in Egypt, sourced from different geographic locations. The three commonly cultivated *H. vulgare* varieties in Egypt, namely Giza 136 (G.136), Giza 127 (G.127), and Giza 131 (G.131), were utilized. Fifty grams of powdered plant material from each of the three cultivars underwent extraction using five distinct solvents: 100% methanol, 80% methanol in water, 70% ethanol in water, 80% acetone in water, and distilled water. The yield from cultivar G.136 was 5.9% with methanol, 6.12% with ethanol in water, 11.43% with 70% ethanol in water, 8.23% with 80% acetone in water, and 3.8% with distilled water. Meanwhile, for cultivar G.127, the yields were 4.42% with methanol, 7.23% with 80% methanol in water, 8.39%, 8.38% with 70% ethanol in water, 8.45% with 80% acetone in water, and 12.44% with distilled water. As for cultivar G.131, the yields were 3.19% with methanol, 8.52% with 80% methanol in water, 7.42% with 70% ethanol in water, 6.5% with 80% acetone in water, and 5.5% with distilled water. This process resulted in a total of 15 samples (three cultivars in five different solvents). To extract the compounds, all of the samples underwent sonication for 30 min, three times using 500 mL each time [8].

Ultra high-performance liquid chromatography-mass spectrometry analysis (UHLPC-MS)

The combined extracts were concentrated under reduced pressure. Ten milligrams of each extract was accurately

weighed and then subjected to UHPLC-MS/MS analysis and measured their antioxidant activity.

Antioxidant activity measurements

DPPH radical scavenging activity

The three varieties of barley with different solvents were evaluated for their antioxidant capacity using the DPPH as mentioned by Boly et al. [9]. Briefly, in a 96-well plate ($n=6$), 100 µL of freshly made DPPH reagent (0.1% in methanol) was together with 100 µL of the sample. The reaction was allowed to proceed for 30 min in the dark at room temperature. The subsequent decrease in DPPH color intensity was measured at 540 nm after the incubation period. FluoStar Omega, a microplate reader, was used to record the results. The following equation describes how data are expressed as means ± standard deviation, compared to torolox the standard drug.Percentage\,inhibition= Average\,absorbance\,of\,blank-Average\,absorbance\,of\,the\,testAverage\,absorbance\,of\,blank×100Microsoft Excel® was used to analyze the data, and Graph Pad Prism 5® was used to get the IC_{50} value by converting the concentrations to their logarithmic value and choosing a nonlinear inhibitor regression equation. (log (inhibitor) vs. normalized response−variable slope equation) [10].

Ferric reducing antioxidant power assay (FRAP)

With a few minor adjustments to be performed in microplates, the Benzi et al. [11] method for the ferric reducing ability assay was used. In summary, a freshly made TPTZ reagent (300 mM acetate buffer (pH 3.6), 10 mM TPTZ in 40 mM HCl, and 20 mM$FeCl_3$, respectively) was used. In a 96-well plate ($n=3$), 190 uL of freshly made TPTZ reagent was combined with 10 uL of the sample. The reaction was then allowed to sit at room temperature for 30 min while kept in the dark. The final measurement of the blue color after incubation was made at 593 nm. Data are displayed as means ± SD. FluoStar Omega, a microplate reader, was used to record the results. The ferric reducing ability of the samples is presented as µM TE/mg sample using the linear regression equation extracted from the calibration curve, compared to torolox the standard drug.

Molecular docking studies

A molecular docking study was conducted using the Discovery Studio 4.1 program and the LIPDOCKER methodology. The isolated component was docked against the active site of antioxidant, PDB (ID: 2Y9X). Heavy atoms were created, superfluous chains were eliminated, hydrogens were added, and the protein was purified. The CHARMm forcefield and MMFF94 as a partial charge were used in the simulation. Fixed constraints and protein minimization were applied. The receptor binding site was located using the complicated ligand interaction site.

ADMET/TOPKAT prediction

The in silico ADMET (Absorption, Distribution, Metabolism, Excretion, and Toxicity) investigations were conducted using the Discovery Studio 4.1 program. These analyses aimed to predict the pharmacokinetic properties of the drug under examination, offering insights into its potential behavior within the body. The outcomes also yielded crucial structural information guiding the assessment of potential antioxidant activity. Graphical representations and numerical data were generated and presented. Additionally, the toxicity protocol TOPKAT was applied to the same set of compounds, evaluating various criteria including Ames Prediction, Carcinogenicity, and Rat Oral LD50 g/kg body weight.

Results

DPPH radical scavenging activity

In this experiment, the presence of hydrogen or electrons supplied by the antioxidant constituents in the samples resulted in the initial purple color of the DPPH radical changing to yellow. Figure 1 demonstrates that the antioxidant capacity of various sample extracts varies according to the polarity of the utilized solvents. As IC_{50} values decrease, the degree of antioxidative activity increases [12].

Fig. 1 [Images not available. See PDF.]

DPPH activity of the three barley varieties in different solvents. Significant differences among means of different treatments were determined using Bonferroni posttests at $P<0.001$ ($n=3$) with all solvent extracts compared to each other. a, b, c, d significant difference compared to methanol, water, acetone, and 80% methanol of G.136, a′, b′, c′,

d′ significant difference compared to methanol, water, acetone, and 80% methanol of G.127, a″, b″, c″, d″ significant difference compared to methanol, water, acetone, and 80% methanol of G.131, *corresponding to $P<0.05$, **corresponding to $P<0.01$, and the significance difference with $P<0.001$

All tested varieties exhibited a significant difference with a P value less than 0.0001. However, variety G.131 methanol extract besides varieties G.127 and G.136 acetone extracts did not exhibit a significant difference with $P>0.05$ in comparison with the standard drug, trolox, in terms of their antioxidant activity. This implies that they possess antioxidant properties. Besides, among all the varieties, variety G.136 acetone extract had the highest antioxidant activity (IC_{50}: 55.62 µg/ml), whereas variety G.127 acetone extract had the second-highest antioxidant activity (IC_{50}: 58.77 µg/ml). However, the methanolic extract of variety G.136 did not show any measurable DPPH activity.

Ferric reducing antioxidant power assay (FRAP)

A significant difference was found between the tested cultivars at a significance level of $P<0.0001$, as illustrated by the antioxidant capacity of various sample extracts in Fig. 2. After comparing the acetone extracts of different varieties, the G.136 variety showed the highest antioxidant activity (447 µM trolox/mg extract), while the G.127 variety showed the subsequent highest antioxidant activity (426 µM trolox/mg extract). As expected from the results of DPPH, the ethanolic extracts of cultivars G.136 and G.127 showed the lowest levels of antioxidant activity (132.1 and 91.2 µM trolox/mg extract, respectively).

Fig. 2 [Images not available. See PDF.]

FRAP activity of the three barley varieties in different solvents. Significant differences among means of different treatments were determined using Bonferroni posttests at $P<0.001$ ($n=3$) with all solvent extracts compared to each other. a, b, c, d, e significant difference compared to methanol, ethanol, water, acetone, and 80% methanol of G.136, a′, b′, c′, d′, e′ significant difference compared to methanol, ethanol, water, acetone, and 80% methanol of G.127, a″, b″, c″, d″, e″ significant difference compared to methanol, ethanol, water, acetone and 80% methanol of G.131, *corresponding to $P<0.05$, **corresponding to $P<0.01$, and the significance difference with $P<0.001$

Ultra high-performance liquid chromatography-mass spectrometry analysis (UHLPC-MS)

Previously, sixty-four compounds using various solvents were discovered from all extracts (under publication). Because the acetone fraction has the highest activity in the previously mentioned antioxidant activity, we shed light on its prominent components. In the acetone fraction of the three cultivars, the major identified 18 compounds are shown in Table 1 and Fig. 3. Proanthocyanidin was the most prevalent chemical class among the identified phytochemicals in the three cultivars, followed by flavonoids and hordatines in the acetone fraction. Proanthocyanidin and flavonoid abundance were highest in G.131 of all the cultivars. However, cultivars, G.127, displayed the greatest quantity of hortatines (Fig. 4).

Chemical classes among the three varieties

Based on a comparison of the detected component amounts in the three cultivars, quercetin 3-*O*-glucoside had the highest abundance among the three cultivars, with the G.131 cultivar exhibiting the highest concentration of the other varieties in addition to iso-orientin and hordatine B1; iso-orientin was also prominent in G.127 cultivar as well as prodelphinidin B3. Moreover, the main compounds in variety G.136 were tricin and procyanadin B2 as shown in Fig. 5.

Dominant compounds in the three barley cultivars (G.131, G.127 and G.136)

Molecular docking studies

Molecular docking

The polyphenol oxidase enzyme PPO, which was obtained from the Protein Data Bank (PDB ID: 2Y9X), was docked to the identified phytochemicals and trolox, as reference antioxidant standard, to determine their potential binding mechanisms and virtual binding affinities. Docking of the 18 major detected compounds using the LIPDOCKER protocol after ligand preparation showed a LipDock score ranging from (−61.3546 to−143.402) (Table 2). Trolox showed hydrogen bond interaction with the essential amino acids (His85, Glu322, and Asn81) and hydrophobic interaction with (His 244).

Table 2. LipDock score of the dominant compounds beside their amino acid interactions along with the reference trolox and the ligand drug

	Compounds	LipDock score	Key amino acid interaction	
Hydrogen bond	Pi-bond	1	Caffeic acid	86.5240

In vitro predictive Absorption, Distribution, Metabolism, Excretion, and Toxicity (ADMET) study

The ADMET investigation, carried out using Discovery Studio 4.1 Software, focused on the molecular composition of the compound and included the computation of various parameters [30]. These parameters included: ADMET solubility level, Blood Brain Barrier Level (BBB LEV), and CYP2D6. Most of the compounds in the ADMET plot exhibited BBB levels ranging between 3 and 4. In the HIA plot, a significant portion of the compounds were located outside the 99% ellipse. Furthermore, many of these compounds had an ADME aqueous solubility rating falling between 3 and 4. The CYP2D6 score serves as an indicator of whether a specific chemical structure is inhibitory or non-inhibitory to the cytochrome P450 2D6 enzyme.

The key property, PSA (polar surface area), is a factor associated with drug bioavailability. Generally, molecules with a PSA greater than 240 are assumed to have limited bioavailability when passively absorbed (Fig. 7; Table 3).

Fig. 7 [Images not available. See PDF.]

ADMET Plot of the 2D polar surface area (PSA_2D) against calculated ALogP98 for examined compounds

TOPKAT toxicity studies

The compounds that were previously prepared underwent (TOPKAT) toxicity protocol [31], which involved evaluating them based on specific criteria, including Ames Prediction, Hepatotoxic Prediction, Rat Oral LD_{50}, and Carcinogenic Potency. This methodology was designed to gauge the potential toxicity of newly developed substances (Table 3).

Discussion

Natural antioxidants are significantly more beneficial and efficient in combating oxidative stress when compared to their synthetic counterparts. Medications derived from plant products are considered safer for consumption [32].

The DPPH radical dot assay is commonly employed to evaluate the free radical scavenging capabilities of an antioxidant molecule. It is recognized as a standard and straightforward colorimetric method for assessing antioxidant properties [33].

It is noteworthy that the acetone extract from variety G.136 exhibited the most substantial antioxidant activity. Following closely, the acetone extract derived from variety G.127 demonstrated the second-highest antioxidant potency. Conversely, it is essential to highlight that the methanolic extract obtained from variety G.131 did not manifest any detectable DPPH activity.

The FRAP assay stands out as a straightforward, rapid, and cost-effective direct technique for gauging the total antioxidant activity of reductive antioxidants present in a test sample [34].

In line with the findings from the DPPH assay, it was observed that the G.136 variety exhibited the highest antioxidant activity, followed by the G.127 variety with a slightly lower but still significant antioxidant activity. Interestingly, in contrast with the acetone extracts discussed earlier, the ethanolic extracts of cultivars G.136 and

G.127 displayed the lowest levels of antioxidant activity.

Numerous studies have suggested that pure water is not an efficient solvent for extracting polyphenols due to their higher solubility in solvents that are less polar than water [35]. Comparable findings were published by Zhu et al. [36] concerning the significant antioxidant activity of the Chinese-grown barley acetone extract.

Among the identified phytochemical classes in the three cultivars, proanthocyanidins were the most prevalent, followed by flavonoids and hordatines in the acetone fraction. Specifically, proanthocyanidins and flavonoids were most abundant in G.131, while G.127 exhibited the highest quantity of hordatines. Quercetin 3-*O*-glucoside was the most abundant component across all cultivars, with G.131 having the highest concentration of this compound compared to the other varieties.

A docking study was applied on the most prominent compounds in the acetone fractions, hordatine A1, prodelphinidin B3, hordatine B1, and procyanidin B2 exhibited the highest LipDock interaction energy scores compared to trolox.

Furthermore, these compounds also demonstrated the highest abundance in the LCMS/MS results. Likewise, these compounds previously revealed antioxidant activity [37, 38].

After making ADMET and TOPKAT studies of the dominant compounds in the acetone fractions, the compounds' Absorption, Distribution, Metabolism, and Excretion Toxicity could be determined.

This suggests that they are unlikely to permeate the blood–brain barrier and, consequently, are unlikely to cause adverse effects in the central nervous system (CNS) adverse effects. They are likely to have limited absorption in the intestines suggesting that they possess good aqueous solubility; the expected values for these compounds indicate good passive oral absorption for most of them, which is a positive attribute for their pharmacological effectiveness.

In this context, since these compounds are classified as non-inhibitors of CYP2D6, it suggests that their usage is not likely to lead to adverse effects such as liver impairment.

The results of all TOPKAT Ames probabilities, applications, and scores indicated that these compounds are non-mutagenic and non-carcinogenic, and they fell within the anticipated ranges.

Conclusion

The present study offers valuable insights into the antioxidant applications of different solvents extracts of three different cultivars. The acetone extracts of the three cultivars showed the best results compared to other solvents. G.136 variety showed the highest level of antioxidant activity in both the DPPH and FRAP assays. A docking study was conducted for the 18 major compounds in the acetone fractions of the three varieties followed by ADMET and TOPKAT studies. Hordatine A1, prodelphinidin B3, hordatine B1, procyanidin B2, and isovitexin 7-*O*-glucoside demonstrated the highest LipDock scores when compared to the reference standard drug. Additionally, these compounds exhibited the highest areas among other constituents in the three cultivars. The results of the current study could offer valuable insights for defining new research avenues regarding the utilization and applications of the examined extracts with specific solvents as pharmaceutical and nutraceutical agents.

Plant authentication

The Whole barley grains (*Hordeum vulgare* L.) from three distinct cultivars were gathered from the Agriculture Research Center in Egypt and sourced from different geographic locations in Egypt. The three commonly cultivated *H. vulgare* varieties in Egypt, namely Giza 136 (G.136), Giza 127 (G.127), and Giza 131 (G.131) were utilized.

ABSTRACT (ENGLISH)

Background

The study of plant-based medications, or phytomedicine, involves a wide spectrum of biological activities. Due to the existence of secondary metabolites, herbal medicine has been used and practiced throughout history for the

treatment of both acute and chronic conditions. Over the past century or so, numerous novel compounds with medicinal potential have been derived from plants. In the age of growing super infections and the emergence of resistant strains, natural medicines are inspiring optimism.

Main body of the abstract

The review discusses the role of herbal medicine as antibacterial agents and their use in wound care and management of wounds and the critical role of secondary metabolites of herbal plants in fighting bacterial infections. Some medicinal plants such as St. John's wort (SJW) (*Hypericum perforatum*), Rosemary (*Rosmarinus officinalis*), Ginger (*Zingiber officinale*), and nopal cactus (*Opuntia ficusindica* (*L.*)) also possess wide range of biological activities and can give a synergistic effect if combined with antibiotics. In addition, natural biopolymers play an important role in the management of wounds as well as the physiological processes of the skin (hemostasis, inflammation, proliferation, and remodelling).

Method

A narrative review of papers relevant to the use of phytomedicine in treating infections was conducted by using electronic databases PubMed, CrossREF, and Google Scholar.

Short conclusion

Phytomedicine is one of the top options for the treatment of chronic illnesses for millions of people around the world. To learn about the bioactive components of medicinal plants, their medical benefits, and their synergistic or additive effects to enhance the action of medications, substantial new studies are still needed.

Highlights

Phytomedicine involves a wide spectrum of biological activities.
Bioactive compounds extracted from plants are used for the treatment of both acute and chronic conditions.
Natural plant &secondary metabolites play a significant role in the treatment of bacterial infections.
Natural biopolymers are used in wound care and restoring physiological processes of the skin.
Substantial new studies are needed to learn about bioactive components medical benefits, and their synergistic or additive effects.

FULL TEXT

Background

An herbal remedy known as phytomedicine is utilized all over the world to treat or prevent physical and mental illnesses [1]. Herbal medicine or a phytopharmaceutical preparation is a type of medication that is made in a crude form solely from whole plants or specific plant parts [2]. Herbal medicine, which has a history spanning more than 3000 years and was enumerated in Sheng Nong's herbal book "*The Devine Farmer's Classic of Herbalism*" [3], is the foundation of traditional Chinese medicine (TCM). Herbal medicine is one of the most sought-after treatments by 3.5–4 billion people worldwide, mainly in Africa, India, and China, according to the World Health Organization (WHO) [4]. Products made from medicinal plants have greatly increased over the past 10 years, which has revolutionized and improved phytomedicine. There are about 35,000 plant species that are utilized as medicines, but only 20% of them go through the phytochemical analysis stage and only 10% make it to the biological screening stage, leaving the rest in need of further study [5]. As herbal medicine becomes more and more popular, it is important to maintain quality, safety, and to prevent potential toxicity [6–8]. In addition to long-term boiled extract and cold infusion of plants, plants can be extracted using alcoholic, vinegar, and hot water as well as other solvents, times, and temperatures [1]. Due to the existence of secondary metabolites, which are abundant in bioactive substances, herbs are used to treat both acute and chronic illnesses, including depression, cardiovascular disease, inflammation, and others [9, 10]. Plant constitutes are used directly as therapeutic agents or as models for pharmacologically active compounds or as starting materials for the synthesis of drugs (Table 1) such as morphine which was produced from opium extracted from *Papaver somniferum,* digoxin from *Digitalis purpurea*, antimalarials such as quinine from *Cinchona* bark, and over 60% of cancer therapeutics are based on natural products such as paclitaxel from the Pacific yew tree [11–15]. Due to inadequate research methodologies, time-consuming, and expensive isolation techniques, there is little information available regarding the composition of the majority of herbal medications. As a

result, this page discusses the crucial role of medicinal plant extract in the battle against bacterial infections and the management of skin wounds and disorders such as atopic dermatitis (AD) and diabetic foot ulcers (DFUs). Additionally, extracellular matrix (ECM) and biopolymers derived from microorganisms, animals, and plants (cellulose, hyaluronic acid, collagen, alginate, and chitosan) all have bioactive qualities that make them useful in the treatment of wounds and the healing process.

Table 1. List of drugs derived from plant origin and their clinical use

Drug	Plant origin	Clinical uses	References
Aescin (Fig. 1)	*Aesculus hippocastanum*	Aescin has potent anti-inflammatory, antioxidant, antiedematous, and vaso-protective effects. It is used in the management of haemorrhoids and hematoma	[16]
Aesculetin (Fig. 1)	*Fraxinus rhynchophylla*	Aesculetin is a phenolic coumarin derivative compound that has anti-inflammatory, antinociceptive, antioxidative, and anticancer effects, in addition to its effectiveness against allergic asthma	[17]
Agrimophol (Fig. 1)	*Agrimonia Pilosa*	Agrimophol is a phloroglucinol compound identified by high-throughput screening (HTS) method. It acts by disturbing pH_{IB} homeostasis of *Mycobacterium tuberculosis*	[18, 19]
Allyl isothiocyanate (Fig. 1)	*Brassica nigra*	A black mustard volatile oil responsible for the bitter taste and pungent odour. It has the potential to be used as antibacterial, anticancer, antifungal, and antihelminthic, in addition to its antifermentative and antibrowning in food industry	[20, 21]
Anisodamine (Fig. 1)	*Anisodus tanguticus*	An atropine derivative with nonspecific cholinergic antagonist activity. It has a cardiovascular properties that include depression of cardiac conduction and protection against arrhythmia	[22, 23]
Artemisinin (Fig. 1)	*Artemisia annua* L	A sesquiterpene lactone with potent antimalarial activity in addition to its ability to treat some viral infections and various neoplasms	[24]

Aspirin (Fig. 1)	Willow tree bark	Anti-inflammatory and antiplatelet agent	[25, 26]
Atropine (Fig. 1)	*Atropa belladonna*	An Anticholinergic and Cholinergic Muscarinic Antagonist	[27]
Berberine (Fig. 1)	*Berberis vulgaris*	A nonbasic and quaternary benzylisoquinoline alkaloid used for the treatment of skin diseases, inflammatory disorders, respiratory diseases affections of eyes, tumours, microbial pathologies and for wound healing	[28]
Bromelain (Fig. 1)	*Ananas comosus*	Anti-inflammatory, antiedematous, antithrombotic, fibrinolytic, anticancerous, and facilitate the death of apoptotic cells	[29]
Camphor (Fig. 1)	*Cinnamomum camphora*	Camphor used for the treatment of various symptoms such as infection, inflammation, muscle pain, congestion, and irritation in various regions	[30]
Camptothecin (Fig. 1)	*Camptotheca acuminata*	A natural alkaloid acts as a DNA topoisomerase 1 poison with antitumour activity	[31]
Catechin (Fig. 1)	*Camellia sinensis*	Catechins are polyphenol compounds from tea leaves and have a strong antioxidants activity. They can prevent or reduce skin damage	[32]
Cocaine (Fig. 1)	*Erythroxylum coca*	Topical anaesthesia of the mucous membranes of the nasal, oral, and laryngeal cavities in addition to off-label use as vasoconstrictive in the treatment of epistaxis before cauterization or packing	[33, 34]
Codeine (Fig. 1)	*Papaver somniferum*	Codeine is an alkaloid from opium or morphine used as a sedative, hypnotic, central analgesic, antinociceptive and is also used in insomnia and tuberculosis due to incessant coughing	[35]
Colchicine (Fig. 1)	*Colchicum autumnale*	Treatment of gout	[36]

Convallatoxin (Fig. 1)	*Convallaria majalis*	A cardiac glycosides used to treat atrial fibrillation and cardiac failure through inhibition of Na^+/K^+-ATPase	[37, 38]
Curcumin (Fig. 1)	*Curcuma longa*	Curcumin prevents carcinogenesis by affecting angiogenesis, cancer cell growth, in addition to the suppression of cancer cell metastasis and induction of cancer cell apoptosis	[39]
Deslanoside (Fig. 1)	*Digitalis lanata*	A cardiac glycoside used to treat supraventricular arrhythmias congestive heart failure and chronic atrial fibrillation. Moreover, studies showed its ability to inhibit the tumour growth of human prostate cancer cells	[40, 41]
Digoxin (Fig. 1)	*Digitalis purpurea*	A cardiac glycoside that has inotropic effects and is used to manage systolic dysfunction in congestive heart failure (CHF) patients and also work as atrioventricular nodal blocking agent to manage atrial tachydysrhythmias	[42]
Emetine (Fig. 1)	*Cephaelis ipecacuanha*	An alkaloid used to treat amoebiasis	[43]
Ephedrine (Fig. 1)	*Ephedra sinica*	A sympathomimetic drug prescribed as a nasal decongestant. Furthermore, it used as antipyretic and diaphoretic effects	[44, 45]
Etoposide (Fig. 1)	*Podophyllum peltatum*	Podophyllotoxin used as chemotherapeutic drug against various cancers due to its anticancer activity	[46, 47]
Galantamine (Fig. 1)	Amaryllidaceae family (*Galanthus nivalis* and *Galanthus woronowii*)	An oral acetylcholinesterase inhibitor used for therapy of Alzheimer disease	[48, 49]
Glaucarubin (Fig. 2)	*Simarouba glauca*	An antimalarial and anticancer drug	[50]
Glaucine (Fig. 2)	*Glaucium flavum*	Isoquinoline alkaloid used as a cough suppressant	[51]

Glycyrrhizin (Fig. 2)	*Glycyrrhiza glabra*	It is used as a remedy for gastrointestinal problems, cough, bronchitis, arthritis and widely used to treat gastritis and peptic ulcers	[52]
Gossypol (Fig. 2)	*Gossypium species*	A lipid-soluble polyphenol that exhibits significant antineoplastic effects against various cancer types	[53]
Hesperidin (Fig. 2)	*Citrus species*	A bioflavonoid compound with antioxidant, antibacterial, antimicrobial, anti-inflammatory, and anticarcinogenic properties	[54]
Hyoscyamine (Fig. 2)	*Hyoscyamus niger*	An alkaloid used as mild antispasmodic, analgesic, sedative, and mydriatic	[55]
Irinotecan (Fig. 2)	*Camptotheca acuminata*	A topoisomerase I inhibitors used to treat various types of cancer	[56]
L-Dopa (Levodopa) (Fig. 2)	*Mucuna pruriens*	A drug used in the management of Parkinson's disease	[57]
Morphine (Fig. 2)	*Papaver somniferum*	A natural alkaloid with potent and analgesic effects used for severe pain, control of pain from angina pectoris, or acute myocardial infarction and other medical uses	[58, 59]
Ouabain (Fig. 2)	*Strophanthus gratus*	Cardenolide compound used for the treatment of congestive heart failure by inhibiting Na^+/K^+-ATPase. It also has a potential use in the treatment of cancer	[60, 61]
Paclitaxel (Fig. 2)	*Taxus brevifolia* Nutt	A broad-spectrum anticancer compound	[62]
Papain (Fig. 2)	*Carica papaya*	A cysteine protease known for its antibacterial activity, wound healing properties, inhibition of platelet, and inhibition of atherosclerosis	[63, 64]
Papaverine (Fig. 2)	*Papaver somniferum*	An alkaloid used as a vasodilator and direct-acting smooth muscle relaxant	[65]

Physostigmine (Fig. 2)	*Physostigma venenosum*	A reversible acetylcholine esterase inhibitor in both the periphery and central nervous system. It is used to treat glaucoma and anticholinergic toxicity	[66, 67]
Pilocarpine (Fig. 2)	*Pilocarpus jaborandi*	An alkaloid used to treat glaucoma and xerostomia	[68]
Pseudoephedrine (Fig. 2)	*Ephedra sinica*	A sympathomimetic used to treat the symptoms of paranasal sinuses and obstruction in the nasal cavity, in addition to vasomotor rhinitis, allergic rhinitis, and otitis media	[69]
Quinine (Fig. 2)	*Cinchona ledgeriana*	Prevention and therapy of malaria	[70]
Reserpine (Fig. 2)	*Rauvolfia serpentina*	An alkaloid extract used to treat hypertension	[71]
Scopolamine (Fig. 2)	*Hyoscyamus niger*	A natural alkaloid with potent anticholinergic effects that used for the treatment of nausea, vomiting, and motion sickness	[72]
Sennosides A, B (Fig. 3)	*Cassia species*	Anthraquinone glycosides used as Laxative by relaxing and loosening the bowels	[73]
Tetrahydrocannabinol (THC) (Fig. 3)	cannabis	A potent psychoactive compound used as an antiemetic anti-inflammatory and has the ability to reduce neuropathic and chronic pain	[74]
Theophylline (Fig. 3)	*Theobroma cacao*	Used as second-line treatment of asthma and chronic obstructive pulmonary disease (COPD)	[75, 76]
Thymol (Fig. 3)	*Thymus vulgaris*	A phenolic monoterpene used mainly for the treatment of the upper respiratory system. It is used as expectorant, anti-inflammatory, antibacterial, antiseptic, and antiviral	[77]
Tubocurarine (Fig. 3)	*Chondodendron tomentosum*	A competitive blocker of nicotinic acetylcholine receptors used for the relaxation of skeletal muscles	[78, 79]

Yohimbine (Fig. 3)	*Pausinystalia yohimbe*	A monoterpenoid, indole alkaloid act by selective inhibition of presynaptic α2-adrenergic receptors (ARs) and used as a stimulant and aphrodisiac to improve erectile function	[80]

Method

We evaluated the scientific literature collected from PubMed, CrossREF, and Google Scholar databases, considering all the articles published between 1975 and 2023. The keywords used were “herbal plants”, “phytomedicine”, “secondary metabolites”, “synergistic”, “antibacterial”, and “wound healing”. Article titles and abstracts were manually screened, and studies not related to the topic were excluded.

Main text

Antibacterial activities of medicinal plants

Globally high rates of morbidity and mortality are mostly caused by infectious diseases. Millions of people per year die as a result of the advent of bacterial strains that are resistant [81]. Antibiotic resistance in bacteria evolves through intrinsic or acquired resistance, by chromosomal mutation, or by horizontal gene transfer (HGT) [82, 83]. Several mechanism can lead to the development of antibiotic resistance such as alteration in cell membrane permeability either by reducing antibiotic penetration or increasing its elimination by efflux pumps; moreover, bacteria can deactivate the antibiotic itself or modify the antibiotic targets, in addition to other alternative pathways which were described in literature and are illustrated in Fig. 4 [83–88]. The most harmful microorganisms for human health have been recognized by the World Health Organization (WHO) and are categorized into three priority groups: critical pathogens (*Acinetobacter*, *Enterobacteriaceae*, *and Pseudomonas*), high-priority pathogens (*Campylobacter*, *Enterococcus faecium*, *Helicobacter pylori*, *Nisseria gonorrhoeae, Staphylococcus aureus*, *Salmonella* spp.), and medium-priority pathogens (*Streptococcus pneumoniae*, *Shigella* spp.) [83, 89–91]. Pathogenic plant bacteria can cause diseases on susceptible plant hosts which starts usually with low numbers of pathogen cells and then colonize and multiply to large amounts in living plant tissue. This results in the alteration of plant’s developmental system which eventually leads to reduction of plant growth and yield. Disease severity depends on the host genetic constitute, environmental conditions, and the pathogen [92]. Herbal plants produce unlimited wide variety of secondary metabolites which are mostly aromatic and phenol derivatives that gives them the ability to safeguard plants against pathogens [9, 93, 94]. Plants use oxygen for their growth and development but in stress like pathogen attack; the usage of oxygen causes the production of reactive oxygen species (ROS) in the plant and results in photo-oxidative damage [95–97]. In stress conditions plants induce excessive biochemical changes to activate defence pathways such as changing cell wall composition, detoxification of several ROS

species, induction of enzymatic and nonenzymatic components, and alteration of pathogen activates [98–101]. Numerous studies have demonstrated that various chemicals components of herbal plants possess antibacterial properties that can protect the human body against diseases without being damaging to cells [102]. Herbal or synthetic antimicrobial agents are both possible. The main negative effect of synthetic substances including antibiotics, metals, and metal oxide nanoparticles is the production of ROS, which is extremely hazardous and can lead to cancer [103]. On the other hand, herbal antimicrobial compounds including cinnamon, thyme, chamomile, eucalyptus, lemon balm, garlic, ginger, and others are free scavengers that can prevent ROS generation [102]. Antimicrobial phytochemicals can be divided into several categories such as phenolics and polyphenol (e.g. catechol and caffeic acids (Fig. 5)) [104]; terpenoids and essential oils (e.g. camphor, farnesol and artemisinin (Fig. 5)) [104, 105]; alkaloids (e.g. morphine (Fig. 5)) [104]; lectins and polypeptides (e.g. Thionins (Fig. 5)) [106–108]; polyacetylenes (e.g. 8*S*-heptadeca-2(*Z*),9(*Z*)-diene-4,6-diyne-1,8-diol (Fig. 5)) [109], and many others.

Chemical structure of antimicrobial phytochemicals including catechol, caffeic acids, camphor, farnesol, artemisinin, morphine, thionins, 8*S*-heptadeca-2(*Z*),9(*Z*)-diene-4,6-diyne-1,8-diol, luteolin, quercetin, epicatechin, benzoic, cinnamic acids, tyrosol, hydroxytyrosol, sulphoraphane, proanthocyanidin (TPA), quercetin 3-*O*-glucoside, quercetin pentosides, gallic acid, naringenin, salicylic acid, kaempferol, astragalin, tellimagrandin I, II, rugosin D, and spiraeoside

Antibacterial phytochemicals

Phenolics and polyphenol

Polyphenols are a wide class of chemical substances found in plants that have a variety of biological functions [110]. Flavonoids (such as luteolin (Fig. 5), quercetin (Fig. 5), catechin (Fig. 2), and epicatechin (Fig. 5)) and nonflavonoids (such as benzoic, cinnamic acids, tyrosol, and hydroxytyrosol (Fig. 5)) are two categories of polyphenols that can be simple, large, or complex compounds[111]. Phenolic compounds have been used in traditional medicine, and although their mode of action as antibacterial agents is still not completely understood, it does appear to be distinct from that of antibiotics, reducing the risk of cross-resistance and making them a promising agent against resistant pathogens [112–114]. Inhibiting the growth of *Helicobacter pylori* is one of the potential benefits of polyphenols, which are powerful antioxidant and anti-inflammatory compounds found in foods like broccoli, garlic, liquorice, cranberries, and curcumin [115, 116]. Due to antibiotic resistance and issues with patient compliance, *H. pylori* eradication rates with triple therapy, which includes clarithromycin, metronidazole, or amoxicillin in combination with a proton pump inhibitor, are lower than 50–70%. The bismuth-containing quadruple therapy, as well as sequential and hybrid regimens, is now advised for treating *H. pylori* infection. There is not currently a therapy with >90% eradication rates, though [117–121]. To determine the impact of polyphenol components (garlic, liquorice, cranberry, curcumin, and broccoli) on the elimination of *H. pylori* infection, Wang et al. [122] conducted a meta-analysis study. The study discovered that polyphenol compounds may have a positive impact on the elimination of *H. pylori*, since the total elimination rate of the bacteria was higher in the polyphenol compounds group than in the control group. The research backs the adjuvant use of polyphenolic substances in the treatment of *H. pylori*. The polyphenol content of garlic makes it a potent alternative to conventional *H. pylori* treatment, according to in vitro studies [123–125]. Additionally, liquorice has anti-*H. pylori* properties [126]. Studies conducted in vitro revealed that *Glycyrrhiza glabra* and its aqueous extract have anti-*H. pylori* activity. Possible mechanisms of action include blocking dihydrofolate reductase, DNA gyrase, protein synthesis, and *H. pylori* adherence to human stomach tissue. Additionally, the components of cranberry juice prevent the adherence of a number of pathogenic infections, including the influenza virus, *E. coli*, and *H. pylori* [127–129]. According to in vitro research, *H. pylori* was prevented

from proliferating and was caused to produce a coccoid form by the polyphenols in cranberry extract [130–132]. Turmeric root contains the poly-phenolic compound curcumin (diferuloylmethane) (Fig. 5) [133]. Curcumin administration significantly reduced inflammation in gastric mucosa infected with *H. pylori*, according to animal studies [134]. Additionally, in vivo administration of sulphoraphane-rich fresh broccoli (Fig. 5) sprouts to mouse models reduced *H. pylori* colonization and prevented lipid peroxidation in the stomach mucosa [135, 136]. Żurek et al. [137] investigated the biological potential of polyphenolic substances isolated from walnut (*Juglans regia* L.). The edible kernels of walnuts, which also include polyunsaturated fatty acids (PUFA), tocopherols, phytosterols, and vitamins in addition to a number of other bioactive chemicals, are a rich source of polyphenols [138–141]. In addition, other parts of walnuts such as leaves are valuable products as well and their content was assessed spectrophotometrically by UPLC-PDA-MS/MS method. Several phenolic compounds were identified and expressed as total phenolic (TPC), proanthocyanidin (TPA) (Fig. 5), and total flavonoid contents (TFC) with quercetin 3-*O*-glucoside (Fig. 5) and quercetin pentosides (Fig. 5) dominating. Aqueous walnut leaf extracts antibacterial and antifungal activities were tested against Gram-negative bacteria (*E. coli*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*), Gram-positive bacteria (*Staphylococcus aureus*, *Enterococcus faecalis*, *Streptococcus pyogenes*), and fungus. (*C. albicans*). Result showed highest susceptibility (at 10 mg/ml concentration) against *K. pneumoniae*, and *S. pyogenes,* less bactericidal activity against gram-positive and without any antifungal effect. These findings may be explained by the fact that gram-negative bacteria's cell walls contain lipopolysaccharide (LPS), which creates a hydrophilic environment and shields it from hydrophobic molecules. The aqueous and ethanol extracts of walnut leaves may contain more hydrophilic compounds as a result, leading to higher inhibitory activity against gram-negative bacteria [137]. In similar context, Bouslamti et al. [142] tested antioxidant and antibacterial activity of *Solanum elaeagnifolium* leaf and fruit extracts against Gram-positive (*Staphylococcus aureus* and *Bacillus subtilis*), Gram-negative bacteria (*Escherichia coli* and *Proteus mirabilis*), and *Candida albicans*. HPLC and colorimetric methods were used to determine the chemical composition of *S. elaeagnifolium* fruits and leaf extracts which are quercetin (Fig. 5), luteolin (Fig. 5), gallic acid (Fig. 5), and naringenin (Fig. 5). Result showed that the extracts generated good antioxidant activity and potent antifungal activity. Nonetheless, further studies are needed to assess potential adverse effects. Meadowsweet plant (*Filipendula ulmaria* (L.) Maxim.) has been also used in traditional medicine due to its wide range of pharmacological effects [143, 144]. For the biological activity of meadowsweet, phenolic secondary metabolites are thought to be responsible, including phenolic acids and their derivatives (such as gallic acid and salicylic acid in Fig. 5), flavonoids and flavonoid glycosides (such as kaempferol and astragalin in Fig. 5), and tannins (such as tellimagrandin I, II, and rugosin D) [145, 146]. Meadowsweet extracts from different organs and parts (leaves, flowers, fruits, and roots) have been studied for their antioxidant and antibacterial properties by Savina et al. [147] Gram-negative bacteria *P. aeruginosa* and Gram-positive bacteria *B. subtilis* were used to investigate the antibacterial activity of flower and fruit extracts. All portions of the meadowsweet plant had a high overall phenol level, whereas the flowers had a high flavonoid concentration. The primary flavonoids in meadowsweet include luteolin, kaempferol derivatives, and spiraeoside (Fig. 5), which all have potent antibacterial properties. Meadowsweet plants were also found to have significant amounts of salicylic acid and its derivatives, which are thought to have anti-inflammatory effects. Furthermore, it was shown that meadowsweet roots had greater total catechin and proanthocyanidin contents than other sections, while the fruits had higher total tannin contents, particularly tellimagrandins I and II and rugosin D. All of the components had anti-inflammatory and antibacterial effects.

Terpenoids and essential oils (EOs)

More than 17,500 plant species can produce essential oils (EOs), which are volatile secondary metabolites with a particular flavour or scent [148]. The cytoplasm and plastid of plant cells produce EOs compounds, which are then stored in intricate secretory structures including glands and secretory cavities before being present as liquid drops in the flowers, leaves, stems, fruits, bark, and roots of plants. In addition to many other substances like fatty acids, oxides, and derivatives of sulphur, the primary constituents of EOs include terpenes, terpenoids, and phenylpropanoids [149, 150]. EOs are produced through mechanical cold pressing of plants, steam distillation, dry

distillation, hydrodistillation, and more recent techniques including microwaves and supercritical fluid extraction. Depending on the method used, different chemical compositions of EO were obtained [150–152]. Due to their biological characteristics, including their antibacterial qualities, EOs have been utilized as perfumes, food spices, and in folk medicine [153]. Terpenes, which make up the majority of essential oils (EOs), are generated from the isoprenoid pathway and are made up of isoprene units (C5). On the basis of this, terpenes are classified as monoterpenes (C10), sesquiterpenes (C15), diterpenes (C20), triterpenes (C30), and carotenoids (C40). Terpenes have a variety of chemical properties, including alcohol (terpineol, menthol, carveol, linalool, and citronellol; Fig. 6), aldehyde (citral and citronellal; Fig. 6), ketone (carvone; Fig. 6 and camphor; Fig. 5), phenol (thymol; Fig. 3; and carvacrol; Fig. 6); ether (eucalyptol; Fig. 6), and hydrocarbon (pinene, and limonene; Fig. 6) groups [154, 155]. An antibacterial, antifungal, antioxidant, anti-inflammatory, analgesic, antimutagenic, and wound-healing compound, thymol is a phenolic monoterpene. Due to its strong antibacterial characteristics, it also enhances digestion, lessens respiratory issues, and is used in dentistry to treat infections of the oral cavity [156]. *Majorana syriaca*, sometimes known as thyme, is a widespread east Mediterranean aromatic species with a high content of essential oils that give the plants their distinct flavour and perfume as well as antibacterial and antifungal properties. Due to its high volatile oil content, *M. syriaca* is used in traditional medicine to cure the flu, colds, and cough. The primary essential oil in thyme is thymol, which is used in mouthwashes as an antibacterial. Additionally, thyme extracts are added to cough syrups to treat coughs and other respiratory issues like bronchial issues. Thyme essential oils' high phenol concentration is what gives them their potent antibacterial properties, allowing for usage as a potent disinfectant, in oral medicinal preparations, and as a flavouring ingredient in numerous food products [157–161]. Abu-Lafi et al. [162] used static headspace-gas chromatography/mass spectrometry (SD-GCMS) analysis to determine essential oils in thyme leaves and identified 29 monoterpenes (oxygenated and hydrocarbons) such as thymol, carvacrol, *a*-phellandrene, *a*-pinene, *c*-terpinene, *o*-cymene, *p*-cymene, and *b*-myrcene (Fig. 6). The primary components of oxygenated monoterpenes in thyme leaves were the phenolic substances thymol and its geometric isomer carvacrol. The investigation also revealed the presence of thymoquinone, which is known to play a protective function against oxidative damage brought on by chemicals that produce free radicals, such as carbon tetrachloride. Free terpenes present in EOs were investigated for their antibacterial activity by Guimares AC et al. [154]. Results showed that hydrocarbons such terpinene, camphene, R-(-)-limonene, and (+)-α-pinene have inferior antibacterial action to oxygenated terpenes like phenolics (Fig. 6), which is consistent with the findings of earlier studies [163–167]. Eugenol and terpineol showed rapid and excellent bactericidal action against *Salmonella enterica* and *S. aureus* strains, respectively. Moreover, carveol, citronellol, and geraniol exhibited rapid bactericidal effect against *E. coli*. Therefore, hydroxyl groups in phenolic and alcohol compounds resulted in higher antimicrobial activity than hydrocarbons [154]. The antibacterial properties of EOs from *Cinnamomum cassia* bark and *Eucalyptus globulus* leaves are well established. These EOs' main secondary metabolites, 1,8-cineole (Fig. 6) and *trans*-cinnamaldehyde (Fig. 6), are what provide these compounds their therapeutic properties. However, ethnobotanical physicians prefer the use of entire EOs over purified components to treat bacterial infections [168–170]. Therefore, a set of 6 g-positive and -negative bacteria were used by Nguyen HTT et al. [171] to evaluate the antibacterial activity of plant EOs to their separated main components. According to the findings, entire oils of eucalyptus and cinnamon with low concentrations of 1,8-cineole (61.2%) and *trans*-cinnamaldehyde (89.1%) have more favorable effects than the active components that have been refined to less than 99%. Additionally, CC crude extract had greater and stronger effects on both gram-positive and gram-negative bacteria compared to EG. The study's findings support the use of complete essential oils for bacterial infections in traditional medicine since they offer advantages over isolated constituents that might not have the same effects when used as medications. To combat foodborne infections, EOs can also stop bacterial growth [172]. Another study by Trinh et al. [173] looked at the antibacterial properties of *trans*-cinnamaldehyde, the major component of Cinnamomum cassia essential oil, in relation to the *Listeria innocua* strain. The accumulation of *trans*-cinnamaldehyde in the hydrophobic core of the cytoplasmic membrane of *L. innocua*, which results in membrane disruption, was found to be the cause of the antibacterial action of *trans*-cinnamaldehyde as well as other minor *C. cassia* essential oil. Although there was no evidence of large hole

creation or cell lysis, viable but nonculturable (VBNC) cells did start to appear. To use *C. cassia* EO and *trans*-cinnamaldehyde rationally in food preservation, a better understanding of their modes of action is required. Kolozsváriné Nagy J et al. [174] tested EOs of cinnamon, eucalyptus, thyme, clove, tea tree, rosemary, lemon grass, lemon balm, and citronella grass against *Xanthomonas arboricola* pv. *pruni* (*Xap*) which is responsible for water-soaked spots on the surface of leaves, and fruits that may lead to severe infections and complete destruction of the plant. High-performance thin-layer chromatography (HPTLC)-*Xap* combined with solid-phase microextraction-gas chromatography/mass spectrometry (SPME-GC/MS) was used to identify active EOs' components. All EOs inhibited bacterium isolates with superiority to cinnamon with MIC values of 31.25 µg/mL and 62.5 µg/mL, while the tea tree EO was the least effective with the highest MIC values. Compounds that are identified to have antibacterial activity by HPTLC zones are *trans*-cinnamaldehyde in cinnamon, thymol in thyme, eugenol in clove, terpinen-4-ol (Fig. 6) in tea tree, borneol in rosemary (Fig. 6), citral in lemon grass and lemon balm, and citronellal and nerol in citronella grass (Fig. 6). Biofilms produced by bacteria are one of the reasons for the resistance of bacteria and can act as reservoirs for spoilage bacteria in food such as *Shewanella putrefaciens* which is the chief spoilage bacteria in fish [175, 176]. Therefore, Xie et al. [177] studied antibacterial effectiveness of *Ocimum gratissimum* L. essential oil (OGEO) in vitro against *Shewanella putrefaciens* to be used as natural preservative. The main active ingredients of OGEO are eugenol and caryophyllene (Fig. 6) which have antibacterial activity according to previous studies. The study demonstrated that OGEO had a positive inhibitory effect on the growth of *S. putrefaciens* and act by disrupting the formation of biofilms and cell membranes of the bacteria with minimum inhibitory concentration and minimum bactericidal concentration of 0.1%. inhibiting *S. putrefaciens* by EOs provide a new method of inhibiting the spoilage of food. *Ocimum basilicum* (Great basil or Saint-Joseph's wort) from *Lamiaceae* family contains many bioactive secondary metabolites such as polyphenols, flavonoids, and terpenes. Main EOs included in the plan are linalool, methyl estragole, methyl cinnamate, and methyl chavicol (Fig. 6) [178–181]. *Ocimum basilicum* has many pharmacological activities and has been used in traditional medicine as antioxidant, anticancer, antiviral, antiaging, and antimicrobial properties [182–184]. Studies showed that the biological activity of O. *basilicum* is related to cinnamic acid (Fig. 5) derivative of the polyphenoid rosmarinic acid (Fig. 6) [185]. Eid et al. [186] studied *O. basilicum* seeds essential oil biological activity and showed that it had a broad-spectrum antibacterial activity. The oil suppressed the development of all tested microbial strains (minimum inhibitory concentrations (MICs) between 1 and 2.3 µg/mL) and fungus strain *C. albicans* (MICs of 1.3 µg/ml for fungus). Antibacterial activity may refer to the presence of phenolic components in the essential oil which trigger intracellular ATP and potassium ion leakage and lead to cell death. Yaldiz et al. [187] also investigated antibacterial, antiquorum sensing, and antibiofilm capabilities of the ethanol extract and essential oil derived from *O. basilicum*. Results revealed that in addition to having antifungal effects on *C. albicans*, basil essential oil also demonstrated antibacterial activity and antiquorum sensing activity against some Gram-positive and -negative bacterial species.

Fig. 6 [Images not available. See PDF.]

Chemical structure of essential oils (EOs) and terpenoids including terpineol, menthol, carveol, linalool, citronellol, citral, carvone, carvacrol, eucalyptol, a-pinene,limonene, a-phellandrene, c-terpinene, o-cymene, p-cymene, b-myrcene , camphene, eugenol, 1,8-cineole, terpinen-4-ol, nerol, caryophyllene, methyl estragole, methyl cinnamate, methyl chavicol, and rosmarinic acid

Alkaloids

Alkaloids are a wide and diverse group of secondary metabolites found in 300 plant families and can be found as well in bacteria, fungi, and animals. Alkaloid name came from their basic nature and is characterized by the presence of a basic nitrogen atom in the form of a primary (RNH_2), secondary (R_2NH), or tertiary amine (R_3N). Alkaloids can be monomers or oligomers and can be classified into three major categories: true-alkaloids with N-atom in the heterocycle, proto-alkaloids without N-atom, and pseudo-alkaloids with a basic carbon skeleton [112, 188–192]. Heterocyclic alkaloids can be divided into 14 subgroups that include, pyrrolizidines, pyrrolidines, indoles, isoquinolines, quinolizidines, purines, piperidines, tropanes, and imidazoles [193]. A rich source of bioactive

compounds is Marine invertebrates which developed a defence chemical system to protect themselves from predation. Marine sponges are a rich source of secondary metabolites which are responsible for their numerous biological activities such as anti-inflammatory,anticancer, antiviral, antibacterial, and anticoagulant activities [194–196]. The sponge *Luffariella variabilis* exhibit antibacterial activity against gram-positive bacteria due to the presence of sesterterpenes manoalide, secomanoalide,and *trans*- and *cis*-neomanoalide (Fig. 7) [197]. Moreover, the sponges *Poecillastra* sp. and *Jaspis* sp., contain psammaplin A (Fig. 7), a bromotyrosine-derived natural product, while the sponge *Siliquaria* sp. contain the motualevic acids (A–F) (Fig. 7) a halogenated glycyl-lipid conjugates which all inhibit gram positive-bacteria only and are inactive against gram-negative bacteria [198, 199]. Antibacterial and antibiofilm activity of another group called the pyrrole-imidazole alkaloids was studied and tested against gram-positive and -negative bacteria. Bromoageliferin (Fig. 7) is a member from pyrrole-imidazole alkaloids family isolated from marine sponges with other members such as oroidin and sceptrin (Fig. 7). Reports documented the inhibition of *Rhodospirillum salexigens* SCRC 113 biofilms formation a marine bacterium by oroidin and bromoageliferin which resulted in using them as templates to develop numerous analogues and study their antibiofilm activity [200–209]. Melander et al. [210] studied pyrrole-imidazole alkaloids (monomeric and dimeric alkaloids) ability to inhibit biofilm formation and suppress antibiotic resistance against gram-negative *Acinetobacter baumannii* and gram-positive methicillin-resistant *S. aureus* (MRSA). Result showed that monomeric alkaloid oroidin exhibited modest activity against both strains, while stevensine (monomeric oroidin analogue) (Fig. 7) was inactive. On the other hand, the dimeric alkaloids Sceptrin was slightly more active against *A. baumannii*, while dibromosceptrin (Fig. 7) and bromoageliferein were both more active against MRSA with bromoageliferin as the most potent compound. Result indicated that both monomeric and dimeric alkaloids can inhibit phenotypic and genotypic bacterial resistance mechanisms; therefore, a high-throughput screening is needed to identify marine natural compounds to be used as adjuvants with antibiotics to restore FDA-approved antibiotics efficacy and to find alternative approaches to combating MDR bacteria. Tuberculosis (TB) is a widespread infectious disease, and due to the increase of multidrug-resistant (MDR) and extensively drug-resistant (XDR) strains new antiTB agents are needed. Arai et al. [211] isolated several compounds from marine sponge of *Haliclona* sp. such as tetracyclic alkylpiperidine alkaloid, 22-hydroxyhaliclonacyclamine B, and haliclonacyclamine A and B alkaloids (Fig. 7) to be used as antidormant mycobacterial compounds. Result showed strong antimycobacterial activity under both aerobic and hypoxic condition against *Mycobacterium smegmatis* and *M. bovis Bacille de Calmette et Guérin* (BCG) from both haliclonacyclamine. Haliclonacyclamine B exhibited bactericidal activity against *M. bovis*(BCG), while hydroxyhaliclonacyclamine B showed weaker antimicrobial activities against *Mycobacterium bacilli* and reduced antimycobacterial activity which may be due to the presence of the 22-hydroxy group. Wijaya et al. [212] studied *Dicranostigma franchetianum* plant from Papaveraceae family and isolated a wide spectrum of isoquinoline alkaloids (IAs) such as berberine, chelerythrine, protopine, and sanguinarine (Fig. 7). Alkaloids were tested against *Mycobacterium tuberculosis* H37Ra and four other mycobacterial strains. Most isolated alkaloids exhibited weak or no antimycobacterial activity; however, benzophenanthridine (6-ethoxydihydrochelerythrine) and bisbenzophenanthridine (*bis*-(6-(5,6-dihydrochelerythrinyl))ether) alkaloid derivatives (Fig. 7) showed moderate antimycobacterial activity against all tested strains. Moreover, semisynthetic berberine derivatives resulted in a significant increase in antimycobacterial activity against all tested strains. Further studies are needed to develop more potent berberine derivatives with low cytotoxic profile. On the other hand, Dong et al. [213] conducted a bioassay-guided phytochemical study on the semi-mangrove plant *Myoporum bontioides* A. Gray, which belong to Myoporaceae family and tested its activity against methicillin-resistant *S. aureus* (MRSA). New sesquiterpene alkaloids and furanosesquiterpenes were isolated from the plant, and result showed that sesquiterpene alkaloids displayed potent anti-MRSA activity. Alkaloids also can be used in food system to prevent or treat foodborne diseases such as oliveridine and pachypodanthine (Fig. 7) an aporphinoid alkaloids. Marco Di et al. [214] tested these alkaloids against *Yersinia enterocolitica* an important foodborne pathogen that cause a gastrointestinal disease in humans called yersiniosis. Result showed that both oliveridine and pachypodanthine inhibited the growth of *Y. enterocolitica* with superiority for oliveridine with lower MIC values which open an opportunity to develop

potential antimicrobial agents to prevent or treat foodborne diseases.

Chemical structure of alkaloids compounds including secomanoalide, neomanoalide, psammaplin A, motualevic acids (**A**–**F**), bromoageliferin, oroidin, sceptrin, stevensine, dibromosceptrin, 22-hydroxyhaliclonacyclamine B, haliclonacyclamine A and B, berberine, chelerythrine, protopine, sanguinarine, 6-ethoxydihydrochelerythrine, *bis*-(6-(5,6-dihydrochelerythrinyl))ether, oliveridine, and pachypodanthine

Lectins and polypeptides

Naturally antimicrobial proteins and peptides can be found in humans, animals, plants, and microorganisms. Plants include proteins called lectins that attach to certain carbohydrates on the surfaces of microbes, aiding in the defensive mechanisms against pathogens. Plant lectins are classified according to their affinity for monosaccharides and complex glycans, but they do not interact with endogenous cellular glycans. Instead, they have a strong affinity for the sugars on bacteria, fungi, and other organisms, which suggests that they serve as a plant defence molecule [215–218]. Lectins have different types including C-type lectins (e.g. endocytic lectins), S-type lectins (e.g. galectins), L-type lectins, P-type lectins, M-type lectins, Jacalin-related lectin (JRL),siglecs, *Oscillatoria agardhii* agglutinin homolog (OAAH), Cyanovirin-N homologs (CVNHs), *Galanthus nivalis* agglutinin-like (GNA-like) lectins, and others [219]. Lectins have been used in medicine as immunomodulators against tumour cells and microbial infections. Moreover, lectins showed to be able to disrupt quorum sensing (QS) signal transduction and interfere with nonessential functions for cell viability [220, 221]. Lectins purified from *Moringa oleifera* leaf (SLL-1, SLL-2, and SLL-3) showed variable antibacterial potency against *E. coli*, *Shigella dysenteriae,* and *S. aureus*, while water-soluble lectin purified from *Moringa oleifera* seeds significantly reduced *S. aureus* but not *E. coli* [222, 223]. On the other hand, mannose-glucose-binding lectin isolated from *Calliandra surinamensis* leaf did not kill *S. aureus* nor *Staphylococcus saprophyticus* but reduced their growth and their biofilm formation with no activity against *E. coli* [224]. In addition, a rich source of lectins is Marine species that include green algae (22%), red algae (61%), and cyanobacteria (17%) [225]. Few literature studies discussed the potential usefulness of algal or cyanobacterial lectins as antibacterial agents [226–228]. Purified lectins isolated from two red algal species, *Eucheuma serra* (ESA) and *Galaxaura marginate* (GMA), showed strong inhibitory action against marine gram-negative *Vibrio vulnificus*, while no action recorded for other two Vibrio species, *V. peagius* and *V. neresis* according to Liao et al. [229] study. Selectivity in the inhibition is referred to the differences in bacterial surface carbohydrates. Furthermore, Hung et al. [230] isolated lectins from *Eucheuma denitculatum* (EDA) red algae which also exhibited activity selectivity against *V. alginolyticus*, but not against *V. parahaemolyticus* or *V. harveyi* due to the binding of lectins to high-mannose N-glycans. Moreover, Holanda et al. [231] isolated lectins from *Solieria filiformis* red alga and tested its activity against gram-negative and -positive bacteria. Result showed that lectins inhibited the growth of the gram-negative species; *Salmonella typhi, Serratia marcescens, Klebsiella pneumoniae, Pseudomonas aeruginosa, Enterobacter aerogenes*, and *Proteus sp.*, while it stimulated the growth of the gram-positive species *Bacillus cereus*. No activity was noticed against *S. aureus, B. subtilis, E. coli*, and *Salmonella typhimurium*. The interaction between the *S. filiformis* lectin and the gram-negative bacteria's cell surface receptors, which encouraged changes in the flow of nutrients, may be the cause of the activity against gram-negative bacteria. These findings raised the possibility of using marine lectins as organic substitutes for antibiotics in the treatment of gram-negative pathogens [232]. As mediators of innate immunity in all living things, antimicrobial peptides (AMPs) or host defence peptides are also recognized to play a significant role in biological processes. Because AMPs are cationic and amphipathic, they can more easily pass through microbial cytoplasmic membranes and cause cell lysis. The usage of AMPs is constrained for a variety of reasons, including their undesirable cell toxicity, restricted availability, high cost during synthesis, sensitivity to protease degradation, and others [233, 234]. Compared to other species, plants have more AMPs, which typically have 20–50 amino acid residues and are abundant in glycine, cysteine, and positively charged residues [234, 235]. Plant AMPs are divided into thionins, defensins, α-hairpinins, nonspecific lipid transfer proteins (nsLTPs), hevein- and knottin-like peptides based on their 3D structure and cysteine signature [236]. A study of

cysteine-rich peptides (CRPs) revealed that they all had a structural component in common called the γ-core that is responsible for their antibacterial activity. This structural element has an antiparallel β-hairpin conformation [237]. Thionins are poisonous to yeast, fungus, and bacteria. Antifungal activity was defined as the development of pores or a specific contact with a particular lipid domain as a result of direct protein-membrane interactions between positively charged thionin and the negatively charged phospholipids in fungal membranes [238, 239]. The antibacterial, antifungal, proteinase, and insect amylase inhibitory properties of plant defensins also classify them as γ-thionins [240, 241]. Although the exact mechanism of action of defensins is yet unknown, and not all plant defensins work in the same way, they almost certainly use glucosylceramides as receptors for fungal cell membrane entry. Ion outflow and membrane rupture are caused by defensins' positive charges repelling one another into the cell membrane [242]. Similar behaviour has been seen with nsLTPs, which interfere with the biological membrane permeability and integrity of pathogens [243]. Gram-positive bacteria (*Bacillus megaterium* and *Sarcina lutea*) and a number of fungi were able to halt the formation of powerful nsLTPs that were isolated from onion seeds [244, 245]. Sunflower (*Helianthus annuus*) seed-derived nsLTP also demonstrated antifungal activity [246]. The α-hairpinins are a different small family of AMPs that includes peptides with a wide range of biological activities, including antifungal and antibacterial activity [247]. The rubber tree (*Hevea brasiliensis*) (which produces latex that is similar to hevein) gave its name to the family of AMPs that resembles hevein. Hevein-like peptides are extremely stable, cysteine-rich substances that withstand heat and protease activity. They are active against a variety of phytopathogens, including bacteria and fungus, due to their capacity to interact with pathogens' cell wall chitin, which is missing in plants [248]. Tk-AMP-K2$_{10\text{-}23}$, a knottin-like peptide isolated from *T. kiharae* seeds, was also discovered to have antibacterial action. According to the results of flow cytometry, there were less *Cr. neoformans* cells, which suggest that the peptide caused cell lysis by interfering with the integrity of the membrane [249–251]. More research and focus are required on peptides that are particularly effective against specific infections in order to create new antimicrobial agents.

Polyacetylenes

A wide variety of biomasses, including plants (particularly species of the Apiaceae family and carrot), marine organisms, fungi, insects, and people, include polyacetylenes, which are naturally occurring molecules characterized by the presence of two or more carbon–carbon triple bonds. There are just a few papers on the antibacterial potential of polyacetylenes, which are renowned for their anti-inflammatory and anticancer properties [252, 253]. A large number of natural polyacetylenes have been isolated such as 8*S*-heptadeca-2(*Z*),9(*Z*)-diene-4,6-diyne-1,8-diol (Fig. 5) from *Bupleurum salicifolium Soland* (Umbelliferae). This polyacetylene showed antibiotic activity against gram-positive bacteria *S. aureus* and *Bacillus subtilis* with no activity against gram-negative bacteria (*E. coli, Salmonella sp., Pseuknas aeuriginosa*) and the yeast *Candida albicans* [109]. Falcarinol-type polyynes (Fig. 8) showed to have antifungal activity that protects carrots from fungi as *Botrytis cinerea Pers*, while panaxydol and panaxytriol (Fig. 8) from *Panax ginseng* found to have cytotoxic effect against numerous cancer cell lines [254–256]. *Exocarpos latifolius Kuntze* stems were used to extract exocarpic acid derivatives (Fig. 8); some derivatives exhibited antimycobacterial activity against *M. tuberculosis*, while others exhibited no activity [253, 257]. Amadaldehyde, a C63 polyacetylenic aldehyde that was isolated from mango ginger (the rhizomes of *Curcuma amada* Roxb.), was shown to have antibacterial and antioxidant activity against microorganisms in addition to cytotoxicity and platelet aggregation inhibitory effect [258]. Several polyynes such as epoxide-ketone are found in one of the most important oriental medicinal plants *P. ginseng C.A. Meyer*. These compounds exhibited antimicrobial activity against several bacteria such as *Bacillus subtilis, S. aureus, Cryptococcus neoformans*, and *Aspergillus fumigatus* which conclude that *P. ginseng* releases antimicrobial polyacetylenes into the surrounding soil from roots to defend the plant[259]. Moreover, triyne carboxylic acid compound (octadeca-9,11,13-triynoic acid) (Fig. 8) isolated from the roots of *Polyalthia cerasoides* (Roxb.), showed antimalarial and antimycobacterial activity against *Plasmodium falciparum* and *M. tuberculosis*, respectively. Furthermore, 13,14-dihydrooropheic acid (Fig. 8) from the extract of *Mitrephora celebica* Scheff, and debilisones A–F (Fig. 8) from the Thai herbal plan *Polyalthia debilis* (Pierre) exhibited antibacterial activity against *Mycobacterium smegmatis* and *M. tuberculosis*, respectively

[260–262].

Chemical structure of polyacetylenes compounds including falcarinol, panaxydol, panaxytriol, amadaldehyde, octadeca-9,11,13-triynoic acid, 13,14- dihydrooropheic acid, debilisones (**A–F**)

Medicinal plants with antimicrobial activities

St. John's wort (SJW) (*Hypericum perforatum*)

There are 500 species in the *Hypericum* (Hypericaceae) family, and they are all found worldwide. The most prevalent species is *Hypericum perforatum*, also known as St. John's wort (SJW), which is one of the most well-known and widely used herbs in the world. The herb has been widely used for therapeutic purposes across the globe [263, 264] and has been included into traditional medicine. The aerial parts or flowering tops make up the crude form of SJW medicine, which is employed in multi-ingredient formulations or as a monopreparation (either as is or as an extract) [265]. The upper stem leaves and flowering tops of *H. perforatum* are used in dietary supplements to treat mild to severe depression [266]. The flowering tops are typically prepared and used for its hypnotic and tonic properties or to speed wound healing. Due to varying extraction techniques, individual plant extracts do not include the entire group of phytoconstituents but only some of them, which causes a number of issues that affect the usage of *H. perforatum* in pharmaceutical formulations. Additionally, some of the active ingredients may experience problems with stability with exposure to time or light[267]. Due to the plant's synthesis of bioactive secondary metabolites like naphthodianthrones, flavonoids, bioflavonoids, phloroglucinols, xanthones, proanthocyanidins, acid phenols, and essential oils [263, 268, 269], it has been the subject of phytochemical studies.

Antibacterial activity of SJW

Sherif et al. [270] investigated the antibacterial activity of the *Hypericum perforatum* plant. The plant extract and its fractions were evaluated by Liquid Chromatography Electrospray Ionization Tandem Mass Spectrometric (LC–ESI–MS/MS) and tested against MRSA, *Enterococcus faecalis, E. coli,* and *K. pneumonia* MDR isolates. The results demonstrated that different extract from *H. perforatum* had a promising antibacterial activity against tested pathogens, particularly MDR-*K. pneumoniae*, with inhibition zones ranging from 17.9 to 27.9 mm and strong antioxidant effects, as opposed to sub-fractions extract, which demonstrated lesser inhibition zones and higher MIC values. Bacterial cell membranes are affected by extract of *H. perforatum*, which causes cell shrinkage and deformation that results in cell lysing. Additionally, the extract promoted cell elongation and thickness, which is similar to the actions of penicillin and the antibiotic cefotaxime, according to published research [271–274]. These findings indicate that these herbal extracts can be used to treat resistant bacteria, but further research is required to clarify why the total extract showed the most potent antibacterial activity over the subfraction? Is it an additive effect of specific compounds that act together with different mechanism to inhibit resistance bacteria or something else?. Using *H. perforatum* flower extracts, Okmen et al. [275] investigated the antibacterial activity of the bacteria that cause mastitis, a complicated condition characterized by inflammation of the parenchyma of the mammary glands and bacterial alterations in milk. Along with coagulase-negative *staphylococci* (CNS), *Staphylococcus, Streptococcus*, and *coliform* bacteria are the pathogens that cause the disease [276]. Although this condition is frequently treated with antibiotics, new antibiotics are still needed to combat germs because of the emergence of antibiotic resistance. The study's findings indicated that *H. perforatum* flower methanol extracts exhibit bactericidal action against gram-positive and gram-negative bacteria (*S. aureus, Proteus vulgaris, P. aeruginosa,* and *E. coli*), with the highest inhibition zone against Coagulase-negative *Staphylococci*. The plant extract also demonstrated antimutagenic qualities. However, additional tests are needed to know the extract constitutes and the bioactive compounds responsible for the biological activities. Polyphenolic substances with pharmacological characteristics are called xanthones. Strong free radical scavengers, xanthones have been shown to have activity against a variety of bacteria, including vancomycin-resistant *enterococci*, methicillin- and multidrug-resistant *S. aureus*, and M. tuberculosis [277–283]. When *H. perforatum* was exposed to *Colletotrichum gloeosporioides* cell wall extracts, xanthone (Fig. 9) buildup was seen as a defence mechanism [284]. After elicitation with *Agrobacteriumtumefaciens*,

Franklin et al. [285] demonstrated that the antioxidant and antibacterial properties in *H. perforatum* cells had dramatically increased. The up-regulation of xanthone metabolism, particularly paxanthone (Fig. 9), which increased 12-fold within 24 h, was the cause of the enhanced activity. After 12 h of co-cultivation, the viability of *A. tumefaciens* was reported to have dramatically decreased. As a result of the buildup of xanthones, *H. perforatum* cell antibacterial activity rose ten times. Numerous infectious illnesses are brought on by *S. aureus*. Due to its development of resistance against practically all standard of care (SOC) antibiotics, Methicillin-resistant S. aureus (MRSA) has, regrettably, become a significant problem. Therefore, it is urgently necessary to create new tactics to combat MRSA [286–288]. Wang et al. [289] investigated the effect of hypericin (HYP) from *H. perforatum* on the susceptibility of *β*-lactam antibiotics (cefazolin, oxacillin, and nafcillin) and their synergistic effect with oxacillin in a murine bacteremia model. Result showed that HYP significantly reduced the minimum inhibitory concentrations (MICs) of *β*-lactam antibiotics and SarA (RNA-binding protein) which is a key regulator that bind on target promoters to control *S. aureus* virulence factors. Moreover, HYP enhanced the efficacy of oxacillin in MRSA bacteremia model; therefore, these results might be due to the synergistic effect of HYP with oxacillin.

Fig. 9 [Images not available. See PDF.]

Chemical structure of bioactive compounds found in St. John’s wort (SJW), rosemary, ginger which include, xanthone, paxanthone, hypericin, carnosol carnosic acid, p-cymene-7-ol, suberoylanilide hydroxamic acid, rosmanol, epirosmanol, isorosmanol, rosmaridiphenol, pyrogallol, ellagic acid, benzoic acid, butylated hydroxytoluene (BHT), butylated hydroxyanisole (BHA), α-curcumene, α-farnesene, β-bisabolene, β-sesquiphellandrene, zingiberene, gingerol, paradol, shogaol, gingerenone-A, zingerone, 6-dehydrogingerdione, 10-gingerol, 12-gingerol, *trans*-anethole, and m-phenylphenol

Rosemary (*Rosmarinus officinalis, L.*)

In addition to its use in food preservation to stop oxidation and microbial contamination, *Rosmarinus officinalis*, L., a member of the *Lamiaceae* family that originated in the Mediterranean, is renowned for its antioxidant, hepatoprotective, antiangiogenic, and potential treatment for Alzheimer's disease properties [290–292]. Numerous polyphenolic substances, including rosmarinic acid (Fig. 6), hesperidin (Fig. 2), carnosol, and carnosic acid, are found in rosemary (Fig. 9). According to various studies [293–295], rosemary essential oil contains 1,8-cineole, camphor, and -pinene p-cymene-7-ol in addition to borneol (Fig. 9). Fresh or dried leaves, flowers, fruits, roots, stems, seeds, and bark can all be used to make plant extracts, while dried samples were shown to contain higher quantities of flavonoids. Air, microwave, oven, and freeze drying are all acceptable drying techniques [296–298].

Antibacterial activity of rosemary

Rosmarinus officinalis was found to have antibacterial properties in many research. In their research on the antibacterial properties of several natural extracts, including rosemary, Fernández-López et al. [299] examined how long the shelf life of veal meatballs could be stored for. The results showed that all of the studied microorganisms were susceptible to rosemary extracts (oil extract, water miscible extract, oil, and water-miscible extract), with oil extract having the strongest inhibitory impact. The most vulnerable bacteria were *Brochothrix* spp., which might be a reference to the antibacterial action of nonpolar phenolic compounds against gram-positive bacteria. Govaris et al. [300], Gomez-Estaca et al. [301], and both Camo et al. [302] and Quattara et al. [303] reported that rosemary EOs prevented food-spoileding bacteria from growing. *Rosmarinus officinalis* and *Ocimum basilicum* essential oils have been shown to have antibacterial action against multidrug-resistant clinical isolates of *E. coli* by Sienkiewicz et al. [293]. Since both EOs were effective against every clinical strain of *E. coli*, it can be inferred that they can be used to treat and prevent the emergence of resistance strains. Probuseenivasan et al. [304] and Mihajilov-Kristev et al. [305] found similar results, confirming rosemary essential oil's potent antibacterial action against *E. coli*. Carnosol, carnosic acid, rosmarinic acid, rosmanol, epirosmanol, isorosmanol, and rosmaridiphenol (Fig. 9) interact with the cell membrane and alter the production of nutrients, genetic material, and fatty acids to produce rosemary’s inhibitory effects. Additionally, they affect electron transport, result in cellular component leakage, interact with proteins in the membrane, and cause a loss of membrane functionality [306, 307]. To increase the effectiveness of

antibiotics against multi-drug-resistant bacteria like MRSA, Ekambaram SP et al. [308] looked into the antibacterial activity and synergistic effect of rosmarinic acid (dimer of caffeic acid) with conventional antibiotics. The agar well diffusion method was used to assess the antibacterial activity of rosmarinic acid against microorganisms. In comparison to using an antibiotic alone, the results demonstrated that rosmarinic acid had a synergistic impact with the medications ofloxacin, amoxicillin, and vancomycin against *S. aureus*. However, only the vancomycin and rosmarinic acid combination was effective against MRSA. The activity of rosmarinic acid on surface proteins known as microbial surface components recognizing adhesive matrix molecules (MSCRAMM's) present in *S. aureus* and MRSA was suggested to be the mechanism of action. Pomegranate, rosemary, and antibiotic were combined in a study by Abu El-Wafa et al. [309]. *P. aeruginosa* isolates with significant biofilm producers and antibiotic resistance were examined for the synergistic effects of the combination. Pomegranate and rosemary plant extracts were the most successful at inhibiting biofilm by lowering swimming and twitching motility, which in turn decreased bacterial cells adhering to surfaces and quorum-sensing (QS) signals. The presence of polyphenol molecules such catechol, pyrogallol (Fig. 9), gallic, ellagic, rosmarinic acid, and benzoic acid may be referred to as these activities. There are, however, limited reports of plant extracts' antibacterial and antibiofilm activity [114, 310–312]. As a result, combining plant extracts with antibiotics may be able to prevent and get rid of microbial biofilms. Pomegranate and rosemary plant extracts combined with piperacillin, ceftazidime, imipenem, gentamycin, or levofloxacin had synergistic effects against a *P. aeruginosa* isolate and dramatically reduced biofilm mass after 24 h compared to the use of the plant extracts separately or together. To investigate the effects of medicinal plants and commercial antibiotics against bacterial pathogens, additional in vitro and in vivo investigations are required. In vitro tests using butylated hydroxytoluene (BHT) and butylated hydroxyanisole (BHA), two antioxidant food additives, and rosemary methanol extract were also conducted by Romano et al. [313] to examine the antioxidant and antibacterial properties of the extract (Fig. 9). The outcomes demonstrated that rosemary extracts (rosmarinic acid, carnosic acid, and carnosol) increased the antioxidant activity of BHT and BHA as well as the antibacterial activity of BHA.

Ginger (*Zingiber officinale*)

Zingiber officinale, a member of the Zingiberaceae family, has been used as a spice and a herbal remedy since ancient times [314]. Due to the presence of numerous bioactive components like terpene (e.g. α-curcumene, α-farnesene, β-bisabolene, β-sesquiphellandrene, and zingiberene) (Fig. 9), and phenolic compounds (e.g. gingerols, paradols, shogaols, gingerenone-A (Fig. 9), quercetin (Fig. 5), zingerone, and 6-dehydrogingerdione (Fig. 9)) [315–319], the ginger root is the most significant component that is used to cure a variety of illnesses including nausea, emesis, headaches, and colds. The majority of biological actions, including those that are antioxidant, anticancer, anti-inflammatory, and antibacterial, are caused by phenolic compounds [319–322]. Additionally, a number of studies [323–328] demonstrated that ginger can prevent and treat a wide range of illnesses, including neurodegenerative diseases, diabetes mellitus, obesity, cardiovascular diseases, respiratory problems, and nausea and emesis brought on by chemotherapy.

Antibacterial activity of ginger

Ginger essential oil is derived from the roots and has potential uses in a variety of industries, including pharmaceuticals, cosmetics, and food. *Shewanella putrefaciens* is a Gram-negative spoilage bacterium that can be found in aquatic products. *Zhang* et al. [329] studied the antibacterial activity of ginger essential oil against this bacterium. Result showed that ginger EO (Zingiberene, zingerone and α-curcumene) displayed significant antibacterial activity with MIC and MBC values of 2.0 and 4.0 μL/mL, respectively, against *S. putrefaciens* by disturbing cell membrane integrity. Additionally, ginger essential oil (EO) has the power to alter biofilm metabolism and kill it, supporting its usage as a natural food preservative. By Wang et al. [330], who extracted ginger essential oil using supercritical CO2 and steam distillation techniques, ginger was also demonstrated to be excellent for food preservation. The primary components were identified by GC–MS as zingiberene and α-curcumene, and their antibacterial efficacy was evaluated mostly against the pathogens that cause food deterioration, *E. coli* and *S. aureus*. Through bacterial cell membrane damage that resulting in protein and nucleic acid leaks, ginger EOs demonstrated remarkable bactericidal efficacy. This decreases bacterial metabolic activity, which ultimately leads to

bacterial cell death. The expression of several genes encoding important enzymes, the tricarboxylic acid cycle, DNA metabolism, and proteins involved in cell membranes is all inhibited by ginger EOs. Similar mechanisms of action were also observed by Zhang et al. [331] who found that ginger extract damaged the *Ralstonia solanacearum* cell membrane's permeability and integrity, leading to the leakage of several cell components, including nucleic acids, proteins, and others, as well as changes in the bacteria's shape. Additionally, Atai et al. [332] showed that ethanol ginger extract can be utilized to treat oral candidiasis and suppress the growth of *Candida albicans*. In the same context, Park et al. [333] assessed the ginger's ability to suppress mouth microorganisms linked to periodontitis. Result revealed that ginger extracts including 10-gingerol and 12-gingerol (Fig. 9) exhibited antibacterial activities against anaerobic Gram-negative bacteria, *Porphyromonas endodontalis, Porphyromonas gingivalis*, and *Prevotella intermedia* which causes periodontal diseases. Chairgulprasert et al. [334] extracted ginger EOs by steam distillation of fresh rhizomes and identified its chemical constituents by GC–MS which found the presence of *trans*-anethole, *m*-phenylphenol, (Fig. 9) estragol, and camphor in the extract. Results showed that petroleum ether and dichloromethane extracts in addition to the EOS were able to inhibit different bacterial pathogens such as *E. coli, S. aureus, Bacillus substilis,* and *Sarcina* sp.; on the other hand, no activity was recorded against *P. aeruginosa.* Research investigations are focusing on the effectiveness of combining medicinal herbs with antibiotics for enhanced antibacterial action. Using antibiotics (Ceftazidime), Sagar PK et al. [335] assessed the antibacterial activity of crude methanol extracts of medicinal plants like eucalyptus, clove, and ginger against *P. aeruginosa*. Isolates. With ceftazidime, all plant extracts had a synergistic impact on *P. aeruginosa*. When ginger and eucalyptus extracts were mixed, their separate MICs were not reduced; however, when ginger and clove extracts were combined, a maximum twofold reduction in MIC was discovered. When ginger extract was used with aminoglycosides to treat vancomycin-resistant *enterococci* (VRE), MIC values were also lowered. By increasing membrane permeability and improving the influx of aminoglycosides into enterococcal cells, 10-gingerol has been shown by Nagoshi et al. [336] to be able to lower MICs of many aminoglycosides, including arbekacin, bacitracin, and polymyxin B. The effectiveness of 6-gingerol alone and in combination with amphotericin B against Leishmania in vivo murine models was evaluated by Alireza Keyhani et al. [337]. In addition to its capacity to create an apoptotic index, raise the expression of Th1-related cytokines, and decrease transcription factor levels, the combination demonstrated a strong antioxidant and extreme leishmanicidal activity. When combined with fluconazole, methanol ginger extract demonstrated antifungal activity against drug-resistant *vulvovaginal candidiasis* (VVC) in a mouse model, according to Khan et al. [338]. As compared to fluconazole or ginger extract used alone, which did not entirely cure VVC, in vitro results revealed better activity for the combination of fluconazole and ginger extract against *C. albicans*. Azole-resistant candidiasis may therefore be treated by administering this combination.

Cactus (*Opuntia ficus-indica*)

Opuntia ficus-indica (*L.*), sometimes known as the nopal cactus, is a tropical and subtropical plant found in South Africa, Mexico, Latin America, and Mediterranean nations [339]. All cactus portions contain high levels of polyphenols, which have anti-inflammatory and antioxidant qualities. The most significant source of polyphenols and flavonoids, including gallic acid, is found in flower parts. These compounds have cytotoxic and antioxidant properties that lessen DNA damage [340–342]. Cactus fruit, also known as cactus pear, also contains fibres, ascorbic acid, vitamin E, amino acids, and carotenoids, all of which have hypoglycemic and hypolipidemic effects [342–344]. Due to the abundance of fatty acids, it contains, including oleic acid, palmitic acid, linolenic acid, and linoleic acid (Fig. 10); cactus cladodes can have a hypocholesterolemic impact [345, 346]. Therefore, *Opuntia ficus indica* have been used in traditional medicine due to the abundance natural compounds and derivatives for treating burns, oedema, wounds obesity, and hyperlipidemia, in addition to its antiviral, anti-inflammatory, and hypoglycemic properties[347].

Fig. 10 [Images not available. See PDF.]

Chemical structure of bioactive compounds from nopal cactus including oleic acid, palmitic acid, linolenic acid, linoleic acid, octadecadienoic acid, dihydroauroglaucin, isotetrahydroauroglaucin, cristatumin B, quercetin5,4'-

dimethyl ether, isorhamentin3-O-glucoside, isorhamnetin

Antibacterial activity of Cactus

The extensive use of cactus pears flowers in traditional medicine is a result of their abundance in natural bioactive substances. Protein, fibre, and minerals make up the chemical makeup of cactus hexane extracts, as demonstrated by Ennouri et al. [348]. In the plant extract, octadecadienoic acid and palmitic acid (Fig. 10) were the primary components and potassium was the leading mineral. Antibacterial activity against *E. coli* and *S. aureus* was highly effective which suggest using cactus as a food preservative. There are few studies available on the antibacterial activities of *O. ficus-indica*. The plant has proven to be effective in wound healing and skin conditions such as healing laser-induced skin burns. Khémiri et al. [349] demonstrated that cactus was able to inhibit cutaneous infections by showing antimicrobial effect against *Enterobacter cloacae,* antifungal activity against *Penicillium, Aspergillus, and Fusarium* (opportunistic cutaneous moulds), and antiyeast effect against *Candida sake* and *Candida parapsilosis*. Therefore, cactus-extracted oil is a good healing agent due to its antibacterial effect and the ability to reduce reepithelialization phase. Future investigations are needed to identify the active compounds in the oil extract and its mechanism of action involved in the healing process. Ammar et al. [350] also evaluated cactus flowers extracts (mucilaginous and methanol) antioxidant and antibacterial activities for enhancing wound healing in excision wound model in rats. A beneficial effect was noticed on cutaneous repair which assessed by acceleration in wound contraction and remodelling phases. Both extract showed antibacterial activities against tested gram-negative and gram-positive bacterial strain, *E. coli, S. aureus, Bacillus subtilis,* and *Listeria monocytogenes*, while no antibacterial activity was noticed against *P.aeruginosa.* The result supports the use of *O. ficus-indica* as therapeutic agent for dermal wound healing, but more research is needed to know the exact mechanism of action. Alqurashi et al. [351] explored biological activities of oil from *Opuntia ficus-indica* seed and showed that it possesses an inhibitory action against *Saccharomyces cervisiae* while no activity against *Aspergillus niger.* On the other hand, Elkady et al. [352] isolated endophytic *Aspergillus niger* fungus from cactus fruit peels and tested the effect of endophytic ethyl acetate extract and its isolated compounds (dihydroauroglaucin, isotetrahydroauroglaucin, and cristatumin B) (Fig. 10) on resistant bacterial strains. Result showed excellent activity against Gram-negative and gram-positive resistant bacteria. Another study done by Elkady et al. [353] tested methanol extract of cactus against pneumonial pathogens (*Streptococcus pneumoniae, Klebsiella pneumoniae, P. aeruginosa, Legionella pneumophila, Moraxella catarrhalis, and Stenotrophomonas maltophilia*). The isorhamentin3-O-glucoside and isorhamnetin (Fig. 10) compounds show moderate antibacterial activity against all tested microorganisms, while quercetin5,4'-dimethyl ether, which was isolated from the cactus ethyl acetate fraction, demonstrated the most antibacterial activity. According to these findings, *O. ficus-indica* and the components that were extracted from it can work as new all-natural antibacterial agents for the treatment of infectious disorders. Further studies in vivo are needed to confirm the antibacterial activity of the extracts. Sánchez et al. [353] studied antibacterial and antibiofilm activity of several methanolic plant extracts against nosocomial microorganisms. Methanolic plant extracts were tested against specific clinical bacterial isolates by using well diffusion method, and results showed that Prosopis *laevigata* extract was active against all the clinical isolates with highest inhibition diameter against *S. aureus* strain compared to *Gutierrezia microcephala* and *O. ficus-indica* that showed lesser inhibition diameter and no activity for Nothoscordum *bivalve* extract. *E. coli* was less susceptible, while *K. pneumoniae* and E*. faecalis* were more resistant to the extracts except for P*. laevigata* and *O. ficus-indica.* The major reduction on the specific biofilm formation index (SBF) in dose-dependent manner and on cytotoxic activity (using brine shrimp lethality test) was caused by *O. ficus-indica.* Unfortunately, there are no available studies and data on the synergistic effect of *O. ficus-indica* with antibiotics which highlights the need for researcher to focus on studying synergistic or additive effect of herbal plants, especially *O. ficus-indica* with antibiotic to discover new treatments.

Medicinal plants and wound healing

The epidermis, dermis, and hypodermis are the three layers of the skin, one of the biggest organs in the body. Additionally, it serves as the initial line of defence against aggressors like infections, chemicals, and physical contact. Due to the function of the epidermis, which blocks the entry or exit of water- or water-soluble substances,

and the hypodermis, which blocks heat loss due to the poor thermal conductivity of fat, it also has the capacity to prevent water loss and preserve temperature [354–357]. In order to maintain skin hemostasis during inflammation, immune cells and nonimmune cells form a structure known as skin-associated lymphoid tissue (SALT). Additionally, the skin's microbiome, which includes bacteria, fungi, and viruses, is crucial for immune response, concluding that the skin serves as more than just a physical barrier [354, 358, 359]. Over the years, natural product ingredients such polyphenols, fatty acids, probiotics, polysaccharides, and others have demonstrated their efficacy as immune system modulators. The secret to controlling or curing skin inflammatory problems may lie in using natural products [360–362]. Skin can react to infectious agents through innate and adaptive immune processes, just as other tissues like mucosal surfaces. To isolate the damaged area, stop bleeding, and initiate the coagulation cascade, a clot must first form in order for the wound healing process to begin. Then comes the inflammatory phase, where immune cells begin to infiltrate and high levels of pro-inflammatory mediators are discovered to stop pathogen entry and more serious problems. The next stage is the proliferative phase, which is characterized by a significant growth of skin-resident cells including fibroblasts and high levels of angiogenesis. The remodelling phase, which may last for more than a year after the injury, is the longest and involves the skin regaining its natural structure. Any issue throughout these stages may hamper wound healing, which may then result in infections, excruciating pain, and occasionally neurological damage [363–366]. Several factors can cause impaired wound healing such as local factors that influence the characteristics of the wound like oxygenation and infections and systemic factors in which overall health or disease state affects the ability to heal like hormones and diabetes [367–370]. Impaired wound healing can result from a variety of factors, including local ones that alter the characteristics of the wound, such oxygenation and infections, as well as systemic ones, like hormones and diabetes, that have an impact on overall health or disease states and the capacity to heal. Numerous abnormalities, including fibrosis, scarring, and nonhealing wounds like persistent ulcers, can result from aberrant wound repair [371, 372]. New compounds with antioxidant, anti-inflammatory, and anticarcinogenic properties are being researched to prevent skin damage. Natural substances have been employed as antitumoural, analgesic, anti-inflammatory, and antioxidant agents [373, 374]. Table 2 lists the top plants for healing wounds.

Table 2. Most used medicinal plants in treating skin disorders

Plant name	Active compounds	Therapeutic uses	References
Achillea millefolium L	Flavonoids, monoterpenes, and sesquiterpenes	Skin inflammatory and wound healing	[375–379]
Aloe vera	Acemannan (Fig. 11)	Wound healing	[380, 381]
Bletilla striata	Triterpenoids and polysaccharides	Drug delivery, wound dressing, and wound healing	[382, 383]
Blumea balsamifera	L-Borneol (Fig. 11)	Dermatitis, eczema, skin bruises, and skin injury	[384, 385]
Boswellia sacra	Boswellic acids (Fig. 11)	Improvement of blood circulation, pain treatment, and rheumatoid arthritis	[386–389]

Caesalpinia sappan	Brazilin and Sappanchalcone (Fig. 11)	Improvement of blood circulation, pain treatment, and oedema	[390, 391]
Calendula officinalis	Esculetin, and Quercetin-3-O-glucoside (Fig. 11)	Burns, dermatitis, and wound healing	[392–394]
Celosia argentea	Celosin I and Celosin II (Fig. 11)	Skin sores and ulcers	[395, 396]
Centella asiatica	Asiaticoside and Madecassoside (Fig. 11)	Wounds healing	[397–399]
Cinnamomum cassia	Cinnamaldehyde (Fig. 5)	Analgesia and improvement of blood circulation	[399, 400]
Commiphora myrrha	Furanoeudesma-1,3-diene and Terpene (Fig. 12)	Gastrointestinal diseases, wounds, and pain	[401–404]
Curcuma longa	Curcuminoids (Fig. 12)	Digestive diseases, liver disorders, menstrual difficulties, pain disorders, sprains, and wounds	[405, 406]
Entada phaseoloides	Tannin (Fig. 12)	Aging, atherosclerosis, cancer, diabetes, and neurodegenerative disorders	[407, 408]
Ganoderma lucidum	Ganoderma lucidum polysaccharide	Cancer, diabetes, hepatitis, leukaemia, and ulcer	[409–413]
Ligusticum striatum	Phthalide lactones, and alkaloids	Antiatherosclerotic, antioxidant, neuroprotective, and vasorelaxant	[414–418]
Panax ginseng	Ginsenosides (Fig. 12)	Laser burn, excision wounds models in mice, cell migration, and wound healing assays	[419–424]
Polygonum cuspidatum	Emodin, polydatin, and resveratrol (Fig. 12)	Hepatitis, hyperlipidemia. Jaundice, scald, skin burns, and suppurative dermatitis	[425–428]
Rheum officinale	Emodin (Fig. 12)	Chronic kidney disease, hepatitis, and wounds healing	[429–431]

Sanguisorba officinalis	Polysaccharides, tannins, triterpenoid glycosides, and triterpenoids	Burns, chronic intestinal infections, haemorrhoids, menorrhagia, and scalds	[432–434]
Sophora flavescens	Kushenol, and sophoraflavanone B (Fig. 12)	Asthma, burns, dysentery, eczema, fever, hematochezia, inflammatory Jaundice, oliguria, and vulvar swelling	[435]
Wedelia trilobata	Kaurenoic acid (Fig. 12) and Luteolin (Fig. 5)	Arthritic painful joints, rheumatism, and stubborn wounds	[436, 437]
Zanthoxylum bungeanum	Afzelin, hyperoside quercitrin, and rutin (Fig. 12)	Skin wrinkles	[438, 439]

Fig. 11 [Images not available. See PDF.]

Chemical structure of active compounds found in medicinal plants used to treat skin disorders including, acemannan, L-Borneol, boswellic acids, brazilin, sappanchalcone, esculetin, quercetin-3-O-glucoside, celosin I, celosin II, asiaticoside, and madecassoside

Fig. 12 [Images not available. See PDF.]

Chemical structure of active compounds found in medicinal plants used to treat skin diseases cont. including cinnamaldehyde, furanoeudesma-1,3-diene, tannin, ginsenoside, emodin, polydatin, resveratrol, kushenol, sophoraflavanone B, kaurenoic acid, afzelin, hyperoside, and rutin

Biopolymers

Pathogenic microorganisms (bacteria, viruses, and unicellular and multicellular eukaryotes) can cause several series diseases which are a public health concern [440]. Different pathogens accumulate in acute and chronic wounds such as *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Streptococcus pyogenes*, *Pseudomonas aeruginosa*, and others which can affect wound healing process and increase life-threatening problems [441, 442]. Because they are naturally occurring biomolecules derived from bacteria, animals, and plants, biopolymers play a significant role in wound care. These bioactive features include antimicrobial, cell proliferative, angiogenic, and immune-modulatory polymers. These qualities, along with their biodegradability, renewability, and decreased antigenicity, rendered them more advantageous for the healing process than synthetic materials, which have problems with biocompatibility because of their harmful effects [443–445]. Natural biomaterials like cellulose, hyaluronic acid, collagen, alginate, and chitosan (Table 3) are frequently used in the wound care industry. With the advancement of technology, the characteristics of biopolymers can be improved to meet a variety of wound care needs, including tissue repair, scar-less healing, and integrity restoration of lost tissue [446, 447]. By preventing microbes from directly interacting with the bacterial cell wall, producing ROS to increase oxidative stress, and inducing the leaking of macromolecules like DNA and proteins from microorganisms, antimicrobial biomaterials can aid in the healing of wounds [442, 448].

Table 3. Natural biopolymers used in wound healing process

Biopolymer	Source	Biological role	References
Collagen	Cattle and porcine slaughterhouse wastes	Skin tissue engineering, nerve regeneration, vitreous replacement, coating of bioprostheses, and others	[449–452]

Cellulose	Plant's cell wall (e.g. *Hibiscus Cannabinus*) and in several bacteria (e.g. *Gluconacetobacter,* *Agrobacterium*, and *Sarcina*)	Artificial skin substitute and as regeneration of tissue for wound healing purposes	[453, 454]
Alginate	Brown algae	Biomedical, cosmetics, pharmaceutical, food industries	[455–459]
Hyaluronic acid	Synovial fluid, articular cartilage, and mammalian bone marrow	Bone regeneration, tissue engineering, drug delivery, tumour cell targeting, skin aging treatment, reduced wrinkles, skin firmness, skin hydration, wound healing, and others	[459–462]
Chitosan	Partially deacetylation of chitin	Wound healing, tissue engineering, cartilage regeneration, gene delivery, drug delivery, bioadhesive, and others	[459, 463]
κ-carrageenan	Red seaweeds (Rhodophyceae)	Anti-inflammatory, antithrombotic, cytoprotective, antiviral, antitumour, antioxidant, antipathogenic, drugs delivery, wound dressing, and wound repair	[464, 465]
Silk fibroin	Silkworms, spiders, and other insects	wound healing, skin restoration, cellular adhesion, wound contraction, re-epithelialization, angiogenesis, collagen production, stimulation of cell migration, and inactivation of the apoptotic pathway	[466–468]

Extracellular vehicles (EVs)

Extracellular matrix (ECM), growth factors, and hormones are just a few of the biomaterials and composites that have recently undergone modifications to improve cell survival, motility, and proliferation. One of the most promising methods for wound healing is extracellular vehicles (EVs). EVs are released by a variety of cells and are crucial for the phases of wound healing (hemostasis, inflammation, proliferation, and remodelling) as well as intercellular communication that promotes regeneration. Additionally, by labelling EVs with certain surface proteins, they can be created to carry particular cargo and employed for targeted delivery [469–473]. Exosomes, which are created during endosomal sorting, microvesicles, which directly arise from plasma membranes, and apoptotic bodies, which are created following cell death, can all be classified as subpopulations of EVs [474–476]. The regulation of hemostasis and each stage of wound healing are considerably aided by EV. The most prevalent EVs in blood circulation are platelet-derived EVs (PEVs) [476–478]. The activated form of integrin IIb-3 mediates the role of PEVs from thrombin-stimulated platelets in the development of fibrin clots [479]. This form of integrin αIIbβ3 has a high affinity for fibrinogen. PEVs were also discovered to bind tissue factor (TF) and factor XII, as well as to stimulate the generation of thrombin, but only in the presence of factor VII and xii, indicating that they mediate both intrinsic and extrinsic coagulation pathways [480]. Neutrophil-derived EVs (NDEVs) have been shown to have pro- or anti-inflammatory effects by boosting the production of ROS and IL-8 [481]. EVs are also involved in inflammation. Additionally, EVs take part in the remodelling phase (starting fibroplast differentiation) and the proliferation phase (EVs from wound edge keratinocytes, or KCs-EVs) [482]. EVs can be made from plants, stem cells, or engineering [482, 483]. Membranous vesicles formed from plants are similar to mammalian exosomes but have different chemical

compositions and include fewer proteins and no cholesterol in the lipid layer. EVs made from plants are less harmful, safer, and expensive. Wheat, broccoli, ginger, grapefruit, grape, lemon, and EVs were also discovered in the xylem and phloem of woody plants, according to recent investigations [484, 485]. Several plant have been known in pharmacognosy and phytochemistry to own antibleeding and hemostatic properties such as *Rubia cordifolia*, *Alchornea cordifelia*, *Aspilia africana*, *Baphia nitida*, *Ageratum conyzoides*, *Chromolaena odorata, Jathropha curcas* , *Landolphia owariensis, Dalbergia sissoo*, *Aloe spesiosa*, *Beta vulgaris*, *Humulus lupulus*, *Salix alba*, and others [486–488]. Different studies demonstrated the effect of plant-derived EVs on wound healing; Perut et al. [489] isolated and purified plant-derived exosome-like nanovesicles (EPDENs) from strawberry juice of *Fragaria* x *ananassa* which is characterized of high anthocyanins, folic acid, flavonols, vitamin C, and short RNAs and miRNAs contents. The uptake of *Fragaria*-derived EPDENs by mesenchymal stromal cells (MSC) did not affect cell viability and prevented oxidative stress which may be due to the presence of vitamin C. Additionally, exosome-like nanovesicles isolated from Citrus limon L. (EXO-CLs) were investigated and examined in vitro on MSC by Baldini et al. [490]. The findings indicated that EXO-CLs contained short RNA sequences (20–30 bp), vitamin C, and citrate. EXO-CLs were taken up by MSC and had a significant antioxidant activity, according to in vitro tests. Ju et al. team also found that grape exosome-like nanoparticles (GELNs) have a protective effect against dextran sulphate sodium-induced colitis and facilitate intestinal tissue remodelling [491]. Similar outcomes were also observed with ginger-derived EVs, which promoted intestinal wound healing and are presently being investigated in clinical trials for inflammatory bowel disease and colon cancer [320, 482, 484]. Other plant-derived EVs, such as those from grapefruit and wheatgrass, improved wound healing by boosting cell viability and motility [485, 492]. The formation of hypertrophic scars and keloid lesions has also been demonstrated to be decreased by herbal extracts and active herbal compounds, including onion extract, epigallocatechin gallate from green tea, resveratrol obtained from peanuts, and others [493]. To retain EVs at the wound site and encourage longer, more effective results, they can be applied topically or encapsulated into scaffolds like hydrogels. Natural polymers like chitosan, alginate, and collagen are examples of hydrogels. Synthetic polymers like polyethene glycol, polyglycolic acid, and polyurethane are also possible [494–497]. A promising method to introduce EVs into the wound site with extended release involves encapsulating them in hydrogels [498]. To create naturally produced EVs for wound healing, further research on particular plant species is required.

Treatment of skin disorders

Diabetic foot ulcers (DFUs)

Patients with uncontrolled diabetes mellitus frequently develop diabetic foot ulcers (DFUs), which can be brought on by poor glycemic management, peripheral vascular disease, neuropathy, or inadequate foot care [499]. According to the International Diabetes Foundation [500], there are 40–60 million persons worldwide with DFUs. DFUs can be treated using several methods, including as gene therapy, stem cells, skin substitutes, and antibiotics. Due to the high cost of local debridement (removal of nonviable wound tissue) and negative pressure therapy, antibiotic resistance as a result of prolonged use, the ineffectiveness of growth factors to inhibit bacterial growth, and the existence of stem cell and gene therapies in the experimental stage, nonsurgical treatments for DFUs must be quick and inexpensive [501]. Due to their anti-inflammatory qualities, several herbal extracts have been utilized as traditional treatments to treat wounds. Liu et al. [501] designed an experiment to explore the effects of five herbal extracts on wound healing, *Bauhinia purpurea* (inhibit inflammation, and act as analgesic and antipyretic) [502], *Paeoniae rubrae* (ameliorating inflammation by inhibiting glycogen synthase kinase 3β (GSK3β)) [503], *Angelica dahurica* (accelerate wound healing by regulating inflammation) [504], *Acorus calamus* L (promote collagen maturation) [505], and *Radix Angelicae biseratae* (inhibit inflammation and regulate immune system in osteoarthritis) [506]. In order to determine the mechanisms of action for wound healing, the mixture of herbal plants was identified by Ultra-High-Performance Liquid Chromatography (UHPLC) and Quadrupole Exactive-Mass Spectrometer (QE-MS) and tested in vivo on a rat model with diabetic ulcer wound utilizing transcriptomics and proteomics. The mixture speeds up the healing of wounds by encouraging angiogenesis and the growth of M2 macrophages, according to the results. Specific miRNAs and proteins were found to be crucial for controlling wound healing by

transcriptomics and proteomics. Consequently, the herbal combination may offer a potential method to quicken the healing of diabetic wounds [501].

Atopic dermatitis (AD)

Atopic dermatitis (AD), a chronic and relapsing inflammatory skin condition that affects children and is characterized by itchy, eczematous skin lesions, is another skin condition [507, 508]. Intense itching results in skin damage that compromises tissue repair and allows microorganisms to infiltrate the skin [509, 510]. The absence of precise disease processes is a challenge for the development of successful AD therapeutics. Flavonoids, a type of secondary metabolite found in plants, exhibit a variety of antiallergic properties, including antioxidant, anti-inflammatory, antiangiogenic, antibacterial, and antiviral effects [511, 512]. In foods ingested as part of a daily diet, quercetin (Fig. 5) is an illustration of a flavonoid [513]. Quercetin inhibits the release of histamine, proinflammatory cytokines, and interleukin (IL)-4 and -13, among other antiallergic characteristics. Despite this, there have only been a few research on quercetin's effects on AD [514, 515]. Therefore, Beken et al. [516] studied the effect of quercetin on AD model of human keratinocyte and treated it with IL- 4, -13, and tumour necrosis factor-α (TNF-α) to mimic AD in vitro. Result showed that quercetin accelerated wound healing by reducing AD-inducing agents IL-1β, IL-6, IL-8, thymic stromal lymphopoietin, phosphorylation of extracellular signal-regulated kinase 1/2/mitogen-activated protein kinase (ERK1/2 MAPK), and nuclear factor-kappa B (NF-κB), while it upregulated the expression of IL-10, and antioxidant enzymes; glutathione peroxidase (GPx), superoxide dismutase-1 (SOD1), SOD2, and catalase (CAT), in addition to mRNA expression of Twist and Snail. Therefore, quercetin may act as a potential therapy for AD symptoms.

Conclusions and future recommendations

Extensive and inappropriate uses of antibiotics resulted in the development of antimicrobial resistance and the rise of bacterial strains that were resistant to multiple drugs (MDR) and multiple drugs extensively (XDR), which made the most powerful medications useless. Antimicrobial resistance is very concerning and urgent issue, and scientists are aware that the shelf life of antibiotics is finite. Natural product research is receiving a lot of interest internationally. Today, millions of people around the world turn to phytomedicine as one of their top options for the treatment of chronic illnesses. Medicinal plant extracts are crucial in the fight against infectious diseases that pose a threat to public health globally. Alkaloids, phenolics, polyphenols, terpenoids, essential oils, lectins, polypeptides, and polyacetylenes are a few examples of antimicrobial phytochemicals that can be utilized as adjuvants or substitutes against bacterial infections. Medicinal plants including St. John’s wort (*Hypericum perforatum*), Rosemary (*Rosmarinus officinalis*), Ginger (*Zingiber officinale*), and nopal cactus (*Opuntia ficus-indica* (*L.*)) are attracting the interest of researchers due to their high phytochemical contents. Additionally, probiotics, polysaccharides, polyphenols, fatty acids, and other bioactive substances can modulate the immune system and treat inflammatory skin diseases such atopic dermatitis (AD) and diabetic foot ulcers (DFUs). Natural anticarcinogenic, anti-inflammatory, and antioxidant substances can be employed to stop skin deterioration. Biopolymers derived from microorganisms, animals, and plants (cellulose, hyaluronic acid, collagen, alginate, and chitosan) and extracellular matrix (ECM) have bioactive properties that make them promising approaches for wound healing. These properties include antimicrobial, immune-modulatory, cell proliferative, and angiogenic effects.

It is essential to create innovative plans and tactics to deal with the issue of rising AMR. Medicinal plants contain unlimited source of bioactive compounds which has been used in the treatment of many diseases, especially against bacterial infections. Despite that fact, natural compounds have not yet been thoroughly investigated and many are still unexplored. Therefore, researchers should make efforts to isolate and identify new bioactive compounds from plant source to face antibacterial resistance and find new effective treatments. Researchers should focus on using appropriate extraction methods to isolate compounds from bioactive extracts, study the mechanism of action, test the compounds in vivo in animal models, and apply structural modification to improve pharmacodynamics and pharmacokinetics. Moreover, further studies should be done on the synergistic or additive interactions between plant compounds itself and with antibiotics to enhance the action of medications.

Prevention of paclitaxel-induced peripheral neuropathy: literature review of potential pharmacological interventions

Mahmoud, Aalaa Mahmoud Ahmed Shawqi1; El Said, Nouran Omar1 ; Shash, Emad2; Ateyya, Hayam11 Future University in Egypt, Department of Pharmacy Practice and Clinical Pharmacy, Faculty of Pharmacy, New Cairo, Egypt (GRID:grid.440865.b) (ISNI:0000 0004 0377 3762)2 Cairo University, Comprehensive Center of the National Cancer Institute, Cairo, Egypt (GRID:grid.7776.1) (ISNI:0000 0004 0639 9286)

ABSTRACT (ENGLISH)

Background

Paclitaxel administration is considered a keystone in the management of many types of cancers. However, paclitaxel chemotherapy often leads to peripheral neuropathy which is the most prominent adverse effect that reduces the patient's quality of life and demands dose reduction leading to decreased disease curing. Paclitaxel induces peripheral neuropathy through disruption of microtubules, distorted function of ion channels, axonal degeneration, and inflammatory events. So far, there is no standard medication to prevent the incidence of paclitaxel-induced peripheral neuropathy (PIPN).

Main body

Numerous preclinical studies in rats and rodents showed that several therapeutic agents have neuroprotective mechanisms and reduce the incidence of PIPN, proving their effectiveness in the prevention of PIPN in animal models. Different mechanisms, such as reduction of the expression of inflammatory mediators, quenching of reactive oxygen species, prevention of neuronal damage, and other mechanisms, have been explored. Moreover, many clinical trials have further established the neuroprotective effect of several investigational drugs on PIPN. Twenty preclinical studies of pharmacological interventions were reviewed for their preventive effect on neuropathy. These medications targeted cannabinoid receptors, oxidative stress, inflammatory response, and ion channels. Additionally, 25 clinical studies with pharmacological preventive interventions of PIPN have been reviewed, of which only 10 showed preventive action in PIPN.

Conclusion

Prevention of PIPN is currently considered an emergent field of research. This review highlights the potential interventions and presents recent findings from both preclinical and clinical studies on the significant prevention of PIPN to help in effective decision-making. However, further well-designed research is required to ascertain recommendations for clinical practice.

FULL TEXT

Background

Taxanes are considered first-line chemotherapeutic agents often used in several cancers including those of the breast, ovaries, prostate, gastric, head and neck, and non-small lung cancers [1]. Paclitaxel is one of the important and commonly used antineoplastic agents in this class due to its microtubule-stabilizing mechanism of action. It is commonly used in the management of several cancer types with extensive evidence proving its antimitotic effect [2, 3].

One of the prime adverse effects of taxanes including paclitaxel is peripheral neurotoxicity known as peripheral neuropathy [4]. Up to 97% of patients receiving paclitaxel will develop paclitaxel-induced peripheral neuropathy (PIPN), which turns into a chronic condition in more than 60% of cases [5]. It decreases the efficacy of the chemotherapy by causing patient discomfort and often resulting in dosage reduction or chemotherapy treatment termination. Significantly, those who suffer from chronic neuropathy have considerably poorer long-term quality of life [4].

Peripheral neuropathy is a neurological disorder affecting sensory, motor, and autonomic peripheral nerves [6]. Neuropathic pain resulting from paclitaxel administration develops because of somatosensory nerve damage. Mice administered with paclitaxel exhibit elevated activating transcription factor-3 levels in their large and medium dorsal root ganglion (DRG) neurons, which is indicative of neuronal damage [7]. In PIPN, axonal deterioration and depletion of intra-epidermal nerve fibers (IENFs) was reported, showing that DRG injury is the primary cause of taxane-induced nerve damage [8]. Taxane-induced peripheral neuropathy has been linked to several pathophysiological pathways, including oxidative stress, mitochondrial damage, and microtubule disruption [9].

These pathological pathways are demonstrated in Fig. 1.

Fig. 1 [Images not available. See PDF.]

Pathophysiology of paclitaxel-induced peripheral neuropathy (PIPN). *ATP* adenosine triphosphate, *C3* complement 3, *CX3CL1 C-X3-C motif chemokine ligand 1*, *IL* interleukin, *TNF* tumor necrosis factor, *ROS* reactive oxygen species

Paclitaxel alters microtubule dynamics which results in impairment in the passage of nutrients, organelles, and neurotransmitters across the neuronal axon leading to axonal degeneration or axonopathy [10]. Also, mitochondrial dysfunction such as morphological alterations, electrolyte imbalance, and reactive oxygen species (ROS) generation has been considered an important element in PIPN. Furthermore, PIPN in rats was linked to the emergence of behaviors caused by pain and mitochondrial disruption in myelinated fibers and C-fibers [11]. Oxidative stress and inflammatory mediators also have a critical importance in the pathophysiology of PIPN [11, 12]. The number of cycles, length of therapy, patient's age, use of other neurotoxic medications, as well as the presence of risk factors like diabetes, alcoholism, and previous neuropathy, have been linked to the development of PIPN. Additionally, genetic polymorphism in genes like CYP2C8 (cytochrome P450 family 2 subfamily C member 8) and KCNN3 (potassium calcium-activated channel subfamily N member 3) is also linked to the occurrence of PIPN [13].

The most common clinical presentation of PIPN patients is paranesthesia, tingling, and burning "stock and glove." In more extreme cases, however, it can lead to loss of sensation, motor deficiencies, and autonomic malfunction. Patients typically exhibit sensory symptoms with a "stocking and glove" description, affecting the extremities and extending toward the proximal body parts. Hyperalgesia and allodynia, due to tactile and heat stimuli, may be experienced [14, 15].

Because of the evolving pathophysiologic pathways mechanisms and the diversity of causes and risk factors, preventive interventions are desperately needed to lower the prevalence of PIPN [16]. Despite emerging evidence, there are no established pharmacological interventions for PIPN prevention. This review aims to map the existing literature on interventions evaluated for the prevention of PIPN. A summary and overview of the types of pharmacological interventions studied through preclinical and clinical trials and their effects on outcomes were reported in this review. Additionally, an insight into the effects of genetic polymorphism on the development of PIPN was also reviewed.

Literature search

We conducted a comprehensive search in several databases, including MEDLINE through PubMed, Web of Science, the Cochrane Library, EBSCOhost, and Scopus. Studies that were published in the English language from year 1999 to year 2023 are included in this review. The search keywords used were "prevention," "neuropathy," "paclitaxel," "neurotoxicity," "chemotherapy-induced peripheral neuropathy," "controlled clinical trials," and "preclinical studies."

Main text

Preclinical studies for the prevention of paclitaxel-induced peripheral neuropathy

Multiple preclinical studies in rodent models indicate that various pharmacologic agents may offer protective effects against peripheral neurotoxicity induced by paclitaxel.

One study in experimental rats showed that the antianginal trimetazidine reduced apoptosis, oxidative stress, and neuroinflammation which are all effects resulting in axonal degeneration and are linked to recurrent paclitaxel administration. The mode of action was shown to be due to the upregulation of Notch1 and progranulin [17]. Additionally, another study further confirmed PIPN reduction by trimetazidine through modulating toll-like receptor 4 (TLR4)/p38 and Klotho protein expression in Swiss albino mice [18].

The angiotensin-II receptor blocker (ARB) losartan demonstrated protective properties against PIPN in experimental rats. Its administration proved its anti-inflammatory effect on microglia in the central nervous system (CNS) through the reduced expression of inflammatory mediators such as tumor necrosis factor-alpha (TNFα) and interleukin-6 (IL-6) and stimulation of peroxisome proliferator-activated receptor gamma (PPARγ) [19]. Similarly, telmisartan, another

ARB, reduced PIPN in mice through its inhibition of cytochrome-p450-epoxygenase (CYP2J6) and the prevention of oxidized lipid synthesis [20]. The involvement of Angiotensin-2 was further demonstrated in the preclinical study where ramipril administration attenuated functional neuropathy secondary to paclitaxel in mouse models [21].
An animal study investigating the potential anti-inflammatory role of hesperidin in PIPN has shown positive results. Hesperidin administration reduced oxidative stress and inflammatory response in nerve tissue secondary to paclitaxel use. This is assumed to be because hesperidin's antioxidant nature allows it to scavenge reactive oxygen species (ROS) generated from mitochondria, subsequently preventing membrane damage caused by ROS [22].
The antioxidant effects of vitamin C and curcumin have been investigated in suppressing PIPN with demonstrated benefits in the reduction of TNFα and IL-6 levels in the DRG of rats [23, 24]. Melatonin was found to exhibit similar effects in reducing mitochondrial damage and attenuating PIPN in animal studies [25].
Furthermore, rosuvastatin showed a reduction in pro-inflammatory mediators and oxidative stress in paclitaxel-treated mice [26]. This is speculated to be due to possessing pleiotropic and anti-inflammatory properties, further confirming its anti-neuropathic potential in rat models [27].
Medications used in the treatment of neuropathic pain such as duloxetine, pregabalin, and amitriptyline were found to attenuate PIPN in animal models [28–30]. The preventive mechanism was found to be via downregulation of pro-inflammatory biomarkers such as IL-6 and TNFα as well as upregulation of the antioxidant capacity.
Metformin was studied in paclitaxel-treated mice, and the results indicate the effectiveness of metformin in attenuating hyperalgesia priming induced by paclitaxel through its stimulation of adenosine monophosphate-activated protein kinase (AMPK) [31].
On the other hand, the effect of alogliptin, a dipeptidyl peptidase 4 (DPP-4) inhibitor, on chemotherapy-induced peripheral neuropathy was investigated using mice, and its protective effect was demonstrated only against oxaliplatin-induced neurotoxicity but not that induced by paclitaxel nor bortezomib [32].
Moreover, co-treatment with the phosphodiesterase (PDE) inhibitor cilostazol halted the dedifferentiation of Schwann cells, secondary to paclitaxel administration, mediated by cyclic adenosine monophosphate (cAMP) signaling and demyelination in a mixed culture of Schwann cells and DRG neurons [33].
The role of glutamate neurotransmitter and the development of PIPN was confirmed in rat models where the co-administration of valproate suppressed glutamate accumulation and paclitaxel-induced mechanical allodynia [34].
It was previously shown that the acute administration of paclitaxel to neuroblastoma cells in culture increased the binding of the cytoplasmic calcium-binding protein neuronal calcium sensor 1 (NCS-1) to the inositol 1,4,5 tris-phosphate receptor (InsP3R) [35, 36]. A preclinical investigation confirmed that a single prophylactic injection of Ibudilast or lithium might inhibit PIPN in mice before they received paclitaxel therapy. These substances work by interfering with the way paclitaxel, NCS-1, and the InsP3R interact [37].

Clinical studies for the prevention of paclitaxel-induced peripheral neuropathy

Several clinical randomized studies have been reported in the literature demonstrating the use of investigational drugs in the prevention of PIPN showing promising evidence of their effectiveness. Table 1 summarizes the clinical studies investigating the potential role of different agents in the prevention of peripheral neuropathy (PN) secondary to paclitaxel chemotherapy.

Table 1. Clinical studies for the prevention of paclitaxel-induced peripheral neuropathy (PIPN)

Study	Population	Chemotherapy dosing	Number of patients	Intervention	Measured outcomes	Summary of findings

Aghili et al. [38]	Breast Cancer (BC) Patients	Paclitaxel 175 mg/m^2 every 3 weeks	40	1. Gabapentin 900 mg daily PO 2. Placebo	1. NCV 2. Neuropathy grading assessed by NCI-CTCAE version 4.0	1. Significant differences in the incidence of neuropathy 2. Significant differences in Nerve Conduction velocity
Pandey et al. [39]	Breast, Ovarian and Lung Cancer Patients	Paclitaxel 135–200 mg/m^2 every 3 weeks or 60–80 mg/m^2 weekly.124	136	1. Gabapentin 300 mg 2. Placebo	1. Neuropathy grading assessed by NCI-CTCAE version 5.0 2. NCV 3. QOL assessed by EORTC-QLQ-CIPN20 score	1. Incidence of neuropathy grade 2 was lower in Gabapentin group
Ghoreishi et al. [40]	BC Patients	Paclitaxel 175 mg/m^2 every 3 weeks	57	1. Omega 3 fatty acids 1920 mg daily PO 2. Placebo	1. Neuropathy grading assessed by rTNS 2. Nerve conduction Study 3. Serum levels of omega-3 fatty acids	1. Significant differences in neuropathy
Bakry et al. [41]	BC Patients	Paclitaxel 175 mg/m^2 biweekly	73	1. Metformin 850 mg twice daily PO 2. Placebo	1. Neuropathy grading assessed by NCI-CTCAE version 5.0 2. Quality of life (QOL) assessed by FACT-GOG-NTX subscale 3. BPI-SF 4. Serum NGF 5. Serum neurotensin NT	1. Significant differences in incidence of grade 2–3 neuropathy

Khalefa et al. [42]	BC Patients	Paclitaxel 80 mg/m^2 weekly for 12 weeks	75	1. N-acetylcysteine 1200 mg daily or twice daily PO 2. Control	1. Neuropathy grading assessed by NCI-CTCAE v4.0 and mTNS 2. QOL assessed by FACT-GOG-NTX subscale 3. Serum NGF 4. Serum MDA	1. Significant differences in neuropathy grade 2–3, mTNS, and QOL scores
2. Significant increase in serum NGF and decrease in serum MDA	Haroun et al. [43]	BC Patients	Paclitaxel 175 mg/m^2 biweekly	59	1. Cilostazol 100 mg Twice daily PO 2. Placebo	1. Neuropathy grading assessed by NCI-CTCAE version 4 2. QOL assessed by FACT-GOG-NTx subscale 3. Serum NGF 4. Serum NfL
1. Significant difference in neuropathy between the two groups 2. Significant increase in serum NGF in cilostazol group 3. No significant difference in NfL	Gelmon et al. [44]	Metastatic BC Patients	Paclitaxel 250 mg/m^2 every three weeks	37	1. Amifostine 910 mg/m2 IV 2. Control	1. Reduction of neurotoxicity associated with paclitaxel 2. Compare myelosuppression, myalgias, and response rate in two groups
1. No significant differences in neuropathy between the two groups	Loven et al. [45]	Ovarian Cancer Patients	Paclitaxel 175 mg/m^2	43	1. Glutamate 1500 mg daily PO 2. Placebo	1. Signs and symptoms of peripheral neuropathy

1. No significant differences in frequency of signs or symptoms	Leal et al. [46]	Cancer Patients	Paclitaxel 150–200 mg/m^2 and Carboplatin AUC = 5–7 every 21–28 days	185	1. Glutathione 1.5 mg/m^2 IV 2. Placebo control	1. QOL assessed by EORTC-QLQ-CIPN20 score 2. Neuropathy grading assessed by NCI-CTCAE v4.0 3. FACT-O questionnaire

1. No significant differences in acute pain score 2. No significant differences in in EORTC-QLQ- CIPN20 scores	Hershman et al. [47]	BC Patients	Paclitaxel 175 mg/m^2 biweekly, Paclitaxel 80 mg/m^2 weekly, Docetaxel 75 mg/m^2	409	1. Acetyl-L-carnitine 3000 mg daily PO 2. Placebo	1. Neurotoxicity scored by FACT-NTX score 2. FACT-Taxane-TOI 3. FACIT-Fatigue Scale
1. Significant deterioration in Neurotoxicity (NTX) scores	Pachman et al. [48]	BC Patients	Paclitaxel 80 mg/m^2 weekly	47	1. Minocycline 200 mg on day one followed by 100 mg daily 2. Placebo	1. Pain scores and other continuous variables converted to a 0 - 100 scale to assess the quality of life of the patient 2. Area under the curve of the entire course of treatment assessed 3. EORTC-QLQ-CIPN20 score

1. Significant difference in acute pain scores 2. No significant differences in sensory neuropathy score of the EORTC-QLQ-CIPN20 between the two groups	Shinde et al. [49]	Cancer Patients	Paclitaxel 80 mg/m^2 weekly	46	1. Pregabalin 150 mg daily PO 2. Placebo	1. EORTC-QLQ-CIPN20 score
1. No significant differences in acute pain score 2. No significant differences in in EORTC-QLQ- CIPN20 scores	Argyriou et al. [50]	Patients with solid or nonamyloid cancer malignancy	Paclitaxel-based regimens	32	1. Vitamin E 300 mg twice daily, 2. Control	1. PNP score
1. Significant differences in incidence of neuropathy and (PNP) scores	Argyriou et al. [51]	Patients with nonamyloid malignancies	Paclitaxel, Carboplatin, or their combinations	31	1. Vitamin E 600 mg daily 2. Control	1. PNP score

1. Significant differences in neuropathy scores between the two groups	Heiba et al. [52]	Patients with solid or nonamyloid malignancies	Taxane-Based Regimens	140	1. Vitamin E 400 mg twice daily 2. Control	1. Neuropathy grading assessed by NCI-CTCAE v. 5.0
1. Significant differences in duration and severity of neuropathy between the two groups	Aghabozorgi et al. [53]	BC Patients	Paclitaxel Based Regimens	40	1. Duloxetine 30 mg daily 2. Placebo	1. Neurotoxicity assessed by PNQ 2. Nerve Conduction Study

1. According to PNQ: 50% of the placebo group (n=20) had neurotoxicity, in the duloxetine group (n=20) two patients had mild neurotoxicity 2. Nerve Conduction tests show significant differences between the two groups related to the mean of median of sensory latency, Median Motor latency and Median motor velocity 3. No significant difference between the two groups related to the relative risk of polyneuropathy	Abbas et al. [54]	Patients with different malignancies	Paclitaxel 80 mg/m^2 weekly	50	1. Glutamine 15 gm daily 2. Control	1. Clinical Examination including vibrations, and grading of power in muscles, cranial nerve examination, and postural drop 2. NCI-CTC 3. Nerve conduction study

1. No significant difference in neuropathy between the two groups	Holotiuk et al. [55]	BC Patients	AT regimen (paclitaxel 175 mg/m^2 - doxorubicin 60 mg/m^2) or ET regimen (paclitaxel 175 mg/m^2, - epirubicin 90 mg/m^2	100	1. Alpha lipoic acid ALA 600 mg P.O. once daily and ipidacrine hydrochloride 20 mg P.O. three times a day 2. Control	1. Electroneuromyography Examinations

1. Significant reduction in the severity of nerve damage	Sánchez-Lara et al. [56]	Non-small cell lung cancer (NSCLC) Patients with stage IIIb and IV	Paclitaxel 175 mg/m^2 and Cisplatin 75 mg/m^2/Carboplatin AUC = 6	92	1. Eicosatetraenoic acid (EPA) 2. Control	1. Body weight, body composition, inflammatory parameters, and HROL
1. Significant difference in neuropathy between the two groups	Davis et al. [57]	Patients with solid tumors	Paclitaxel 175 mg/m^2 then carboplatin AUC = 6	117	1. Recombinant human LIF 2 or 4 μg/kg subcutaneous	1. CPNE Score

1. No significant differences in CPNE or any of the individual neurologic tests	2. Placebo	Schloss et al. [58]	Patients with a neoplastic disease	Regimens include Paclitaxel, Docetaxel, Oxaliplatin, or Vincristine	47	1. Vitamin B complex 2. Placebo
1. Neuropathy scored by TNS 2. Neurotoxicity assessed by PNQ 3. EORTC-QLQ-CIPN20 score	1. No significant difference in prevention of CIPN	Cho et al. [59]	Non-small cell lung cancer patients (NSCLC)	Paclitaxel Based Regimens	16	1. Lafutidine 10 mg twice daily 2. Placebo
1. Neuropathy grading assessed by NCI-CTCAE v5.0 2. PNQ 3. FACT-GOG-NTX subscale	1. No significance differences in prevention of CIPN	Kaku et al. [60]	Ovarian or Endometrial Cancer	Paclitaxel 175 mg/m^2-Carboplatin AUC = 5–6 (TC regimen)	29	1. Goshajinkigan (GJG) 7.5 gm/day (three times daily) 2. Control

1. CPT 2. Pain assessed by VAS 3. FACT-Taxane 4. Neuropathy grading assessed by NCI-CTCAE version 3.0	1. Significant Difference in the prevention of neuropathy favoring Goshajinkigan	Su et al. [61]	BC Patients	Regimens include Paclitaxel 175 mg/m^2, or Docetaxel 90 mg/m^2	183	1. Ganglioside monosialic acid (GM1) 80 mg once per day for 3 days (The day before start of Taxane therapy) 2. Placebo
1. FACT-NTX 2. Neuropathy grading assessed by NCI-CTCAE version 4.0 3. ENS	1. Significant difference in reduction of severity and incidence of Taxane-Induced Peripheral Neuropathy	Werida et al. [62]	BC Patients	Four cycles of doxorubicin plus cyclophosphamide every 21 days, followed by 12 cycles of paclitaxel weekly	64	1. Alpha Lipoic Acid 600 mg PO once daily 2. Placebo

Anticonvulsants

Pregabalin and gabapentin are commonly reported to treat different neuropathic pain. A randomized double-blinded clinical pilot study on the use of pregabalin in preventing PIPN reported no significant difference in worst pain scores between the control arm and the pregabalin arm. Moreover, there were no differences across the arms in the worst, average, and least pain area under the curve (AUCs) throughout the first cycle of therapy ($p=0.48$, 0.62, 0.22, and 0.07, respectively) or the maximum of average pain. Additionally, the European Organization of Research and Treatment of Cancer Quality of Life Questionnaire (EORTC-QLQ-CIPN20) sensory subscale did not significantly differ between the two arms according to growth curve models or AUC analysis ($p=0.88$ and $p=0.46$, respectively) [49].

In another double-blinded, placebo-controlled study 40 breast cancer patients were randomly assigned to receive gabapentin or placebo. In all four cycles, the gabapentin group's neuropathy was primarily grade 1, with no reported cases of ≥ grade 3 neuropathy. In the gabapentin group, the rate of grade 2 and 3 neuropathy was considerably

lower (P<0.001) than in the placebo group. After four cycles of paclitaxel, the gabapentin group's Nerve Conduction Velocity (NCV) changed to be lower than that of the placebo group (17.7% vs. 61.0% reduction in NCV for sural nerve and 21.9% vs. 62.5% fall in NCV for peroneal nerve) [38].

Biguanides

A double-blinded randomized controlled trial (RCT) assessing the efficacy of metformin in the prevention of PIPN showed that the development of grade two or more peripheral neuropathy (PN) was significantly lower in the metformin group compared to placebo (p=0.001). Additionally, the time to develop PN was significantly longer in the metformin group. Furthermore, serum nerve growth factor (NGF) was significantly lower in the metformin group, and comparable levels of serum neurotensin were found in the two study groups [41].

Nutritional supplements

Omega 3 fatty acid protective effect in PIPN was assessed in a double-blinded RCT and showed a significant difference in PN occurrence (OR 0.3, 95% CI (0.10–0.88), p=0.029). The two study groups did not show a significant trend in terms of PIPN severity differences; nevertheless, the placebo group had greater frequencies of PN in all score categories (0.95% CI (−2.06 −0.02), p=0.054). [40]

Vitamin E neuroprotective effect was evaluated in three RCTs, where the incidence of PIPN and modified peripheral neuropathy (PNP) score were significantly lower with Vitamin E. [50] Also, neurotoxicity was more common in the control group than in the vitamin E-supplemented patients [51]. The frequency of ≥ grade 2 neuropathy, was comparable across the two arms; and only a non-significant difference in grade 3 neuropathy was reported. When comparing the two arms, there was a significant difference in the time length of neuropathy, which was measured from the onset of the first ≥ grade 2 or PN to the point at which it resolves to grade 1 neuropathy [52].

Vitamin B complex when used in conjunction with neurotoxic chemotherapy regimens did not prevent CIPN nor was it more effective than a placebo [58].

One RCT indicated the administration of alpha lipoic acid (ALA) in conjunction with the inhibitor of acetylcholinesterase ipidacrine hydrochloride (IPD) significantly reduced the extent of damage to the sural nerves (SNs) and superficial peroneal nerves (SPNs) caused by paclitaxel in patients prescribed for polychemotherapy (PCT). This was done by identifying significant differences in the electroneuromyography (ENMG) indicators of sensory nerve parameters between the studied groups [55]. Another double-blinded RCT showed that the percent of peripheral neuropathy grade 3 was significantly lower in the ALA group. Furthermore, the FACT-GOG-Ntx-12 questionnaire total score was significantly higher in the ALA group. Regarding the biomarkers, ALA group showed lower levels of brain natriuretic peptides (BNP), tumor necrosis factor-alpha (TNF-α), Malondialdehyde (MDA), and NT in comparison with the control group [62].

A controlled study assessed the oral nutritional supplement Eicosatetraenoic (ONS-EPA) acid effect in patients with advanced non-small cell lung cancer, compared to the control group. Patients in the ONS-EPA group showed significantly reduced neuropathy [56].

Another supplement, acetyl-L-carnitine (ALC) has been studied in PIPN. Over two years, CIPN was statistically significantly worse after twenty-four weeks of ALC therapy [47].

Goshajinkigan (GJG), a traditional Japanese herbal medicine, has been evaluated in a randomized controlled trial showing that (GJG) has a neuroprotective effect and nerve-repairing effect in CIPN [60].

Amino-acids and peptides

A randomized controlled study investigating glutamine in PIPN reported an overall frequency of neuropathy across all grades to be 78% at three months and 80% at six months. At six months, the incidences of grade 1 (48%), grade 2 (22%), and grade 3 (10%) neuropathy were recorded and (20%) did not experience neuropathy. Weekly paclitaxel-induced symptoms were mostly of grades 1 and 2, but not grade 4 symptoms. No significant differences were observed across the treatment groups in terms of the symptoms and weekly PIPN was not improved by glutamine [54].

Glutamate has been evaluated in a double-blinded RCT, showing that the selected dosage regimen was ineffective in the prevention of PIPN. Both groups' frequency of signs and symptoms was similar; however, the glutamate

group's neurotoxicity symptoms tended to manifest at lower severity levels. Additionally, there was similarity between the two groups in the frequency of aberrant electrodiagnostic findings [45].

A double-blinded RCT evaluated the use of glutathione for the prevention of paclitaxel/carboplatin-induced peripheral neuropathy. The results revealed no statistical significance difference in determining neurotoxicity with grade 2 using the National Cancer Institute Common Terminology Criteria for Adverse Event (NCI-CTCAE) v4.0 scale or in the time to development of neurotoxicity with grade 2. Moreover, no significant difference in neurotoxicity was measured by the EORTC-QLQ-CIPN20 [63].

Cytokines

Another double-blinded RCT showed that Recombinant Human Leukemia Inhibitory Factor (LIF) was not protective against carboplatin/paclitaxel-induced CIPN. There was a comparable standardized composite peripheral neuropathy electrophysiology (CPNE) score between the baseline and cycle 4, the last cycle, or the post-treatment assessment in both groups [57].

Mucolytic agent

N-acetylcysteine was evaluated for its effect on the prevention of PIPN because of its activity in reducing oxidative stress and elimination of ROS. RCT results demonstrated that when compared to the low-dosage group (61.9%) and the control group (100%), the high-dose group's occurrence of grades 2 to 3 PN was significantly reduced (28.6%). A significant improvement in QOL and modified total neuropathy score (mTNS) scores was recorded. Additionally, there were significant differences in serum MDA levels between the high-dosage and low-dose groups, as well as significantly greater levels of NGF in the high-dose group [42].

Phosphodiesterase inhibitors

Cilostazol has been evaluated for its preventive effect on PIPN, and when comparing the cilostazol group (40%) to the control group (86.7%), there was a significant difference in the occurrence of grade 2 and 3 peripheral neuropathies. The control group had a greater rate of clinically significant worsening in neuropathy-related quality of life compared to the cilostazol group. The cilostazol group showed a greater percent increase in serum NGF from baseline. At the end of the study, the circulation levels of the neurofilament light chain (NfL) were found to be comparable across the two arms [43].

Tetracycline antibiotics

Minocycline was studied in a multicentric, double-blinded, pilot trial and reported no significant dissimilarity during the first cycle of treatment. Still, there was a significant difference in the daily average area under the curve (AUC) pain score attributable to paclitaxel acute pain syndrome (P-APS), in favor of minocycline. Additionally, there was a tendency toward improvement in the daily worst pain AUC score across the 12 cycles. The overall EORTC-QLQ-CIPN20 sensory subscale did not significantly change between minocycline and placebo, despite the decrease in P-APS linked to minocycline usage [48].

Antidepressant

Over a long time, the antidepressant duloxetine has been evaluated for the management of CIPN, and recently, it was assessed in a double-blinded RCT to prevent PIPN. According to Patient Neurotoxicity Questionnaire (PNQ), 10 (50%) of the 20 participants in the placebo group experienced neurotoxicity (two mild cases, three moderate cases, four severe cases, and one disabled case). Nonetheless, two patients in the duloxetine group experienced moderate neurotoxicity. Median motor, sensory latency, and motor velocity were shown to have significant variations across the groups. The relative risk of polyneuropathy (relative risk: 1), however, was comparable between the two groups. According to the findings, an electrodiagnostic investigation supported the possibility that duloxetine could be a beneficial medication for breast cancer patients in reducing PIPN [53].

H2 antagonist

A small, randomized placebo-controlled study was conducted to evaluate lafutidine in the prevention of PIPN. Due to limited recruitment, the planned total of patients was not attained. Neuralgia of grade 2 or above affected 22.2% of the lafutidine group compared to 14.3% in the control group. In the lafutidine group, 100% of the participants had peripheral sensory neuropathy grade 2 or above, compared to 71.4% in the control group ($p=0.175$). In neither

group, there was evidence of PN of grade 3 or higher. The two groups' PNQ scores did not differ significantly from one another. Following the fourth cycle, there was a tendency for the lafutidine group to have lower FACT/GOG-Ntx scores than the control group. Between the two groups, there was no statistically significant difference in progression-free survival (PFS) [59].

Others

A randomized double-blinded placebo-controlled study was conducted to assess the effect of ganglioside monosialic acid (GM1) in the prevention of PIPN, which showed that the GM1 group had a lower incidence of PN grade 1 or higher in CTCAE v4.0 grading. Additionally, the GM1 group had a better significant difference in the FACT-NTX score. Moreover, a lower significant difference in the Eastern Cooperative Oncology Group Neuropathy scale (ENS) in the GM1 group was reported [61].

Assessment tools of PIPN including patient-reported outcome measurements (PROMs)

Patient-reported outcome measures (PROMs) are used more widely as a significant tool for the assessment of PIPN and are considered a valuable tool for collecting PN symptoms. PROMs are mostly used as endpoint measures in PIPN treatment and prevention clinical trials, as well as in research settings to characterize the natural history of neuropathy development and recovery. The most investigated PROMs were the EORTC-QLQ-CIPN20 and FACT-GOG-Ntx.

EORTC-QLQ-CIPN20

EORTC-QLQ-CIPN20 is a 12-item quality-of-life questionnaire that was developed to gather information on patients' experiences with CIPN-related symptoms and functional limitations. The CIPN20 comprises three subscales motor, sensory, and autonomic. Using a four-point rating system, patients indicate how much they have experienced each symptom (or "item") over the past seven days (1 = Not at all, 2 = A little bit, 3 = Quite a little, and 4 = Very much). Higher scores indicate a greater symptom burden. The three subscales are each calculated as the sum of component items, linearly transformed to a 0–100 scale [64].

FACT-GOG-Ntx

The FACT/GOG-Ntx was developed in cooperation between the Gynecologic Oncology Group (GOG) and the Functional Assessment of Chronic Illness Therapy group. The original 11-item FACT/GOG-Ntx11 questionnaire was created to assess the magnitude of CIPN and its effects on patients' quality of life in relation to motor, sensory, and auditory neuropathy and dysfunction. A five-point rating system is used for each item (0 = Not at all, 1 = A little bit, 2 = Somewhat, 3 = Quite a bit, and 4 = alot). The items' scores are reversed according to the FACIT groups' scoring convention, with greater total scores indicating better quality of life [65, 66].

Genetic single nucleotide polymorphisms associated with PIPN

Polymorphisms associated with paclitaxel metabolism

PIPN sensitivity may be raised by polymorphisms in genes related to the metabolism of the drug. Increased severity of PIPN has often been linked to single nucleotide polymorphisms (SNPs) in the ABCB1 gene [67–69]. In previous reports of patients with breast cancer receiving taxanes, SNPs in CYP2C8 and CYP3A4 were identified as causes of ≥ grade 2 CIPN [68, 70, 71].

Polymorphisms associated with microtubule function

Genes linked to microtubule function have been investigated to anticipate their relationship with PIPN since taxanes alter microtubule function and could contribute to PIPN pathogenesis. In 1303 European patients receiving paclitaxel, a SNP in the β tubulin IIb-encoding gene TUBB2A was linked to PIPN [72]. However, in 454 patients with ovarian cancer treated with paclitaxel and carboplatin, additive SNPs in MAPT and GSK3B were linked to reported neuropathy [73].

Polymorphisms associated with inherited neuropathies

The relationship between CIPN and genes linked to hereditary neuropathies has also been investigated. In African American patients receiving paclitaxel, SBF2, linked to Charcot-Marie-Tooth (CMT) disorder, was linked to CIPN [74]. Another study involving 58 individuals receiving paclitaxel discovered that FZD3 was linked to CIPN but not SBF2 [74]. Also, FGD4 was linked to CIPN in a trial investigating 219 breast cancer patients receiving taxanes [75].

In a larger cohort of 855 patients of European origin treated with paclitaxel, findings confirmed variation in FGD4 gene was linked to the reported sensory CIPN [76]. Another trial examining 269 cancer patients undergoing treatment in Alliance N08C1 found that ARHGEF10 was linked to CIPN when 49 CMT genes were examined in blood samples [77]. These results have been proved in 138 patients receiving paclitaxel in Alliance N08CA [78].

Polymorphisms associated with inflammatory pathways

An increasing corpus of research indicates that PIPN is influenced by inflammation, and changes in inflammatory pathways were linked to neuropathic pain [9, 79]. SNP in FCAMR, which encodes the FC receptor, led to a substantial relationship with CIPN in 3,431 breast cancer patients receiving paclitaxel treatment [80].

Polymorphisms associated with ion channels

Moreover, PIPN may potentially result from disruption of neuronal function via ion channels [9, 81] and SCN10A encode sodium channels located in the dorsal root ganglia, specifically Nav1.7 and Nav1.8. Among 186 Japanese patients with taxanes-treated breast and ovarian cancer, a SNP in the encoding gene SCN9A was linked to the development of≥grade 2 CIPN [82].

Polymorphisms associated with neuronal function

Genes related to cellular repair pathways and nervous system development and function have been connected to PIPN. In patients receiving taxanes, CIPN is linked to changes in the genes coding the Eph receptors (EPHA4, EPHA5, EPHA6, EPHA8), a class of tyrosine kinase receptors responsible for nerve growth and regulation [83–87]. Also, in 107 patients of gynecologic malignancies undergoing taxane or platinum chemotherapy, polymorphisms in the neural development-related genes SOX10 and GPX7 were linked to CIPN [88].

Future perspectives

Potential difficulties in many clinical trials investigating PIPN prevention include small sample sizes, the absence of placebo control groups, varying dosing and treatment regimens of investigational medications, non-standardized definitions and assessments of neuropathy, and inclusion of cancer patients receiving different chemotherapy treatment protocols. These factors limit the generalizability and interpretation of study findings. To manage these obstacles, future trials should ensure randomized placebo-controlled designs with adequate statistical power. Standardizing objective neuropathy assessments and definitions of clinically significant PIPN across studies would enable cross-trial comparisons. Additionally, narrowing eligibility criteria to specific chemotherapy protocols may yield more homogeneous cohorts for evaluating preventive interventions.

Conclusion

Preventing paclitaxel-induced neuropathy is a complex and evolving field. The literature on PIPN prevention is characterized by the heterogeneity of study designs, patient populations, and outcome measures, making conclusive evidence challenging. The literature suggests a variety of potential approaches such as pharmacological interventions; however, more high-quality research is needed to establish clear recommendations for clinical practice.

ABSTRACT (ENGLISH)

Background

The purpose of the present study was to enhance the memory-boosting activity of the standardized hydroalcoholic *Camellia sinensis* extract (CSE) by the formation of nanophytosomes with Leciva S70 phospholipid. The central composite design was used to optimize the solvent evaporation method for the formulation of *C. sinesis* phytosomes (CSP).

Results

The optimized formulation had a mean particle size of 212.3 nm ± 0.39, PDI of 0.238 ± 0.0197, and zeta potential of −42.02 ± 0.995 mV. *C. sinensis* phytosome formation was confirmed by analytical techniques. The aqueous solubility of the developed CSP was 95.92 ± 0.31, which is 7.34 times greater than that of pure CSE (13.07 ± 0.19). CSP was found more effective than either pure CSE (26.42 ± 0.4654%) or the physical mixture (32.15 ± 0.4596%) in releasing the CSE from the formulation (72.16 ± 0.5248%). Acute toxicity study corroborated the safety of CSP in rats. CSP demonstrated a significant ($p<0.05$) reduction in escape and transferred latency on both days (15th and 16th) as compared to CSE, indicating the improvement of the memory-boosting activity. Furthermore, CSP-treated rats significantly improved acetylcholine (Ach) levels and brain tissue concentration compared with CSE. Moreover, the phytosomal formulation of CSP exhibited its rationality with an improvement of bioavailability by 3.21 folds compared with pure CSE.

Conclusion

The presence of phospholipids in the CSP formulation and the formation of smaller particles may aid in crossing the blood–brain barrier, increasing brain tissue concentration and bioavailability. This, in turn, leads to an increase in memory-boosting activity.

FULL TEXT

Background

Neurodegenerative diseases are chronic, debilitating conditions marked by significant cognitive impairments, gradual death of neurons, and secondary abnormalities in the white matter tract [1]. Alzheimer's disease (AD) is a progressive, neurodegenerative brain disease that affects memory and other cognitive abilities over time. It causes dementia, behavioral changes, memory and thinking skill impairments, personality disorders, and diffuse anatomical abnormalities in the brain [2]. AD is characterized by the deposition of β1 amyloid peptide plaque deposition, cholinergic cell loss, especially in the basal forebrain, and neurofibrillary tangles [3]. Acetylcholine (Ach), a neurotransmitter, is lost along with cholinergic cells. Dementia appears to be caused mainly by a decline in Ach in the brains of AD patients [4]. In 50 to 70% of cases, Alzheimer's dementia affects persons in their middle to late years. As people become older, the prevalence of AD doubles every five years after the age of 65.

Currently, individuals diagnosed with AD and other forms of dementia, such as transient ischemic episodes, stroke, organic brain disorders, mental retardation, and multi-infarct dementia, have limited pharmaceutical treatment alternatives at their disposal. The current therapies are essentially symptomatic; there has not been a noteworthy therapeutic breakthrough that prevents, modifies, or controls dementia and AD [5]. The most popular AChE inhibitors used to treat cholinergic deficiency in the brain are donepezil, rivastigmine, and galantamine; however, they have limitations such as a short duration of action, a low bioavailability, and a restricted therapeutic index [6]. Additionally, due to additional negative effects and non-specificity in the site of action, several synthetic drugs promoted as cognitive enhancers, including piracetam, amphetamine, pemoline, pyritinol, and others, are not safe for long-term use in humans. Their usage is also constrained by significant side effects such as hepatotoxicity [7]. Only one or two of every 10,000 of these chemical and synthetic compounds are clinically successful and safe enough for regulatory approval in the clinical process, despite the drawn-out development process. In reality, clinical trials for approximately half of all drug candidates fail. So considering these major drawbacks of synthetic molecules, many pharmaceutical firms are currently focusing on the development of plant-derived drug delivery systems [8]. Over the past decade, herbal and ayurvedic drugs from the plant kingdom have become a subject of world importance in neurodegenerative disorders with both medicinal and economic implications. Regular and widespread use of herbs throughout the world has increased serious concerns over their quality, safety, and efficacy. Thus, proper scientific evidence or assessment has become the criteria for the acceptance of herbal health claims [9]. However, the scientific literature supporting the efficacy of herbal therapies is incomplete. Few well-controlled studies support the efficacy of herbal remedies in the treatment and clinical improvement of patients with neurodegenerative disorders like dementia, AD, and Parkinson's disease. Available scientific evidence has not yet confirmed the validity of their popular role in the treatment of these diseases [10]. The use of herbal medicine becoming popular due to the toxicity and side effects of allopathic medicines. Medicinal plants play an important role in the development of potent therapeutic agents.

The herbs acting on the brain are called Nootropic herbs and their isolated constituents are referred to as smart drugs. These herbs enhance memory as well as increase blood circulation in the brain. Different plants have been used as memory enhancers in folkloric medicine [11]. Therefore, it is necessary to prepare herbal formulations by using some reputed herbal sources as a memory enhancer. However, water-soluble phytoconstituents (like flavonoids, tannins, glycoside &aglycones, etc.) are poorly absorbed either due to their large molecular size which cannot absorb by passive diffusion or due to their poor lipid solubility; severely limiting their ability to pass across the lipid-rich biological membranes, resulting poor bioavailability [12]. Lipid solubility and molecular size represent the primary limiting factors for drug molecules to traverse biological membranes and achieve systemic absorption following oral or topical administration. The particle size reduction is achieved by using two novel techniques phytosomes and nanonization to easily pass through the blood–brain barrier for maintaining their concentration at the site of action [13, 14]. Standardized plant extracts or mainly polar phytoconstituents like flavonoids, terpenoids, tannins, and xanthones when complexed with phospholipids like phosphatidylcholine give rise to a new drug delivery technology called phytosome (or herbosome) showing much better absorption profile following oral administration owing to improved lipid solubility which enables them to cross the biological membrane, resulting enhanced

bioavailability at lesser dose [15, 16].

The *Theaceae* family includes the *C. sinensis* plant, generally referred to as the tea plant. It is a prominent medicinal herb in many indigenous medical systems, including Ayurveda, Unani, and homeopathy, and is utilized extensively by tribal people in China and India. Polyphenols, including (but are not limited to) catechin, gallocatechin, epicatechin, epigallocatechin, epicatechin gallate, and epigallocatechin gallate (EGCG), are found in *C. sinensis*, with EGCG having the highest concentration and being the most active phytoconstituents. It contains alkaloids (caffeine, theobromine, and theophylline), polysaccharides, vitamins, volatile oils, and minerals [17]. It has many biological activities, including stimulant, diuretic, astringent, antioxidant, anticancer, anti-inflammatory, anti-obesity, antistress, hepatoprotective, cardioprotective, antiviral, antidiabetic, neuroprotective, gastrointestinal tract problem relieving activity, anti-inflammatory, analgesic, antipyretic, antiallergic, and skeleton muscle system reducing activity. These factors contribute to its enormous popularity. Green tea's potent effect on creating or lowering neurotransmitters, including acetylcholine, dopamine, and serotonin, all of which are involved in memory and learning, contributes to its ability to improve these processes [18, 19]. Polyphenols may also aid in the prevention and treatment of dementia [20].

The main objective of the present investigation was to increase the water solubility, bioavailability, and memory-enhancing activity of the standardized hydroalcoholic *C. sinensis* extract by forming a vesicular complex with Leciva S70 phospholipid in the form of phytosomes.

Material and methods

Materials

The standardized hydroalcoholic *C. sinensis* leaf extract was provided by Arjuna Remedies in Kerala. Leciva S70 (Phospholipid) was provided by VAV Life Sciences Pvt. Ltd, Mumbai Sigma-Aldrich supplied Epigallocatechin 3 gallate (EGCG), scopolamine HBr (hydrobromide), and piracetam. The dialysis membrane 60 was provided by Analab Fine Chemicals. Ethanol, methanol, n-octanol, and chloroform were furnished by Sigma-Aldrich Corporation. The rest of the materials were of superb analytical quality.

Methods

Preparation of *C. sinensis* phytosomes

The formulations for the *C. sinensis* leaf extract-loaded phytosomes (CSP) were developed using solvent evaporation techniques. 250-ml round-bottom flasks were filled with various ratios of *C. sinensis* extract (CSE) and Leciva S70 (1:1, 1:2, and 1:3). Then, 50 ml of ethanol was added to this. The reaction was conducted by maintaining the RBF-containing reaction mixture at different temperatures (40, 50, and 60 °C) for a predetermined time (1/2, 3 h), following the CCD. During heating, the reaction mixture was stirred. The solution was then evaporated and stored in a vacuum desiccator for a night to remove any trace of solvent that might have been left over after the initial incubation. The dry mixture was held in an amber bottle for later use [20].

Experimental design and statistics

The effects of independent parameters like drug ratio (% w/w), temperature (^{o}c), and time (Hr), on entrapment efficiency (EE), were analyzed using central composite design (CCD), an optimization tool based on the response surface methodology. Using Design Expert 7.0.0 software, the experimental data were analyzed. Table 1 lists the levels of the considered independent variables and their experimental ranges for EE (% w/w).

Table 1. Experimental central composite design factors at three levels regions

Central composite design (CCD)	Coded factors	Levels		
−1	0	+1	*Independent variables*	

			Phospholipid: drug ratio (% w/w)	X
1	2	3	Temperature (°C)	Y
40	50	60	Time (Hr)	Z
1	2	3	*Dependent variable*: Entrapment efficiency in % (A)	

Entrapment Efficiency (EE)

The efficiency of the developed phytosomes was assessed through a solvent extraction method as described previously. One hundred mg of the formulation was weighed and evenly dispersed throughout 10 ml chloroform. The produced phytosomes and Leciva S70 were dissolved in chloroform making CSE insoluble. The resulting mixture was centrifuged (Remi, Mumbai) at 5000 RPM. The sediment was removed from the transparent supernatant solution. Alcohol (ethanol) was used as the solvent in a UV/VIS spectrophotometer (UV 3000+, LAB INDIA) for non-aggregated CSE which showed a peak at 274 nm. Finally, a calibration curve was used to estimate the Epigallocatechin 3 gallate concentration using the Y = 0.02275x + 0.017429 regression equation.

Particle size

Particle size distribution and mean particle size of the optimized batch of CSP were determined at a constant temperature of 25 °C using Malvern Instrument, Malvern, UK (Model: ZEN 3600). The water was used to distribute the particles evenly. The polydispersity index (PDI) was used to determine the extent to which size distributions varied [21].

Zeta potential determination

The zeta potential was analyzed using the Scientific SZ-100 HORIBA (for Windows [Z Type] Ver2.40) analyzer. The optimum CSP formulation was tested for stability by zeta potential analysis. The average zeta potential, charge, and mobility of optimized CSP were measured after 60 s of study [22].

FTIR spectroscopy

The FTIR spectra of CSE, physical mixture (PM), CSP, and Leciva S70 (phospholipid) were obtained using an FTIR-7600 (Lambda Scientific) spectrophotometer. All samples were dried in a hot air oven at 50 °C for two hours to remove moisture. Each sample (~1 mg) was evenly mixed with potassium bromide (approximately 100 mg), then compressed at a pressure of 10 Ton/nm^2 to form a disk-shaped pellet. The resulting pellet was placed inside the sample container and scanned from 4000 to 500 cm-1 at a resolution of 4 cm-1.

Powder X-ray diffraction (XRD)

The polymorphic states of CSE, Leciva S70, PM, and CSP were investigated utilizing a powder X-ray diffractometer (Model: D8 Advance, Bruker AXS, USA) equipped with a Bragg–Brentano geometry (θ/2) optical setup to record X-ray diffraction patterns. The samples were scanned between 3 and 60 degrees, with a setup angle range of between 0.2 and 2θ and a count time of 0.5 s.

Solubility analysis

The solubility of CSE, PM, and CSP was determined by using the method already described [23]. Briefly, the excessive amount of samples was dissolved in either water or n-octanol (10 ml) in airtight glass containers at room temperature (25 °C). The glass bottles containing the solutions were shaken with an orbital shaker (RIVOTEK) for 24 h and centrifuged for 20 min at 4000 RPM (REMI, India). The clear supernatant was isolated and passed through a membrane filter (0.45μ). 1 ml of this filtrate was then diluted appropriately and analyzed at 274 nm using a UV/ VIS spectrophotometer (UV 3000+, LAB INDIA).

In Vitro *release studies*

The in vitro release of CSE, PM, and CSP was performed using a dialysis membrane (MW cut off>12,000 KDa). Before filling the samples, the dialysis membrane was soaked in distilled water for 1 min. Fifty mg of CSE was dissolved in a buffer solution (4 ml) to form a suspension. Under the same conditions, an equivalent amount of CSP was dispersed into to buffer solution. The dialysis bag was filled with the prepared dispersions and tied from both ends. The dialysis membrane bag containing the sample was suspended in a mixture of phosphate-buffered saline (PBS) (200 ml, pH 7.4) and Tween 20 (1% w/v) in a glass beaker. The buffer solution was stirred under magnetic stirring at 100 RPM maintaining a temperature of 37 ± 0.5 °C. The samples (5 ml) were withdrawn at a predetermined time interval and replenished with an equal volume of freshly prepared buffer to maintain the sink condition. The aliquots were filtered using a 0.45-micron membrane filter before being measured at 274 nm (Telange et al. 2017) using a UV/VIS spectrophotometer (UV 3000+, LAB INDIA). In addition to these studies, we have performed Differential scanning calorimetry (DSC), Scanning electron microscopy (SEM), Proton Nuclear Magnetic Resonance and stability study. The detailed experimental methods of these studies is provided in Additional file 1.

Acute toxicity study

All animal handlings and experiments were approved by the Animal Ethical Committee of Crystal Biological Solution, Pune, with approval number CRY/2122/070. Acute toxicity testing was performed on healthy, non-pregnant, and nulliparous female Wistar rats. Four experimental groups of 12 female rats ($n=3$) were formed. Groups I and II were given CSP formulations at 300 mg/kg bw, while groups III and IV received 2000 mg/kg bw. The dose titration was done with the population from each group's safety in mind. The Wistar rats were starved for three hours before and after the dosage. Throughout the trial, water was available at all times. Individual animals were monitored for the first 30, 60, 120, 180, and 240 min following treatment and once a day for the next 14 days [24].

Dosing and sampling schedule

For the in vivo memory-enhancing activity investigation, 36 Wistar rats of both sexes (male and female) weighing 175–240 gm were employed. The animals were divided into six groups each containing 6 in each groups. As per CPCSEA guidelines, rats were provided with free access to food and water and kept in an animal house with standard laboratory conditions (constant room temperature (25 ± 2 °C), relative humidity (50–70% RH), and a 12-h light/dark cycle). Carboxymethyl cellulose (CMC) 0.5% (10 ml/kg bw) was administered to Group I (Control) for 15 days, (Negative control) Scopolamine HBr (0.4 mg/kg bw) was received to Group II (Negative control) by i.p. route on the 15th day. In Group III (the Positive control group), subjects were given piracetam orally at a regular dose (200 mg/kg body weight) for 15 days. Group IV received an oral dose of *C. sinensis* extract (CSE) (250 mg/kg bw) for 15 days, followed 45 min later by an i.p injection of scopolamine HBr (0.4 mg/kg bw). After 15 days of oral administration of CSP formulation (equal to 250 mg/kg bw of CSE), scopolamine HBr (0.4 mg/kg bw) was injected (i.p.) after 45 min of CSP formulation administration in Group V, 15 days of oral piracetam (200 mg/kg bw) were followed by 45 min of injection (i.p) of scopolamine HBr (0.4 mg/kg bw) in Group VI.

In 0.5% (w/v) CMC solution, CSE, CSP, and piracetam solutions were produced. All animals were treated according to the schedule and exposed to a behavioral analysis study. Simultaneously, the same groups were employed for three different models. Animals were pre-treated with MWMT, EPMT, and PCT on alternating days before the tests. On day 15, 90 min following the administration of the relevant dose, the transfer latency (TL)/ or the escape latency (EL) was determined. Both of these measurements took place. After 24 h had passed since the last session, the retention of all learned tasks was assessed [25].

In vivo *memory-enhancing/boosting activity*

In this study, the term “memory-enhancing/boosting activity” means to elevate the memory and cognitive functions which were determined using various behavioral tests including Morris Water Maze Test, Elevated Plus Maze Test, Pole Climbing Test, and the measured outcomes like escape latency, transfer latency, acetylcholine, serotonine, and dopamine levels. The memory-enhancing efficacy of optimized CSP in contrast to CSE was compared.

Elevated plus maze test

Using an exteroceptive behavioral paradigm, the EPMT was utilized to examine the effects of training on rat memory and learning (where the stimulus was external to the body). The apparatus had two bare arms (each 50 cm × 10 cm) and two covered arms (each 50 cm × 40 cm × 10 cm). Extending the arms from a central platform, the maze was raised to 50 cm from the floor (10 cm × 10 cm). On day one, the rats were placed one by one at the very tip of the open arm, with their backs to the platform in the middle. The rat’s opposite gender was identified in any covered areas to see if the test rat’s retentive memory caused it to go quicker toward that region. The TL was determined by recording the time it took the rat to move inside any of the covered arms containing the opposing gender while using all four of its legs. On the first day, each animal’s TL was noted. Within the first 90 s, the animal was allowed to enter one of the covered arms. If it did not, it was coaxed into gently entering one of the arms. A time limit of 90 s was imposed there. After the rat had explored the maze for ten more seconds, it was put back in its cage. The retention of this learned task was evaluated 24 h after the last dose or on day 16 of treatment. A considerable decrease in the TL value of retention showed memory improvement [26].

Morris water maze test

The MWMT was performed in a circular swimming pool of 100 cm in diameter and 50 cm in height. The circular pool was built with filling and draining facilities and installed on a framework with the water level at waist height. The circular tank’s floor was divided into four equal quadrants. Up to a depth of 30 cm of water was added. One of the pool’s four corners has a plastic platform dug 2 cm below the water’s surface (9 cm in diameter and 28 cm in height). The milk was used to make the pool opaque. The trial platform was consistently situated in the same spot.

The rats were trained to swim without a platform on the first day of the test. Then, after a brief introduction, the animals were released into the tank and given 10 s to explore the exhibit, including sitting on the secret platform. After 90 s, if the rat still had not found the platform, it was placed on it and left there for 10 s. On alternating days, rats were trained for 15 days. The trial was successful when the rat sat on the hidden platform within 90 s. If rats spend more than three minutes looking for the hidden platform, that is a mistake. Throughout the investigation, the experimental setting remained the same. Memory improvement was indicated by a considerable fall in the EL value [27].

Pole climbing test

The cognitive processes of learning and memory retention were studied using Cook’s pole climbing equipment. The apparatus consists of a soundproof experimental chamber (25 × 25 × 25 cm) with a floor grid. The chamber’s floor grid is made of stainless-steel rods. The chamber’s floor grid received a scrambled shock (6 mA). A hole at the room’s center top was used to suspend a pole with a diameter of around 2.5 cm. Wistar rats were placed in the chamber and given 45 s to investigate their surroundings. The buzzer served as the conditioned stimulus (CS), and the 45 s of electrical shock through the grid floor served as the unconditioned stimulus (US). Once the animal connected the sound of the buzzer to the impending foot shock, it could avoid the pain by climbing the pole after the signal was given. A record of the EL quantity was kept. The animals were initially screened using this paradigm, and only those who exhibited an escape response on at least one of the trials were included [26].

Estimation of acetylcholinesterase activity in rat’s brain

On the 16th day, after conducting MWMT, EPMT, and PCT, Five Wistar rats from each group were anesthetized by giving an intramuscular injection (Ketamine Hydrochloride IP) and decapitated. Instantaneously after removal, the brains were washed in icy saline and frozen at -80^{0}C for later use. 0.1 M phosphate buffer (pH 8.0) was used to homogenize the tissue after measuring its weight (0.1 gm of tissue per ml of phosphate buffer). Two and a half milliliters of buffer and one hundred microliters of DTNB 5,5-dithio bis (2-nitrobenzoic acid) were placed in a cuvette. Then, 4 ml aliquots of the homogenate were added. The resulting mixture was well mixed, and the absorbance was

measured in a photometric calorimeter at 412 nm. After recording the basal measurement, 20 ml of the substrate (i.e., acetylthiocholine) was added to the solution mentioned above when the absorbance reached a steady value. The change in absorbance was measured every two minutes for 10 min. [27].

Estimation of dopamine concentration in Rat's brain

DA GENLISA™ ELISA kit was used for the quantitative determination of dopamine in Wistar rat brain homogenate solution by sandwich ELISA technique. Fifty µl of prepared rat dopamine (DA) standard solutions of 0.3, 0.6, 1.2, 2.4, 4.8, and 9.6 ng/ml was added to respective standard wells. These standard solutions were used for the construction of the calibration curve. Forty µl of Wistar rat brain homogenate sample solution from groups I to VI was added to respective sample wells. Ten µl of biotinylated DA antibody was added to the respective sample wells. The biotinylated DA antibody was not added to standard wells because the standard solution contains the biotinylated antibody. Fifty µl of streptavidin-HRP conjugate was added to all sample wells. Mixed well. The plate was covered with a sealer and incubated for 60 min at 37 °C. The plate was aspirated, washed four times with diluted wash buffer (1X), and the residual buffer was blotted by firmly tapping the plate upside down on absorbent paper. Wipe out all liquid from the bottom outside of the microtiter wells, as any residue can interfere with the reading step. Fifty µl TMB Substrate A was added followed by 50 µl TMB Substrate B in all the wells. The plate was covered and incubated at 37 °C for 10 min. The wells had turned bluish. Fifty µl of stop solution was added to all wells. The wells were turned from blue to yellow. Absorbance was recorded at 450 nm with a microplate reader within 10–15 min after the addition of the stop solution [28].

Estimation of serotonin concentration in rat's brain

The Rat Serotonin, ST GENLISA™ ELISA kit was used for the quantitative determination of serotonin in Wistar rat brain-homogenated solution by sandwich ELISA technique. Fifty µl of prepared serotonin (ST) standard solutions of 7.5, 15, 30, 60, 120, and 240 ng/ml was added to respective standard wells. These standard solutions were used for the construction of the calibration curve. Forty µl of Wistar rat brain homogenate sample solution from groups I to VI were added to respective sample wells. Ten µl of biotinylated ST antibody was added to the respective sample wells. The biotinylated ST antibody was not added to standard wells because the standard solution contains the biotinylated antibody. Fifty µl of streptavidin-HRP conjugate was added to the respective sample wells and also the standard wells. The streptavidin-HRP conjugate was not added to the blank well. Mixed well. The plate was covered with a sealer and incubated for 60 min at 37 °C. The plate was aspirated and washed four times with diluted wash buffer (1X), and the residual buffer was blotted by firmly tapping the plate upside down on absorbent paper. Wipe out all liquid from the bottom outside of the microtiter wells, as any residue can interfere with the reading step. Fifty µl TMB Substrate A was added, followed by 50 µl TMB Substrate B in all the wells. The plate was covered and incubated at 37 °C for 10 min. The wells had turned bluish. Fifty µl of stop solution was added to all wells. The wells were turned from blue to yellow. Absorbance was recorded at 450 nm with a microplate reader within 10–15 min after the addition of the stop solution [29].

Histopathological study

One animal from each group received an intramuscular dose of Ketamine Hydrochloride IP at the end of the treatment session, rendering it unconscious so that its brain could be dissected. The removed brain was stored in a 10% (v/v) formalin solution. A hematoxylin and eosin reagent was used to stain between 3- and 5-µ-thick sections. The brain slices were studied with an optical microscope, and pictures were taken with the microscope's attached digital camera at a magnification of 400x.

Procedure for estimation of the concentration of CSE and CSP in brain tissue

The concentration of CSE and CSP in brain tissue was determined using a brain-homogenated solution (4 ml) from animal groups IV and V. The homogenized brain solutions were placed into two distinct 5-ml centrifuge tubes and spun for 15 min at 10,000 rpm. CSE and CSP clear supernatants were separated and used for HPLC analysis.

High-Performance liquid chromatography (HPLC)

Epigallocatechin 3 gallate was used as a marker to estimate the CSE and CSP in brain tissue. A bioanalytical HPLC (Model: Waters 2695 alliance) approach was developed for the Epigallocatechin 3 gallate marker. A Zorbax SB C18

5μ (4.6 × 150) mm column was utilized. This experiment was conducted using the chromatographic gradient technique. As a mobile phase, water with 0.1% (v/v) formic acid and acetonitrile (ACN) with 0.08% (v/v) formic acid were observed. Mobile phase filtration was performed using a 0.45-m millipore filter. The mobile phase flow rate was maintained at 1.0 ml/min, and the column temperature was held at 30°c. At 274 nm, a PDA-type detector was utilized [30]. (Regression Equation: *Y* = 44,929.71 X–4900.50 and Retention time: 7.417 Minutes).

Comparative pharmacokinetic study of CSP and CSE in the blood plasma compartment

18 Wistar albino rats (both sexes) weighing between 240 and 370 g were used in the pharmacokinetic study. Wistar albino rats were housed in a standard laboratory setting and provided free access to food and water as per CPCSEA guidelines. For the study, animals were fasted overnight until 2 h after medication and then given food. Animals were divided into three groups containing six in each group. Group I (Control): 0.5% (w/v) CMC solution (10 ml/kg bw), Group II: CSE (250 mg/kg bw and Group III: CSP formulation (equivalent to 250 mg/kg bw of CSE). CSP and CSE were dissolved individually in a 0.5% (w/v) CMC solution and given to the different groups orally. All Wistar rats were anesthetized with Ketamine Hydrochloride IP (intramuscular injection). The retro-orbital vein was punctured to collect blood samples (0.5–0.7 ml) and collected in Eppendorf tubes at intervals of 0, 0.5, 1, 2, 3, 4, 6, 8, 12, and 24 h. Plasma was separated using centrifugation (Remi, Mumbai, India) at 10,000 rpm for 10 min, and the sample was then frozen at -40°c for further drug analysis [31].

Preparation of plasma samples for HPLC analysis

One ml of purified plasma and 2 ml of methanol were placed in the centrifuge tube. After 30 s of vigorous agitation, centrifugation at 10,000 rpm for 10 min, and collection of the clear supernatant, the tube was discarded. The protein-free solution was stored in a tube at -40°c in the freezer until HPLC analysis was done.

Estimation of pharmacokinetic parameters

A protein-free clear supernatant (20 μl) was put into the chromatographic system that had been designed. The calculated concentration at each time was based on the obtained peak area. Then, directly from plasma concentration–time data estimated by one extravascular compartment model using PK Solver, the pharmacokinetic parameters (maximum plasma concentration) C max, (area under the concentration–time curve) AUC, (corresponding time) t max, (half-life, clearance) CL/F, and (volume of distribution) V/F were calculated.

Results

Preparation of CSP and statistical analysis of EE

Table 2 summarizes all the formulation batches as per CCD with independent and dependent variables. Table 3 summarizes the model statistics suggesting a quadratic model.

Table 2. Three independent factors central composite design matrix and corresponding entrapment efficiencies from the experiment

Cor total	1931.992	19				

The model *F* value was found to be 48.66, making it statistically significant. A model *F* value this large could only have occurred by chance 0.01% of the time. There is only a 0.01% chance that a model *F* value this large is due to noise. The likelihood of error value (prob>F) was then used to evaluate the significance of each model term. If " prob >*F*" is less than 0.0500, then the model terms are significant; if it is more than 0.1000, they are not significant. Based on the F values, all three independent factors substantially impacted the EE of the developed phytosomes. When

controlling for factors like temperature and time, the phospholipid-to-drug ratio (%w/w) was the most crucial factor in EE (%). It has also been found that the phospholipid: drug ratio and temperature positively affected EE (%). The lack-of-fit test indicated that independent variables have a considerable effect on the response if their value is insignificant. Nonsignificant lack of fit, however, is good. The lack-of-fit F score of 1.72 indicates that the lack of fit is not statistically significant compared to the total error. R^2 value, which measures how well a model fits data, was calculated to be 0.9777, indicating that the model has a good fit. The corrected R^2 value of 0.9576 agrees reasonably well with the expected value of 0.8812 for the same variable. The signal-to-noise ratio is the standard by which accuracy is judged. It is preferable if the ratio is higher than 4. In this scenario, the signal-to-noise ratio of 25.039 was satisfactory [32]. They also prove the model's utility for steering one's way through the design process. 3D response surface plots are shown in Fig. 1 and indicate a strong influence of the studied factors X, Y, and Z on the EE. Increasing levels of X, Y, and Z were found to be favorable conditions for obtaining higher EE.

Fig. 1 [Images not available. See PDF.]

Three-dimensional surface response plot showing the interactive effect of **a** Phospholipid: Drug ratio and Temperature, **b** Phospholipid: Drug and Time, and **c** Temperature and Time on EE

Validation of the Model

An additional batch of the CSP formulation was formulated and tested for model validation. The EE of the optimized batch was found to be 94.75 ± 1.06%, which is very near to the model predicted value, confirming the validity and applicability of the suggested model. The percentage bias was estimated using the following equation and was found to be 1.82, less than 3%, confirming the model's relative robustness [33]**.**Bias%=Predicted value-Observed value/Predicted value×100.

Particle size

The particle size of the optimized formulation was determined to be 212.3 nm ± 0.39 and is exhibited in Fig. 2a. The polydispersity index (PDI) for the optimized formulation was found to be 0.238 ± 0.0197.

Fig. 2 [Images not available. See PDF.]

a Particle size distribution and **b** Zeta potential of optimized CSP

Zeta potential

The zeta potential is another critical parameter used to evaluate the stability of the formulation and is shown in Fig. 2b. The optimized formulation obtained after preparation was measured to have a zeta potential of −42.02 ± 0.995 mV.

Fourier transform infrared spectroscopy (FTIR)

The FTIR spectra of CSE, Leciva S70, Physical mixture (PM) of CSE and Leciva S70, and CSP are shown in Fig. 3 (from a to d). In CSE spectra, (a) peak appeared at 3417.96 cm^{-1}, representing OH stretching vibration for intermolecular hydrogen bonding substituted on a cyclic ringed structure left to the peak at 2925.48 cm^{-1} due to C-H stretching in Alkanes. The presence of a peak due to C-O stretching at 1238.08 cm^{-1} because of conjugation of the oxygen with the ring, along with the presence of a peak at 1342.21 cm^{-1} due to O–H in planer bending absorption, confirmed the phenolic structure. The presence of a peak at 1629.55 cm^{-1} and 1452.14 cm^{-1} due to aromatic C = C stretching and 1693.19 cm^{-1} due to C = O stretching confirmed the presence of the carbonyl is in conjugation with the aryl group. Generally, the C = O group from ketone appears in the range of 1720–1708 cm^{-1} for simple aliphatic ketone. Still, this band shifted to a lower frequency (1700-1680 cm^{-1}) when the C = O group was in conjugation with the phenyl or aryl group. C–N stretching absorption occurred at 1093.44 cm^{-1} in CSE.

Fig. 3 [Images not available. See PDF.]

FTIR spectra of **a** CSE, **b** Leciva S70, **c** PM, and **d** CSP

FTIR spectra of pure Leciva S70 (b) revealed a peak at 3415.32 due to OH stretch. The peak appeared at 2925.48 cm^{-1} and 2856.06 cm^{-1} (C-H stretching present in the long fatty acid chain), 1743.33 cm^{-1} (C = O stretch in

the fatty acids), 1236.15 cm^{-1} (P=O stretch), 1093.44 cm^{-1} (P–O–C stretch) and 970.02 cm^{-1} ($-N^{+}(CH_2)_3$ stretch). PM FTIR spectra (c) showed peaks that were characteristics of CSE and Leciva S70 phospholipid at 3415.32, 3010.34, 2929.34, 2856.06, 1737.55, 1631.48, 1463.71, 1230.36, 1087.66, and 968.09 cm^{-1}.

The FTIR spectra of CSP formulation (d) exhibited a broad peak at 3403.03 cm^{-1} (intermolecular hydrogen bonded O–H stretch), 2925.48 cm^{-1} (intense peak related to CSE due to C-H stretch), 1743.33(C=O stretch), 1625.70 and 1461.78 (due to C=C stretching in the aromatic ring), 1193.72 (P=O stretching), 1093.44 cm^{-1} (P-O-C stretch) and 973.88 cm^{-1} ($-N^{+}(CH_2)_3$ stretch).

Powder X-ray diffraction

Figure 4 shows CSE, Leciva S70, PM, and CSP x-ray diffraction patterns. CSE was found to be crystalline because its diffraction pattern showed several strong, sharp peaks, and one relatively broad peak. The presence of several sharp peaks and one relatively broad peak in the diffraction pattern is indicative of a crystalline material, as described by Andersan et al. [34]. Peaks for crystallinity in CSE were observed at 2θ values of 9.5, 12.45, 14.29, 24.14, 30.79, 34.20, 35.98, and 38.83°. Leciva S70 phospholipid exhibited two small and relatively broad peaks at 2θ values of 5.6, 7.5, and 20.27°, respectively. The physical mixture (PM) diffractogram presented few crystalline peaks with lower intensity than CSE and two peaks associated with Leciva S70 at 2θ values of 7.6, 9.47, 12.48, 19.93, 30.76, and 34.23^{0}. Possible causes for the diminished crystalline peak strength include the in situ production of partial aggregates between CSE and Leciva S70, a decrease in the amount of CSE in the sample, and interference from the Leciva S70 molecule.

Fig. 4 [Images not available. See PDF.]

XRD overlay spectra of CSE, PM, Leciva S70, and CSP

Solubility analysis

The solubility tests were performed on CSE, PM, and CSP using water and octanol. The lipophilic character of CSE was demonstrated by its lower aqueous solubility (13.07±0.19 μg/ml) and comparatively higher n-octanol solubility (383±2.00 μg/ml). Compared to the CSE, the physical mixture (PM) had 1.74 times higher aqueous solubility but no significant difference in n-octanol solubility. On the other hand, CSP had a much higher aqueous solubility (7.34 times) than CSE ($p<0.05$).

In vitro *release study*

Results of in vitro release of CSE, PM, and CSP are shown in Fig. 5. The release profiles of CSE and PM were found to be identical and nonsignificant throughout the study period. The release profile of CSE after 12 h was found to be 26.42±0.4654%, and for PM, it was 32.15±0.4596%. CSP followed a similar release pattern as CSE and PM during the initial 20 min. However, CSE's release from CSP significantly increased and reached 72.16±0.5248% after 12 h. In addition to these results few study results are provided in additional file 1. Differential scanning calorimetry (DSC) result is presented in Fig. S1. Scanning electron microscopy (SEM) results is shown in Fig. S2 and Proton Nuclear Magnetic Resonance data presented in Fig. S3. Also, the stability study result of the CSP formulation is shown in Table S1.

Fig. 5 [Images not available. See PDF.]

In vitro drug release of CSE, PM, and CSP (The data are shown as the Mean±Standard Deviation=3)

Acute toxicity study

Female rats administered 300, and 2000 mg/kg bw of a CSP formulation showed no signs of death. Furthermore, all the animals did not show any clinical signs of toxicity immediately after dosing and appeared normal for up to 4 h.

In vivo *memory-enhancing activity*

EL/TL on the first day (i.e., the 15th day of drug treatment) reflected the acquisition of learning behavior, and the second day (i.e., the 16th day) reflected the retention of knowledge or memory in the animals. Evidence of memory enhancement was seen in a statistically significant ($p<0.05$) drop in EL and TL values. The findings of an in vivo investigation on memory enhancement can be seen in Fig. 6(a–c).

Fig. 6 [Images not available. See PDF.]

Effect of CSE and CSP on spatial learning and memory in the a) EPMT, b) MWMT, and c) PCT. Data are expressed as Mean ± SEM values ($n = 6$ in each group). **a** = compared to a vehicle-treated normal control group; **b** = compared to the scopolamine HBr-treated group; **c** = compared with the piracetam-treated group; and **d** = compared with CSE + scopolamine HBr-treated group. (*$p < 0.05$, **$p < 0.01$, ***$p < 0.001$, ****$p < 0.0001$) (one-way ANOVA followed by Tukey's multiple comparisons test)

Elevated Plus Maze Test

TL parameter (in seconds) was measured in EPMT. The reduction in TL was considered to be a memory improvement. The results of EPMT are shown in Fig. 6a. The animal group administered with scopolamine HBr showed a significant increase in TL ($p < 0.05$) on the 15th and ($p < 0.001$) on the 16th day compared with the vehicle-treated control group. The piracetam, CSP + scopolamine HBr, and piracetam + scopolamine HBr-treated group revealed a significant reduction in TL ($p < 0.001$, $p < 0.0001$, and $p < 0.01$) on the 15th day and ($p < 0.001$, $p < 0.0001$ and $p < 0.001$) on 16th day respectively when compared to vehicle-treated group. A significant reduction in TL ($p < 0.0001$) on both days was found in piracetam, CSE + scopolamine HBr, CSP + scopolamine HBr, and piracetam + scopolamine HBr-treated groups when compared to scopolamine HBr-treated group. When CSE + scopolamine HBr was compared to the piracetam-treated group, an increase in TL ($p < 0.05$) was noticed. CSP + scopolamine HBr-treated group showed a significant decrease in TL ($p < 0.01$) on the 15th day and ($p < 0.001$) on the 16th day compared to the CSE + scopolamine HBr-administered group. Overall, there was a significant decrease in TL of CSP formulation administered in animals compared to all groups.

Morris water maze test

The results of MWMT are shown in Fig. 6b. On day 16, EL was higher in the scopolamine HBr group ($p < 0.05$) compared to the control group. On days 15 and 16, EL was considerably ($p < 0.0001$) lower in the piracetam and CSP + scopolamine HBr-treated animal group compared to the control and scopolamine HBr-administered animal group. The CSE + scopolamine HBr-administered group exhibited a decrease in EL ($p < 0.01$) on the 15th and ($p < 0.001$) on the 16th day as compared to the scopolamine HBr-treated group. When the CSE + scopolamine HBr group was compared with the piracetam-treated group, it was observed that EL ($p < 0.01$) significantly increased on both days, i.e., the 15th and 16th day. When the EL of the CSP + scopolamine HBr group was compared to that of the CSE + scopolamine HBr group, a statistically significant drop was found on day 15 ($p < 0.01$) and day 16 ($p < 0.001$). The group given piracetam + scopolamine HBr had a significantly lower EL when compared to the control, scopolamine HBr, and CSE + scopolamine HBr-treated groups ($p < 0.0001$, $p < 0.0001$, and $p < 0.05$) on the 15th day and ($p < 0.001$, $p < 0.0001$, and $p < 0.05$) on the 16th day, respectively. However, the CSP + scopolamine HBr-treated group reduced EL significantly compared with CSE + scopolamine HBr, piracetam, and piracetam + scopolamine HBr-administered groups [26].

Pole climbing test

In the Pole Climbing Test, EL is the amount of time it takes the animal to ascend to avoid a foot shock following the sound of a buzzer. The reduction in EL (in seconds) was considered a memory improvement. The results of PCT are shown in Fig. 6c and found that the scopolamine HBr-administered group increased EL on the 15th ($p < 0.05$) and ($p < 0.001$) on the 16th day when compared with a control-treated group. Compared to scopolamine HBr-treated rats, piracetam and CSP + scopolamine HBr showed a statistically significant reduction in EL ($p < 0.0001$) on both days. Both CSE + scopolamine HBr and piracetam + scopolamine HBr resulted in lower EL levels 15 days after administration ($p < 0.01$, $p < 0.001$) and 16 days after administration ($p < 0.001$, $p < 0.0001$). It was noticed that the CSP formulation-treated group revealed a significant reduction in EL as compared to pure extract. In the case of all treated groups except scopolamine HBr, no significant increase or decrease in EL was observed compared to the control group on both days [26].

Acetylcholine esterase activity

CSE and CSP were tested for their influence on brain Ach esterase activity in scopolamine HBr-induced Wistar rats.

The results are depicted in Fig. 7. For this study, we evaluated Ach esterase activity using one-way ANOVA, then Tukey's multiple comparison test. Compared to the control group that received the vehicle, the scopolamine HBr group showed a statistically significant (p<0.01) increase in Ach esterase activity. This leads to a decrease in Ach transmitter level due to the breakdown of Ach by activated Ach esterase enzyme. A significant (p<0.001) reduction in Ach esterase activity was seen in the CSP + scopolamine HBr-treated group compared to the control group. Compared to the vehicle-treated control group, Ach esterase activity was not significantly different in any treatment groups besides those receiving scopolamine HBr and CSP + scopolamine HBr. Treatment with piracetam, CSP + scopolamine HBr, piracetam + scopolamine HBr, or CSE + scopolamine HBr significantly reduced Ach esterase activity (p<0.0001, p<0.0001, p<0.0001, p<0.001) and increased Ach level at the cholinergic synapse compared to scopolamine HBr administration. Animals who were given CSP + scopolamine HBr showed a more significant reduction in acetylcholine esterase activity (p<0.01) than those given CSE + scopolamine HBr group.

Effect of CSE and CSP on brain Ach esterase activity in scopolamine-induced Wistar rats. Data are shown as the Mean ± SEM values (n = 5 in each group). **a** = compared to the vehicle-treated normal control group, **b** = compared to the scopolamine HBr-treated group and **c** = compared to the CSE + scopolamine HBr-treated group (*p <0.05, **p <0.01, ***p <0.001, ****p <0.0001) (one-way ANOVA followed by Tukey's multiple comparisons test)

Estimation of dopamine concentration in Rat's Brain

The brain dopamine estimation was carried out by sandwich ELISA, and one-way ANOVA followed by Tukey's multiple comparison tests was used for the evaluation of dopamine level. The brain dopamine concentration level is shown in Fig. 8. The brain dopamine concentration was significantly increased in the piracetam and CSP-scopolamine HBr-treated groups (p<0.01) when compared to the control. Piracetam and CSE-scopolamine HBr, CSP-scopolamine HBr, and piracetam-scopolamine HBr-treated groups showed significantly increased in dopamine level (p<0.0001, p<0.05, p<0.0001, p<0.05) compared to scopolamine HBr-treated group. When the CSP-scopolamine HBr-treated group was compared with the CSE-scopolamine HBr-treated group, we found a significantly increased dopamine level (p<0.05). The brain dopamine concentration was found to be 18.07 ± 1.790 and 11.60 ± 1.718 ng/ml in the CSP and pure extract-treated groups, respectively.

Data are expressed as Mean ± SEM values (n = 5 in each group). **a** = compared to a vehicle-treated normal control group; **b** = compared to the scopolamine HBr-treated group; **c** = compared with CSE + scopolamine HBr-treated group. (*p <0.05, **p <0.01, ***p <0.001, ****p <0.0001) (one-way ANOVA followed by Tukey's multiple comparisons test)

Estimation of serotonin concentration in rat's brain

The brain serotonin level was determined by sandwich ELISA techniques. The result is exhibited in Fig. 9. A one-way ANOVA followed by Tukey's multiple comparison tests was used for the evaluation of serotonin levels. There was a significantly increased level of serotonin in piracetam, CSE-scopolamine HBr, CSP-scopolamine HBr, and piracetam-scopolamine HBr (p<0.0001, p<0.01, p<0.0001, p<0.01) compared to the control group. Brain serotonin levels were significantly increased (p<0.0001) in all groups when compared to the scopolamine HBr-treated group. There has been a significantly increased level of serotonin (p<0.0001) in the CSP formulation-treated group when compared to the CSE-scopolamine HBr-treated group. The brain serotonin concentration was found to be 47.92 ± 1.690 and 36.99 ± 1.742 ng/ml in the CSP formulation and pure extract-treated groups respectively.
Fig. 9 [Images not available. See PDF.]

Brain serotonin concentration level. <0.0001) (one-way ANOVA followed by Tukey's multiple comparisons test)

Histopathological study

The results of the histopathological examination of the brain are shown in Fig. 10. The normal control group did not exhibit any toxicity in terms of neuronal and vascular degeneration or glial cell infiltration (Fig. 10a). Moderate vascular deterioration, cerebral neuronal degeneration, necrosis, and glial cell infiltration were all observed in the brain of the disease-control animal (Fig. 10b). However, other animals belonging to different treatment groups showed mild pathological changes when compared with disease control. A mild type of glial cell infiltration and neuronal and vascular degeneration was observed in the piracetam (Fig. 10c) and CSE (Fig. 10d) administered group. The brains of CSP-treated animals showed only mild neuronal and vascular degeneration and glial cell infiltration as compared to CSE-treated group (Fig. 10e).

Estimation of the concentration of CSE and CSP in brain tissue

CSE and CSP concentrations were measured in given animals over 15 days and were found to be 1.143 ± 0.045 µg/ml and 2.683 ± 0.21 µg/ml, respectively.

Comparative pharmacokinetic study of CSE and CSP in the blood plasma compartment

Table 5 displays the pharmacokinetic parameters that were determined using the PK Solver software. The results of the research showed that C_{max}, T_{max}, and $AUC_{0-\infty}$ were significantly higher (*p<0.05*) in animals given CSP as compared to those given CSE. Additionally, a longer absorption half-life was found for CSP. The fact that the CL/F and V/F were significantly (*p<0.05*) lower in the CSP-administered group mice compared to the CSE-treated animals provided additional support for CSP's longer residency and duration of effect.

Table 5. Results of comparative bioavailability study after oral administration of CSE and CSP formulation

Pharmacokinetic parameters	Treatment	
CSE (250 mg/kg)	CSP (~ 250 mg/kg of CSE)	C_{max} (µg/ml)
0.404 ± 0.116	0.828 ± 0.134	T_{max} (hours)
1.71 ± 0.013	3.72 ± 0.018	AUC 0-t (µg/ml*h)
2.492 ± 0.164	8.666 ± 0.186	AUC 0-inf (µg/ml*h)
2.762 ± 0.119	8.864 ± 0.131	t1/2 ka (hours)
0.549 ± 0.123	1.867 ± 0.224	V/F (mg/kg)/(µg/ml)
867.41 ± 0.019	300.74 ± 0.039	CL/F (mg/kg)/(µg/ml)/h

Discussion

C. sinensis phytosomes were formulated by a solvent evaporation method using Leciva S70 as a phospholipid at varying phospholipid: drug ratio, temperature, and time. The effects of these independent variables were determined on the EE of *C. sinensis* extract. In the optimization study, the optimal criterion was the achievement of maximum

EE at specific concentrations of the three independent variables. The optimum response of EE was reported to be 96.51% at phospholipid: drug concentration of 3% w/w, at a temperature of 60 °C, and time of 3 h using the desirability function, with good desirability of 1. The particle size of the phytosomes is quite an important parameter that needs to be considered during the development of formulations. Particle size significantly influences the distribution of the formulation within tissues and organs. It has been noted that the average particle size for drug distribution to the brain and other organs ranges from approximately 100 to about 1000 nm, with the precise value contingent upon the dosage form and administration method. A PDI value of up to 0.3 is considered to be acceptable. It suggests a homogeneous population of phospholipid vesicles, which is desirable in lipid-based drug delivery applications like liposome and nanoliposome formulation [35]. Values of zeta potential greater than -30 mv are considered as satisfactory and indicative of solid physical stability. Phospholipid type and structure determine the zeta potential value. This indicated that the developed CSP formulation had good physical strength due to its nanometer particle size, low PDI, and moderate zeta potential value [36].

When FTIR spectra of CSP were compared with CSE and Leciva S70 phospholipid spectra, it was observed that the OH stretching frequency of CSE at 3417.96 cm^{-1} changed to 3403.03 cm^{-1} in the CSP formulation indicated the presence of weak intermolecular interactions. The CSE peaks at 1033.66, 1147.44, 1238.08, and 1342.21 cm^{-1} were found to be disappeared and appeared to be new broad doublet strong peak at 1093.44 (similar to the peak of Leciva S70 but more intense as compared to Leciva S70) and 1193.72 cm^{-1}. The absorption frequency and intensity of peak at 1629.55 cm^{-1} in CSE appeared too shortened along with a slight change in absorption frequency in CSP formulation and found at 1625.70 cm^{-1}. In CSE and Leciva S70 FTIR spectra, a tiny peak was observed at 1093.44 cm^{-1}, which appeared strong and intense in the CSP formulation and indicated the presence of interaction. The changes in absorption frequencies of peaks in CSP formulation compared to CSE and Leciva S70 revealed the presence of weak intermolecular interaction between CSE and Leciva S70 phospholipid may be the reason for the formation of CSP [37, 38]. X-ray diffraction study was used to identify the crystal structure of various solid compounds. It is used to determine the degree of crystallinity. Amorphous material scatters at all wavelengths and gives a scattered pattern (continuous background); however, the crystalline material includes a crystal structure and produces definite diffraction lines or spots. The diffraction pattern of CSP revealed only one broad peak at 2θ values from 18.83 to 27.14°, and maximum peat height was obtained at 22.97°. Most of the prominent crystalline peaks often seen in diffraction patterns of CSE were not present in those of CSP. As a result of CSE phospholipid complex formation, most of the crystalline peaks of CSE disappeared. Based on its diffraction pattern, CSP indicated that CSE in the Leciva S70 matrix might exist in either a molecularly distributed or amorphous form [39].

The optimized formulation followed a zero-order drug release kinetic model with a significance value of $P<0.05$. The higher wettability and solubility of CSE in the prepared CSP formulation may account for the considerable difference in CSP release rate from CSE and PM. In the CSP formulation, CSE was changed from a crystalline to an amorphous state, which extended both the rate and the extent of release over 12 h. The enhanced solubility of CSP was due to the amphiphilic nature of LECIVA S 70. The increased wettability and enhanced dispersion of CSP due to changes in the structural morphology of crystalline CSE into partial amorphization imparted due to the amphiphilic nature of LECIVA S 70 phospholipid [40]. There was no significant change in the CSP formulation during 6 months. However, a slight drop in EE and an increase in vitro release were detected throughout the storage period. This could be due to the release of drugs from the lipid matrix [20]. The temperature influences the lipid matrix over time, resulting in slender drug release from the interior and a modest increase in drug release. As the length of the storage period increased, slight increases in particle size and a slight decrease in zeta potential were observed. This could be attributed to the effect of temperature, which causes disturbances in the formed electrically double diffuse layer of formulation, but it could also be attributed to something else. Animals showed no clinical signs of intoxication at daily observations up to 14 days at a studied dose. Therefore, under the OECD 423 Guidelines and the specified laboratory circumstances, the LD50 value for CSP was determined to be >2000—5000 mg/kg body weight, placing it in GHS Category 5 and making it safe for use. CSP exhibited higher efficiency compared with CSE in MWMT, EPMT, and PCT. Administration of CSE, CSP, and piracetam for 15 consecutive days protected memory from

memory impairment to different extents induced by scopolamine HBr. Hence, there was no observed increase in EL/TL even after the administration of scopolamine HBr on the 16th day. Thus, there was no significant practical effect on memory retention on the 16th day. Piracetam was used as a Positive control and showed significant improvements in memory in terms of EL/TL, as expected. Smaller particle size and the interaction between phospholipid and CSE, which improves the overall hydrophilicity and solubility of CSE, may account for the relative absorption of CSP after oral administration. From this, we can infer that the EL/TL in MWT, EPMT, and PCT were significantly lower in the CSP formulation-administered group compared to the CSE-administered group. Administration of CSP dose equivalent to pure extract (CSE) significantly increased the Ach level and inhibited Ach esterase activity. Acetylcholine is essential in controlling cognitive function in experimental and clinical settings. So CSP was more effective in increasing the level of Ach than CSE by decreasing the AchE activity [41, 42]. Dopaminergic neurons projecting from the substantia nigra to the striatum play a critical role in motor functions, while dopaminergic neurons originating in the ventral tegmental area (VTA) and projecting to the nucleus accumbens, hippocampus, and other cortical structures regulate rewarding learning [43]. Dopamine is the principal neurotransmitter involved in both the central nervous system (CNS) and peripheral nervous systems and plays a critical role in learning and memory. This release of dopamine helps us learn to associate the rewarding stimulus with the behavior that led to it [44]. Dopamine also plays a role in the consolidation of memories. This is the process by which memories are stored in the long term. When we learn something new, dopamine helps to strengthen the connections between the neurons that represent that information. This makes it more likely that we will be able to remember the information in the future. Dopamine levels are also important for working memory. This is a type of short-term memory that allows us to hold information in mind while we are working on a task. Dopamine helps keep information in working memory by increasing the activity of neurons in the prefrontal cortex. This allows us to focus on the task at hand and avoid distractions [45]. The prepared phytosome formulation (CSP) protects memory from scopolamine-induced memory impairment and enhances cognitive function by increasing dopamine concentration. A decline in DA concentration or inhibition of its synthesis or metabolism rates in the CNS can result in impairment of critical neurologic functions, such as cognition, behavior, and fine movements. The neurodegenerative disease often affects mental performance, particularly memory processes, and pathological changes have been reported to occur in the cholinergic, glutamatergic, serotonergic, and noradrenergic transmitter systems [45]. From these findings, it appears that several neurotransmitters are in some way involved in the formation and retrieval of memory traces. Measurement of cognitive performance in rats incorporates modulatory functions such as sensory, attentional, motivational, emotional, and motor processes. Serotonergic activity has been linked to emotional processes and may play a particular role in emotional-related work. Serotonin, one of the most important neurotransmitters in the central nervous system, is synthesized by the amino acid tryptophan and is important in learning and memory. Indeed, 5-HT pathways, 5-HT reuptake site/transporter (SERT), and 5-HT receptors are present in brain areas implicated in learning and memory [46]. Serotonergic projections originate in the ascending raphe nuclei localized in the brain stem, where 5-HT synthesis, storage, and reuptake occur, and extend to almost all forebrain areas involved in learning and memory [47]. 5-HT exerts an influence via cholinergic and glutamatergic pathways over the transfer of information. Decreased brain serotonin levels impaired memory [48]. So, in this study, we found a significantly increased serotonin level in the CSP formulation-treated group as compared to the pure extract, which exhibited an increase in memory and learning. Acute and chronic central nervous system illnesses share the characteristics of neuroinflammation. Neuroinflammation is caused by glial cells like astrocytes and microglia being persistently activated in the brain and releasing inflammatory mediators such as cytokines, matrix metalloproteinases (MMPs), reactive oxygen species (ROS), and nitric oxide [10]. An unpaired t test was used to compare CSE and CSP results, and it was observed that the concentration of CSP was significantly (p<0.05) greater than that of CSE. This demonstrates how CSE was delivered to the brain more effectively when it was a phytosome formulation rather than a pure extract. This could be the result of phospholipid being present in phytosomes, which might have changed GI permeability and prevented an apically directed efflux mechanism. It was found that the bioavailability of the CSP formulation was 3.21 times higher than that of the CSE formulation.

Molecular aggregates and phospholipids work together to promote intestinal absorption and water solubility, which increases the plasma bioavailability of CSP after a single oral dosage.

Saima Rubab et al. also studied the neuropharmacological potential of various morphological parts of *C. sinensis* and it was observed that both leaves and seeds are active as neuropharmacological agents and can be used as memory-boosting agents. Neuropharmacological evaluation of seed and leaf extracts on mice revealed dose-dependent effects. Seed extract demonstrated significant stimulant activity, while leaf extract induced notable calmness and moderation. Tests including head dip, open field, and rearing showed increased motor function with both extracts, with leaf extract notably calming. Seed extract exhibited greater stimulant effects in cage cross, swimming, and traction tests. Leaf extract showed similar effects but induced more calmness at higher doses. Micro-morphological investigation of Camellia sinensis is suggested for accurate identification. These findings highlight differing effects of plant parts, with seed extract being more stimulating and leaf extract inducing calming effects [49]. Similarly, Saima Rubab et al. performed phytochemical and pharmacological potential of *C. sinensis*. both seed and leaf showed significant analgesic effects. However, compared to seed extract which showed highly significant (p <0.001) increase in concentration dependent manner, leaf extract displayed highly significant results even at low dose with better results at high dose compared with standard [50, 51].

Muhammet Emin Cam et al. performed Morris's Water Maze Test to determine the potential of *C. Sinensis* leaves hydroalcoholic extract in AD. It was observed that the AD group reached the target quadrant later than the control group (p<0.05) in all days and the total time spent in the quadrant decreased. In the MWM test, rats underwent spatial learning evaluation. Throughout training, all groups showed reduced time to locate the underwater platform, indicating learning. However, the Alzheimer's disease (AD) group exhibited prolonged training duration, indicating spatial memory impairment. Metformin treatment notably improved learning abilities, as evidenced by decreased training time compared to the AD group. Overall, the MWM test revealed enhanced spatial learning with metformin treatment, highlighting its potential therapeutic efficacy in cognitive decline associated with AD [52]. Similar observations were also noted in our experiments. The culmination of our investigation aligns with the outcomes observed by other research groups, affirming the potential efficacy of CSP formulation as a cognitive enhancer, surpassing the effects elicited by conventional CSE methodologies. This assertion is substantiated by a collective appraisal of research findings across various groups, suggesting a notable advantage conferred by CSP in enhancing memory functions.

Conclusion

Overall, the findings of this study suggest that the developed CSP formulation holds significant promise as a memory-enhancing agent, outperforming the effects of the conventional CSE. The observed improvements in memory, cognitive function, and bioavailability underscore the potential of nanophytosomes in enhancing the therapeutic properties of natural extracts for neurological applications. Further research and clinical studies are warranted to explore the translational potential of this CSP formulation in the context of cognitive disorders and related conditions.

Acknowledgements

For their assistance with this study, the authors are indebted to the Principal of Bharti Vidyapeeth College of Pharmacy at Kolhapur. In addition, the authors would like to extend their appreciation to Arjuna Remedies, Kerala, who generously sent a sample of their *Camellia sinensis* extract. The authors also want to thank Crystal Biological Solutions for all the help and support they gave them during the project. Finally, ChromeIn, Pune Chromatographic Technology &Services are acknowledged for their assistance with HPLC analysis.

Author contributions

VM was involved in experimental work, writing/drafting manuscript. SK helped in design of experiments. HM and HT contributed to supervision of the project.

ABSTRACT (ENGLISH)

Background

Nutrient stress (NS), one of the hallmarks of the tumour microenvironment, can render cancer cells tolerant to cytotoxicity. Fibroblasts, on the other hand, have cancer cell-like traits, such as plasticity and resiliency. Hence, this study aimed to evaluate the cytotoxicity of the drug on reseeded human U87 glioblastoma (GBM) cells as well as on mouse L929 fibroblasts in the form of monolayer and colonies that grew after NS induction.

Results

No treatment for 48 h showed a statistically significant difference in U87 cell viability when compared to the 50% hypothetical value. However, temozolomide (TMZ) (151.0 µg/ml) and azithromycin (AZI) (92.0 µg/ml) significantly diminished the number of U87 cell colonies compared to the untreated control, and AZI also outperformed doxycycline (DOXY) (147.0 µg/ml). L929 fibroblasts survived NS, but the cytotoxicity of AZI, DOXY, and AZI + DOXY (92.0 + 147.0 µg/ml) substantially increased than in L929 fibroblasts without NS induction.

Conclusions

The present findings suggest that NS does not inevitably contribute to cytotoxic drug tolerance in GBM cells. In addition, although fibroblasts can withstand NS, they can also become susceptible to cytotoxic drug-induced death; nevertheless, the type of drug may play a role.

FULL TEXT

Background

High-grade glioma, notably glioblastoma (GBM), is one of the most challenging cancers to treat, partly due to its high degree of heterogeneity. Despite the discovery of drugs that can interfere with GBM growth, such as temozolomide (TMZ), most patients succumbed to death. The major issues are that not all patients respond to the same effective drugs, and even if they do, patients ultimately develop resistance. Although much work is currently being expended on immune-based therapies [1], alternative effective agents are in constant demand.

Azithromycin (AZI) and doxycycline (DOXY) are intriguing candidates of antibiotics actively being studied for their anticancer attributes. Both drugs have exhibited substantial anti-proliferative and pro-apoptotic effects in different human cancer cells [2–5]. They are also capable of modulating various therapeutic targets associated with cancer

hallmarks, including angiogenesis and pro-survival autophagy [2, 4, 6, 7]. Furthermore, they are effective against drug-tolerant persister cells of a wide range of origins, such as cancer stem-like cells, in part by inhibiting mitochondrial oxidative phosphorylation (OXPHOS) [3, 8–10].

The tumour microenvironment (TME) is composed of a complex network of cells (e.g., malignant/stromal cells) and non-cellular components (e.g., extracellular matrix proteins) that surround and interact with one another, which mutually contribute to tumour growth and development. The metabolism of tumours, including GBM, is malleable to factors in the environment in which they emerge. Metabolism is the chemical process that allows cells to use available nutrient resources to sustain their survival and propagation. The availability and quantity of nutrients, as well as other elements that enable metabolism, such as oxygen, and the presence of other cells (such as fibroblasts, endothelial and immune cells) that compete for or fuel such nutrients, are all intrinsic factors that can influence tumour behaviours [11].

Nutrient scarcity is one of the hallmarks of TME, and the Warburg effect (a glucose-dependent glycolytic aerobic process) is an atypical metabolic phenomenon of cancer cells. As a result, cancer cells not only reprogram their metabolism but also develop various mechanisms to meet their energy demands and sustain survival. For instance, they switch metabolism towards mitochondrial OXPHOS and phenotype to a quiescent state in response to glucose stress [12, 13]. Secondly, cancer cells secrete molecules that promote angiogenesis to improve blood flow and delivery of oxygen and nutrients, as well as attract other cells (e.g., fibroblasts) that can provide additional resources [14, 15]. Indeed, the ability of cancer cells to adapt, survive, and propagate under such an intricate milieu promotes evolution, driving them towards a more aggressive phenotype/behaviour and resulting in drug resistance [11, 13, 16, 17].

Aside from that, tumour behaviours are greatly influenced by activated fibroblasts, one of the most abundant stromal cells in the TME. They are renowned as cancer-associated fibroblasts and are heterogeneous, with distinct functions that include tumour growth, survival, and metabolism, as well as mediating drug resistance [14, 15]. Ironically, fibroblasts have cancer cell-like traits, such as plasticity and resiliency, and they are associated with all stages of tumour progression [15]. Tumours have even been dubbed “wounds that do not heal” [18].

To that end, it is of interest to expound the impact of nutrient stress (NS) on drug cytotoxicity in GBM cells and fibroblasts. Our earlier findings showed that the concentrations of TMZ, AZI, and DOXY that caused 50% of U87 GBM cell monolayer to be affected (IC_{50}) under nutrient-favourable conditions for 48 h were 151.0, 92.0, and 147.0 µg/ml, respectively [19]. This study investigated their effects on U87 cell viability and colonies, as well as L929 fibroblast viability after the induction of NS.

Methods

Drugs and reagents

TMZ (Sigma-Aldrich, St. Louis, MO, USA), AZI (BioVision, Milpitas, CA, USA), DOXY (Sigma-Aldrich, St. Louis, MO, USA), 1 × phosphate buffer saline (PBS) (Gibco, Thermo Fisher Scientific, Waltham, MA, USA), 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) (Invitrogen, Thermo Fisher Scientific, Waltham, MA, USA), 10.0% neutral buffered formalin (NBF) (Sigma-Aldrich, St. Louis, MO, USA), and gram crystal violet reagent (GCC Diagnostics, UK). Note that AZI (Sigma-Aldrich, St. Louis, MO, USA) was used to treat NIH3T3 and human dermal fibroblasts (HDF), but the manufacturer discontinued the drug in the middle of the study.

Culture of GBM cells and fibroblasts

The human U87 GBM cell line (HTB-14) was obtained from the American Type Culture Collection (ATCC) (Rockville, MD, USA) and maintained at 37 °C with 5% CO_2 and 95% humidity in Dulbecco’s Modified Eagle Medium (DMEM) (4.5 g/l glucose with L-glutamine and sodium pyruvate) (Nacalai Tesque, Kyoto, Japan), supplemented with 10% foetal bovine serum (FBS) (Tico Europe, Amstelveen, Netherlands) and 1% non-essential amino acid (Nacalai Tesque, Kyoto, Japan). Mouse connective tissue L929 and embryonic NIH3T3 fibroblasts (ATCC), and HDF (RIKEN Cell Bank, Tsukuba, Ibaraki, Japan) were cultured in the same manner as GBM cells.

NS induction

To induce NS in GBM cells, U87 cells were seeded in T75 flasks at a density of 1.0×10^3 in a final volume of 12 ml

and maintained under standard growth conditions. In brief, the medium was refreshed on days 30 and 33, cells were then subcultured on day 36, and harvested on day 38, followed by seeding. To induce NS in normal cells, L929 fibroblasts were seeded in T75 flasks at a density of 1.0×10^3 in a final volume of 12 ml and maintained under standard growth conditions. In brief, the medium was refreshed on day 48, fibroblasts were then subcultured on day 54, and harvested on day 56, followed by seeding.

The cells were sustained in culture for a period until some adherent (spindle-shaped) cells were observed (Fig. 1), day 30 and day 48 for GBM cells and fibroblasts, respectively. GBM cells were fully repopulated on day 36, while fibroblasts were on day 54. This field is based on the principle that metabolic activities in cancer cells differ from normal cells, with cancer cells exhibiting rapid abnormal growth and higher metabolic demands.

Fig. 1 [Images not available. See PDF.]

Representative of **a** U87 cells and **b** L929 fibroblasts following nutrient stress (NS) induction (10 × magnification, scale bars = 100 µm)

Determination of U87 cell viability

A total of 1.0×10^3 cells in a final volume of 100 µl was seeded in 96-well plates and cultured for 72 h before being treated. After 48 h of cytotoxic drug treatments, the MTT assay was carried out in accordance with the manufacturer's protocol, and the percentage of cell viability was calculated using the following equation:Cellviability %=Meanabsorbanceoftreatedcells-MeanabsorbanceofblankMeanabsorbanceofuntreatedcells-Meanabsorbanceof blank×100

Determination of U87 cell colonies

Cells were seeded in 6-well plates at a density of 1.0×10^3 in a final volume of three ml and maintained under standard growth conditions. On day 21, the medium was refreshed, and cells were further incubated until day 25, after which they were treated for 48 h. On day 27, cells were fixed with two ml of 10.0% NBF for 20 min, rinsed once with two ml of 1 × PBS, and stained in two ml of 0.01% crystal violet for 20 min. In each well, eight regions were randomly captured under a visual field (5 ×) using a phase-contrast inverted microscope (Zeiss, Germany), and the number of colonies with at least 50 cells was counted using ImageJ software (NIH Image, Bethesda MD, USA).

Determination of L929 fibroblast viability

A total of 5.0×10^3 cells in a final volume of 100 µl was seeded in 96-well plates and cultured for 24 h before being treated, followed by an MTT assay. The effects of cytotoxic drugs on the viability of fibroblasts, such as L929, NIH3T3, and HDF without NS induction were also assessed after 48 h of treatment.

Statistical analysis

Data passed the Shapiro–Wilk normality test ($p > 0.05$). One-sample *t*-test with 50% as a standard value of interest or the hypothetical value was performed using the SPSS version 26 software (IBM Corporation, NY, USA). While one-way analysis of variance (ANOVA) with Tukey's post hoc test and two-way ANOVA with Sidak's post hoc test were computed using the GraphPad Prism version 6.01 software (San Diego, CA, USA). All analyses were two-tailed and *p* value less than 0.05 was considered significantly different.

Results

Drug cytotoxicity on U87 cell viability

None of the treatments showed a statistically significant difference in U87 cell viability (Table 1). In other words, the drug cytotoxicity does not substantially differ from the hypothesised value of 50%. Besides, one-way ANOVA revealed no statistically significant difference between TMZ (151.0 µg/ml) (positive control group), AZI (92.0 µg/ml), DOXY (147.0 µg/ml), and AZI + DOXY (92.0 + 147.0 µg/ml) treatments ($F(3, 8) = 0.726$, $p = 0.565$) (Fig. 2). All in all, there is insufficient evidence to reject the null hypothesis in favour of an alternative hypothesis. It could not be statistically corroborated that NS induction renders GBM cells tolerant to cytotoxic drugs under the present test conditions.

Table 1. Effect of nutrient stress (NS) induction on drug cytotoxicity in U87 cells

Treatment	Mean (SD)	*t* statistic (degrees of freedom)	*p* value (2-tailed)*	Mean difference (95% confidence interval)
TMZ	71.26 (11.75)	3.133 (2)	0.089	21.26 (−7.94, 50.46)
AZI	95.39 (28.83)	2.728 (2)	0.112	45.39 (−26.21, 117.00)
DOXY	76.56 (19.28)	2.386 (2)	0.140	26.56 (−21.33, 74.45)
AZI + DOXY	83.03 (21.18)	2.701 (2)	0.114	33.03 (−19.58, 85.64)

*One-sample *t*-test

Fig. 2 [Images not available. See PDF.]

Drug cytotoxicity on reseeded U87 cell monolayer after nutrient stress (NS) induction. Data are the mean (standard deviation, SD) of three technical replicates from three independent experiments ($n=3$)

Drug cytotoxicity on U87 cell colonies

The cytotoxicity of tested drugs was further evaluated on U87 colonies that grew after the NS induction. One-way ANOVA discovered a statistically significant difference between groups ($F(4, 40)=7.455$, $p=0.0001$) (NC (61.89 (7.66), TMZ (47.00 (9.19), AZI (38.44 (7.02), DOXY (57.89 (15.68), and AZI + DOXY (51.33 (8.59)). Based on Tukey's post hoc test, TMZ and AZI significantly diminished the number of U87 cell colonies compared to the untreated group or negative control (NC) (Fig. 3). AZI also markedly outperformed DOXY.

Fig. 3 [Images not available. See PDF.]

Drug cytotoxicity on U87 cell colonies that grew after nutrient stress (NS) induction. Data are the mean (SD) of a single replicate from nine independent experiments ($n=9$). One-way ANOVA, followed by Tukey's post hoc test; *$p<0.05$; **$p<0.01$; ***$p<0.001$

Drug cytotoxicity on L929 fibroblasts

To compare the cytotoxicity of studied drugs, fibroblasts were treated at the IC50 levels in GBM cells. Based on the comparison made to the 50% hypothetical value, only AZI + DOXY treatment significantly decreased the viability of L929 fibroblasts (Table 2). It is worth noting that the mean difference in L929 fibroblast viability across treatments was lower than the hypothetical value, contrasting to U87 cells (Table 1).

Table 2. Effect of nutrient stress (NS) induction on drug cytotoxicity in L929 fibroblasts

Treatment	Mean (SD)	*t* statistic (degrees of freedom)	*p* value (2-tailed)*	Mean difference (95% confidence interval)
TMZ	33.17 (12.86)	−2.267 (2)	0.152	−16.83 (−48.78, 15.11)
AZI	25.27 (12.33)	−3.475 (2)	0.074	−24.73 (−55.36, 5.89)

DOXY	24.70 (12.61)	−3.474 (2)	0.074	−25.30 (−56.64, 6.04)
AZI + DOXY	11.33 (2.60)	−25.73 (2)	0.002**	−38.67 (−45.13, −32.20)

*One-sample *t*-test; ***p*<0.01

Further to that, a two-way ANOVA showed a non-significant difference between treatment groups (F (3, 16) = 1.303, p = 0.308) and a significant difference between treatment groups before (TMZ (40.27 (2.42), AZI (52.43 (7.42), DOXY (46.97 (10.26), and AZI + DOXY (46.40 (6.24)) and after NS induction (F (1, 16) = 36.56, p<0.0001); however, the interaction between before and after NS was not significant (F (3, 16) = 2.418, p = 0.104). A Sidak's post hoc test demonstrated that AZI, DOXY, and AZI + DOXY treatments exhibited an increased cytotoxic effect on L929 fibroblasts after the NS induction (Fig. 4). These data indicate that the induction of NS altered their sensitivity to tested drugs, except for TMZ, which had no meaningful difference between before and after NS. In fact, the lack of interaction between before and after NS suggests that the NS induction does not affect the cytotoxicity of the drug in fibroblasts; nevertheless, the type of drug may play a role.

Fig. 4 [Images not available. See PDF.]

Drug cytotoxicity on L929 fibroblasts and on reseeded L929 fibroblasts after nutrient stress (NS) induction. Data are the mean (SD) of three technical replicates from three independent experiments (n = 3). Two-way ANOVA, followed by Sidak's post hoc test; *p<0.05; **p<0.01

Additionally, a two-way ANOVA showed a significant difference between treatment groups (F (3, 16) = 18.35, p <0.0001) and a significant difference between fibroblast types (NIH3T3 vs. HDF) (F (1, 16) = 59.28, p<0.0001) (TMZ (66.27 (11.23) vs. 99.17 (2.29), AZI (44.80 (2.12) vs. 56.83 (7.58), DOXY (48.40 (7.63) vs. 78.60 (3.26), and AZI + DOXY (61.23 (5.70) vs. 83.30 (13.55)); though, the interaction between fibroblast types was not significant (F (3, 16) = 2.21, p = 0.127). A Sidak's post hoc test demonstrated that drug cytotoxicity differed across fibroblast types (Fig. 5), except for AZI. Despite this, the lack of interaction between fibroblast types suggests that the drug types may affect the effects.

Fig. 5 [Images not available. See PDF.]

Drug cytotoxicity on NIH3T3 fibroblasts and human dermal fibroblasts (HDF). Data are the mean (SD) of three technical replicates from three independent experiments (n = 3). Two-way ANOVA, followed by Sidak's post hoc test; *p<0.05; ***p<0.001

Discussion

In a previous study, AZI and DOXY have shown promising anticancer effects in GBM cells [19]. Nevertheless, the role of NS in driving tumour cells to adaptive growth and survival, as well as its involvement in the development of drug resistance, is a matter of ongoing research.

The main finding herein is that NS-induced U87 cells essentially do not develop into a drug-tolerant phenotype. The mean differences in U87 cell viability across treatments were not statistically significant. Moreover, TMZ and AZI retained their effectiveness in reducing U87 cell colonies. In these situations, different drug mechanisms and targets that certainly influence the findings cannot be ruled out. Indeed, the probable divergence of biological activities and oncogenic signalling pathways between reseeded monolayer and grown aggregates warrants further exploration. In particular, NS promotes chemoresistance [13, 16]. As per Mondal and colleagues, NS induction leads to phenotypic reprogramming, driving U87 cells into a glioma stem cell-like phenotype. Explicitly, NS-induced U87 cells demonstrated increased drug efflux capacity, which is consistent with the MTT cell viability assay, as the cytotoxicity of TMZ, cisplatin, and paclitaxel decreased on these cells [16].

On the other hand, glucose deprivation caused a marked sensitisation of U87 cells to TMZ and carboplatin, nearly

doubling the rate of apoptosis [13]. Nevertheless, further analysis revealed that it drove U87 and U251 GBM cells to exit the cell cycle and enter quiescence, and augmented autophagy, allowing them to withstand TMZ- and carboplatin-induced cytotoxicity. Indeed, autophagy is responsible not only in chemoresistance but also tumour survival by acting as a self-degradation channel that maintains metabolism and homeostasis, as well as an intracellular recycling platform that supplies the nutrients needed for growth [13, 14]. Likewise, when glucose was substituted with galactose, PANC1 pancreatic cancer cells switched to autophagy-dependent mitochondrial OXPHOS [12].

In contrast to the aforementioned, we previously found that 21-day survived U87 cells without medium replenishment were completely susceptible to AZI and DOXY treatments [19]. Notably, AZI exhibited preferential cytotoxicity in CAL27 oral squamous and Detroit 562 pharyngeal cancer cells under amino acid-deprived conditions by blocking autophagic flux [2]. GBM, like other cancers, prioritises glucose to produce adenosine triphosphate via aerobic glycolysis, but switches to mitochondrial respiration when nutrients or glucose are scarce [12, 13, 20]. At its core, AZI and DOXY have superior cytotoxicity to nutritionally stressed cells probably owing, in part, to the fact that they mediate cell death through mitochondrial respiration [3, 8–10] and autophagy inhibition [2, 4].

In a different study, tetrathiomolybdate (TM) has been discovered to be more toxic to neuroblastoma cells in low-glucose conditions, regardless of normoxia and hypoxia [21]. This can be partly attributed to the role of TM, which increases glucose consumption and activates glycolysis, making them vulnerable to death in low-glucose settings. Onodera and colleagues, alternatively, delineated that the redox system inhibitors, including penicillic acid (PA), have preferential cytotoxicity to PANC-1 pancreatic cancer cells in a nutrient-deprived condition [22]. In this case, nutrient deprivation raises the reactive oxygen species, while PA form an adduct with glutathione (GSH) and a lack of precursor amino acids required for GSH synthesis drops its level, rendering them defenceless to oxidative stress-mediated apoptotic death.

Herein, it was also discovered that L929 fibroblasts that survived for 48 days in nutrient-deprived conditions (re-enter the cell cycle and proliferate after being subjected to nutrient-favourable conditions) were more susceptible to AZI-, DOXY-, and AZI + DOXY-induced cytotoxicity. In different studies, AZI shows preferential cytotoxicity to senescent fibroblasts [23, 24], and AZI and DOXY both have senotherapeutic potential [24, 25]. These facts likely, in part, explain why the fibroblasts were more susceptible to them after NS induction. Certainly, NS activates autophagy, while autophagy promotes senescence in cancer cells and fibroblasts [14, 26]. Ironically, cancer cells with senescence reversal exhibit more aggressive behaviours [27], whereas autophagic-senescent fibroblasts promote tumour growth and metastasis metabolically through paracrine production of high-energy mitochondrial fuels [14]. Although acknowledging the specificity of drugs of interest is beyond the scope of the present work since fibroblasts were cultured under the same conditions as GBM cells, which may have altered their typical behaviours, data shows that they are adaptable in nature. Fibroblasts are known to have a high degree of plasticity and can change their behaviour depending on the signals and cues from the microenvironment [15]. In a different study, the IC_{50} value of AZI was reported to be 115 (49) μg/ml in primary human connective tissue-derived fibroblasts cultured in alpha-MEM supplemented with 10% FBS and 1 mM glutamine [28]. DOXY had an IC_{50} value of 310 μM in primary human skin-derived fibroblasts cultured in DMEM containing growth ingredients, including GlutaMAX, 4.5 g/l glucose, 10% FBS, and 1 mM sodium pyruvate [3]. In the study by Lamb et al., DOXY over the range of 50 to 500 μM showed little or no cytotoxicity in hTERT-BJ1 human foreskin fibroblasts (culture conditions not specified); though at 50 μM, it was significantly cytotoxic against MCF7 and T47D mammospheres [10].

Future recommendations

NS possesses the promise of sensitising cancer cells to chemotherapeutic regimens, which is intricately linked to the mechanism of action of the cytotoxic drugs. To further demonstrate the usefulness of AZI and/or DOXY in the context of cytotoxic preference in NS circumstances, the next envisioned phase entails the utilisation of an in vivo animal model that incorporates dietary restriction, such as through short-term fasting.

Conclusions

In short, this study suggests that NS does not inevitably contribute to cytotoxic drug tolerance in GBM cells. On the

other hand, although fibroblasts can withstand NS, they can also become susceptible to cytotoxic drug-induced death; however, the type of drug may play a role.

ABSTRACT (ENGLISH)

Background

Osteoporosis is a crucial health concern interconnected with physical disabilities as well as financial burdens. It arises from an imbalance between osteoblasts and osteoclasts, provoking the reduction of bone mass and the disturbances in bone structure with high fracture risk. Considerable efforts were done to prevent and mitigate this public health issue. Nonetheless, further understanding of the etiopathology of osteoporosis and the underlying genetic and epigenetic pathways is required.

Main body

Emerging evidence indicates that noncoding RNAs, including long noncoding RNAs (lncRNAs) and circular RNAs (circRNAs), play crucial roles as epigenetic regulators in various pathological processes, including osteoporosis. LncRNAs are RNA transcripts with higher structural complexity that are developed owing to their secondary and tertiary structures, which allow them to create different binding sites for other biomolecules, such as DNA, RNA, and proteins. Another class of noncoding RNAs is circRNAs, which have a covalently closed loop structure without the 5′ cap and 3′ polyA tail and are formed by back-splicing of pre-mRNAs. Because of their closed structure, circRNAs are largely stable, resistant to RNA-degrading nucleases, and possess substantially longer circulatory half-lives than linear RNAs. Interestingly, both lncRNAs and circRNAs serve as competing endogenous RNAs by sponging multiple miRNA binding sites as well as interact with RNA-binding proteins (RBPs), thereby controlling the expression of their target genes. Several studies indicated that altered expression of these regulators could influence many biological processes in bone cells.

Conclusion

The current review provides current opinions on the role and the underlying mechanisms by which lncRNAs and circRNAs affect osteoblastic and osteoclastic activities. The deep understanding of these noncoding RNAs in

osteoporosis offers distinctive avenues for innovative treatment strategies.

FULL TEXT

Background

Osteoporosis is a devasting metabolic bone disease with declined bone mass, loss of microarchitecture, fragility, and high susceptibility to fractures. Globally, it is one of the crucial reasons for the long-term physical impairments prevailing in an aging population. Therefore, osteoporosis represents a serious universal health issue that imposes a heavy load on society and healthcare systems [1].

Bone homeostasis is a constant state of formation and resorption through osteoblast and osteoclast activities, respectively. Osteoporosis occurs due to elevated osteoclastic activity without osteoblastic compensation [2]. Diverse molecules such as estrogen, parathyroid hormone, calcitonin, and vitamin D are implicated in the development and progression of the disease [3]. Earlier studies have also linked the development of osteoporosis to a battery of risk factors, such as modifiable and non-modifiable ones. Modifiable risk factors include weight, smoking, alcohol consumption, inactivity, calcium/vitamin D status, and the administration of corticosteroids. On the other hand, non-modifiable risk factors comprise advancing age, sex, race, and genetic characteristics [4]. Interestingly, the majority of these variables influence osteoporosis by modulating the activity of osteoblasts and osteoclasts. Nevertheless, genetic factors are regarded as one of the most significant predictors of osteoporosis [5].

Osteoporosis can be classified as either a primary or secondary disease. Primary osteoporosis includes juvenile, postmenopausal (type-I), and senile osteoporosis (type-II) [6]. Juvenile osteoporosis occurs in childhood and adolescence as a result of genetic mutations that could predispose to quantitative or qualitative disturbances in the connective tissue component of bone. Type-I osteoporosis, also named hormonal osteoporosis, is triggered by estrogen decrement during menopause; meanwhile, type-2 or senile osteoporosis, as the name implies, affects both genders and reaches peak incidence in the mid-seventies. Secondary osteoporosis occurs as a result of underlying medical conditions, such as renal disorders, malignancies, endocrine diseases, or therapeutic interventions [7].

Currently, dual-energy X-ray absorptiometry (DEXA) is the gold standard technique for diagnosing osteoporosis and predicting skeletal fracture risk. Despite its value, DEXA can only detect changes in bone structure that have already occurred, which can take a considerable time to become detectable, and it provides limited insights into disease progression and treatment effectiveness [8]. As well, since osteoporosis is recognized as a ‘silent disease’, it is frequently undiagnosed until a symptomatic fracture occurs [9]. Therefore, there has been a growing interest in exploring alternative approaches, such as epigenetic studies, for the early detection of osteoporosis before the occurrence of fractures.

The epigenetic landscape exhibits a fundamental role in osteoporosis pathogenesis. Intriguingly, epigenetics arises from the overlapping between genes, a non-modifiable risk factor, and the environment, as a modifiable risk factor for osteoporosis. Previous reports documented that epigenetics control a variety of biological processes, such as chromosome inactivation and cell differentiation [10]. Moreover, epigenetic regulations could manipulate the etiopathogenesis of osteoporosis via controlling osteoblasts and osteoclast cells [11], as shown in Fig. 1.

Fig. 1 [Images not available. See PDF.]

ncRNAs regulate osteogenesis and osteoclastogenesis signaling pathways involved in the development of osteoporosis

LncRNAs are noncoding RNA transcripts >200 nt that are not translated into proteins. LncRNAs are implicated in physiological and pathological cascades, so they are nominated as important regulators and possible biomarkers for a variety of human disorders, including osteoporosis [12]. lncRNAs exert their role in several human diseases via functioning as miRNA reservoirs, binding to messenger RNAs (mRNAs) or pre-mRNAs, and controlling post-transcriptional expression [13]. In osteoporosis, lncRNAs participate in bone proliferation, apoptosis, and the inflammatory response, resulting in the regulation of osteogenic and osteoclastogenic processes.

Circular RNA is a distinct form of endogenous ncRNA, with transcripts ranging in length from hundreds to thousands

of nucleotides. The reverse splicing that occurs between the splice acceptor at the 5′ end and the splice donor at the 3′ end of the pre-mRNA creates a covalently closed loop structure for circRNAs. The unique structure of circRNAs confers significant stability, rendering them resistant to RNA-degrading nucleases and resulting in significantly longer half-lives in the circulatory system compared to linear RNAs [14]. Recent findings indicate circRNAs have significant involvement in key cellular processes relevant to the progression of various diseases, such as cell differentiation and proliferation, thus serving as innovative biomarkers for diagnosis and prognosis. CircRNAs act as epigenetic regulators through controlling gene splicing or transcription, translating proteins, interacting with RNA-binding proteins (RBPs), and sponging miRNA [15]. Many circRNAs are differentially expressed in osteoporosis to influence the expression of certain genes that are implicated in osteoblastic and osteoclastic activities.

Based on that, the current review endeavors to combine these data and show the expression profiles of lncRNAs and circRNAs in osteoporosis. It also focuses on their regulatory roles as well as their clinical utility as promising therapeutic targets from the perspective of osteogenesis and osteoclastogenesis.

Main text

Osteogenic signaling pathways

Osteogenesis is the differentiation of committed mesenchymal stem cells (MSCs) into mature, active osteoblasts through several stages of precursors. Osteogenesis is achieved through interrelated cascades including hippo, Wnt, notch, and bone morphogenetic protein (BMP). These axes modulate diverse transcription factors, such as runt-related transcription factor 2 (RUNX2). RUNX2 participates in triggering the dedication of MSCs to the osteogenic lineage and functions upstream from the other transcription factors specific to osteoblasts, such as osterix (Osx) and distal-less homeobox 5 (Dlx5) [16]. The Wnt/β-catenin pathway plays a potential role in the stabilization of β-catenin that sequentially migrates to the nucleus and controls the expression of genes related to osteoblastogenesis [17]. Dickkopf-1 (DKK1) is mainly expressed by osteoblasts and bone marrow stromal cells (BMSCs) and antagonizes the Wnt pathway.

Another signaling pathway is BMP, which is one of the members of the transforming growth factor (TGF)-β superfamily and plays a crucial role in regenerating osteogenic differentiation in osteoblasts. Briefly, BMP receptors bind with BMP ligands, resulting in phosphorylation of Smad1/5/8, which then attaches to the co-Smad (Smad4) to form a complex. The resultant complex moves to the nucleus, where it regulates the genes that affect osteoblast development in conjunction with co-activators and corepressors [18].

The Hippo signaling cascade modulates osteoblastic activity and thereby participates in bone development and maintenance. Sometimes, the Hippo pathway is turned off by inactivating (dephosphorylating) mammalian STE20-like protein kinases 1 and 2 (MST1/2) and large tumor suppressors 1 and 2 (LATS1/2). This results in the activation of the yes-associated protein (YAP) and the transcriptional coactivator with the PDZ-binding motif (TAZ), allowing them to translocate into the nucleus. Subsequently, YAP and TAZ act as transcriptional co-activators, interacting with transcription factors to regulate the expression of target genes related to osteoblast cell proliferation, differentiation, and survival [19].

Notch signaling, a highly preserved intercellular pathway, governs cell differentiation and proliferation as well as determines cell fate via the activation of cell surface receptors (Notch 1-4) and their delta-like ligands (DLL) 1, 3, 4, and Jagged 1, 2. This pathway promotes the expression of downstream target genes involved in osteogenesis regulation [20].

LncRNAs involved in osteogenesis regulation

LncRNAs that promote osteogenesis

BMSCs have a high osteogenic capability, which is considered an effective practical strategy for hindering bone loss. Previous reports elucidated the involvement of the lncRNAs in BMSC proliferation and differentiation. Herein, we review the expression of potential lncRNAs in osteoporosis and their significant roles in either promoting or inhibiting osteogenic differentiation, as shown in Table 1 and Fig. 2, respectively.

Table 1. The expression of lncRNAs-related osteogenesis in osteoporosis

LncRNAs that promote osteogenesis			
LncRNA	Expression in osteoporosis	Samples	References
LncRNA HAGLR	Downregulated	Peripheral blood of PMOP patients and OVX mice	[21]
LncRNA RAD51-AS1	Downregulated	hBMSCs of osteoporotic patients	[23]
LncRNA KCNQ1OT1	Downregulated	Bone tissue samples of PMOP and OVX mice	[24]
GATA4-mediated lncRNA MALAT1	Downregulated	Bone tissues of PMOP patients and OVX mice	[26]
Quercetin-mediated lncRNA MALAT1	Downregulated	OVX mice	[29]
Prrx-2-mediated lncRNA MIR22HG	Downregulated	OVX mice	[30]
LncRNA TERC	Downregulated	DEX-induced osteoporosis in BMSCs	[31]
LncRNA SNHG14	Downregulated	OVX mice	[34]
LncRNAs that inhibit osteogenesis			
LINC00205	Upregulated	Bone tissue samples of osteoporotic patients	[35]
LINC01234	Upregulated	Plasma of osteoporotic patients	[37]
LncRNA PCBP1-AS1	Upregulated	Bone tissue samples of osteoporotic patients	[38]
LncRNA KCNMA1-AS1	Upregulated	Bone tissue samples of osteoporotic patients	[40]
LncRNA SNHG1	Upregulated	Serum of osteoporotic patients	[41]
IRF-1-mediated lncRNA XIST	Upregulated	OVX mice	[42]

Fig. 2 [Images not available. See PDF.]

Role and mechanistic insights of lncRNAs in osteogenesis. All shapes shaded in green denote biomarkers increased during osteogenesis. All shapes shaded in red denote biomarkers decreased during osteogenesis

LncRNA homeobox D gene cluster antisense growth-associated long noncoding RNA (HAGLR) exhibited a significant decrease in the peripheral blood of patients with postmenopausal osteoporosis (PMOP) compared to

healthy controls. Conversely, its expression increased during BMSC osteogenic differentiation. In OVX mice, the overexpression of HAGLR alleviated PMOP by upregulating homeobox protein A10 (Hoxa10) expression through inhibition of miR-182-5p [21]. Indeed, Hoxa10, a crucial transcription factor in the osteogenic process, plays a pivotal role in regulating the production of osteoblasts [22]. In parallel, the **lncRNA RAD51-Antisense RNA 1 (RAD51-AS1)** was remarkably downregulated in human bone marrow stem cells (hBMSCs) obtained from osteoporotic patients compared to those from controls. It was observed that RAD51-AS1 knockdown inhibited the proliferation and differentiation of hBMSCs and boosted their apoptosis. Mechanistically, RAD51-AS1 was determined to stimulate the osteogenic differentiation of hBMSCs by interacting with Y-Box Binding Protein 1 (YBX1) to generate mRNA-protein complexes with SMAD7 and Smad ubiquitin regulatory factor 2 (SMURF2), thus hampering their translation. Additionally, it could transcriptionally upregulate proliferating cell nuclear antigen (PCNA) and SIVA1 by binding to their promoter regions, resulting in activation of the TGF-β signaling pathway [23]. **LncRNA KCNQ1OT1** also showed a significant decrease in PMOP patients compared to control group. Its overexpression enhanced the osteogenic differentiation of MC3T3-E1 cells and alleviated osteoporosis in OVX mice through upregulation of mTOR via sponging miR-421-3p [24].

Besides, GATA-binding protein 4 (GATA4) is crucial in modulating osteoblastic differentiation, bone remodeling, and mineralization [25]. Huang et al. linked GATA4 with **lncRNA metastasis-associated lung adenocarcinoma transcript 1 (MALAT1)** in BMSCs during osteogenesis [26]. The study found that GATA4 overexpression promoted BMSC osteoblastic differentiation through upregulating lncRNA MALAT1. Notably, the expression of both GATA4 and lncRNA MALAT1 was reduced in the bone tissues of both PMOP patients and ovariectomized (OVX) mice. It was confirmed that GATA4 activated the transcription of MALAT1, which in turn formed an RBP complex with K-homology splicing regulatory protein (KHSRP) to decay the stability of neuronal precursor cell-expressed developmentally downregulated 4 (NEDD4) mRNA, the one that is responsible for the promotion of RUNX1 degradation by ubiquitination [27]. In sum, GATA4-mediated lncRNA MALAT1 stimulated osteogenic differentiation of BMSCs via inhibiting RUNX1 degradation through modulation of the KHSRP/NEDD4 axis, ultimately driving bone formation in PMOP. Furthermore, another study has also investigated the role and molecular mechanism of MALAT1 in osteoporosis. Interestingly, several phytochemicals have been found to be effective therapeutics for osteoporosis. Among them is quercetin, which has a promoting effect on BMSC osteogenesis [28]. Feng et al. documented that quercetin treatment could attenuate tumor necrosis factor alpha (TNFα)-impaired BMSCs osteogenesis via upregulating MALAT1 expression [29]. In OVX mice, serum MALAT1 level was markedly decreased, while quercetin treatment restored its level to some extent. Additionally, MALAT1 was involved in the modulating effect of quercetin on TNFα-impaired BMSC osteogenesis. Its knockdown abolished the rescuing effect of quercetin; stimulation of β-catenin expression and mitigation of NF-κB p65 translocation. This, in turn, compromised quercetin's osteogenic ability and facilitated the progression of osteoporosis. In the same context, Paired-Related Homeobox Protein 2 (Prrx2) is a transcription factor that belongs to the paired-related homeobox protein family and has been found to be involved in the regulation of lncRNA expression. Li et al. reported that myoblast-derived exosomal Prrx2 directly attached to the **MIR22HG** promoter and enhanced its expression [30]. Relevantly, high levels of MIR22HG alleviated OVX-induced bone loss by accelerating BMSC osteogenic differentiation through inhibition of miR-128, which in turn stimulated YAP1 expression and thus activated the Hippo pathway.

Other factors have been implicated in the regulation of lncRNAs during osteogenesis, impacting the development of osteoporosis. Dexamethasone (DEX) is a synthetic glucocorticoid that has been reported to regulate MSC osteogenic lineages. **LncRNA TERC** is among the lncRNAs identified to alleviate DEX-induced osteoporosis. It was observed that TERC overexpression mitigated the inhibitory effect of DEX on BMSC osteogenic differentiation by increasing the level of the enhancer of zeste homolog 2 (EZH2) protein. This elevation, in turn, facilitated the histone modification of DKK1, thereby activating the Wnt signaling pathway. Thus, TERC overexpression by lessening DEX-induced osteoporosis could provide an additional therapeutic strategy for glucocorticoid-induced osteoporosis [31]. Also, Autophagy is a mechanism beneficial for cell survival and growth [32], known to maintain bone remodeling by

removing reactive oxygen species (ROS) [33]. Xue et al. have found that **lncRNA Small nucleolar RNA host gene 14 (SNHG14)** overexpression activated autophagy in BMSCs as well as raised bone mineral density (BMD) and bone trabecular number in OVX mice [34]. Mechanically, an elevated level of SNHG14 stimulated myocyte enhancer factor 2C (Mef2c)-mediated autophagy activation through inhibition of miR-493-5p, predisposing to enhancement of the osteogenic ability of BMSCs. Thus, SNHG14 could alleviate osteoporosis progression via activation of autophagy by regulating the miR-493-5p/Mef2c axis.

LncRNAs that inhibit osteoblastogenesis

Certain lncRNAs have been identified as inhibitors of osteogenesis, which impede the process of bone formation and trigger osteoporosis development. For example, **LINC00205** was upregulated in bone tissue samples of osteoporotic patients with or without a spinal fracture, while it was downregulated during the osteogenic differentiation of human mesenchymal stem cells (hMSCs). Precisely, LINC00205 inhibited osteogenic differentiation by targeting miR-26b-5p and enhancing lysine (K)-specific methyltransferase 2C (KMT2C) expression. This latter contributed to a decrease in the expression of osteogenic-related genes such as RUNX2, alkaline phosphatase (ALP), and osteocalcin (OCN), resulting in the progression of osteoporosis [35]. Likewise, **LINC01234** was highly expressed in the plasma of patients with osteoporosis while exhibiting a gradual decrease during osteogenic differentiation of hMSCs. In this study, it was observed that LINC01234 impeded hMSC osteogenic differentiation by augmenting aldehyde oxidase 1 (AOX1) via regression of miR-513a-5p. Notably, the AOX1 gene encodes the cytosolic enzyme that catalyzes the formation of superoxide [36]. Thus, targeting LINC01234 could promote osteogenesis and hinder osteoporosis development [37].

LncRNA PCBP1-AS1 was highly expressed in osteoporotic tissues and decreased during the development of hBMSCs into osteoblasts. The knockdown of PCBP1-AS1 promoted the osteogenic differentiation capacity of hMSCs, while its overexpression exhibited an opposite effect. Mechanistically, PCBP1-AS1 targeted Pak family member p21-activated kinase 2 (PAK2) by inhibiting miR-126-5p [38]. Remarkably, PAK2 is required for various cellular activities, such as cytoskeletal remodeling and chromatin modulation [39]. Additionally, **lncRNA KCNMA1-AS1** was elevated in the osteoporotic subjects. Its suppression upregulated miR-1303, which resulted in the downregulation of cochlin (COCH), a known suppressor of embryonic stem cell differentiation. This led to the promotion of osteogenic differentiation in hMSCs and the mitigation of the progression of osteoporosis [40].

The intricate interplay between lncRNAs and apoptosis reveals a novel aspect of the pathogenesis of osteoporosis. Pan et al. reported that **lncRNA SNHG1** could regulate osteogenic differentiation by influencing pyroptosis, an inflammatory type of apoptosis triggered by inflammasomes and caspase-1 [41]. SNHG1 was observed to be elevated in the serum of osteoporotic patients. Its overexpression could suppress BMSC osteogenic differentiation through interaction with HMGB1, enhancing its expression. This, in turn, activated pyroptosis-associated factors (caspase-1 p20 and gasdermin D-N (GSDMD)-N) and the production of inflammatory interleukins (IL-1β and IL-18), leading to the development of osteoporosis. In tandem, interferon regulatory factor-1 (IRF-1) also participated in controlling cellular apoptosis during osteogenic differentiation through the regulation of **lncRNA X-inactive-specific transcript (XIST)**. Elevated levels of lncRNA XIST were observed in OVX mice, and its knockdown not only alleviated osteoporosis symptoms but also promoted osteogenic differentiation in hBMSCs. Simultaneously, IRF-1 accelerated osteogenic differentiation by repressing the transcription of XIST, which in turn upregulated miR-450b and subsequently decreased F-box and WD repeat domain-containing 7 (FBXW7) expression [42]. FBXW7 is regarded as an efficient tumor suppressor due to its role in cellular apoptosis and has also been observed to be involved in the osteogenic differentiation of BMSCs [43, 44].

CircRNAs involved in osteogenesis regulation

CircRNAs that promote osteogenesis

Several studies, conducted in BMSC-induced osteogenic differentiation, focused on RUNX2 regulation through various circRNA/miRNA axes. For instance, **circ-3626**, an exonic circRNA that arises from the STAG1 gene, was significantly increased during osteogenic differentiation of BMSCs, whereas it was decreased in bone tissues derived from osteoporotic patients and BMSCs of aged mice. Moreover, its overexpression dramatically accelerated

the osteogenic capability of BMSCs. Circ-3626 increased RUNX2 regulation by inhibiting miR-338-3p and thereby upregulating many osteogenic-related genes [45]. Similarly, **circ-RBM23** acted as a suppressor of miR-338-3p, enhancing RUNX2 and regulating the switch between osteogenesis and adipogenesis in MSCs. The authors reported that circ-RBM23 was elevated in osteogenesis, whereas it was depressed during adipogenesis in MSCs, providing a crucial goal for diagnosing and alleviating osteoporosis [46]. Furthermore, **circ_0011269, circ-VANGL1, and circ_0076690** were notably decreased in the clinical samples of osteoporotic patients. In hMSCs, circ_0011269, circ-VANGL1, and circ_0076690 upregulated RUNX2 expression via sponging miR-122, miR-217, and miR-152, respectively. These findings pointed out that the overexpression of these circRNAs promoted osteogenic differentiation and could be implicated in the pathogenesis of osteoporosis [47–49].

Previous reports have revealed the functions of various circRNAs in influencing SMAD5 expression, making them potential targets for therapeutic interventions related to skeletal disorders. **Circ_0001825** is newly recognized to be significantly downregulated in osteoporotic patients. The suppression of circ_0001825 reduced hMSC viability and osteogenic differentiation. Circ_0001825 promoted osteogenesis via sponging miR-1270, resulting in SMAD5 overexpression, which signifies the potential contribution of circ_0001825 to osteoporosis [50]. Another circRNA that has been detected to regulate SMAD5 in osteoporosis is **CircGLIS2.** The expression of circGLIS2 was obviously decreased in osteoporotic patients, while increased in hBMSCs upon osteogenic differentiation. Regression of circGLIS2 notably inhibited osteogenesis-related genes, such as osteopontin (OPN), OCN, and ALP activity. The study reported that circGLIS2 sponged miR-214-3p and upregulated Smad5, which stimulated osteogenic differentiation of the hBMSCs [51]. **Circ_0062582** was also observed to lessen the development of osteoporosis by affecting SMAD5 expression. It was reported that circ_0062582 was remarkably decreased in osteoporosis. Meanwhile, circ_0062582 was increased in osteoblast medium-induced hBMSCs, where it sequestered miR-197-3p and resulted in an elevation of SMAD5, thereby reflecting hBMSC proliferation and osteogenic differentiation [52].

In vitro studies using MSCs revealed that circRNAs play a regulatory role on several genes related to the BMP pathway. Both **circRNA_0048211** and **circ_0016624** were suppressed in PMOP patients compared to healthy controls. During hMSC osteogenic differentiation, the upregulated circRNA_0048211 and circ_0016624 increased BMP2 regulation through targeting miRNA-93-5p and miR-98, respectively, so attenuated development of PMOP [53, 54].

Regarding the Notch pathway, **circRNA_0001795** and **circ-ITCH** promoted osteogenic differentiation of hBMSCs by targeting YAP1 through sponging their respective miRNAs, miR-339-5p and miR-214 [55, 56]. Notably, the expression levels of both circRNAs were notably reduced in osteoporosis, and their depletion correlated with a decrease in the expression of osteogenic-related genes. Additionally, in vivo experiments demonstrated that the upregulation of circ-ITCH enhanced osteogenesis in ovariectomized (OVX) mice.

It has been found that **hsa_circ_0114581** is negatively correlated with osteoporosis pathogenesis. The upregulated hsa_circ_0114581 enhanced the expression of heterogeneous nuclear ribonucleoprotein A3 (HNRNPA3) to encourage osteogenic differentiation by suppressing hsa-miR-155-5p. This study also proved that HNRNPA3 was directly associated with osteogenic-related proteins in BMSCs and femur samples of either human bone tissue or OVX mice, suggesting its relationship with osteogenesis and bone formation [57]. Moreover, low levels of **circ_0019693** were recognized in osteoporotic patients. Its expression was further enhanced during the stages of osteogenic differentiation in BMSC. Intriguingly, it was indicated that circ_0019693 could promote osteogenesis through inhibiting miR-942-5p and increasing purkinje cell protein 4 (PCP4) [58]. When PCP4 is bound to CaM-dependent protein kinase, the rate of Ca^{+2} dissociation from calmodulin (CaM) increases, promoting calcium deposition during mineral nodule formation, which is a valid predictor of bone-forming ability [59]. **Hsa_circ_0006215** is another circRNA coupled between osteogenesis and angiogenesis and involved in the pathogenesis of senile osteoporosis. It was significantly downregulated in the BMSCs of osteoporotic patients, while its overexpression promoted the osteogenic differentiation of BMSCs. In vivo, its overexpression induced the repair of the single cortical bone defect model, suggesting that it could promote bone defect repair. Furthermore, it has been demonstrated that hsa_circ_0006215 influences RUNX2 and VEGF expression in BMSCs through sponging miRNA-942-5p [60]. In

GIOP patients, the **hsa_circ_0006393** level was downregulated compared to control ones. Furthermore, overexpression of hsa_circ_0006393 boosted the expression of osteogenic genes in bone tissue samples obtained from male GIOP patients as well as a GIOP mouse model. It was suggested to have osteogenic influence through inhibiting miR-145-5p and increasing FOXO1 expression [61].

Numerous studies have been conducted on human adipose stem cells (ASCs). It was found that **CircFOXP1** was significantly downregulated in the bone tissues of osteoporotic patients. Indeed, the pro-osteogenic activity of circFOXP1 was evaluated in vivo and in vitro, where circFOXP1 was found to enhance hASC osteogenesis by sponging miR-33a-5p and targeting FOXP1 expression [62]. Thus, circFOXP1 could be regarded as a candidate target for hASC-based therapy of osteoporosis.

Accumulating data indicates that circRNAs have the ability to interact with RBPs and alter their functions [63]. **CircStag1** was remarkably suppressed in the BMSCs of osteoporotic rats and bone tissue samples isolated from osteoporotic patients. Briefly, circStag1 interacted with human antigen R (HuR) and promoted its translocation into the cytoplasm. Sequentially, cytoplasmic HuR led to the stimulation of the Wnt cascade by stabilizing low-density lipoprotein receptor-related protein 5/6 (Lrp5/6), co-receptors for Wnt ligands, and enhancing β-catenin expression. It was also observed that the induction of circStag1 fostered osteogenesis in OVX mice [64]. According to Yao et al., **circ-Plod2** is an exon-type circRNA found in the cytoplasm, where it destabilized the Mpo-dependent osteogenic differentiation of BMSCs while having no effect on adipogenic differentiation or chondrogenic differentiation of these cells [65]. The study also found that the expression of circ-Plod2 was remarkably downregulated in OVX rats BMSCs, and its overexpression effectively lessened osteoporosis among them. Circ-Plod2 mediated its effect by interacting with IGF2BP2 to form an RNA–protein complex, which in turn inhibited the expression of Mpo mRNA in BMSCs. Another circRNA that plays a role in osteoporosis by interacting with RBP is **circPVT1**. CircPVT1 stimulates osteogenesis by inhibiting miR-30d-5p to increase integrin beta-3 (ITGB3) expression [66]. ITGB3, a member of the integrin family, functions as a downstream gene of Homeobox D3, which triggers the Wnt/β-catenin signaling pathway through the involvement of β3 integrin.

CircRNAs that inhibit osteogenesis

Other circRNAs exert a pivotal regulatory role in impeding osteogenesis through modulation of essential pathways and gene expression networks, thereby influencing the overall process of bone formation. A recent study has highlighted the mechanistic insight of **hsa_circ_0006859** in vitro. It was recognized that the expression of hsa_circ_0006859 was augmented in OVX mouse-derived BMSCs but remained modest expressed during osteogenic differentiation. Hsa_circ_0006859 overexpression hindered osteogenesis of BMSCs in the human fetal osteoblast cell line by targeting both miR-642b-5p/ephrin A2 (EFNA2) and miR-483-3p/dedicator of cytokinesis 3 (DOCK3) axes, resulting in the inactivation of the Wnt-signaling pathway [67]. Additionally, it has been reported that **hsa_circ_0008842**, identified as **circZNF367**, was substantially upregulated in the bone tissue of osteoporotic patients and dramatically downregulated in hBMSCs during osteogenic differentiation. The overexpression of circZNF367 suppressed migration and osteogenic differentiation of hBMSCs, both in vitro and in vivo, while its knockdown exhibited opposite effects. CircZNF367 could reduce osteogenic differentiation of hBMSCs through interaction with HuR, which reduced LRP5 mRNA stability [68].

Circ_0006873 was upregulated in the sera of osteoporotic patients and decreased during osteoblastic differentiation. Circ_0006873 could suppress osteoblastic differentiation and favor osteoporosis by sponging miR-142-5p, which in turn enhances PTEN expression and regulates the Akt signaling pathway [69]. Another study has also reported that circ_0006873 was significantly elevated in both serum samples and bone tissue samples of osteoporotic patients. Its overexpression was associated with a significant reduction in osteogenic differentiation of hMSCs through the sequestration of miR-20a and targeting SMURF2 [70].

Lipopolysaccharide (LPS) is a potent inducer of bone loss, resulting in inflammation that exacerbates osteoporosis by disrupting regular bone homeostasis. **CircAtp9b** is LPS-inducible, and its knockdown alleviates the inflammation triggered by LPS [71]. Interestingly, circAtp9b was significantly upregulated in plasma samples and osteoblasts derived from osteoporotic patients. LPS-treated osteoblasts increased circAtp9b expression in a dose-dependent

manner, confirming that the circAtp9b overexpression is likely triggered by LPS. Also, it was shown that circAtp9b upregulation increased LPS-induced osteoblast apoptosis in osteoporosis by sponging premature miR-17-92a and suppressing its maturation, which in turn accelerated osteoporosis progression [72].

There is little known about the role of circRNAs in melatonin (MEL)-induced BMSC osteogenic differentiation and osteoporosis progression. MEL has been detected as a booster of osteoblast proliferation and differentiation, fostering bone formation and reducing bone destruction in osteoporotic mice [73]. In this regard, Wang et al. found that melatonin improved osteogenic differentiation and repressed osteoporosis development by hampering **circ_0003865** expression [74]. This circRNA acts as a sponge for miR-3653-3p, consequently boosting the expression of growth arrest-specific gene 1 (GAS1) while suppressing the expression of bone-forming genes. Similarly, the expression of **circ_0005753** was significantly reduced during the osteogenic differentiation of BMSCs triggered by MEL. Molecularly, circ_0005753 maintained the stability of TXNIP mRNA through the recruitment of PTBP1. This study pointed out that MEL enhanced BMSC osteogenic differentiation through the regulation of the circ_0005753/PTBP1/TXNIP axis, which could shed light on a new treatment pathway to prevent osteoporosis [75]. Zhi et al. determined that exosomal **hsa_circ_0006859** was obviously upregulated in the serum of PMOP, efficiently distinguishing osteoporotic and osteopenic patients from healthy controls [76]. As well, it discriminated between osteoporotic and osteopenic patients with high specificity and sensitivity. Besides, ectopic expression of circ_0006859 provoked adipogenic differentiation and impeded osteoblastic differentiation in BMSCs via sponging miR-431-5p to induce ROCK1 expression. Thus, hsa_circ_0006859 may be a potential biomarker for the diagnosis and prognosis of osteoporosis and could modulate the harmony between adipogenesis and osteogenesis in BMSCs. According to whole transcriptome sequencing, Zhang et al. determined the expression profile of circRNAs in the peripheral blood of male osteoporotic patients versus healthy controls, and found that a total of 398 circRNAs were differentially expressed [77]. **Hsa_circ_0042409** was among the top 10 upregulated circRNAs and was recognized to be involved in the development of osteoporosis through regulating the expression level of kinesin light chain 1 (KLC1) via sponging hsa-miR-195-5p. Additionally, another study observed a significant upregulation of **circ_0134944** in both PMOP patients and OVX mice. Its enhanced expression suppressed osteogenesis in BMSCs through targeting miR-127-5p, causing an increase in pancreatic and duodenal homeobox 1 (PDX1) and sphingosine kinase 1 (SPHK1). PDX1 is a well-established transcription factor that regulates the activity of multiple genes by binding to their promoter regions, such as SPHK1, which has an impact on the regulation of osteogenic differentiation [78]. Furthermore, **Hsa_circ_0002060** knockdown in the human fetal osteoblast cell line (hFOB1.19) reversed the effect of DEX, which decreased matrix metalloproteinases (MMP) and increased ROS. Hsa_circ_0002060 modulated the survival of hFOB 1.19 cells by targeting miR-198-5p, resulting in an elevation of Bax expression that in turn triggered the apoptosis of osteoblasts. Additionally, hsa_circ_0002060 knockdown alleviated the progression of osteoporosis in OVX mice through the Jun N-terminal kinase (JNK) signaling pathway [79].

Collectively, manipulating these interrelated molecules could be beneficial in the management of osteoporosis. Thus, we reviewed the expression and molecular mechanisms by which circRNAs mediate osteoblast differentiation (Table 2 and Fig. 3).

Role and mechanistic insights of circRNAs in osteogenesis. All shapes shaded in green denote biomarkers increased during osteogenesis. All shapes shaded in red denote biomarkers decreased during osteogenesis

Osteoclastogenic signaling pathways

Osteoclastogenesis is the fusion of osteoclast precursors, which originate from hematopoietic cells to form multinucleated, active osteoclasts. Macrophage colony-stimulating factor (M-CSF), also known as CSF-1, and receptor activator for nuclear factor κB Ligand (RANKL) are two crucial cytokines that bind to their respective receptors, colony-stimulating factor-1 receptor (c-Fms) and RANK, to stimulate osteoclastogenesis through the regulation of delicate signaling pathways [80]. M-CSF stimulates the production and survival of osteoclast precursor cells by activating extracellular signal-regulated kinase (ERK) and serine/threonine kinase 1 (Akt). Meanwhile, RANKL facilitates the development of osteoclast precursors into osteoclasts by attracting TRAF6 to the RANK receptor, which then activates various downstream targets, including NF-κB, JNK, ERK, p38, and PI3K/Akt. This ultimately leads to the activation of the key regulator of osteoclast differentiation, nuclear factor of activated T cells 1 (NFATc1). This latter controls several osteoclast-specific genes, including TRAP, cathepsin K, and osteoclast-associated receptor (OSCAR) via interaction with other osteoclastic transcription factors, such as microphthalmia-

associated transcription factor (MITF) and c-Fos [81]. Additionally, the RANK/RANKL/OPG pathway is crucial for the metabolism of bone tissue, as RANKL stimulates the production and differentiation of osteoclasts, while osteoprotegerin (OPG) inhibits its action through binding to it [82]. Here, we summarized the relevant research investigation of lncRNAs (Table 3) and circRNAs (Table 4) in order to offer novel insights for future osteoporosis studies and treatments, with a specific focus on osteoclasts, as depicted in Fig. 4.

Role and mechanistic insights of lncRNAs/circRNAs in osteoclastogenesis

LncRNAs that promote osteoclastogenesis

lncRNAs have been demonstrated to govern osteoclastogenesis by controlling the expression of certain mRNAs. **LncRNA AK077216** was considerably upregulated during osteoclastogenesis in the bone marrow and spleen tissues of OVX mice. LncAK077216 overexpression upregulated NFATc1 and accelerated RANKL-induced osteoclastogenesis by downregulating NIP45 [83]. Additionally, **lncRNA GAS5** was upregulated in the plasma of osteoporotic patients compared to healthy participants and effectively distinguished between them with high sensitivity and specificity. It has been found that GAS5 overexpression promoted osteoclast apoptosis by sponging miR-21, thus exhibiting a protective effect in osteoporosis [84]. A previous study demonstrated that miR-21 was involved in the pathogenesis of osteoporosis through modulation of reversion-inducing cysteine-rich proteins with Kazal motifs (RECK), which play a role in cell apoptosis, proliferation, and differentiation in TNF-α-treated MSCs [85]. **LncRNA CRNDE** was also highly expressed in osteoclasts obtained from PMOP compared with those from healthy controls. After CRNDE knockdown, the cell percentage was significantly increased in the G0/G1 phase but decreased in the S-phase, promoting osteoclast apoptosis rate. Moreover, CRNDE improved osteoclast proliferation by regulating the PI3K/AKT signaling pathway [86].

LncRNAs that inhibit osteoclastogenesis

Extracellular vesicles (EVs) released by MSC have significant immunoregulatory effects on bone healing in osteoporosis. The **lncRNA NRON** was rich inside BMSC-derived EVs that have been triggered by bioactive glass nanoparticles (BGN) in an osteoporosis model of OVX mice. NRON reduced osteoclast differentiation through interaction with the nuclear factor of activated T cell transcription factors and blocking the nuclear translocation of NFATc1 [87]. Likewise, **lncRNA FTX** was significantly suppressed in the serum and bone tissues of osteoporotic patients compared to controls ones. FTX overexpression reduced osteoclastgenesis through upregulation of Notch1 by sponging miR-137 in CD14 + peripheral blood mononuclear cells (PBMCs) [88].

CircRNAs involved in osteoclastogenesis regulation

CircRNA that promote osteoclastogenesis

CircZNF367 was found to be upregulated in an OVX mouse model of osteoporosis. CircZNF367 promoted osteoclast differentiation by interacting with fused in sarcoma (FUS), facilitating its translocation into the cytoplasm to trigger the enhancement of CRY2 mRNA stability [89]. C**ircFam190a** was significantly upregulated in vitro and in an OVX mouse osteoporosis model, where it induced significant bone loss. The study reported that circFam190a could promote osteoclast formation and function by enhancing the binding between AKT1 and HSP90β, thereby protecting AKT1 from proteasome-mediated degradation and augmenting its stability as well as its activity [90]. Unfortunately, the existing clinical drugs were reported to impede osteoclasts and interfere with normal bone turnover. However, targeting specific osteoclast precursors may be more effective in preserving bone homeostasis. **circBBS9 (mmu_circ_0001757),** a highly conserved circRNA, was substantially upregulated in mononucleated pre-osteoclasts versus bone marrow macrophage (BMM). Moreover, the **circBBS9** homolog in humans **(hsa_circ_0134188)** was augmented in osteoporotic human bone samples as well as in PBMC-derived osteoclasts. Knockdown of circBBS9 using siRNA-circBBS9-loaded nanoparticles inhibited BMM multinucleation in vitro. As well, these particles avoided bone loss in an OVX-induced mouse model. Molecularly, knockdown of circBBS9 in osteoclast precursors inhibited osteoclast multinucleation via the miR-423-3p/Traf6 axis, demonstrating that

circBBS9 is an efficient post-transcriptional regulator [91]. C**ircRNA_28313** knockdown significantly inhibited osteoclastic differentiation within BMM cells in vitro, while suppressed OVX mice stimulated bone resorption in vivo. CircRNA_28313 acted as ceRNA by binding to miR-195a, resulting in upregulation of CSF1 and the development of osteoclast differentiation [92].

CircRNA that inhibit osteoclastogenesis

Hsa_circ_0021739 was downregulated in PMOP, and its expression was associated with the lumbar vertebra, femur, and forearm T-scores. Overexpression of hsa_circ_0021739 has also been shown to reduce hsa-miR-502-5p levels and hinder osteoclast differentiation [93]. Besides, Liu et al. screened the differential expression of circRNAs in PMOP using RNA-sequencing and found that **circ_0007059** expression was decreased in patients and during the osteoclast differentiation of hBMSCs [94]. The authors also demonstrated that circ_0007059 overexpression lessened hBMSC differentiation into the osteoclasts. Molecularly, circ_0007059 sponged miR-378 expression, which resulted in an upregulation of BMP-2 expression that was accompanied by a decrease in osteoclast-specific gene expression and TRAP staining, thus attenuating osteoporosis development. Moreover, **circHmbox1** was notably decreased during the formation of osteoclasts triggered by TNF-α in vivo and in vitro. CircHmbox1 acted by inhibiting miR-1247-5p to activate Bcl6. Interestingly, Bcl6 is a transcriptional repressor required in osteoclast development and the preservation of bone homeostasis. The study also demonstrated that exosomes with low expression of circHmbox1 produced by TNF-α-induced osteoclasts could inhibit osteoblast differentiation. Indeed, circHmbox1 overexpression remarkably alleviated the osteoporotic phenotypes in OVX mice [95].

Other CircRNAs related to osteoporosis and osteoporotic fracture

Yang et al. have observed that osteoporosis and fracture were indirectly correlated to **circ_0076906** expression while directly correlated to that of **circ_0134944** in PBMCs of postmenopausal women [96]. In vitro, inhibiting circ_0076906 expression augmented the expression of miR-548i, which in turn reduced the expression of osteoglycin (OGN). This latter is a bone anabolic factor that has been linked to the mineralization and osteogenesis processes by adjusting the expression of osteogenesis-specific genes. The study also demonstrated that the circ_0134944 upregulation suppressed miR-630 and enhanced the expression of toll-like receptor 4 (TLR4). TLR4 is highly expressed in bone marrow, immune cells, adipocytes, and osteoblasts and is involved in osteoblastogenesis and osteoclastogenesis [97, 98]. Thus, circ_0076906 and circ_0134944 were associated with a risk of osteoporotic fracture, leading to osteoporosis [96]. Besides, Wen et al. observed that the expression level of **hsa_circ_0076906** was greatly decreased in both bone tissue and serum samples of the osteoporotic group compared to the control group, besides its gradual induction during osteogenic differentiation of hMSCs [99]. Circ_0076906 was found to promote MSC differentiation and relieve osteoporosis through upregulating OGN expression by inhibiting miR-1305. Additionally, **circHIPK3** was significantly upregulated in both tissue and serum samples from osteoporotic fracture patients compared with controls. CircHIPK3 was shown to sponge miR-378a-3p and to upregulate HDAC4, which is a histone deacetylase that controls osteoblast differentiation by inhibiting Runx2 transcriptional activity [100].

Conclusions

This article provides an overview of the expression patterns of lncRNAs and circRNAs in osteoporosis. It also discusses their involvement in the differentiating of osteoblasts and osteoclasts, as well as the underlying molecular mechanisms implicated in their effects. Many lncRNAs and circRNAs act by interacting with RBP or sponging miRNAs to control the expression of targeted genes, hence impacting many pathways involved in osteogenesis and osteoclastogenesis. Despite the fact that both lncRNAs and circRNAs possess great potential in the prediction, diagnosis, and prognosis of osteoporosis, their regulatory ability in targeting proteins is still largely unknown. More future studies are also warranted on circRNAs in osteoporosis since they are scanty in comparison with those on lncRNAs. Moreover, studying the interactions of lncRNAs and circRNAs is of interest for gaining a deeper understanding of the pathogenesis of osteoporosis and promoting the discovery of new therapeutics and drugs.

RNA-binding protein
RECK
Reversion-inducing Cysteine-rich proteins with Kazal motifs
ROS
Reactive oxygen species
RUNX2
Runt-related transcription factor 2
SMURF2
Smad ubiquitin regulatory factor 2
SNHG14
Small nucleolar RNA host gene 14
SPHK1
Sphingosine kinase 1
TAZ
Transcriptional coactivator with PDZ-binding motif
TGFβ
Transforming growth factor β
TLR4
Toll-like receptor 4
TNF-α

Tumor necrosis factor alpha
XIST
X-inactive-specific transcript
YAP
Yes-associated protein
YBX1
Y-Box Binding Protein 1

ABSTRACT (ENGLISH)

Background

Hyaluronic acid (HA) has a broad range of cosmetic and therapeutic applications due to its unique physicochemical properties and involvement in various essential biological processes, including cell signaling, wound reparation, and tissue regeneration.

Main body

In this review, we provide a comprehensive overview of HA, including its history, physicochemical properties, roles, molecular biology, and biochemistry (including occurrence, biosynthesis, and degradation), as well as its chemical modifications and conventional and emerging production methods. We also examine HA's medical, pharmaceutical, and cosmetic applications and its derivatives in arthrology, ophthalmology, wound healing, odontology, oncology, drug delivery, 3D bioprinting, and cosmetology. Finally, we discuss the potential role of HA in preventing Covid-19.

Conclusion

Hyaluronic acid, a naturally found substance, has shown immense potential in the clinic. Thus, it is imperative to highlight its applications in the diverse fields impacting the lives of patients and healthy individuals.

FULL TEXT

Background

Hyaluronic acid (HA) is a naturally occurring glycosaminoglycan found in vertebrate connective, epithelial, and nervous tissues. This versatile substance has a broad range of applications in the medical and cosmetic industries, such as dermal fillers, osteoarthritis treatment, ophthalmology, and vesicoureteral reflux. In 2018, the global HA market was valued at USD 8.3 billion, with a projected Compound Annual Growth Rate (CAGR) of 7.8% during the forecast period [1–3]. HA was first discovered in cow's eyes in 1934 and later identified in humans and other animals. It is primarily found in the extracellular matrix of connective tissue, synovial fluid, and vital tissues such as the eye's vitreous, cartilage, fascia, and umbilical cord. In 1979, pharmaceutical-grade HA was produced by extracting and purifying the polymer from rooster combs and human umbilical cords [2]. HA is abundant in soft connective tissues, including skin, lungs, kidneys, brain, and muscles. Its unique viscoelastic properties, biocompatibility, and non-immunogenicity make it an ideal substance for clinical applications and cosmetic purposes [2, 4]. Due to changing beauty standards and rising health awareness, there has been a significant increase in nonsurgical cosmetic procedures, with hyaluronic acid injectables being the second most frequently performed procedure after Botox, with a total spending of more than USD 5 billion in America in 2015 [5, 6]. This review explores HA's potential benefits and limitations in various applications, such as tissue engineering, drug delivery, and wound healing, by examining this substance's positive and negative aspects to provide a comprehensive overview of its use in medicine and cosmetics.

Main text

Physiological functions of hyaluronic acid

Hyaluronic acid (HA) is a macromolecule that plays a vital role in the human body. It is a high molecular weight glycosaminoglycan composed of glucuronic acid and *N*-acetylglucosamine linked together via glycosidic bonds. In the body, it exists in sodium hyaluronate and is present in various soft connective tissues, including the skin, lungs, kidneys, brain, and muscle tissues [7]. HA's biological functions are diverse and significant. It plays a crucial role in regulating tissue hydration and water transport, maintaining the elasto-viscosity of connective tissues, and facilitating the supramolecular assembly of proteoglycans in the extracellular matrix. HA also engages in numerous receptor-mediated roles, such as cell detachment, mitosis, migration, tumor development and metastasis, and inflammation [8]. When bound to water molecules, HA forms a hydrated gel and acts as a water-binding agent that lubricates movable body parts, such as joints and muscles. HA's properties and functions have led to a broad range of

applications in the medical field. For example, it is commonly used in dermal fillers for cosmetic purposes and is also used to treat osteoarthritis. The increasing demand for nonsurgical cosmetic procedures has led to a surge in using hyaluronic acid injectables [9] (Fig. 1).

Fig. 1 [Images not available. See PDF.]

Applications of hyaluronic acid (HA) in different fields. HA is a versatile biomaterial with various applications in various areas. This figure provides an overview of the diverse applications of HA, including drug delivery, tissue engineering, cosmetic procedures, and wound healing. The figure shows that HA can form nanoparticles for drug delivery, including oral drugs, micelles, and tumor-targeting nanoparticles. HA nanoparticles can also be used in ocular applications, enhancing drug delivery to the eye and improving ocular bioavailability. HA has also been used in tissue engineering, including cardiovascular tissue engineering, stem cell delivery, reconstructive and plastic surgery, and scaffold construction for knee replacement and cartilage regeneration. HA hydrogels, cryogels, and carbon nanotubes have enhanced tissue regeneration and repair. HA is commonly used as a filler for facial rejuvenation and volumization in cosmetic procedures. HA-based liposomes can also be used for targeted drug delivery in cosmetics. Other applications of HA include embryo implantation, wound healing, and microneedle patches. HA has been shown to improve embryo implantation rates and promote wound healing. Microneedle patches incorporating HA can enhance transdermal drug delivery and promote skin hydration [Figure generated using https://www.biorender.com/]

Molecular biology and biochemistry

Hyaluronan is a linear glycosaminoglycan comprising approximately 10,000 disaccharide units of d-glucuronic acid and *N*-acetyl-d-glucosamine (Fig. 2A). The synthesis of HA is carried out by hyaluronan synthases, which are membrane-bound enzymes forming functional dimers with six transmembrane segments. The polymer chain is expelled through the plasma membrane during hyaluronan synthesis. The active form of the hyaluronan synthase enzyme was isolated from streptococci as a complex and characterized as a 42 kDa protein through immunological cross-reaction with the streptococcal enzyme and affinity labeling techniques [10]. Three mammalian genes are responsible for hyaluronan synthesis (HAS1, HAS2, and HAS3), each contributing to hyaluronan production with different molecular weights. The biological effects of hyaluronan are distinct from other biologically active molecules and are influenced by its molecular weight (Mw) [11, 12].

Fig. 2 [Images not available. See PDF.]

A Structure of hyaluronic acid. **B** Schematic diagram illustrating the key steps involved in hyaluronic acid (HA) synthesis and degradation. The diagram shows that the synthesis of HA is regulated by various factors, such as growth factors, cytokines, kinases, and other proteins that modulate the activity of HA synthases (HAS1, HAS2, and HAS3). These enzymes are responsible for synthesizing HA chains, which are then bound by HAS protein complexes and extruded onto the cell surfaces and into the extracellular matrix (ECM). The biological actions of HA are tightly regulated by its degradation, which is carried out by several hyaluronidase enzymes, including HYAL-1, HYAL-2, HYAL-3, HYAL-4, PH20/SPAM1, HYAL-P1, and ROS. These enzymes cleave the HA chains into smaller fragments, which can be metabolized or eliminated from the body

There is a total of 15 g of hyaluronan (HA) in the human body, and about 30% of it undergoes degradation through two distinct mechanisms (Fig. 3). One mechanism involves specific enzymatic degradation mediated by hyaluronidases, while the other mechanism is nonspecific and occurs due to oxidative damage caused by reactive oxygen species (ROS) [13–15]. ROS encompass hydrogen peroxide, peroxynitrite, nitric oxide, superoxide, and hypohalous acids. These ROS are generated during inflammatory responses in conditions like sepsis, tissue inflammation, and ischemia–reperfusion injury. They can degrade hyaluronan, a process that can occur due to ROS. The human genome contains six identified gene sequences related to hyaluronidase: HYAL-1, HYAL-2, HYAL-3 genes, HYAL-4 and PH20/SPAM1 genes, and HYAL-P1 pseudogene. These genes are associated with the production of hyaluronidase enzymes, which are involved in the degradation of hyaluronan [16, 17]. The degradation

of HA occurs partially within the tissue itself, but a significant portion occurs in local lymph nodes and within the endothelial cells of the liver. The remaining 70% of HA undergoing systemic catabolism is transported by hyaluronan, primarily carried to the lymph nodes through the lymphatic system. Within the lymph nodes, hyaluronan is internalized and broken down by the endothelial cells of the lymphatic vessels. Additionally, a small fraction of HA enters the bloodstream and undergoes degradation by the endothelial cells in the liver [18–20]. Hyaluronidase-mediated degradation of HA plays a crucial role in various critical regulatory processes, including embryonic development and wound healing. The significance of HA degradation by hyaluronidases is evident in mucopolysaccharide hyaluronidase deficiency, a lysosomal storage disorder characterized by elevated levels of HA in the plasma due to a defect in hyaluronidase activity [21, 22]. HA exhibits one of the most rapid turnover rates among molecules in the mammalian body. It is estimated that approximately one-third of the 15 g of HA present in an average adult human is turned over daily (Fig. 4). The high turnover of HA in various tissues requires equally high rates of synthesis and degradation [23–25].

Fig. 3 [Images not available. See PDF.]

Summary of the production of HA. This figure provides an overview of the methods used to produce HA, including in vitro production, bacterial production, and extraction from animal tissues. The first method described is in vitro production, which involves using enzymes derived from *Streptococcus pyogenes* and *Pasteurella multocida* to synthesize HA in a controlled laboratory setting. This method allows for the production of HA with precise molecular weight and purity, making it ideal for pharmaceutical and biomedical applications. The second method described is bacterial production, which involves using various strains of bacteria, including *Streptococci, Enterococcus faecalis, Escherichia coli, Bacillus subtilis,* and *Lactococcus lactis*, to produce HA. This method is relatively inexpensive and scalable, making it suitable for large-scale production of HA for commercial and industrial purposes. The third method described is an extraction from animal tissues, which involves isolating HA from various animal sources, including rooster comb, human umbilical cord, bovine synovial fluid, and vitreous humor of cattle. This method is less commonly used due to the challenges associated with obtaining HA from animal tissues, but it remains an essential source of HA for specific applications

Fig. 4 [Images not available. See PDF.]

Schematic diagram illustrating the electrospun nanofibers and hydrogel scaffold composite for tissue engineering applications. The figure shows that electrospinning is used to fabricate nanofibers from a hyaluronic acid (HA) polymer, which is then cross-linked with 1 M NaOH and 0.5% CaCl2 to form a hydrogel scaffold. The resulting composite material provides a suitable substrate for cell proliferation and stretching, which can lead to the formation of functional tissue structures. The electrospun nanofibers provide a high surface area-to-volume ratio, facilitating cell adhesion and migration, while the hydrogel scaffold offers mechanical support and promotes cell proliferation. The composite material can also be further functionalized with growth factors or other bioactive molecules to enhance tissue regeneration [Figure generated using https://www.biorender.com/]

Isolation from biological sources and manufacturing by biotechnology

HA is a glycosaminoglycan that serves vital functions in tissue hydration and cellular processes. Within the body, HA is synthesized by attaching sugar molecules to the reducing end of the polymer. This synthesis occurs within the plasma membrane of various cells, including fibroblasts. The resulting HA molecule extends into the pericellular space, contributing to its important physiological roles [26]. Historically, hyaluronic acid was extracted from animal tissues such as rooster combs, human umbilical cords, or other vertebrate tissue. However, this process was found to be relatively complex and expensive [27, 28]. In recent years, hyaluronic acid has been obtained through in vitro production or extraction from the cell walls of bacteria of streptococcal origin. Two types of hyaluronic acid can be produced depending on the method: isolation-origin HA and fermentation-origin HA. Isolation-origin HA is obtained through a series of steps that include the removal of epithelium from the rooster comb, followed by grinding of the comb. Subsequently, the ground material is treated with acetone, ethanol, and sodium chloride to extract and purify

the hyaluronic acid [29]. In contrast, the production of fermentation-origin HA involves the continuous fermentation of Streptococcus in a controlled culture environment, such as a chemostat. However, it is essential to note that fermentation-origin HA often contains substantial amounts of endotoxins and elevated bacterial levels, necessitating the removal of these impurities through subsequent purification steps [30]. Therefore, additional purification steps are required to minimize the presence of bacterial proteins. Remarkably, hyaluronan has been discovered in the capsule of specific microbial pathogens, including Pasteurella multocida and certain strains of Streptococcus (Fig. 5). These microorganisms have developed enzymatic systems that resemble those found in vertebrate hosts to facilitate hyaluronan synthesis within their capsules [31, 32]. These microorganisms employ hyaluronan as a protective capsule around their cells, effectively evading the host's immune system and facilitating adhesion and colonization of the bacterial cells. This hyaluronan-based encapsulation serves as camouflage, allowing the microorganisms to bypass the animal defense mechanisms [21, 33]. Isolation-origin HA generated in biological systems is often associated with proteins and other glycosaminoglycans, necessitating thorough purification processes [34, 35]. Complex purification processes are essential to obtain a genuine product from traditional resources like rooster combs while minimizing the degradation of the molecular chains. However, even with sophisticated purification and sterilization methods, the final product's molecular weight will likely decrease, resulting in a lower molecular weight [36, 37]. Furthermore, the production of isolation-origin HA from traditional sources also poses a risk of viral contamination, necessitating complex purification procedures that can be costly [38–40].

Fig. 5 [Images not available. See PDF.]

Applications of hyaluronic acid (HA) and its derivatives in various fields. The figure shows that HA and its derivatives can be used as a drug delivery system, where they serve as carriers for different therapeutic agents, including small molecules, proteins, and nucleic acids. The biocompatibility and biodegradability of HA make it an ideal material for sustained drug release, enhancing the therapeutic efficacy of the delivered agent. In cancer therapy, HA and its derivatives have been used for targeted drug delivery, as well as for imaging and diagnosis. HA-based nanoparticles can selectively accumulate in tumor tissues, releasing the drug payload and effectively inhibiting tumor growth. HA, and its derivatives have also been used in soft tissue regeneration, including wound healing, cartilage repair, and bone regeneration. HA-based scaffolds and hydrogels can support cell adhesion, proliferation, and differentiation, forming functional tissue structures. HA and its derivatives are commonly used in skin care products in the cosmetic industry due to their moisturizing and anti-aging properties. HA-based fillers can also be used for facial rejuvenation and volumization. Other applications of HA and its derivatives include dietary supplements, urology, odontology, and wound treatment. HA-based materials can be used in urology for bladder augmentation and incontinence treatment. In odontology, HA-based materials can be used for tissue engineering and implantology. In wound treatment, HA-based dressings can promote healing and prevent infection [Figure generated using https://www.biorender.com/]

Modification of HA

HA possesses various functional groups, such as carboxylic acids, *N*-acetyl groups, and alcohols, that can be modified to alter the properties of resulting materials for enhanced hydrophobicity and biological activity [41, 42]. These modifications are commonly carried out through chemical cross-linking or radical polymerization, leading to hydrogels known as hylans. Although HA is highly hydrophilic and soluble in water, it is often required to have limited solubility or insolubility for its use in medical devices. It can be achieved by conjugating or cross-linking HA [43, 44]. Chemical modification of HA enables its transformation into diverse physical forms such as viscoelastic solutions, hydrogels with varying stiffness, electrospun fibers, flexible sheets, macroporous and fibrillar sponges, nonwoven meshes, and nanoparticulate fluids, which find applications in various clinical and preclinical settings [44–46]. This is achieved by targeting three functional groups: primary and secondary hydroxyl groups, carboxylic acid, glucuronic acid, and *N*-acetyl groups. Different approaches, such as addition/condensation chemistry or radical polymerization, can cross-link these groups [47]. However, the direct application of HA-based products in humans presents substantial challenges in their development (Fig. 6). The market for these products is expensive, and ongoing efforts are being made to create new formulations. The globalization of the industry has heightened the need for stringent

quality controls to guarantee the safety of cosmetic products [47, 48]. Consequently, there is an immediate requirement to advance the development of cost-effective and efficient techniques for identifying and detecting toxic components present as contaminants or impurities.

Fig. 6 [Images not available. See PDF.]

Application of hyaluronic acid (HA) hydrogel in the regeneration of dental pulp and cosmeceuticals. **A** shows that HA hydrogel can regenerate damaged dental pulp. Dental pulp stem cells are mixed with the HA hydrogel and injected into the damaged pulp using a syringe. The HA hydrogel provides a suitable microenvironment for the proliferation and differentiation of dental pulp stem cells, leading to functional dental pulp tissue regeneration. In addition to dental pulp regeneration. **B** HA hydrogel can be incorporated into skincare products, such as creams and serums, to improve skin hydration and reduce the appearance of fine lines and wrinkles. HA hydrogel can also be used as a filler in facial rejuvenation procedures, providing immediate volumization and contouring [Figure generated using https://www.biorender.com/].

Nanofibers and nanomicelles

Nanofiber scaffolds have a broad range of applications in fields such as tissue engineering, wound dressing, cosmetics, and drug delivery [49]. Biopolymers are ideal materials for these scaffolds due to their biodegradability and biocompatibility. However, the industrial development of such formulations is challenging due to modifying HA with toxic reagents during chemical processes, which are challenging to eliminate from the final product, making it unsuitable for pharmaceutical applications [50, 51]. Nanofibers based on photocurable ester derivatives of HA or its salt have been developed to overcome this issue. The skin barrier at the topmost layer, the stratum corneum, can prevent the penetration of drugs. However, nanosized colloidal systems, such as nanoparticles, liposomes, nanoemulsions, micelles, and polymeric suspensions, have demonstrated the ability to enhance drug penetration through this barrier [52, 53]. These systems have received significant attention for delivering cosmetic and pharmaceutical compounds topically for local or systemic administration [54, 55]. Research on polymer-based drug delivery has aimed at developing biodegradable polymer systems to reduce the risk of accumulating non-biodegradable particles in the body [56]. HA is an intriguing material as a topical drug delivery agent since it is a substantial part of the skin's extracellular matrix and can be found in both the epidermis and dermis [57].

Hydrogels

Hydrogels are intricate polymeric networks characterized by a three-dimensional architecture that enables them to absorb substantial quantities of water while preserving their structural integrity [58]. Due to its very important physiological and biological roles in maintaining homeostasis in the human body, hydrogels made from HA have been developed for several biomedical applications such as, drug delivery, tissue engineering and regeneration, as well as diagnostics, etc. [59, 60]. Market for HA-based hydrogels is continuously expanding and HA hydrogels are already being used in medicine as viscosupplements, dermal fillers, would dressings, etc.

Although HA can form molecular networks in the presence of a solvent due to its conformation and molecular weight, it cannot form a physical gel alone which further warrants for further chemical modifications such as covalent cross-linking and use of gelling agents to prepare HA hydrogels. Chemical cross-linking, with some limitations, has been a versatile method to obtain HA hydrogel with excellent mechanical, chemical, and thermal stability [61]. HA-based hydrogels can be prepared by several methods, such as polymerization, enzymatic cross-linking, condensation reactions, and click chemistry. HA hydrogels can be directly cross-linked with the help of cross-linking agents such as glutaraldehyde, divinyl sulfone, bisepoxide, and carbodiimide. [62, 63]. Using Diels Alder-based click reaction, HA-based hydrogels with tunable properties were developed by reacting furan modified HA with peptide derivatized with bismaleimide in order to mimic extracellular matrix (ECM) for breast cancer cells invasion [64]. Furthermore, by avoiding the use of cytotoxic copper as a catalyst, HA-PEG hydrogels were synthesized by reacting cyclooctyne modified HA with azide functionalized PEG. This hydrogel showed excellent mechanical properties, gelation time, and high stability [65, 66]. Recently, using another naturally occurring click chemistry between cyanobenzothiazole and cysteine, an in situ forming injectable HA hydrogel with encapsulated camptothecin

nanocrystals was prepared for long-term treatment of inflammatory arthritis [66].

On the other hand, non-covalent bonds and supramolecular interactions have been researched to prepare physical hydrogels with tunable properties by applying various cues like pH, light, temperature, etc. [67, 68]. Taking advantage of inclusion complexation properties of cyclodextrins, self-assembled HA hydrogel was formed by reacting β-cyclodextrin with adamantane functionalized HA which displayed excellent shear thinning properties [69]. Interestingly, using gelling agents such as Pluronic F-127, thermosensitive HA hydrogel was prepared by mixing HA in water with Pluronic F-127. Due to the hydrophobic interactions of acetyl groups of HA and methyl groups of Pluronic F-127, stable and mechanically stronger hydrogel was formed which avoided the typical burst release of drugs when only Pluronic F-127 was used in hydrogel preparation [70].

Films

HA films have several advantages over conventional formulations like gels, ointments, and solution as films can be stable, long-lasting, and can enhance patient compliance. There have been continued research on HA-based films for the treatment of diverse diseases by overcoming the drug delivery barriers of drug molecules as well as delivery system itself [71, 72]. HA films have been found to have limited medical applications that require extended stability in aqueous environments due to their fast dissolution in water, poor mechanical stability, and rapid in vivo degradation. However, these limitations can be overcome by implementing physical and chemical cross-linking techniques [57, 73, 74]. To be suitable for biomedical applications, films must possess specific properties, such as self-supporting, adequate mechanical strength when hydrated, biocompatibility, biodegradability, non-cytotoxicity, and the ability to adjust in vivo stability [75, 76]. A new type of water-insoluble film composed of palmitoyl esters of hyaluronan (pHA) was developed in 2016 to overcome the solubility limitations of hyaluronan films [77]. A new method was formed in 2019 for creating free-standing films from lauroyl derivatives of HA without the need for cross-linking agents, plasticizers, toxic solvents, and activators. This method involves an artless single-step solution casting process. The resulting films were homogeneous, exhibited good mechanical strength, and were flexible. Hydrophobized or cross-linkable hyaluronan derivatives exhibit higher resistance to biodegradation. They can serve as scaffolds for cell culture and matrices for controlled drug-related augmentation of soft tissues via viscosupplementation [78]. Conjugation of hyaluronan with drugs also provides an exciting approach for targeted drug delivery [79]. Significant attention has been given to the preparation of hyaluronic acid derivatives that can undergo cross-linking reactions under mild physiological conditions to broaden their applications.

Applications of hyaluronan

HA is a biocompatible polysaccharide with distinctive physicochemical characteristics. These properties render it highly versatile and applicable in numerous medical domains [8]. In the human body, the total quantity of HA is estimated to be around 15 g in a 70-kg adult [80]. While HA is predominantly present in the skin, constituting approximately 50% of the overall HA content in the body, it is also distributed throughout various other tissues and fluids. HA can be found in the vitreous humor of the eye, the umbilical cord, and synovial fluid, as well as in all tissues and bodily fluids. This includes skeletal tissues, heart valves, the lungs, the aorta, the prostate gland, and specific structures of the penis, such as the tunica albuginea, corpora cavernosa, and corpus spongiosum [80–85].

HA in arthrology

Autograft reconstruction is a commonly employed surgical technique for treating severe ligament injuries. However, this approach has limitations, including the risk of donor site morbidity. Tissue engineering techniques that involve culturing isolated fibroblasts on scaffold materials offer a promising alternative to autografts [86, 87]. Successful regeneration in ligament and tendon tissues has been demonstrated through various scaffold materials. These scaffolds encompass both naturally occurring substances and synthetic materials. An effective strategy for ligament tissue engineering involves incorporating glycosaminoglycans (GAGs) or GAG-like materials as essential scaffold components [88]. The principal constituent of GAGs, integral components of extracellular matrices, has been proven to promote tissue healing in diverse tissue types. It is achieved through several mechanisms, including enhanced delivery of growth factors, improved cellular adhesion and proliferation, and the facilitation of anti-inflammatory response [89–91]. HA's biological effects could play a critical role in promoting the regeneration of ligament tissues.

Moreover, the use of HA and hylans for intra-articular treatment has gained broader acceptance as a therapeutic approach for managing pain associated with osteoarthritis [92, 93]. HA plays a crucial role in maintaining the viscoelastic properties of synovial fluid in the knee. In osteoarthritic joints, HA concentration is typically lower than in healthy joints. Therapy aims to restore the lost viscoelastic properties of synovial fluid by introducing HA. This can help alleviate osteoarthritis pain by reducing nerve impulses and sensitivity associated with the condition [94–96].

HA for eye drops and ophthalmic surgery

Hyaluronan possesses distinctive characteristics, such as stabilization of the reduction of friction during blinking, tear film, and prevention of harmful substances from binding to the eye due to its various properties such as viscoelasticity and hydrophilicity, which greatly diminish the signs of dry eye [8, 97, 98]. Its viscoelasticity is mainly related to its cushioning and lubricating effect, as it is a component of the eye (aqueous humor) and synovial fluid. This unique rheological property is exploited in applying hyaluronan in ophthalmic surgery, where it is mainly used to establish and maintain a secure status to progress healing of the postsurgical area [30, 99]. The benefits of HA in ophthalmology extend to various aspects. HA aids in stabilizing the tear film, reducing healing time, minimizing adhesion risk, decreasing free radicals' formation, and normalizing intraocular pressure. The rheological properties of sodium hyaluronate have been examined for ophthalmic viscosurgical device (OVD) applications during cataract surgery. It has been concluded that the viscoelastic and flow properties of binary formulations consisting of sodium hyaluronate and HPMC (hydroxypropyl methylcellulose) are suitable for use as OVD. These formulations effectively maintain the ocular spaces and can be administered quickly [100, 101]. Furthermore, the adhesive properties of both sodium hyaluronate and HPMC in the binary formulation provide an additional advantage. These properties enable the formulation to effectively interact with the corneal endothelium, resulting in durable protection of ocular tissues. This interaction enhances the overall efficacy and safety of the formulation in maintaining ocular health during surgical procedures or therapeutic interventions [98, 102, 103].

HA in wound healing and tissue repair

CD44, the primary receptor for HA, is a versatile transmembrane glycoprotein expressed in various isoforms and found in nearly all human cell types. CD44 can interact with HA and various growth factors, cytokines, and extracellular proteins. This comprehensive interaction profile allows CD44 to participate in diverse cellular processes and signaling pathways involved in development, tissue homeostasis, inflammation, and cancer progression. The ability of CD44 to engage with multiple ligands highlights its significance as a critical regulator of cell adhesion, migration, proliferation, and signaling events within the extracellular microenvironment [104]. The interaction between HA and CD44 is implicated in many intracellular signaling pathways that govern various cell biological processes. These processes include receptor-mediated internalization and degradation of hyaluronan, angiogenesis (the formation of new blood vessels), cell migration, proliferation (cell growth and division), aggregation (cell clustering), and adhesion to extracellular matrix (ECM) components. The HA-CD44 interaction is a critical modulator of these cellular activities, contributing to tissue development, wound healing, immune response, and other physiological and pathological processes [105, 106]. CD44 emerges as a pivotal player in inflammation and wound healing, encompassing intricate biological processes to restore damaged tissue. Throughout all phases of tissue repair, including cellular migration, inflammation, angiogenesis (formation of new blood vessels), remodeling, and scar formation, extracellular matrix components, including HA, exert significant regulatory influence. CD44, through its interaction with HA and other molecules, exerts precise control over these sequential events, orchestrating the complex interplay required for effective tissue repair and regeneration [107]. HA is a fundamental component of the ECM and possesses distinctive properties contributing to its crucial role in tissue regeneration. Besides its structural support, HA can also function as part of a feedback loop, promoting cell proliferation and migration in actively growing tissues. This interaction between HA and cells helps regulate critical tissue development, repair, and regeneration processes. HA contributes to the dynamic balance required for effective tissue growth and remodeling by influencing cell behavior [108]. Furthermore, the role of HA in maintaining water homeostasis can contribute to tissue hydration, which in turn has a beneficial impact on the healing process. During periods of rapid tissue proliferation, regeneration, and repair, there is an increase in HA levels. This heightened presence of HA helps

retain moisture, providing a hydrated microenvironment that supports cellular activities and facilitates optimal conditions for tissue healing and recovery. The ability of HA to regulate water balance within tissues underscores its significance in promoting efficient healing processes [109, 110]. As HA is implied in every step of the wound healing procedure, exogenous application of HA can provide faster healing.

HA in odontology

In dentistry, biological materials such as HA have a broad range of applications, including regeneration and reconstruction of dentine, gingiva, dental pulp, cancellous bone, mucosal wound repair, and constructing a biophysical barrier between gingiva and jaw bones [111]. HA can act as a biocompatible scaffold or niche for mesenchymal stem cell (from apical papilla) differentiation, polarity, and a biophysical trigger or reservoir for the controlled release of various cytokines and chemokines for paracrine and autocrine signaling [112]. Additionally, HA can neutralize bacterial hyaluronate lyase enzymes, exerting a bacteriostatic effect.

Oral ulcer

Recurrent aphthous stomatitis (RAS), known as canker sores, is the most prevalent inflammatory ulcerative condition affecting the oral mucosa. However, the management of oral ulcers remains a challenge for clinicians. While topical corticosteroids, antibiotics, and antimicrobial agents are widely used, there are feeble proofs supporting the efficacy of any topical therapy. For these molecules to be effective, they should be easily applicable and preserved at the site of mucosal ulcer (MU) for an extended period [113]. Several studies have explored HA as a topical remedy for MU of the oral cavity. Notably, topical treatment of chronic aphthous MU with 0.2% HA gel for two weeks has promoted healing without side effects. Lee et al. demonstrated the effectiveness of topical 0.2% HA gel in treating oral MU in patients with RAS and Behçet's disease, suggesting improved symptoms [114, 115]. Hence, the primary activity of HA appears to be in tissue regeneration, performing a wide range of biological activities, including activating phlogistic responses, aiding cellular differentiation, proliferation, migration, and vasculogenesis, and reducing collagen deposition and scarring [116].

Gingivitis and periodontitis

Gingivitis is a highly prevalent disease that affects 82% of the population. Dental plaque has been identified as a crucial etiological factor in developing gingivitis and periodontitis [117]. Consequently, treating gingivitis and periodontitis aims to reduce dental plaque accumulation. In vitro studies have demonstrated that HA inhibits bacterial growth and interferes with bacterial morphology [118, 119]. Regarding clinical studies, it has been found that HA reduces plaque accumulation and inhibits gingival inflammation. A survey by Gizligoz et al. examined the plaque inhibitory impact of HA mouthwash compared to chlorhexidine. It was found that HA revealed an almost similar plaque inhibitory effect to chlorhexidine [120]. Jentsch et al. evaluated the effectiveness of the topical treatment of 0.2% HA. They concluded that it benefitted gingivitis by lowering the plaque indices and improving the papillary bleeding index (PBI) concerning gingival crevicular fluid (GCF) variables [121]. Similarly, Pistorius et al. proposed that the topical application of a HA reduced the PBI and sulcus bleeding index (SBI) [122]. Additionally, Sahayata et al. claimed that oral application of 0.2% HA gel in gingivitis, in addition to dental scaling and oral hygiene, offered a successful consequential response in the gingival index (GI) and PBI of placebo or control group (scaling plus placebo gel) and negative control group (scaling only) [123]. Dental scaling and root planning with topical HA are beneficial therapies for controlling gingivitis and probing depths (PDs) in individuals with chronic gum disease. Annsofi Johannsen et al. explained the beneficial effects of HA-based formulations in treating periodontitis [124]. The adjunctive application of hyaluronan gel could benefit periodontal health. The hyaluronan-based scale and root planning (SRP) protocol resulted in statistically significantly more significant reductions in abnormal dental bleeding in SRP control. Additionally, Hyaluronan has also been proven to induce bacteriostatic effects in vitro [124].

Surgery

In a comparative analysis, the health status of peri-implant mucositis and peri-implantitis during the recovery period of functional implants using HA or CHX gels. Their results demonstrated a reduced bleeding index in the HA group compared to the control group managed with CHX. Therefore, treating peri-implant mucositis and per-implantitis patients with 0.2% HA gel may be beneficial. Ballini et al. proposed combining autologous bone graft with the

esterified low-molecular HA formulation can accelerate bone regeneration in periodontal intrabone anomalies [125]. Additionally, the topical spray of 0.2% HA proved beneficial in managing inflammation and trismus during postoperative surgeries. Romeo et al. also demonstrated that the utility of essential amino acids with 1.33% HA solution could aid in secondary intention healing in laser-induced wounds during the total excisional biopsy of the gingiva and palate of the oral cavity [126]. Although it is not beneficial in pain perception, it can considerably expedite the repair processes [119].

HA in bioinks for 3D bioprinting

Manufacturing a three-dimensional (3D) object by layer-wise deposition or combination of materials, including plastics, metals, ceramics, powders, liquids, and living cells, is called 3D printing. When utilized in biomedical engineering and regenerative medicine to produce complex biological scaffolds or viable tissue structures that in vivo tissues and organs, 3D printing technology is referred to as 3D bioprinting; it holds immense potential for the fabrication, personalized prosthetics, precision implants, and histological models, and for pharmaceutical interventions such as controlled drug delivery, and microphysiological systems or organ-on-chip based drug discovery and development [127–129]. In 3D bioprinting, bioink is the main component, and different biomaterials are utilized as bioinks that are evaluated for crucial properties to ensure ease in the process [130]. It is imperative that bioinks possess high biocompatibility and physiological relevance to nurture viable cells, are mechanically sturdy after printing, and offer precise resolution during 3D printing. Therefore, biophysical characteristics, such as extrusion compatibility and mechanical properties, fluidic nature, viscosity, biodegradability, and cytotoxicity, must be evaluated [131]. Among the leading bioprinting materials used in 3D bioprinting to develop biological structures is HA, a natural ECM. HA is primarily employed because of its biological integrity, elasticity, mechanical and biodegradation properties, mimicking ECM composition, self-assembling ability, and yielding good resolution during printing [132]. To obtain increased stability and cell viability, HA can also be combined with different semi-synthetic or chemically defined polymers, such as hydrogel polymers, which exhibit stable rheology properties and excellent biocompatibility, resulting in gels that demonstrate printability in good shape. This development of biomaterials and cell biology has paved the way for bionic and regenerative medicine to become vital research fields with fast growth [133].

HA in cancer therapy

Cancer is a significant contributor to morbidity and mortality globally, with an estimated 18.1 million new cases and 9.6 million deaths reported in 2018 [140]. In recent decades, the progress of nanotechnology in medicine has offered new and promising solutions and insights for detecting, preventing, and treating cancer [143, 144]. HA plays a crucial role in various aspects of cancer cell behavior, primarily through its interactions with the stromal environment. The dysregulation of HA synthesis and the subsequent overproduction of HA often occur during the malignant transformation of cells. The impact of HA on tumor development can vary depending on the specific circumstances being evaluated, as it has the potential to either suppress or support tumor growth [146]. Extensive research has provided substantial evidence regarding the role of hyaluronan in promoting malignancies. It has been observed that increased invasion and dissemination of cancer cells can be attributed, at least in part, to the mesenchymal conversion facilitated by HA overexpression [147]. Experimental studies have demonstrated that various components of the hyaluronan signaling pathway, such as HA synthases, HA receptors, and HYAL-1 hyaluronidase, significantly promote tumor growth, metastasis, and angiogenesis. These findings highlight the potential of targeting each component as a therapeutic approach to cancer treatment [148]. The role of hyaluronan in cancer progression can vary depending on the expressed isoforms of HA synthases (HAS). Cancer cells at different stages may utilize the three HAS isoforms differently to enhance their survival. This suggests that the specific isoform of HAS expressed by cancer cells could influence their behavior and response to treatment, highlighting the importance of considering the isoform-specific effects of HA in cancer research and therapy [149]. Multiple strategies have been devised to target different HA (hemagglutinin) family members. These strategies encompass small-molecule inhibitors, antibody-based therapies, and vaccine-based interventions [150]. These treatment approaches aim to block the intracellular signaling mediated by HA, which is critical in promoting tumor cell proliferation, motility,

invasion, and the induction of endothelial cell functions. HA has been incorporated into nanoparticle formulations to achieve targeted delivery of chemotherapy drugs and other anticancer compounds to tumor cells. These preparations take advantage of the interaction between HA and cell-surface HA receptors, offering several advantages, such as being nontoxic, nonimmunogenic, and amenable to modifications for enhanced efficacy [148, 151]. The utilization of HA nanosystems shows great potential in facilitating the targeted and safe delivery of chemotherapeutic drugs and other anticancer compounds specifically to tumor cells. By leveraging the unique properties of HA and its interactions with cell-surface receptors, these nanosystems can enhance the specificity of drug delivery while minimizing potential adverse effects on healthy tissues. This targeted approach holds promise in improving the efficacy and safety of cancer treatments [152]. The utilization of HA nanoparticles offers several advantages in anticancer therapy. One such advantage is the ability to improve the half-life of anticancer agents and concentrate their delivery to cells that overexpress HA receptors. This targeted approach enables the potential for enhanced effectiveness at lower doses, leading to reduced drug-related toxicities. Many antineoplastic drugs have been successfully conjugated to hyaluronic acid, developing novel compounds with promising antitumor effects. For instance, HA-modified polycaprolactone nanoparticles encapsulating naringenin have demonstrated encouraging results. In vitro studies have shown enhanced drug uptake by cancer cells, indicating improved cellular internalization. Furthermore, in vivo experiments on rats with urethane-induced lung cancer revealed inhibited tumor growth following treatment with these nanoparticles. This highlights the potential of HA-based formulations to enhance therapeutic outcomes in cancer treatment [153]. Furthermore, it has been observed that HA-coated chitosan nanoparticles facilitate the delivery of 5-fluorouracil specifically to tumor cells that overexpress the CD44 receptor. The HA coating on chitosan nanoparticles enhances their affinity to CD44 receptors, enabling targeted drug delivery. This targeted approach improves the uptake of 5-fluorouracil by tumor cells and enhances its therapeutic efficacy against cancer. This finding underscores the potential of HA-coated chitosan nanoparticles as a promising strategy for improving drug delivery and enhancing the effectiveness of anticancer therapies [154, 155]. Paclitaxel, a widely studied compound, has demonstrated significant potential as an anticancer agent. However, its poor solubility in water has limited its therapeutic use. Recent research has focused on addressing this challenge by exploring novel approaches, such as utilizing unsaturated derivatives of HA and various HA-paclitaxel conjugates. These innovative strategies aim to enhance the aqueous solubility of paclitaxel and improve its delivery to target cancer cells. Researchers have sought to overcome its solubility limitations and enhance its therapeutic efficacy by conjugating paclitaxel to HA. Additionally, this approach can potentially reduce drug-related toxicities associated with conventional formulations. Furthermore, other anticancer agents are successfully linked to HA beyond paclitaxel, aiming to overcome toxicity and impart new physicochemical characteristics to the drug. These efforts seek to improve drug stability, enhance targeted delivery, and optimize therapeutic outcomes. These advancements in HA-based conjugates and derivatives showcase the potential of HA as a versatile platform for improving the delivery and efficacy of various anticancer agents. Such research holds promise for developing safer and more effective treatments for cancer patients [105, 156]. Eurand Pharmaceuticals implemented a similar strategy using methotrexate (MTX), an antimetabolite and folic acid analog commonly used as an antineoplastic drug. They developed an HA-MTX conjugate and conducted studies to evaluate its efficacy. The HA-MTX conjugate demonstrated significant activity in a liver metastasis tumor model, indicating its potential in treating metastatic liver tumors. Additionally, it exhibited activity in a mammary carcinoma model, demonstrating its effectiveness in combating breast cancer. These findings highlight the promising therapeutic potential of the HA-MTX conjugate in targeting and treating neoplastic conditions. By conjugating MTX with HA, the researchers aimed to enhance drug delivery, potentially improving the treatment outcomes and reducing adverse effects associated with conventional MTX formulations. This research demonstrates the valuable application of HA-based conjugates in expanding the therapeutic options for anticancer drugs like MTX, potentially offering more effective and targeted treatments for liver metastasis and mammary carcinoma [157]. Toxicology and pharmacokinetics analyses have displayed an extended half-life and amplified area under the curve (AUC) worth concerning free MTX [158]. Recent work has highlighted the importance of hyaluronan in oncology and should be further researched.

HA for skin

The skin serves as a homeostatic indicator of overall physical and emotional well-being. Alterations in dermal characteristics such as temperature, tone, muscle tension, and hydration reflect somatic and emotional changes that occur in an individual, with the latter being beyond conscious control [134]. Skin aging is a complex, progressive, and irreversible process marked by biochemical, morphological, and biophysical changes in the body. With the global population aging and the increasing aesthetic demands of patients, the desire to appear youthful and healthy is gaining momentum. In the past, surgical interventions were the primary option for rejuvenation [135]. However, novel noninvasive outpatient techniques have revolutionized aesthetic dermatology. Injectable fillers, in particular, have garnered considerable attention due to their efficiency and safety [136]. Wrinkle filling remains a primary indication, but restoring volume and contours to achieve a natural, balanced look is equally vital in contemporary aesthetics. Additionally, advanced techniques have been developed to correct chin/nose deformities, and it is preferable to use biodegradable agents for aesthetic dermatology instead of permanent ones [137, 138]. Complications arising from using permanent agents in aesthetic dermatology can be particularly challenging to treat compared to those associated with biodegradable agents. Fortunately, a range of skin treatments, including injectable hyaluronic acid-based fillers (HAFs), are available to address age-related changes [139]. Fillers constitute an effective tool in skin rejuvenation, and while bovine collagen was previously the primary filler used for wrinkles and lip augmentation, since 1996, HA has become the preferred choice. Modern HA is produced through bacterial fermentation, eliminating the risk of animal-derived contamination, and because it is not species-specific, skin testing is not required [137, 140]. Recent statistics suggest that over 85% of dermal filler surgeries utilize HA derivatives. This figure will rise in the future, as no other potential filling agent is currently available to counter HA's popularity [141]. HA's efficacy, ease of administration, low toxicity, and high safety profile have made it the gold standard compound among fillers, and the list of cosmetic dermal fillers available continues to expand rapidly [142]. As the aging population seeks inexpensive and safe options to revise the signs of aging without major surgery, the popularity of HA-based fillers is only expected to increase [142].

The strength of HA to cross the biological barrier is primarily determined by its molecular weight (MW). High-MW HA, with a weight exceeding 600 KDa, has poor skin permeability and typically forms a very thin protective hydration veneer on the epidermis [45]. In contrast, low-MW HA can penetrate through the deeper layers of the skin and permeate up to the hypodermis level. Thus, using HA enables a comprehensive rejuvenation of the face, as thin HAs can be administrated by mesotherapy to rehydrate the skin's surface. In contrast, high-MW HAs have been used to address wrinkles, nasolabial folds, dark circles, under-eye hollows, and lip augmentation. High-MW HAs are also employed for tissue volume increase, highlighting the versatility of this approach [19]. Due to its unique viscoelasticity, biocompatibility, biodegradability, and non-immunogenicity, HA has been extensively applied in dermatology for its biomedical benefits, including skin anti-aging, anti-wrinkle, anti-nasolabial folds, skin rejuvenation, and dermal hydration properties [143]. HA can be administered through various routes, including ophthalmic, nasal, parenteral, topical, and intravenous, and in clinical, nutraceutical, nutritional, and cosmetic industries. Topical delivery systems offer several advantages over oral or parenteral delivery modes, such as overcoming the hepatic first-pass metabolism, improved prognosis, excellent dermal barrier permeability, and minimizing possible toxicity-related clinical adverse or side effects [45]. HA has been utilized to formulate microparticles for controlled dermal release of caffeine to medicate cellulite, topical hydrogels containing nonsteroidal anti-inflammatory drug diclofenac to manage actinic keratosis, and for manufacturing, HA-derived liposomes for healing dermal and subcutaneous wounds [45]. HA has also been extensively utilized for preparing transdermal formulations through various approaches, such as chemical tempering to create conjugates or physiochemical methods to create microneedles, including OVA-HA conjugates for noninvasive vaccination and HA-based microneedles for controlled release of insulin to treat Type I diabetes [144]. In current cosmetic trends, HA is commonly found in moisturizers, creams, gels, and serums due to its hydrating properties, lipid barrier enhancement, fine lines and wrinkles reduction, and skin tightening effects. Moreover, sunblock derived from hyaluronan may assist in preserving spry skin and shielding it against the detrimental impact of ultraviolet radiations

attributed to HA's potential free radical scavenging effects. Overall, HA's diverse and promising applications in various fields of medicine and cosmetics have established it as a highly desirable and versatile biomaterial.

Covid-19 and hyaluronic acid

In modern times, the coronavirus disease 2019 (COVID-19) pandemic posed a severe threat to international biosecurity and public health. The etiology of this respiratory illness is a novel coronavirus known as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Clinical investigations revealed that SARS-CoV-2 infection triggers a biphasic immune response. During the initial incubation period, a first-line defense-based protective phase is activated, which requires the activation of the adaptive immune system to intercept the virus replication and disease progression to severe stages. Therefore, strategies to enhance immune responses at this stage are paramount [145]. To establish an effective host immune response during the disease incubation period, the host must be in good physical condition, which can induce peculiar antiviral immunity. However, if the adaptive immune response is compromised, the infection will continue replicating, leading to massive tissue damage, particularly in tissues with high ACE2 expression [146]. This triggers an inflammation-driven damaging phase characterized by lung parenchymal tissue inflammation mediated primarily by alveolar macrophages and other granulocytes. Pneumonitis is the primary etiology of lethal upper and lower respiratory tract disorders during the severe stage of the disease. Hence, suppressing the proinflammatory system is critical to managing the clinical symptoms when severe damage to lung parenchyma occurs. SARS-CoV-2 infection is classified into three different stages: stage I is an incubation phase when the patient is usually asymptomatic and sometimes the virus cannot be detected in body specimens; stage II, a non-critical symptomatic phase with detectable viral immunogens; and stage III, an extreme respiratory or general symptomatic stage with elevated viral load in the body. Histopathological examinations of the tissues collected from COVID-19 patient atopies revealed edema and the presence of abnormal hyaline membrane pulmonary mesenchyme, forecasting the existence of acute respiratory distress syndrome (ARDS) [147].

Hyaluronan, a primary constituent of the lung extracellular matrix (ECM) in the lungs, is found in the pulmonary mesenchymal tissue. It is a key player in airway homeostasis by regulating cellular functions, growth factors, cytokine behavior, and biomechanical forces, among other aspects [148]. In various respiratory diseases, such as COPD, atypical asthma, idiopathic arterial pulmonary hypertension, and ARDS, airway hyaluronan levels are elevated and are associated with poor lung function [149, 150]. Furthermore, there is mounting evidence that hyaluronan and its degradation products are of critical significance in the pathophysiology of the respiratory tract. Aerosolized exogenous hyaluronan has been shown to exert beneficial effects against airway inflammation, protect against bronchial hyperreactivity and remodeling, and disrupt biofilms associated with chronic infections [151, 152]. Therefore, exogenous hyaluronan may serve as a novel therapeutic option in conjunction with conventional medical or surgical therapy for respiratory tract diseases involving inflammation, epithelial survival, remodeling, and the microbiome, such as rhinitis, asthma, COPD, cystic fibrosis, ARDS, and pulmonary hypertension, and should be considered for COVID-19 treatment [153, 154].

Hydroxychloroquine is currently one of the leading drugs being investigated worldwide for COVID-19 [155]. To mitigate its intrinsic toxicity, enhance its bioavailability, localization, and controlled release, and improve its efficacy, a proposal has been developed to conjugate it with HA to formulate a hyaluronic acid-hydroxychloroquine conjugate [156]. The ability of hyaluronic acid to form conjugates with pharmacologically active compounds offers an opportunity for this approach [157]. However, no clinically approved immunoglobulins or specific therapeutic drugs are available for COVID-19. Rigorous research is ongoing to screen potential therapeutic targets that may aid in developing effectual prevention and successful treatment strategies [158].

HA in drug delivery

Conjugating active ingredients to HA can create pro-drugs with efficient physicochemical features, improved shelf life, stability, and therapeutic potency and safety compared to free drugs [2]. Since hyaluronan possesses multiple physiochemical properties, HA-drug conjugates can exert their biological activities as such. Moreover, therapeutic actions can also be achieved upon drug release when the chemical bonds linking active ingredients and HA are catalyzed in the biological system, ideally at the peculiar target sites [48, 159]. A diverse range of active ingredients

can be compounded into HA for topical or intravenous application. HA is primarily utilized in controlled release or targeted drug delivery systems because of its excellent biocompatible gelation properties. One example is a polymer network created by gelating the adipic dihydrazide derivative of HA cross-linked with reagent poly (ethylene glycol)–propionaldehyde. This macromolecule gives rise to a hydrogel [72, 160]. Transdermal drug delivery using HA is possible, but the challenge lies in that HA, a high molecular weight compound, cannot cross the stratum corneum. To overcome this issue, nanoparticles of HA can be utilized, which can deliver the drug to the dermis. Moreover, bioavailability has always been a limitation in ocular drug delivery due to various barriers [161, 162]. However, coating chitosan-based nanoparticles with HA can increase the cornea's retention time, thereby enhancing dexamethasone's bioavailability by almost two times. These nanoparticles are also suitable for gene delivery, as they are highly compatible with the mucous and ensure efficient transfer without loss of cell viability [163]. During eye-related surgeries, HA is employed to equilibrate the morphology of the frontal chamber. HA-based nanoparticles (NPs) in polymeric thin films can also serve as a hybrid therapeutic system for the controlled release of vitamin E to manage skin wounds [164]. HA formulations with phospholipids can develop surface-modified liposomes before or after liposome formulation [165]. HA-modified liposomes have shown great promise as drug carriers. They enhance drug stability in the dynamic blood flow, extend drug half-life, lower toxicity, improve tissue absorption and barrier permeability, sustain prolonged or controlled active ingredient release, and enhance therapeutic efficacy through synergistic actions [166]. HA and its derivatives have a strong affinity for CD44 receptors, specific receptors in cancerous tumors [167]. This makes HA an ideal candidate for targeted and effective delivery of anticancer drugs, given its high biocompatibility, non-immunogenicity, and non-toxicity [105]. Many approaches, like nanotheranostics and nanocarriers such as carbon tubes, quantum dots, and graphene, are used in conjugation with HA to achieve an efficient delivery system. In addition to anticancer drugs, HA is also used to deliver genes and proteins. HA-based microspheres and microparticles have been investigated as potential combinational compounds to enhance the bioadhesive properties, control drug delivery, and improve the ointments' physical quality. For instance, spray-dried HA-based microspheres have shown precision delivery of ofloxacin to the pulmonary tissues via nasal inhalation. This leads to better pharmacological impact than free ofloxacin and intravenous or oral routes of administration. HA and its derivatives have been utilized alone or in conjugates to formulate pro-drugs, surface-modified liposomes, NPs, microparticles, hydrogels, and other controlled drug delivery carriers [168, 169]. All these drug delivery systems are subject to intensive pharmaceutical optimization for harnessing the maximum benefits. This extensive biomedical and clinical reach is still in its infancy, as most of the findings are based on in vitro experiments, and there is a long way to go for the industrialization of HA-based pharmaceutical products [170].

Conclusion

This paper comprehensively overviews the natural biopolymer HA and its unique physicochemical characteristics, including biodegradability, biocompatibility, efficacy, safety, and immunogenicity (Table 1). HA has been generally utilized and proven successful in various biomedical applications, including controlled drug delivery and release, osteoarthritis treatment, open-wound healing, ocular surgery, odontology, cosmetology, regenerative medicine, and biomedical engineering. Extensive research from academia and the biomedical industry has been carried out to understand the various derivatives of HA and their applications. The game-changing potential of HA has been a driving force for this research. The application of HA for 3D bioprinting has also been discussed, along with its proposed use in combating the current COVID-19 crisis. Overall, the versatility and potential of HA make it a promising candidate for numerous future biomedical applications, and continued research in this field will undoubtedly yield more significant findings.

Table 1. Summarizing different types of HA forms available, their properties, and potential applications

Type of HA	Molecular weight	Properties	Potential application	Reference

Nanofibers	15–150 kDa	High porosity Mechanical strength Flexibility compared to microfibers Large surface area-to-volume ratio	Wound dressing Scaffolds for tissue engineering Drug release delivery systems Serums for cosmetics Nano masks Coatings for medical devices	[171–175]
Microfibers	100–700 kDa	Solubility is adjustable Different textile technologies can weave it Sterilizable	Tissue regeneration Pre- or postsurgical use Drug delivery or another active ingredient delivery Controlled release delivery system	[176–178]
Staple fibers	350 kDa–2.7 M	It can be loaded with growth factors or MRI contrast agents It can be combined with other HA forms for multilayer applications	Drug delivery and drug release materials Active layers for wound healing devices 3D structures Antiseptics Hemostatic Pads Scaffolds with GFs	[179–182]
Hydrogels	60–1000 kDa	Fully biocompatible and biodegradable Possible to incorporate cells, fibers, micro or nanoparticles, or active substances	Scaffolds Regenerative medicine Viscosupplementation Postsurgical adhesion Reservoir drug release Wound healing Cartilage tissue engineering Bioprinting Contact lenses preparation Super porous hydrogels in hygiene products	[73, 183–185]

Thin Films	15–1000 kDa	Swelling, degradation rates, and mechanical properties can be controlled by the type of modification and the degree of substitution	Prevention of postoperative adhesions Tissue engineering (cell sheets) Controlled release of active substances or growth factors Soluble or insoluble options Controlled dissolution materials Transparent or colored	[78, 180, 186, 187]
Micelles	10–20 kDa	Self-assembly into polymeric micelles with distinctive core–shell structures Non-covalent encapsulation of poorly water-soluble drugs HA in the shell can be used as a targeting molecule	Dermatology Topical applications and carrier system Enhancing penetration of encapsulated compounds into skin, hair, and nails Drug delivery systems—Parenteral applications	[52, 188–191]

Future perspective

Looking ahead, the future perspective of HA and its formulations are propitious and diverse, with ongoing research indicating novel applications and opportunities in various fields. Genetic manipulation of the HAS synthase enzyme and isoenzymes in cancer therapy offers a new approach to combat cancer progression. At the same time, research into identifying cancer-associated HAS proteins presents new opportunities for cancer therapy. In regenerative medicine, HA derivatives have significant implications for immunomodulation, angiogenesis, nerve regeneration, and hybrid materials, suggesting new avenues for treating novel diseases such as COVID-19. In addition to cancer therapy and regenerative medicine, HA can potentially treat chronic inflammation, cardiovascular disease, and neurodegenerative disorders, with new and innovative applications emerging continually. For example, HA-based hydrogels are being explored for controlled drug delivery and drug release, biotechnology, and biosensors for detecting disease biomarkers. At the same time, HA is being investigated as an adjuvant in vaccines for infectious diseases.

Furthermore, 3D bioprinting using HA-based bioinks shows significant potential for tissue engineering and regenerative medicine. Advances in genetic engineering and biotechnology offer the production of tailored HA derivatives with enhanced properties and functionality, expanding the scope of its applications. Hyaluronic acid has also shown promising results in wound healing and skin regeneration, making it a popular ingredient in cosmetic products. At the same time, its potential in treating eye disorders and orthopedic applications is being actively researched. Its biocompatibility and ability to mimic natural ECM components make it an ideal candidate for bioengineering and implant coatings. At the same time, its presence and expression level can be correlated with disease severity and progression, making it a valuable tool for diagnosis and monitoring. As our understanding of HA and its properties continues to evolve, the possibilities for its applications and potential in biomedical research are vast. The future of HA and its derivatives looks bright, with continued research offering the potential for developing innovative therapies and treatments.

Author contributions

ARCS and HMUF were involved in data collection and analysis, manuscript writing. HA and PRK helped in manuscript writing, editing, coordination. SN assisted in supervision, manuscript editing. NM contributed to manuscript structure, conceptualization, administration, supervision. All authors have read and approved the manuscript.

Funding
