Begonia rubrovenia C.B. Clarke (Begoniaceae) is an ornamental plant majorly found in North Easton Himalayan regions especially in the states of Arunachal Pradesh, Meghalaya, Tripura and Manipur and is also found in Bangladesh [8]. In Meghalaya, the plant is locally named as Johusia by the Jaintia tribes where, the tender shoots and roots of the plant are commonly used as a vegetable and herbal tea prepared from the leaves, used as a best remedy to treat colic and dysentery like illness [8–10]. Traditionally, *B. rubrovenia* roots are used by the tribal peoples in Meghalaya to treat diarrhoea, liver disorders, stomach problems, peptic ulcers and skin related disorders [8, 10, 11]. Yet, there are very less reports available on the phytochemistry and pharmacological activities on this plant. However, the genus Begonia has been reported to have quercetin, rutin, luteolin, vitexin, isovitexin, orientin, isoorientin, friedelin and beta-sitosterol as some of the major phytoconstituents [12]. The plant under study is traditionally used to treat diarrhoea, however the traditional claim of the plant against diarrhoea is still not scientifically proven. Thus, the current study is an attempt to justify the antidiarrhoeal potential of *B. rubrovenia* using chemical-induced diarrhoea models following *in- vivo* and *in-silico* protocols.

Methods

Extraction and phytochemical evaluation

The plant *B. rubrovenia* was procured from West Khasi hills district of Meghalaya, India and was authenticated by Dr. Dongarwar, a botanist of our institute (Specimen number 10705). Next to authentication, the roots of the respective plant were dried under shade for at least 2–3 weeks. Then the dried roots were ground into coarse powder, further the coarse powder material (500 g) was extracted with ethanol as solvent (1.5 L) by Soxhlet assembly. After extraction, the volume of the collected extract was concentrated by rotary evaporator and the final extract (4.94% w/w) was kept under desiccator for further use. After complete extraction procedure, the obtained extract was screened for primary and secondary phytochemicals following standard test protocols [13]. Further, the screened phytoconstituents (total alkaloids, phenolics, tannins, saponins, and carbohydrates) were quantified as per the procedures described by Prasad et al. [12].

Standardization of extract

The occurrence of quercetin in ethanolic extract of *B. rubrovenia* (EBV) was confirmed by thin layer chromatography (TLC) screening and therefore quercetin ((Sigma-Aldrich, USA) was used as a standard marker for standardization of EBV using High Performance Liquid Chromatography (HPLC). For HPLC analysis, stock solution of EBV (1 mg/mL) and quercetin (0.1 mg/mL) was prepared in methanol. Further, a solution of methanol and water constituting 0.1% formic acid (80:20) was employed as a mobile phase with 10 µL of injection volume and 1.0 mL/min flow rate. The peaks of extract were matched with the standard quercetin peak with respect to retention time and presence of quercetin was confirmed [14].

Animals

Before selection of animals, the experimental protocol for antidiarrhoeal study was approved from the Institutional Animal Ethical Committee (IAEC/UDPS/2022/01 on 21/05/2022). After approval, healthy Wistar rats of either sex (150–200 g) were taken from the registered central animal house of our department (Reg. No.: 92/1999/CCSEA).

The animals were placed in their respective cages for at least 1–2 week to acclimatize in surrounding environment providing temperature, humidity and lightening facility along with feed and water as per standard protocol.

Acute oral toxicity study

Acute oral toxicity (AOT) study was carried out to determine the safety margin of EBV employing Organization for Economic Cooperation and Development (OECD)- 425 guidelines. Animals (overnight fasted) under the protocol were administered orally with EBV in increasing manner and different neurological and behavioural parameters were observed like sleep, palpitation, diarrhoea, drowsiness, sedation, tremors, lacrimation, writhing, salivation, gasping, convulsions and lowering respiratory rate for 48 h. Further, for any kind of mortality, these animals were monitored for another 14 days. In addition, weight of organs of the animals treated with EBV and control were measured and difference in their weights was recorded [15, 16].

Normal faeces excretion (NFE) rate

Previously fasted rats (3 h) were randomly categorized into six groups: First group (Normal control) was administered with suspension of 0.5% w/v carboxy methyl cellulose (CMC), second to fourth group was served with three different doses (100, 200 and 300 mg/kg) of EBV (dose selection was confirmed from AOT study), fifth group rats were treated with quercetin 50 mg/kg and the last group was served with standard loperamide drug (Torrent Pharmaceuticals India Ltd., India) at a dose of 2 mg/kg. All the test samples were prepared in 0.5% w/v CMC and were given orally using oral gavage. Weight of faeces in all the groups were noted in wet as well as in dry conditions (dried at 50 °C for 24 h) at 1st, 3rd, 5th and 7th hours after administration of EBV and finally wet to dry ratio was calculated [17].

Castor oil-induced diarrhoea

Castor oil induced (COI) diarrhoea rat model

In this model, castor oil was served as diarrhoea inducing agent, which was given after the gap of one hour of treatment to all the rats under study except the normal control rats. The fasted rats were randomly grouped into six groups, among them group 1 (Normal control) and group 2 (Diarrhoea control) rats received 0.5% CMC suspension. Rats from group 3–5 were administered with EBV at the dose of 100, 200 and 300 mg/kg p.o. respectively, and rats in groups 6 and 7 received quercetin and standard loperamide. All the rats after receiving castor oil (1 ml) were immediately placed in cages previously lined with plastic sheets and different diarrhoeagenic parameters were observed and determined for a period of 4 h after castor oil administration [18, 19].

COI gastrointestinal transit test model

This model was used to evaluate the antimotility effect of EBV and quercetin by employing charcoal meal. Approximately, 18 h fasted rats were divided into five groups, where 0.5% CMC suspension was prepared and given to Group 1 (Normal control) and Group 2 (Diarrhoea control) rats orally. Group 3 rats were administered with optimized dose of EBV, i.e. 200 mg/kg, which was confirmed from NFE study and COI diarrhoea rat model. Quercetin and atropine (0.1 mg/kg s.c.) (Sigma-Aldrich, USA) were administered to Group 4 and 5 rats, respectively. Further, 1 mL castor oil, was administered to rats, 30 min after the above treatment. This was followed by administration of 1 mL of suspension of 5% deactivated charcoal meal prepared in aqueous tragacanth (10%), 30 min after castor oil administration. Then, all the animals were sacrificed after 30 min of charcoal meal administration and intestinal part was isolated and distance travelled by the charcoal was measured with respect to total length of intestine. Finally, Peristaltic Index (PI) in percentage was calculated and was compared with diarrhoea control rats [18].

COI intestinal fluid accumulation test

Before commencing the protocol, rats were fasted for about 18 h and were categorized into 5 different groups with 6 animals in each group. Group 1 and 2 were served as normal control and diarrhoea control and received 0.5% CMC suspension by oral gavage. Groups 3–5 were treated with EBV (200 mg/kg), quercetin and loperamide, respectively. Diarrhoea was induced by giving castor oil (1 ml) to all rats except normal control rats just half an hour after the treatment. Immediately, 30 min after receiving castor oil, all the rats were sacrificed to remove the small intestine. Intestinal volume and weight of intestinal content of each rat were measured from each group [15].

PGE_2-induced enteropooling

Previously fasted rats were classified into four group (n = 6), where first (Normal control) and second (PGE_2 control) group animals received tragacanth suspension (2% w/v) orally and third and fourth group animals were treated with EBV extract (200 mg/kg) and quercetin (50 mg/kg) orally. PGE_2 (Astra Zeneca, India) was used as an inducing agent and was prepared in saline solution which contained 5% alcohol. PGE_2 was introduced via gavage in rats from groups 2 to 4. About 30 min later, all the rats were killed and small intestine was removed, intestinal volume was measured by using measuring cylinder [15].

Ions concentration and cytokines estimations

The colons isolated during the COI fluid accumulation test were first rinsed, homogenized in deionized water and finally centrifuged. The supernatant received after centrifugation was analysed for the determination of concentration of different ions like Na^{2+}, Ca^{2+}, Cl^- and K^+ with the help of Nulyte Electrolyte Analyzer [20]. Further, cytokines level (IL-1β and TNF- α) were also checked in previously isolated colonic tissues from different groups of rats using marketed Enzyme-linked Immunosorbent Assay (ELISA) kits (R&D Systems).

Na^+/K^+–ATPase assay

Na^+/K^+–ATPase assay was carried out to determine the efficacy of EBV and quercetin against Na^+/K^+–ATPase protein. The colonic tissues collected from the dissected rats from each group were first thoroughly cleaned. Then, they were homogenized according to the method by Gal-Garber et al. [21]. The homogenized solutions obtained were centrifuged and the supernatant collected were utilized for Na^+/K^+-ATPase assessment as per the method described by Parmar et al. [22].

Biochemical analysis and histopathology

The colonic tissues procured from the sacrificed rats were utilized for biochemical analysis. Initially, the colonic tissues arranged from COI fluid accumulation test were rinsed by tyrode solution, homogenized with 7.4 pH phosphate buffer and supernatants obtained after centrifugation of homogenized solutions were used for the estimations of different biochemical analytes. Nitric acid (NO) was estimated in the colonic segment by adapting the method given by Green et al. [23] and total carbohydrate content was evaluated by Yemm and Willis method [24]. Total DNA and protein concentration were determined by using methods described by Burton [25] and Lowry et al. [26] respectively. Further, the levels of antioxidants (SOD, CAT and LPO) were analysed in rat's colon with the help of standard protocol mentioned by Laloo et al. [27].

Histopathological studies were performed on colons collected from COI fluid accumulation testing. The initially blotted, dried and fixed (10% formalin) colons were dehydrated (with acetone) and finally embedding was carried out using paraffin wax. The colons fixed in paraffin wax were cut into small and thin sections with the help of microtome. Before observing the sections into the microscope (Leica DM-2000, Leica, Germany), they were stained with haematoxylin and eosin staining reagent for clear understanding of the histopathology.

In silico study

Preparation of the ligand

The ligand, quercetin, was prepared using the Marvin sketch tool in the Sanjeevani online program. The resulting 3D structure of the ligand was then imported into Biovia Discovery Studio 2022 (DS 2022) software. To optimize the ligand's energy, an energy minimization process was performed using the CharmM forcefield. Additionally, multiple conformations of the ligand were generated based on an *in-silico* pH of 7.4. Among these conformations, the one with the lowest energy was selected and subsequently docked into the active site of the enzyme protein.

Preparation of the proteins

The PDB structures of the proteins TNF-α (PDB ID: 1TNF), IL1-β (PDB ID: 1I1B), and EP3 prostanoid receptor (PDB ID: 6AK3) were obtained from the RCSB PDB website (https://www.rcsb.org/). The protein structures were prepared using the "Prepare Proteins" protocol incorporated in DS 2022. During the preparation, all water molecules were removed from the proteins and the protein structure was minimized using CharmM forcefield. The entire process was conducted with an *in-silico* pH of 7.4 to ensure consistency.

Molecular docking

The docking process was conducted using the CDOCKER protocol, which is known for its accuracy in predicting ligand–protein interactions. Following the docking simulations, the binding energy of ligand–protein complex was calculated. To refine the ligand conformation and to improve the accuracy of the results, an *in-situ* ligand minimization step was performed. The calculation of the binding energy took into account the non-bonded interactions, with a non-bond list radius of 14.0 Å employed for this purpose. Subsequently, an analysis of the binding poses and ligand orientation within the active site was conducted [28].

Molecular dynamic simulation

Among the three ligand–protein complexes obtained from molecular docking, the complex (Quercetin-6AK3) showing maximum binding energy was further subjected to molecular dynamics simulation using DS 2022. The simulation utilized CHARMm forcefield for both the small molecule and the protein. The system was set up with explicit periodic boundary conditions, maintaining an orthorhombic cell shape. The protein–ligand complex was solvated while ensuring a minimum distance of 7 Å from the boundary. A salt concentration of 0.145 was introduced, with sodium and chloride ions serving as the cation and anion, respectively. To initiate the simulation, an initial minimization step was performed using the steepest descent method. The minimization was carried out for a maximum of 5000 steps, with an RMS gradient of 0.1. Following the minimization, a standard dynamics cascade was executed, consisting of heating, equilibration, and production phases. The system was gradually heated from an initial temperature of 50–300 K over duration of 20 ps. Equilibration was then performed at 300 K without restraints for 50 ps. During the production phase, the system was simulated in the NPT ensemble at 300 K, using a temperature coupling decay time of 5 ps. The simulation was continued until the Root Mean Square Deviation (RMSD) reached a plateau. Snapshots of the system were saved every 20 ps during the production period. To assess conformational changes in the protein and ligand, several metrics were computed relative to the starting structure. These included the Root Mean Square Deviation (RMSD), Root Mean Square Fluctuation (RMSF), and Radius of Gyration (ROG). These metrics provided insights into the dynamics and stability of the protein–ligand complex throughout the simulation [29].

Network pharmacology

Novel bioactive targets based on docking results were selected to perform the network pharmacology. The suitability of the bioactive compound was evaluated using a cheminformatic tool and information regarding the bioactive target proteins was obtained from the UniProt database. The interactions between the bioactive target proteins and other molecules were analysed using STRING software ver 11.5 [30]. All the obtained data were then used to construct a network linking quercetin, target molecules, and protein–protein interaction data by Cytoscape ver 3.9.1 [31].

Statistical analysis

All the experimental data was analysed by one-way and two-way ANOVA using Tukey's multiple comparisons test, where results were represented as mean ± SEM (n = 6). The experimental data was statistically analysed with the help of GraphPad Prism having version 8 and the results were proven to be significant when p values were found to be <0.05.

Results

Phytochemical standardization

Approximately, 4.94% w/w yield of extract was obtained after extracting the roots from the plant *B. rubrovenia* using ethanol. The results from phytochemical screening revealed that EBV showed the presence of alkaloids, phenols, flavonoids, carbohydrates, proteins, amino acids and steroids. From phytochemical quantification, it was depicted that the extract was found to be rich in total phenolics (362.69 ± 17.44 mg/g GAE), total tannins (250.31 ± 14.47 mg/g TAE) and total flavonoid (197.36 ± 8.45 mg/g RE) contents. During HPLC standardization, well resolved and sharp peaks of quercetin was obtained which was matched with the peak of extract having retention time of 5.2 min and amount of quercetin was found to be 4.72% w/w in EBV (Fig. 1).

Fig. 1 [Images not available. See PDF.]

HPLC chromatogram of EBV representing the presence of quercetin. In figure, **A** HPLC chromatogram of standard

quercetin and **B** HPLC chromatogram of EBV showing presence of quercetin

AOT study

According to the AOT protocol, the rats under investigation did not depicted any abnormal type of behavioural and neurological symptoms up to the dose level of 2000 mg/kg, which confirmed that EBV up to a dose level of 2000 mg/kg was found to be safe (Details are available as Additional file 1).

Normal faecal excretion rate

Table 1 represents the effect of EBV on normal rate of faecal excretion. The results depicted that the rate of faecal excretion was significantly decreased at EBV 200, EBV 300 mg/kg and quercetin, respectively from 5th hr of treatment. But, in case of standard group, rate of faecal excretion was found to decline after 3rd hr of EBV administration itself. Wet to dry ratio was also found to be low in standard loperamide followed by EBV 200, EBV 300 mg/kg followed by quercetin.

Table 1. Effect of *B. rubrovenia* extract on normal faecal excretion rate

Treatment	Faecal wet weight (g) at various times (h) after treatment				Wet/dry weight of faeces
1	3	5	7	Normal Control	0.072 ± 0.003
0.328 ± 0.01	0.543 ± 0.02	0.905 ± 0.03	1.367 ± 0.05	EBV 100	0.379 ± 0.01[a]

Antidiarrhoeal evaluations

The results of COI diarrhoea model are demonstrated in Table 2, where, we observed that there was a significant delay in onset time in all the treated groups except in group administered with EBV at 100 mg/kg in comparison with the diarrhoeal rats. The other diarrhoeagenic features like total number of faeces, total number of wet faeces, total weight of faeces, total loss in body weight of rats, mean defecation rate, diarrhoea score and % protection also showed significant antidiarrhoeal effect in rats treated with EBV, quercetin and standard drug. From the overall observations, EBV at 200 and 300 mg/kg displayed similar response thus, confirming a ceiling effect of EBV from 200 mg/kg dose therefore, for further antidiarrhoeal studies, EBV 200 mg/kg was considered as optimized dose.

Table 2. Effect of *B. rubrovenia* extract on castor oil induced diarrhoea model

Groups	Onset time (min)	Total no of faeces	Total no of wet faeces	Loss in body weight	Total wt of faeces	Mean defecation in 4 h	Diarrhoea score	% Protection
Normal		4.50 ± 0.22		0.16 ± 0.005	0.27 ± 0.01	1.12 ± 0.05	–	100

In table *EBV* Ethanolic extract of *Begonia rubrovenia* at dose level of 100, 200 and 300 mg/kg, p.o.

[a]*pP*<0.05 vs. Normal

The results of COI gastrointestinal transit test are represented in Fig. 2A. The peristaltic index was found to be maximum in case of diarrhoeal control rats; however, it was significantly decreased in rats treated with EBV 200 followed by quercetin treated group, which confirmed antimotility effect of extract and its marker quercetin.

Fig. 2 [Images not available. See PDF.]

Effect of EBV and its marker quercetin on COI gastrointestinal transit test (**A**), COI fluid accumulation test (**B**) and PGE_2 induced enteropooling test (**C**). Values are mean ± S.E.M. (*n* = 6), where **a***p*<0.05 vs. normal control/ethanol in saline and **b***p*<0.05 vs. diarrhoea control/PGE_2 + ethanol. In figure, EBV 200 corresponds to Ethanolic extract of *Begonia rubrovenia* at 200 mg/kg, p.o.

In COI intestinal fluid accumulation test, the intestinal weight and volume were found to be higher in castor oil control rats. Nevertheless, the rats treated with EBV and quercetin showed significant decline in both intestinal weight and volume. The maximum decline was observed in rats who received EBV followed by standard loperamide and quercetin (Fig. 2B). In PGE_2 induced enteropooling test, similar results were obtained where PGE_2 control rats showed maximum intestine volume, however rats receiving EBV and quercetin showed significant decrease in intestinal content (Fig. 2C).

Ions concentration and cytokines estimations

The results of ion concentration determination are given in Table 3, which demonstrated that there was a significant

decrease in the ion concentration of colonic tissue of castor oil control rats. However, in case of treatment groups, there was a significant recovery in the altered ions level. Figure 3A and B represents the cytokine profiling, where the results depicted that, groups receiving EBV, quercetin and standard showed significant decrease in the cytokine levels while castor oil control rats showed significant hike in the levels of cytokines as compared to normal rats.

Table 3. Effect of *B. rubrovenia* extract on castor oil induced intestinal fluid accumulation

Groups	Weight of intestinal content (g)	Volume of intestinal content (mL)	% Inhibition	Na^+ (mmol/l)	K^+ (mmol/l)	Ca^{2+} (mmol/l)	Cl^- (mmol/l)

Na^+/ K^+–ATPase assay

Figure 3C represents the results of effect of EBV and its marker quercetin on Na^+/ K^+–ATPase. From the overall results, it was observed that the groups treated with EBV and quercetin showed profound increase in Na^+/K^+ –ATPase activity in comparison with the diarrhoeal control rats. The results demonstrated by EBV were quite comparable to that of standard loperamide.

Biochemical estimations and histopathological examination

The results of biochemical evaluations are illustrated in Table 4, where we observed that the NO content was observed to significantly decline, whereas cellular proliferative factors like DNA, carbohydrates and proteins were found to significantly escalate in rats receiving EBV 200, quercetin and standard when compared with rats from diarrhoea control group. The results of antioxidant profiling revealed that, the amount of CAT and SOD went on to significantly decline, while LPO level significantly enhanced in rats from diarrhoea control group. Nevertheless, in treatment group's rats, both the antiperoxidative enzymes showed marked enrichment in their levels followed by decrease in peroxidative enzyme LPO.

[a]p < 0.05 vs. Normal

[b]p < 0.05 vs. Castor oil

Figure 4 represents the histopathological changes observed in all the normal, treated and diarrhoea control rat colons. The histopathology of the rat colons in normal groups exhibited well intact and distinct microvilli with normalized glands, whereas the colonic tissues of diarrhoeal rats showed more disruption of epithelia and blunting of the microvilli. Nevertheless, the histopathological view of treated groups demonstrated epithelia free from disruption and well distinct villi, which clearly justified that EBV and quercetin have diarrhoea protecting potential.

In silico study

The calculated binding energies of quercetin with the proteins TNF-α, IL-1β, and EP3 prostanoid receptor are shown in Table 5. The table demonstrated that quercetin exhibited a higher affinity towards the EP3 prostanoid receptor compared to TNF-α and IL-1β proteins. This suggests that quercetin may have a stronger binding interaction and potential therapeutic relevance with the EP3 prostanoid receptor. To visualize the binding interactions between quercetin and the proteins, Fig. 5 displays different binding poses of quercetin at the active site of the respective proteins. The figure provides a visual representation of how quercetin interacts with the binding pocket of each protein, highlighting potential key interactions and conformational changes. These binding poses help in understanding the molecular interactions and potential mechanisms of action between quercetin and the target proteins.

Table 5. Observations of the molecular docking studies

Molecule	Target protein	PDB ID	Binding energy CDOCKER (Discovery Studio)
Quercetin	TNF-α	1TNF	−106.4030 kcal/mol
IL1-β	1I1B	−131.2166 kcal/mol	EP3 prostanoid receptor

Fig. 5 [Images not available. See PDF.]

Molecular docking studies of quercetin against different target proteins. In figure **A** represents 2D interactions of quercetin against IL-1β, **B** represents 3D interactions of quercetin against IL-1β, **C** represents 2D interactions of quercetin against TNF-α, **D** represents 3D interactions of quercetin against TNF-α, **E** represents 2D interactions of quercetin against EP3 prostanoid receptor and **F** represents 3D interactions of quercetin against EP3 prostanoid receptor

The results of the molecular dynamics study are depicted in Fig. 6. The figure provides information on several key parameters that were analysed during the simulation. Firstly, the RMSD of the different conformations was presented in comparison to the initial pose. The RMSD indicates the average deviation or fluctuation of the protein–ligand complex structures throughout the simulation. It helps to assess the stability and conformational changes of the complex over time. The RMSD plot in Fig. 6A demonstrates how the different conformations deviate from the initial structure during the simulation.

Fig. 6 [Images not available. See PDF.]

Molecular dynamics simulations of quercetin against EP3 prostanoid receptor. In figure, **A** Root mean square deviation, **B** Radius of gyration and **C** Root mean square of fluctuation

Additionally, Fig. 6B shows ROG of the protein over the course of the molecular dynamics study. The ROG is a measure of the compactness or overall size of the protein molecule. Monitoring the ROG provides insights into the protein's structural stability and any potential unfolding or compaction events during the simulation. Furthermore, the RMSF of different amino acid residues of the protein is also depicted in Fig. 6C. The RMSF analysis demonstrates the flexibility or mobility of individual amino acids in the protein. It highlights regions or residues that exhibit significant fluctuations or conformational changes during the simulation. The RMSF plot provides information on the dynamic behaviour of the protein and can identify regions that may play crucial roles in ligand binding or protein function.

Network pharmacology

Quercetin was the bioactive compound obtained from *Begonia rubrovenia* and TNF-α (encoded by the gene TNF), IL1-β (encoded by the gene IL1B) and EP3 (encoded by the gene PTGER3) were the bioactive target proteins as

shown by the docking studies. Quercetin was found to be neutrally charged with a molecular weight of 302.23 (> 1250). We found that TNF interacted with 10 different proteins, including IKBKG (encoding NF-kappa-B essential modulator), TRAF2, IL10, BIRC2, FADD, TRADD, and others. Out of 16 molecular processes identified by gene ontology analysis, a process of tumour necrosis factor receptor superfamily binding (GO:0032813) was found with the lowest false discovery rate of 1.77e-07 in which there was modulation of 5 proteins against 48 background proteins (Fig. 7).

Fig. 7 [Images not available. See PDF.]

Interaction network of *Begonia rubrovenia,* quercetin and its molecular targets

IL1-β was also found to have 10 different interacting proteins, including CASP1, CXCL1 &8, CCL3, IL1A, IL10, IL6 and others. Gene ontology data revealed 14 molecular processes, among which cytokine receptor binding (GO:0005126) had the lowest false discovery rate of 6.46e-10, modulating 8 proteins against 264 background proteins. Similarly, EP3 was found to interact with 10 different partners, including GNAS, GNAI1, 2 &3, GNAQ, PTGDR2, PTGES and others. Gene ontology identified a total of 9 molecular function, among which a molecular function of G-protein beta/gamma-subunit complex binding (GO:0031683), having the lowest false discovery rate of 3.30e-09 was identified, modulating 5 proteins against 20 background proteins (Fig. 7).

Discussion

Diarrhoea is a very common gastrointestinal disorder but ranks second in deaths among all the causes of deaths in developing countries profoundly due to lack of sanitation, unhygienic conditions, contaminated water as well as food, malnutrition, etc. [32]. Diarrhoea is either secretory or osmotic type depending upon its etiology [33]. The present investigation overviewed on the antidiarrhoeal efficacy of EBV using castor oil and PGE_2 induced diarrhoea rat models including molecular docking, dynamics and network pharmacological studies.

Oral acute toxicity study is carried out to determine the safest dose of drug for the evaluation of animal experimental study. Here, for estimation of diarrhoeal study OECD guidelines 425 was implemented. Up to 2000 mg/kg dose of the extract, there were no any abnormal behavioural or neurological signs observed in the treated animals which confirmed the extract to be safe up to above dosing. The normal faecal excretion rate study revealed that, the rate of excretion significantly declined in treated rats, which gives us an idea about the antisecretory potential of *B. rubrovenia* extract [19]. In castor oil induced diarrhoea rat model, diarrhoea was found to be more severe in case of diarrhoea control rats. But, the severity of diarrhoea was reduced in all the treated rats, which was depicted through the results showing delay in onset of diarrhoea, decline in total number of faeces, number of wet faeces and mean defecation rate. Also, the profound antidiarrhoeal activity of the EBV and its marker was confirmed from the low diarrhoea score and high % protection values. Both EBV at 200 and 300 mg/kg dose showed quite similar responses in both the studies, i.e. normal faecal excretion and castor oil induced diarrhoea models. Thus we may presume that, ceiling effect was observed from EBV 200 mg/kg and therefore, EBV 200 was considered as effective dose for the next entire antidiarrhoeal evaluations.

Castor oil obtained from the plant *Ricinus communis*, when ingested orally gets metabolized into ricinoleic acid by the intestinal lipase enzymes. This acid forms lesions on the intestinal mucosal membrane, which leads to changes in the permeability of mucosal fluid and disturbance in the electrolyte and water transport that results in hypersecretion and finally diarrhoea [34]. In the present study also, the intestinal volume significantly increased in diarrhoea control rats, whereas it was significantly recovered in rats treated with EBV and its marker quercetin as demonstrated in the results of COI fluid accumulation diarrhoea model. Ricinoleic acid metabolized from castor oil, after oral administration, increases the peristaltic activity of the intestinal smooth muscle [35]. The reduction in the peristaltic movement was observed in EBV and quercetin treatment group as demonstrated through the COI transit study showing very low peristaltic index. The antidiarrhoeal efficacy of EBV against inflammatory diarrhoea was also evaluated by using PGE_2 induced enteropooling study. PGE_2 enhances the gastrointestinal motility by interacting with EP3 receptors of the intestine thus, increase the intestinal volume which leads to diarrhoea [32]. The results of our analysis showed that the extract and quercetin were found to be effective in reducing the fluid volume, which

might be due to inactivation of EP3 receptors expressed in the small intestine.
Ricinoleic acid present in the intestine promotes the release of NO by activating the inducible nitric oxide synthase (i-NOS). Over expression of NO results in increased level of c-AMP mediated through activation of adenyl cyclase. This overall condition decreases the Na^+-K^+- ATPase activity [32]. The results demonstrated that, there was an over expression of NO in diarrhoeal rats, which tend to normalize after treating the animals with extract and quercetin, that ultimately enhanced the Na^+-K^+- ATPase activity. The upsurge in NO results in elevated oxidative stress, which is one of the important parameter responsible for provoking various types of gastrointestinal malfunctioning [34]. This oxidative stress decreases, the CAT and SOD level and increases the LPO level, which was depicted from the diarrhoea control group rats. However, in case of EBV and quercetin treated rats, there was restoration of altered change in the levels of oxidative enzymes, which helps in the maintenance of oxidative stress. Na^+-K^+- ATPase, a basolateral protein enzyme, plays a major role in transport and maintenance of nutrients and electrolytes [14]. Studies have suggested that diarrhoeal condition hampers the cellular proliferative factors (DNA, proteins and carbohydrates) causing decreases in their levels [36]. The cellular proliferative enhancing effect of the extract, quercetin and standard drug was confirmed through the increase in these parameters. The inducing agent castor oil, causes irritation to the intestinal mucosal membrane through ricinoleic acid resulting into inflamed mucosa and consequently release of inflammatory mediators like TNF-α and IL-Iβ, which was observed in diarrhoea control group [35]. Our results also showed that, there was significant decline in the above mediators after treatment, which suggests the role of EBV in treating inflammatory type of diarrhoea. The histopathological examination of colonic tissues confirmed the protective nature of the extract and its marker quercetin showing recovery from the destruction of epithelia and blunting of villi as observed in treated groups.
Flavonoids, alkaloids, tannins, terpenoids, saponins and steroids from the medicinally active plants plays critical role in treating diarrhoea [37]. Our extract was found to be rich in phenolics, tannins, flavonoids which was confirmed from the quantification results. Quercetin belongs to flavonoid category and its presence in the extract was confirmed through the HPLC analysis data. Quercetin was reported to have antidiarrhoeal potential by relaxing the smooth muscles of intestine, which ultimately inhibits the bowel movement by reducing the release of Ca ions (intracellularly) through the sarcoplasmic reticulum [38]. From the overall antidiarrhoeal study we may presume that, quercetin might be one of the major responsible phytoconstituent in the extract for the observed antidiarrhoeal activity in combination with other phytochemicals.
The molecular docking results indicated that, quercetin exhibited a strong affinity towards all the target proteins, particularly the human EP3 prostanoid receptor, with a binding energy of -150.69 kcal/mol. Quercetin was found to have two hydrogen bonds with active site amino acids viz. GLN:103 and SER:336 together with other non-bonded interactions. This suggests that quercetin forms stable interactions with the active site of the EP3 prostanoid receptor, indicating its potential as a ligand for this protein. Subsequently, a molecular dynamics simulation revealed that the RMSD value reaches a plateau after 5 ns, indicating that the complex has achieved stability. This suggests that quercetin remained compatible and firmly bound within the active site of the protein throughout the simulation. Regarding the receptor protein itself, the ROG analysis showed minimal and insignificant fluctuations. This implies that, the protein maintained its overall compactness and stability during the molecular dynamics simulation study. The limited fluctuation in ROG indicates that the receptor protein structure remained relatively intact and does not undergo significant conformational changes or unfolding. Additionally, the RMSF analysis of the amino acid residues further supports the stability of the receptor protein molecule [29]. The RMSF plot indicated that the individual amino acid residues exhibited minimal fluctuation and remained relatively stable throughout the simulation. This suggested that the receptor protein structure is robust and maintained its stability, supporting its functionality and ability to interact with ligands like quercetin [28]. Findings from this in silico studies conducted in this research suggest that quercetin has the potential to interact with the EP3 prostanoid receptor, which may contribute to its antidiarrheal activity.
Quercetin was found to exhibit wide-ranging effect on several molecules in the network analysis. TNF-α, besides interacting with several receptor molecules was also predicted to modulate apoptotic adaptor molecule FADD,

caspase regulator BIRC2, and NF-kappa-B modulator IKBKG [30]. IL1-β was found to interact with significant molecules such as Caspase1, CXCL1 which has chemotactic activity for neutrophils, CCL3 with inflammatory and chemokinetic properties and several interleukins. IL10 molecule was found in the network of both TNF-α and IL1-β indicating extended molecular level effect. Further EP3 molecules has several important predicted functional partners like Appetite-regulating hormone GHRL, Translin-associated protein X TSNAX, Microsomal prostaglandin-e synthase 1 PTGES, and several Guanine nucleotide-binding proteins. The network analysis showed that quercetin can have diverse range of effects by interacting with these proteins and modulate the molecular pathway [31].

Conclusion

The present study concludes that, the antidiarrhoeal potential of EBV may be due its secretion inhibitory and antipropulsive effect. In addition, EBV also showed reduction in NO level, restoration of ions and antioxidants, decreased proinflammatory cytokines expression and enhancement of Na^+-K^+- ATPase activity which may promotes its diarrhoea protecting efficiency. Thus, we have successfully justified the traditional use of *Begonia rubrovenia* in treating diarrhoea, where quercetin played a major role in combination with other phytoconstituents.

Acknowledgements

The financial support to Mrs. Rupali S. Prasad in the form of Senior Research Fellowship from Indian Council of Medical Research, Government of India (Award No. 45/18/2022/TRM/BMS) is deeply acknowledged. We also would like to acknowledge the support provided by Research Scholars Mr. Biru Dudhabhate and Mr. Akash Waghade during the pharmacological studies.

Author contributions

PRI, DL and SKP: Conceptualization, supervision, investigation, RSP, DL and NYY: Collected the plant material, authenticated and initial phytochemical standardization, RSP, NYY, SRD, and DL: Performed the initial pharmacological protocol, RSP, PS, MD, and SKS: Performed the biochemical analysis and cytokine profiling, RSP, SRD and JK: Performed the histopathological and ion analysis, JK, NR and SKS: Performed the docking dynamics and network pharmacology, RSP, SKP, PS and JK: Performed statistical analysis and interpretation of results, RSP, DL, NR, NYY and SRD: Prepared the initial draft of the manuscript, SKP and PRI: Finalized the manuscript and responsible for communication of manuscript to the Journal.

Funding

Funding from Indian Council of Medical Research, Government of India in the form of Senior Research Fellowship to Mrs. Rupali S. Prasad is acknowledged with deep gratitude.

Availability of data and materials

The data could be made available as on request of the journal.

Declarations

Ethics approval and consent to participate

All the pharmacological experimental protocols were performed after approval from Institutional Animal Ethical Committee of Rashtrasant Tukadoji Maharaj Nagpur University, Nagpur, Maharashtra, India (Ref. No. IAEC/UDPS/2022/01 dated 21/05/2022) and were conducted in accordance with accepted standard guidelines of National Institutes of Health Guide for Care and Use of Laboratory Animals. Studies involving plants must include a statement specifying the local, national or international guidelines and legislation and the required or appropriate permissions and/or licences for the study: The plant under investigation was collected from the West Khasi hills district of Meghalaya, India and all the necessary approval right from authentication of plant material approval of the research were been taken from the state government University authorities.

Consent for publication

The consent from all the co-authors have been taken regarding submission of the manuscript to Future Journal of Pharmaceutical Sciences for possible publication.

Competing interests

The authors have disclosed that there are no conflicts of interest. Further, consent from all the co-authors has been taken and the authors are entirely responsible for the composition and content of the article.

Ethnozoological importance of Eisenia fetida and experimental validation of its anticancer activity in ascites Dalton's lymphoma (DL) bearing mice

Borah, Manash Pratim1 ; Prasad, Surya Bali21 Nowgong College (Autonomous), Department of Zoology, Nagaon, India2 North-Eastern Hill University, Department of Zoology, Shillong, India (GRID:grid.412227.0) (ISNI:0000 0001 2173 057X)

ABSTRACT (ENGLISH)

Eisenia fetida, commonly known as the red earthworm, holds significant ethnozoological importance due to its traditional use in various cultures as a medicinal agent. This study aims to explore the potential anticancer effects of *Eisenia fetida* paste (EFP) and evaluate its therapeutic efficacy in mice with ascites Dalton's lymphoma (DL). The EFP extract demonstrated a significant antitumour effect, possibly by initiating programmed cell death and mitochondrial changes in the tumour cells. The viability of tumour cells exhibited a reduction over time due to EFP treatment. Comparative analysis with the reference drug cisplatin revealed that EFP exhibited fewer or no adverse effects on mutagenicity, hepatotoxicity, and nephrotoxicity in tumour-bearing hosts. EFP treatment was found to show progressive increase in the quantity of apoptotic DL cells over time suggesting a time-dependent impact on the induction of apoptosis in the treated groups. These results imply that EFP might serve as a safer substitute for cancer treatment and hold promise for developing new and improved therapeutic strategies against cancer. The main implication of the study is that EFP might serve as a safer substitute for cancer treatment. It suggests a promising avenue for developing new and improved therapeutic strategies against cancer, with the potential to enhance treatment outcomes while minimising adverse effects.

FULL TEXT

Background

Approximately 19.3 million fresh cancer cases across the globe were estimated by the Global Cancer Observatory (GLOBOCAN) in 2020, with China ranked first, followed by the USA and India in third. GLOBOCAN's predictions indicated that the figure of cancer cases in India is predicted to rise significantly by 57.5% from the number of cases reported in 2020 [31]. Cancer can arise from the abnormal growth and division of cells in various tissues throughout the body, giving rise to over a hundred distinct types of cancer. These different types of cancer can exhibit significant variations in their behaviour and how they respond to treatment [13].

The indications of cancer differ based on the disease's type and stage. Common signs may comprise persistent unexplained weight loss, pain, fatigue, changes in the skin, lumps or thickening of tissues, persistent cough or hoarseness, alteration in bowel or bladder patterns, and difficulty swallowing, among others [10, 39, 44]. The diagnosis of cancer involves different methods, such as physical examinations, medical history reviews, diagnostic imaging procedures (such as CT scans, X-rays, MRIs, or PET scans), laboratory tests (like blood tests or biopsies), and genetic testing [18, 21, 24, 36, 52]. The proper treatment options mainly depend on factors such as the cancer's stage, type, and location, alongside the patient's overall well-being [32, 37]. Among the treatment modalities radiation therapy, surgery, chemotherapy, hormone therapy, immunotherapy, and targeted therapy are the most common [7, 49]. Often, a combination of treatments is used to achieve the best outcome.

Across history, natural compounds have held a substantial role in uncovering anticancer medications. Several

commonly used cancer treatments have their origins in nature-derived sources like irinotecan, vincristine, paclitaxel, and etoposide derived from plants, while mitomycin C and actinomycin D come from bacteria and marine bleomycin [14, 15, 26]. These compounds are crucial in cancer therapy and are expected to retain their importance in the coming years. Extensive research has been conducted on phytochemicals, revealing their anti-carcinogenic properties through their influence on multiple mechanisms resulting in initiation, development, and succession of cancer [27, 51]. However, compared to plants, research on animal-derived products for cancer treatment is relatively less. The traditional medicinal practices in Algeria suggested consuming diverse wild animal species, including *Atelerix algirus*, *Varanus griseus*, *Corallium rubrum*, and *Cancer pagurus,* as remedies for various types of cancer [54]. Many communities in North-Eastern parts of India were also found to use different body parts of essential animal species such as gall bladder, horn, fur, intestine, bone, liver, blood, fat, heart as well as tongue as anticancer agents. The Wangsho and Tangsha tribes of Arunachal Pradesh, the Koch-Rajbonshi, Kalita, Ahom, Chutia, Tea tribes of Assam, and Rongmei of Manipur used various types of mammals, birds, reptiles, fish, molluscs, arthropods as home remedies for cancer [8, 29, 58]. While numerous researchers have recorded the therapeutic benefits of various plant species from Assam, there needs to be more comprehensive documentation regarding the traditional utilisation of animals in treating ailments specific to the region. The significance of blister beetles (*Mylabris cichorii*) in zootherapeutics among the Karbis residing in the Karbi Anglong district of Assam has been documented, along with its strong potential in combating ascites Dalton's lymphoma and Ehrlich ascites carcinoma, showing powerful anticancer effects [45, 46, 57, 58]. It was found that bee venom (melittin), scorpion toxin (Chlorotoxin), has significant inhibitory effects on the EGF-induced invasion, proliferation, migration of breast cancer cells [38]. In another study, it was found that marinobufagin exhibits anticancer effects against colorectal carcinoma both in vitro and in vivo [20]. In this study, the use of a particular earthworm (*Eisenia fetida*) was assessed for its anticancer potential in the laboratory against the experimental malignant tumour- murine ascites Dalton’s lymphoma. An initial ethnozoological survey of the adjacent areas of the few wildlife sanctuaries/national park of Assam and the information of some animals used against cancer-suspected disease, an earthworm species were selected to evaluate its anticancer potentials against a murine malignant tumour. The aim of this study is to contribute to the existing ethnozoological knowledge and explore the potential of EFP as an alternative and potentially safer anticancer treatment for future research and therapeutic developments in cancer treatment.

Results

Screening of antitumour activity of earthworm pastes/extracts

Different doses of *Eisenia fetida* paste (EFP) were used to check their antitumour activity regarding alterations in the viability of mice bearing ascites Dalton's lymphoma under different experimental groups. From the different doses of EFP (10, 20, 40, 80, and 160 mg/kg body weight/day) used, the highest increase in the life span in mice carrying ascites Dalton's lymphoma (in mice with DL was noted to be 49.47% with a dose of 40 mg/kg body weight (Table 1).

Table 1. Antitumour activity of EFP against murine ascites Dalton’s lymphoma

Earthworm extracts	Dose (mg/kg body weight/day)	Life span (days) (mean ± SD)	ILS %	Survival on day 30 Survival/total
EFP	Control	19.0 ± 0.816	–	0/10
10	20.2 ± 1.249	6.32	0/10	20
23.4 ± 2.498	23.16*	1/10	40	28.4 ± 1.955

49.47*	3/10	80	24.7 ± 1.417	30.00*
1/10	160	17.2 ± 1.619	− 9.4 7	0/10

Asterisk indicates a significant level of ILS%, which can be considered to have an enhanced curative effect against Ascites-Dalton's lymphoma

Thus, from the preliminary screening of antitumour activity at different doses of EFP, it was derived that the EFP dose of 40 mg/kg body weight has enhanced curative efficiency against murine ascites Dalton's lymphoma. The patterns of comparative changes in ILS after EFP and cisplatin treatments are shown in Fig. 1.

Fig. 1 [Images not available. See PDF.]

A Survival pattern and **B** percent increase in life span (%ILS) of tumour-bearing mice after EFP treatment. Results are expressed as mean SD (*n* = 5). The control refers to untreated tumour-bearing mice, while CDDP stands for cis-diamminedichloroplatinum (II) or cisplatin

Cell viability/cytotoxicity study

The result of EFP on the DL cell viability and spleen cells was checked using the trypan blue exclusion test. EFP treatment caused a time-dependent reduction in the case of tumour cell viability (Figs. 2 and 3). There was less cytotoxicity in spleen than in tumour cells (Figs. 4 and 5). These observations indicate that normal cells exhibited a lower sensitivity to the EFP extract when compared to tumour cells.

Apoptosis study

(AO/EtBr) staining

The DL cell nuclei as control were round-shaped with consistent green fluorescence, indicating viable cells (Fig. 6a). On the other hand, in all the treatment groups, different apoptotic characteristics were noted in DL cells at varying time points (Fig. 6b-e). Various apoptotic features were found in the DL cells of CDDP-treated mice also (Fig. 6f). In each of the treated groups (CDDP and EFP treatment), the quantity of apoptotic DL cells showed a time-dependent increase (Fig. 7).

Fig. 6 [Images not available. See PDF.]

Fluorescence-based apoptosis analysis using AO/EB staining in DL cells. Control DL cells **a**; EFP-treated for 24, 48, 72 and 96 h **b**, **c**, **d** and **e**; and cisplatin for 96 h **f**. Regular arrows showing apoptotic features with membrane blebbing/folding

Fig. 7 [Images not available. See PDF.]

Pattern of percentage apoptotic DL cells (apoptotic index) after treatment with CDDP and EFP. Results are expressed as mean SD ($n=5$)

Scanning electron microscopy and Transmission electron microscopy of DL cells

Scanning electron microscopy (SEM)

DL cells used as control were almost round shape with few projections in the membrane and evenly scattered ruffles over the surface (Fig. 8). CDDP-treated tumour-bearing mice showed a decline in ruffles or microvilli on DL cells and at 96 h of treatment membrane fusion and plasma membrane deformities were observed (Fig. 8f). The development of deformities in DL cells including loss of microvilli from the surface in the initial hour of treatment, the appearance of membrane bleb, as well as cell shrinkage were also observed in EFP-treated tumour-bearing mice (Fig. 8b–e).

Fig. 8 [Images not available. See PDF.]

SEM images including Dalton's lymphoma (DL) cells and control cells **a**, *Eisenia fetida* paste (EFP)-treated cell at 24–96 h **b–e**, Cisplatin (CDDP) treatment at 96 h **f**. The control DL cells exhibited a round shape with projections in the membrane and evenly distributed regular ruffles over the surface. Important cellular appearances on the cells, like membrane blebbing, cell membrane fusion, and cell deformities, are indicated by green arrows

Transmission electron microscopy (TEM)

TEM study was done in DL cells to analyse the possible alteration and changes inside the cells subjected to varying treatment conditions (Fig. 9). DL cells used as control showed cellular processes uniformly distributed over the cell surface along with large clear, uniform nuclei, uniform chromatin, smooth plasma damage and disruption of mitochondrial membrane along with cell membrane and distinct normal mitochondrial features with regular cristae (Fig. 9a, b). CDDP treatment in mice caused mitochondrial damage, cytoplasmic vacuolation, the disappearance of membrane processes and nuclear fragmentation in DL cells (Fig. 9c, d).

Fig. 9 [Images not available. See PDF.]

Ultrastructural features of DL cells. The blue arrow in the control shows DL cells **a** with distinct mitochondria cristae, The blue arrow showing mitochondrial damage and nuclear fragmentation after CDDP treatment from 96 h **b**, **c** and **d**, EFP treatment for 24-96 h **e–l** showed pronounced vacuoles and mitochondrial EFP-treated tumour-bearing mice also developed similar structural features in DL cells as observed for CDDP treatment as indicated by the blue arrows. The mitochondria showed rounded deformed cristae and a few vacuoles at 24 h of treatment (Fig. 9**e–f**). At 48 h to 96 h of EFP treatment, the DL cells showed fragmented nuclei, prominent vacuoles, membrane disorganisation, and disordered organisation of mitochondrial cristae with severe damage observed as indicated by the blue arrows (Fig. 9 **g–l**)

Assessment of toxicity of earthworm pastes/extracts [EFP]

Mutagenic studies

Sperm abnormalities

Different morphological abnormalities were observed in sperms of mice after CDDP and EFP treatment. The categories and forms of sperm anomalies triggered by CDDP encompass head without a hook, looping midpiece, head like a balloon, diffused head, amorphous head and so on. EFP-treated tumour mice also show sperm abnormalities like banana-shaped heads, coiled necks, hammer-shaped heads, and bulged heads in the tumour-bearing mice (Fig. 10b-g). However, mice with tumours treated with EFP showed reduced sperm abnormalities in

the tumour-bearing hosts compared to CDDP treatment (Table 2; Fig. 11).

Fig. 10 [Images not available. See PDF.]

Illustrative images depicting diverse forms of morphological abnormalities in mouse sperm under varying treatment conditions, **a** normal, **b** banana-shaped head, **c**, **d** balloon-like head, **e** hammer-shaped head, **f** coiled neck **g** bulged head

Table 2. Numeric assessment of diverse categories of morphological abnormalities in sperm observed across varying treatment conditions

Treatment	No. of sperms observed	No. of abnormal sperms	BSH	BLH	HSH	CN	BH	Mean of abnormal sperms
Control	500	4	1	0	0	2	1	0.8 ± 0.1
CDDP-treated	500	33	11	6	4	7	5	6.6 ± 0.2
EFP-treated	500	14	3	2	2	4	3	2.8 ± 0.34*

Fig. 11 [Images not available. See PDF.]

Changes in the prevalence of sperm abnormalities resulting from the administration of CDDP (Cisplatin) and EFP (Eisenia fetida paste) treatment. The findings are expressed as mean SD ($n = 4$). *$P \leq 0.05$ as compared to the chosen control; #$P \leq 0.05$ when compared to CDDP

The outcomes are shown as mean ± SD. The analysis was performed with one-way ANOVA long with Tukey's test, with a sample size of 4. A $p \leq 0.05$ level of significance was employed in comparison with CDDP. A normal mouse lacks a tumour and any treatment; CDDP = Cisplatin. BSH = banana-shaped head, BLH = balloon-like head, HSH = hammer-shaped head, CN = coiled neck and BH = bulged head. The examination of sperm was conducted on the fifth day of the treatment.

Chromosomal aberration analysis

A few aberrations, such as isochromatic break and chromosomal fragments, were detected within the bone marrow cells following EFP treatment (Fig. 12). The highest occurrence of the aberration mentioned above was observed after treatment of 24 h. There was a considerable decrease in the mean aberrant metaphase under 24–96 h treatment in both CDDP and EFP-treated groups. CDDP treatment in the tumour-bearing mice showed more chromosomal aberrations than the EFP-treated tumour-bearing mice (Fig. 13).

Fig. 12 [Images not available. See PDF.]

Illustrative images depicting bone marrow metaphase chromosome spreads. **a** Typical array of chromosomes, along with various categories of chromosomal abnormalities, including **b** &**c** Isochromatid break (ICB) and **d** Chromosomal fragment (CF)

Fig. 13 [Images not available. See PDF.]

Statistical examination of mean deviant metaphases, isochromatic breaks (ICB) and chromosomal fragment (CF) after treatment with CDDP **A** and EFP **B**. Results are expressed as mean SD ($n = 3$). The symbol "#" indicates significance at $p \leq 0.05$ compared to CDDP

Renal function (RFT) and Liver function (LFT) tests

Renal function test (RFT)

Serum creatinine, as well as urea level, were determined to examine the changes in renal toxicity. The serum creatinine and urea level measurement in the tumour-bearing control showed a slight variation from their normal counterpart. EFP-treated tumour-bearing mice showed a reduction in serum creatinine and urea levels compared to the control tumour group and were almost equalised with normal mice. However, administration of CDDP resulted in a notable rise in serum creatinine and urea levels compared to the control group (Table 3; Fig. 14.)

Table 3. Levels of serum creatinine and urea across various experimental conditions

Treatment groups	Creatinine (mg/dL)	Urea (mg/dL)
Normal	0.62 ± 0.01	42.76 ± 0.56
Control	1.09 ± 0.08	69.56 ± 1.91
CDDP-treated	2.75 ± 0.06	244.67 ± 2.51
EFP-treated	0.74 ± 0.01*#	48.68 ± 0.29*#

Mean ± S.D. values are expressed with ANOVA, $n = 3$, *$P \leq 0.05$ comparing with the consequent control; #$P \leq 0.05$ vs. CDDP. Blood samples were taken on the 5th day post CDDP or EFP treatment. The normal mice is devoid of tumour as well as any treatment. The control is the mice with tumour and without treatment, EFP = *Eisenia fetida* paste; CDDP = *cis*-diamminedichloroplatinum (II) or cisplatin

Fig. 14 [Images not available. See PDF.]

Changes in serum urea and creatinine levels (mg/dL) of mice with tumours under various treatments. Mean ± S.D. ANOVA was used to express the results as mean SD ($n = 3$), *$P \leq 0.05$ when evaluated with the corresponding control; # $P \leq 0.05$ when compared with CDDP

Liver function test (LFT)

The alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activity were examined to measure the toxicological changes in hepatic functions in hosts exposed to different treatment conditions.

The control mice showed increased activity of both AST and ALT as compared to normal (Table 4). However, compared to the control, EFP treatment exhibited a minimal alteration in ALT and AST activity. On the other hand, CDDP treatment displayed a considerable increase in ALT and AST activity compared to control mice (Table 4; Fig. 15).

Table 4. Levels of serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activity across various experimental scenarios

Treatment groups	ALT (SGPT) U/L	AST (SGOT) U/L
Normal	27.62 ± 0.52	32.10 ± 0.54
Control	58.17 ± 0.21	38.50 ± 0.65
CDDP-treated	85.71 ± 0.78	73.71 ± 0.51

EFP-treated	52.10 ± 0.83*#	26.44 ± 0.42*#

Mean ± S.D. values are presented with ANOVA, $n = 3$, *$P \leq 0.05$ as compared to the chosen control; #$P \leq 0.05$ when compared to CDDP. Blood was collected on the 5th day after CDDP or EFP treatment. The normal mice is devoid of any tumour or treatment condition and the control mice is with the tumour without treatment, EFP = *Eisenia fetida* paste; CDDP = *cis*-diamminedichloroplatinum (II)

Fig. 15 [Images not available. See PDF.]

Changes in serum ALT and AST in mice harbouring a tumour under various treatments. Results are expressed as mean SD ($n = 3$), *$P \leq 0.05$ compared to the control; # $P \leq 0.05$ compared to CDDP

Discussion

Ascites Dalton's lymphoma, also known as T cell lymphoma, has been consistently utilised as a significant model for experimental murine malignant tumours [40, 56]. The reliable measure to assess a drug's antitumour efficacy is considering the extension of the lifespan of the treated hosts with tumours (Prasad, Nicol et al. 2010, [56]. Examination of the survival capability of splenocytes and DL cells in various in vivo treatment scenarios indicated that EFP treatment elicited more significant cytotoxicity in DL cells compared to splenocytes. This suggests that EFP affects normal cells with lower sensitivity than its impact on DL cells (Figs. 4 and 5). The anticancer potential of *Eisenia fetida* extract/paste or compound isolated from it has been observed on a variety of other cancer cell lines such as HCT116 human colorectal cancer, MCF-7 breast carcinoma [34, 48], HeLa and LTEP-A2 cells [25]. This is the first study to look at the antitumor activity of an earthworm extract (Eisenia fetida paste, EFP) from Northeast India.

Apoptosis is an ordered and orchestrated cellular process controlled by a genetically regulated mechanism in different physiological and pathological conditions. It is a strongly held multi-step pathway responsible for cell death to control the cell number [28, 59]. It has a vital role in the development of tumour-related diseases along with other different illnesses. Unrestrained growth and malfunction of apoptosis mechanisms form essential components in the growth and advancement of a malignant tumour [9, 43]. Apoptosis in the cells is identified by the formation of membrane blebs, cell and organelle contraction, DNA fragmentation, nuclear condensations, and cell disintegration at the end [17]. Numerous cancer chemotherapeutic medications have been documented to trigger apoptosis in cancerous cells [22]. Assessments based on the TEM-, SEM- and AO/EtBr-based fluorescence microscopy are excellent indicators for confirmation of apoptotic features [42]. The present AO/EtBr-based fluorescence study of DL cells revealed that the EFP treatment caused severe membrane blebbing, cell shrinkage, cell membrane disintegration, and other apoptotic features in the DL cells in a time-dependent fashion. This may concur with an earlier report from the study using earthworm extract/paste of *Lampito Mauritius* showing similar kinds of apoptotic features in HT29 colon cancer cells [35]. As observed in EFP-treated groups, the reference drug cisplatin treatment also led to the development of apoptotic features in DL cells.

Surface morphological and ultrastructural changes are significant indicators of cellular damage, measured as distinct indicators of apoptosis. SEM studies showed a sequence of alterations on the surface of the DL cells following treatment with EFP and cisplatin. Cisplatin treatment for 96 h showed membrane blebbing, cell shrinkage, membrane projection (microvilli) loss and developed cell deformities compared to control DL cells, which are circular with membrane extensions and undulations in the cell surface. EFP treatments also caused similar surface morphological changes in DL cells. The above alterations in the cell surface morphology after treatment with EFP may indicate the appearance of apoptotic characteristics in DL cells.

TEM studies revealed damage in the cell membrane structure, cytoplasmic vacuolation, mitochondrial damage, etc., as prominent features observed in DL cells. Mitochondria is crucial in controlling apoptosis, maintaining malignant phenotype, and mutagenesis [1, 16, 33] . In the present study, the ultrastructural examination of control DL cells showed distinct mitochondrial features with regular cristae and uniform nuclei, smooth plasma membrane and uniformly distributed cellular processes over the cell processes. Structural abnormalities like mitochondrial

membrane disruption reduced and damaged cristae cell cytoplasmic vacuolation, the disappearance of membrane processes and fragmentation of the nucleus were detected in DL cells at 96 h of cisplatin treatment in vivo. Treatment with EFP also showed severe structural deformities in mitochondria and other cellular organelles. Disruptions in mitochondrial structure and function in developing tumours have been associated with the participation of hypoxia-inducible factor (HIF-1α) in activating the glycolytic enzymes under various oncogenic stimulations [30]. Moreover, the damage in the mitochondria may also be because of the malfunction of the respiratory chain and the decline in membrane potential, resulting in the disturbance of cellular energy; AMPK plays a pivotal role in upholding energy balance during heightened stress conditions. Inhibition of the AMPK pathway occurs in this context [23]

In the present study, different chromosomal abnormalities, including isochromatic breaks, chromatid breaks, exchanges, unions of sister chromatids, and chromosomal fragments, were identified in bone marrow following cisplatin treatment, as documented in previous studies. However, only a few isochromatic breaks and chromosomal fragments were found in the EFP treatment compared to the cisplatin treatment. In the treatment conditions, the total frequency of aberration in metaphase and CA was highest after 24 h of treatment, gradually decreasing as the treatment progressed to later time points. The time-dependent decrease in CA after the treatment could be because of the death of damaged cells or post-replication repair processes in the cells [12]. The quantitative analysis of mean aberrant CA in EFP treatment showed a minimal chromosomal aberration in bone marrow cells compared to cisplatin treatment, suggesting that EFP is much less mutagenic. These findings may also be supported by some naturally occurring cytotoxic compounds such as propolis and bee venom [2, 3]. Thus, the assay results of mutagenic parameters such as sperm abnormalities and chromosomal aberrations indicate less/no mutagenic property of EFP in DL tumour-bearing mice.

Renal (renal function tests, RFT) and liver functions (liver functions test, LFT) are the crucial parameters for understanding the possible kidney and liver toxicity. Changes in serum creatinine and urea have been used to study renal function as important biomarkers [19]. In this study, mice cisplatin treatment resulted in an amplification of serum creatinine and urea levels, indicating the signs of nephrotoxicity. The increased creatinine and urea levels may be due to the reduced rate of glomerular filtration or increased ROS [41]. However, the EFP treatment did not indicate any notable changes in serum creatinine and urea levels, indicating that the EFP does not have any such nephrotoxicity as that observed for cisplatin. This is also supported by another report of earthworm extracts like powder of *Eudrillus euginae* and its toxicity evaluation in Wistar male rats, which suggested that the earthworm powder had no toxic effects in the kidneys in experimental animals [6].

Hepatic functions or LFT (liver function test) is generally determined with the assessment of certain marker enzymes like alanine aminotransferase (ALT) and aspartate aminotransferase (AST) in serum of mice/humans under different experimental/pathological conditions [55]. In the present study, ALT and AST levels were elevated in cisplatin-treated mice, indicating hepatocellular injury in the liver. However, in EFP-treated mice, both AST and ALT levels did not illustrate any such elevation like cisplatin treatment, and it remained almost similar to control mice. This suggests less hepatocellular injury in the EFP-treated tumour-bearing mice. This is in agreement with other reports of hepatoprotective action of earthworm extract of *Lampito mauritii*, Kinberg was reported by Balamurgan et al*.,* in 2008 against liver injury induced by paracetamol in Wister albino rat [6].

Conclusion

This is the first research study assessing the antitumour activity of earthworm extract (*Eisenia fetida* paste, EFP) from North-east India. *Eisenia fetida* paste was incredibly effective against murine ascites Dalton's lymphoma. EFP extract-mediated antitumour effect may potentially encompass the initiation of apoptosis and mitochondrial changes in tumour cells. A decrease in the GSH levels of DL cells after EFP treatment may reduce tumour cells protective ability, which may show more cytotoxic effects under these treatment conditions. Compared to the reference cisplatin, EFP has less/no mutagenicity, hepatotoxicity, and nephrotoxicity in the tumour-bearing hosts. Finally, it may be proposed that this study establishes foundational data for future laboratory investigations to discover novel biological compounds and advance drug development. This data may also help preserve biodiversity and

strategically handle animal resources. Further studies may be initiated to isolate and characterise the bioactive composites from the earthworm extract and understand the molecular aspect of the antitumour mechanism.

Materials and methods

An earthworm, *Eisenia fetida* (Fig. 16), was selected to assess the anticancer efficacy and toxicity in mice with ascites Dalton's lymphoma. The biochemical and toxicity assessment studies were also carried out and are presented in detail in the supplementary file. The earthworms were collected from the Jorhat and Dhemaji districts of Assam and identified with ZSI, Shillong's help. The earthworm extract /paste was prepared from the *E. fetida* to study antitumour activity.

Fig. 16 [Images not available. See PDF.]

Eisenia fetida (**a**. Live earthworm; **b**. Dead earthworm)

Classification -

•Kingdom: Animalia

•Phylum: Annelida

•Class: Clitellata

•Order: Haplotaxida

•Family: Lumbricidae

•Genus: Eisenia

•Species: *E. fetida*

•Common name: Red worm (English), Kesu (Assamese)

Chemicals

Cisplatin (CDDP) solutions (1 mg/ml) were sourced from Biochem Pharmaceutical Industries in Mumbai, India; ethylenediaminetetra-acetic acid (EDTA), sodium arsenite ($NaAsO_2$), sodium sulphate (Na_2SO_4), analytical-grade 2-Thiobarbituric acid (TBA) and the required chemicals were employed in the study and purchased within the country. Refers and stains in double-glassed distilled water were always used to prepare the solutions.

Animal care and tumour maintenance

A total of 200 mice were used in the current study. Healthy, inbred Swiss albino mice of both sexes, aged 10–12 weeks and weighing 25–28 g, were procured from Pasteur Institute, Shillong, Meghalaya. An inbred mouse colony is being upheld within usual laboratory settings at 24 ± 2°C. The mice are housed in propylene cages containing 5–6 animals each, and they are provided with food pellets available commercially (Amrut Laboratory, New Delhi) and unrestricted access to drinking water.

Experimental tumour model

The murine malignant tumour ascites Dalton's lymphoma (DL) was employed in the current study for assessing the antitumour activity and toxicity in the mice bearing tumour. The DL tumour was sustained in the laboratory through consecutive intraperitoneal (i.p.) injections of viable 1×10^7 tumour cells (0.25 ml volume in phosphate-buffered saline, PBS, pH 7.4) into healthy mice by the method described by [47] (Fig. 17). Typically, hosts receiving the tumour transplant survived for 19–21 days.

Fig. 17 [Images not available. See PDF.]

Transplantation of ascites Dalton's lymphoma (DL) tumour cells in Swiss albino mice

Preparation of selected earthworms' extract/paste

Fully matured earthworms, *E. fetida,* were collected from their natural habitats of Jorhat and Dhemaji district of Assam. The preparation of earthworm paste was done with the following technique with small modifications [5]. The earthworms were rinsed under flowing tap water to eliminate any sand particles present on the surface of earthworms and then kept in 0.65% NaCl for 1–2 h at room temperature; the earthworms were provided with moist blotting paper for a duration of 18 to 20 h to facilitate gut clearance. Subsequently, the worms with cleared guts were subjected to a distilled water rinse. These worms were placed in plastic troughs, securely covered with polythene, and exposed to sunlight for 3 days until completely dried. The mucus and coelomic fluid that exuded from the deceased worms caused the worms' digestion, creating a brown-hued earthworm paste (EFP). These earthworm pastes underwent filtration, and the acquired filtrates were concentrated using a water bath set at 35 °C. The obtained earthworm pastes were gathered and preserved at 4˚C until required for further procedures.

To screen anticancer potentials, the crude pastes/extracts were dissolved in phosphate buffer saline (pH 7.4) to acquire requisite dilution for the screening of antitumour activity (Fig. 18).

Fig. 18 [Images not available. See PDF.]

Preparation of earthworm paste/extract

The per cent yield of the extracts was calculated with the following formula:%yieldoftheextract=Weightoftheextract(mg)Weightoftheearthworm(mg)×100

The percentage yield of earthworm *Eisenia fetida* paste (EFP) was about 3.33%.

Treatment protocol and selection of specific dose for further treatment

Preliminary antitumour activities of the animal extracts were determined subsequently by the method of Sakagami et al. [50]. Dalton's lymphoma cells (1×10^7 cells in 0.25 ml PBS) were transplanted intraperitoneally (i.p.) into Swiss albino mice between 10 to 12 weeks old. The tumour transplantation day was considered as day '0'. Evidence of initial tumour growth became apparent within 3 to 4 days following tumour transplantation. Animals with tumour transplants were categorised into six groups for the two selected extracts, each consisting of 10 mice. Commencing on the 6th-day post-tumour transplantation, injections of *E. fetida* paste extracts (EFP) were administered via the intraperitoneal route once daily for five days. Group I, with control animals, was given 0.25 ml of the respective extract vehicle once daily for five days. Groups II, III, IV, V and VI were treated with 10, 20, 40, 80, and 160 mg/kg body weight/day of the earthworm's paste. Any instances of host mortality were documented daily, and the survival trends of the hosts were assessed across the various groups. The impacts of different doses on tumour inhibition were quantified as the percentage rise in average lifespan (ILS), with calculations conducted using the specified formula:ILS=T/C x 100-100where T represents the mean survival days of the treated group of mice, and C denotes the mean survival days of the control group. To determine the most potent dose of the extract, animals were given a range of doses from 10 mg/kg of body weight to 160 mg/kg of body weight per day.

The tumour-transplanted mice of both sexes were allocated randomly into three experimental groups, with 10 mice in each group as follows:

Group-I: Tumour-bearing mice served as control and received PBS (Phosphate buffer solution) only.

Group- II: Tumour-bearing mice were administered with cisplatin daily for 5 consecutive days (i.p., 2 mg/kg body weight) beginning from the 6th day of post-tumour transplantation.

Group-III: Tumour-bearing mice were administered a therapeutic dose of EFP for five consecutive days (i.p., 40 mg/kg of body weight) beginning from the 6th day of post-tumour transplantation.

In different experiments, at intervals of 24, 48, 72, and 96 h following the final treatment (specifically on the 11th, 12th, and 14th days post-tumour transplantation), three mice from each group were euthanised using cervical dislocation [11]. DL cells, tissues (liver, kidney, testes) and blood samples were collected for microscopical, biochemical, and mutagenicity studies, as summarised in Fig. 19.

Fig. 19 [Images not available. See PDF.]

Treatment schedule for survivability study of mice bearing ascites Dalton's lymphoma.

For conducting a comparative analysis of the anti-tumour effect, a recognised anticancer drug, cisplatin (CDDP), at a dose of 2 mg/kg body weight per day via intraperitoneal injection (i.p.), was employed as a reference compound. It was administrated to the host bearing the tumour on the 6th day for five consecutive days post-tumour transplantation. Cisplatin was employed as a reference drug by many researchers in the anticancer study as it has a unique ability to initiate apoptosis in numerous cancer cells [4].

The ascitic DL obtained from the mice was subjected to centrifugation at 2000xg and 4 °C for 15 min. The resulting pellet was then employed as the DL cells. The samples from the control and various treatment groups were used for microscopical, biochemical, enzymatic and haematological studies

Cell viability study

The Trypan blue exclusion test was carried out to assess the viability of both DL cells and splenocytes. In brief, DL cells and splenocytes were harvested from DL-carrying mice in diverse groups at various time points (24, 48, and 96 h). Subsequently, they were washed twice with PBS. Following this, a portion of the cell mixture was combined with an equal quantity of Trypan blue dye (with 0.4% in PBS) and incubated for 2 min [53]. Unstained viable cells and stained non-viable or dead cells were quantified using a Neubauer haemocytometer mounted under a light microscope (Meiji). The percentage of non-viable cells was determined by observing 10–15 distinct selected fields of view within each treatment group, employing the subsequent formula:$$\text{Percentdead cells} = \frac{\text{Averagenumberofdeadcells}}{\text{Averagenumberoftotalcells}} \times 100$$

Fluorescence-based determination of apoptosis

Fluorescence-based apoptosis detection in DL cells was conducted using acridine orange and ethidium bromide (AO/EtBr) staining. DL cells were harvested from mice in various groups at distinct time intervals, precisely 24, 48, and 96 h, while subjected to diverse treatment conditions. Subsequently, they were washed with PBS. The cell suspension was supplemented with the AO/EtBr stain solution (100 µg/ml PBS of each dye), mixed gently, and then incubated for 5 min. The cells underwent a wash with PBS and were meticulously scrutinised under a fluorescence microscope (Leica) to identify any alterations or apoptotic features in the DL cells. Photographic documentation was also performed. A total of 1000 cells were screened, and the proportion of apoptotic and viable cells was tallied from twenty specifically chosen fields of view using a microscope. This procedure facilitated the determination of the apoptotic index.

Scanning electron microscopy and transmission electron microscopy of DL cells

Scanning electron microscopy (SEM)

Ascitic DL cells were collected from animals exposed to various experimental conditions. These cells were washed with PBS and subsequently resuspended in PBS, and a thin smear was prepared on a cover glass. A cover glass bearing the smear was then fixed in a 2.5% (v/v) glutaraldehyde solution at 4ºC. After fixation, the cells underwent rinsing in 0.1 M phosphate buffer and were steadily dehydrated using a sequence of ethanol concentrations: 30%, 50%, 70%, 90%, and 100%, each step lasting for 20 min. Next, the cover glass containing the cells was sectioned into smaller pieces, followed by critical point drying utilising a critical point dryer (CPD-030, BAL-TEC Co.). These

dried samples were then fixed to an aluminium stub using double-stick tape, and a gold coating was applied using an ionic sputter coater (SCD-005, BAL-TEC Co.). The prepared samples were subsequently subjected to observation, meticulous examination, and imaging using a Scanning Electron Microscope (JEOL JSM – 6360).

Transmission electron microscopy (TEM)

The DL tumour was gathered from mice within distinct experimental groups and centrifuged at 1000xg for 10 min at 4 °C. The resulting cell pellets were washed in PBS and then fixed in 3% glutaraldehyde at 4 °C for 2 h. After fixation, they were rinsed in 0.1 M cacodylate buffer. The cell pellets were fragmented into smaller fragments, followed by post-fixation in 1% osmium tetroxide at 4 °C for 15 min. Subsequently, a graded series of acetone (30–50-70–80-90–95%, with two repetitions at each concentration for 15 min each), was used for dehydration. The cell pellets were then placed in dry acetone prepared by adding an excess of $CuSO_4$ crystals to absolute acetone and filtering.

Further steps included two rounds of propylene oxide treatment for 1 h at room temperature, followed by a mixture of propylene oxide and an embedding medium composed of Araldite Cy212, dodecenyl succinic anhydride, tridimethylamino methyl phenol, and dibutylphdyhalate. Thin sections (60–80 nm) were sliced using an ultramicrotome (ultratome-RMC, MTX, USA) and collected on copper grids. These sections were stained using a mixture of lead citrate (5%) and uranyl acetate (5%) (1:1; v/v). The examination used an electron microscope (Jeol electron microscope) operating at 80 kV. The sections were scanned and meticulously inspected, and photomicrographs were captured.

Mutagenic studies

Sperm abnormality studies

On the fifth day of treatment, male mice within various groups were euthanised. The cauda epididymis was excised and immersed in physiological saline. Subsequently, the cauda epididymis was minced into smaller fragments and allowed to rest undisturbed for 20 min to enable the dispersal of spermatozoa. The spermatozoa were then dispersed onto a dirt-free slide, air-dried, and subjected to fixation in absolute methanol for 15 min. On the subsequent day, the spermatozoa were stained using a 1% aqueous solution of eosin-Y. Five hundred spermatozoa were examined for each mouse to identify aberrations in both tail shapes and sperm heads. The assessment followed the criteria established by Wyrobek and Bruce in 1975 [27].

Analysis of chromosomal aberration

An analysis of the chromosomal aberration was conducted according to a methodology outlined in 1994 by Sharma and Sharma [28]. Mice within different groups underwent mitotic arrest, initiated 2 h before euthanasia through an intraperitoneal injection of colchicine (4 mg/kg body weight). The collection of bone marrow cells was done by centrifugation at 1000 rpm and 4 °C for 5 min. The bone marrow was extracted from the femur through continuous flush with PBS (pH 7.4) with a syringe. Following this, the cell pellet was introduced to a pre-warmed hypotonic solution (1% sodium citrate) of 5 mL, and incubation was carried out for 20 min at 37 °C. Subsequently, Carnoy's fixative (methanol: glacial acetic acid, 3:1, v/v) in drops were gently mixed, and the mixture was centrifuged for 5 min at 1000 rpm. The upper layer was removed, and the resulting pellets were gradually separated by gentle tapping. Chilled Carnoy's fixative (5 mL) was introduced to the mixture and incubated for 30 min at 4 °C. Two more repetitions of the fixation process were carried out with a 30-min break. Ultimately, the cells were resuspended in 0.5 mL of the fixative. A small amount of drops of this suspension was placed on dirt and grease-free chilled slides, followed by flaming to facilitate drying. Once air-dried, the slides were stained the following day with Giemsa stain solution (freshly prepared) in Sorensen's buffer (pH 6.8). Subsequently, the slides were mounted using DPX. A hundred well-spread metaphase cells were examined per animal under a light microscope (Leitz). Various

chromosomal abnormalities were identified and scored based on observation.

Renal function (RFT) and liver function (LFT) tests

Blood samples were obtained from mice within distinct experimental groups on the fifth day after treatment through orbital venous sinus bleeding. Two millilitres of blood collected from the mice through orbital venous sinus bleeding and serum was separated by centrifuged at 4000 rpm for 10 min. The collected blood was then processed to separate the serum. After serum separation, changes in alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels were evaluated to gauge liver function. Additionally, serum urea and creatinine levels were measured to assess renal function. This assessment was conducted using a Clinical Chemistry Analyzer (SYNERGY BIO-1904C).

Statistical analysis

All experimental data were presented as the mean ± standard deviation (S.D.), with each determination repeated three times. The differences among multiple groups were assessed using a one-way analysis of variance (ANOVA), followed by a post hoc test (Tukey test). A significance level of $P \leq 0.05$ was deemed as statistically significant. Data were analysed using Origin 8 Software.

Acknowledgements

The authors gratefully acknowledge the Department of Zoology, North-Eastern Hill University, Shillong, for providing the required research facilities to complete the present studies. The author would also like to thank SAIF and NEHU for their assistance with the SEM and TEM studies.

Author contributions

Both the authors are equally involved in conceptualising this research work. Necessary data/sample collection, laboratory experiments, preparation of graphs, tables, Statistical analysis, interpretation and initial manuscript preparation were done by MPB. SBP did further correction and scrutiny of the manuscript. We take the responsibility for the integrity of the work presented in this manuscript. All the authors have read and approved the final manuscript.

Funding

This research did not receive any specific grant from any source.

Availability of data and materials

All the data that support this study are included in the manuscript.

Declarations

Ethics approval and consent to participate

All applicable international, national, and institutional guidelines for the care and use of animals were followed. The maintenance, use of the animals and the experimental protocol of the present study were approved by the North-Eastern Hill University, Shillong, Meghalaya, India, vide PhD registration no. 2247 of 2013 and Institutional Ethics Committee (animal models), North-Eastern Hill University, Shillong, India, dated 21–11-2014.

Consent for publication

All the mentioned authors agreed to submit the work to the Future Journal of Pharmaceutical Sciences.

Competing interests

The authors declare no conflict of interest.

Biogenic metallic nanoparticles as game-changers in targeted cancer therapy: recent innovations and prospects

Todaria, Moulika1; Maity, Dipak2; Awasthi, Rajendra1 1 UPES, School of Health Sciences and Technology, Dehradun, India (GRID:grid.444415.4) (ISNI:0000 0004 1759 0860)2 The Assam Kaziranga University, Jorhat, India (GRID:grid.448720.d) (ISNI:0000 0004 5940 6726)

ABSTRACT (ENGLISH)

Background

Cancer is a significant global health issue, resulting from uncontrolled cell division leading to abnormal cell or tissue growth. Traditional chemotherapeutic techniques have investigated a wide variety of pharmaceutically active molecules despite their poor bioavailability, quick renal clearance, inconsistent distribution, and unavoidable side effects. Green synthesis, unlike chemical methods, prioritizes eco-friendliness and cost-effectiveness. Using natural sources like plant extracts, it minimizes environmental impact, reduces costs, and aligns with sustainability goals. Operating under milder conditions, it consumes less energy compared to traditional approaches. Green synthesis is a highly promising and efficient method for producing nanoparticles due to its versatility and scalability.

Main body

Nanotechnology is making progress in cancer treatment because of nanoparticles' tiny size, large surface area, adaptability, and functionality, as well as their potential to induce apoptotic pathways and fast penetration or internalization into cancer cells. Biosynthesis of metallic nanoparticles using plant or microbe extracts is attracting attention to replace toxic chemicals with phytochemicals that can act as reducing, capping, or stabilizing agents and improve metallic nanoparticles biocompatibility, antitumor, and antioxidant properties. This review focuses on biosynthesized metallic nanoparticles and their anticancer effects on breast, prostate, skin, cervical, colorectal, lung, and liver cancer.

Conclusion

Biosynthesis of nanoparticles for cancer therapy stands at the forefront of innovative and sustainable approaches. Despite challenges, ongoing research demonstrates the potential of biosynthesis to revolutionize cancer nanomedicine, emphasizing the need for continued exploration and collaboration in this rapidly advancing field. Overall, this review offers a comprehensive understanding of the most recent developments in biosynthesized metallic nanoparticles for the treatment of cancer as well as their potential future applications in medicine.

FULL TEXT

Background

Cancer is caused by the excessive proliferation of normal cells, which causes genetic instability and mutations to accumulate within cells and tissues, transforming them into malignant cells. Radiation, smoking, nicotine, toxins in drinking water, food, air, chemicals, certain metals, and infectious agents are all potential external causes of cancer, in addition to internal ones such genetic mutations, weakened immunity, and hormone imbalances [1]. Despite significant efforts by scientists to overcome cancer, it remains difficult to effectively treat. Hair loss, exhaustion, nausea, and other symptoms are possible side effects of conventional chemotherapy, which uses chemicals to destroy cancer cells. Because of these side effects and drug resistance, it is difficult to take advantage of

conventional chemotherapy for the complete treatment of cancer [2]. Nanomedicine has made significant advancements in the treatment of cancer over the past several years and is useful as a drug carrier for chemotherapeutics because of its size, shape, selective binding capability, high permeability and retention impact, surface modification, etc. This allows them to deliver drugs directly to the cancer cells while preserving healthy tissue [3]. Nanoparticles (NPs) have been explored as pharmaceutical carriers for more than three decades to increase the in vivo effectiveness of several existing anticancer molecules. The investigations conducted during 1970s explored anticancer drug-loaded liposomes [4]. NPs are widely used for the delivery of imaging agents, genes, or chemotherapeutics, exploiting their intrinsic toxicity, such as related to the release of hazardous species [5]. Inherent properties, such as antioxidant action, or activities dependent on the application of external stimuli, like hyperthermia in response to the introduction of infrared rays or magnetic fields, may account for the physicochemical characteristics that give NPs their anticancer activity [4]. Metal and metal oxide NPs are being used experimentally to directly kill tumor cells by converting applied magnetic fields into strong hyperthermia or by performing effective photodynamic therapies that can reach even internal tissues by converting in situ penetrating infrared radiation into visible light inside the tumor [6].

NPs are commonly synthesized using top-down (synthesized via size reduction) and bottom-up strategies (NPs are generated from small entities such as atoms and molecules) [7, 8]. Hazardous and poisonous chemicals, expensive laboratory equipment and infrastructure, and the ability to operate under a variety of circumstances, including high temperature and pressure, are all utilized in the various chemical and physical procedures used to create and synthesize NPs. NP synthesis is expensive, and it results in highly toxic and harmful compounds that pose a variety of biological risks. So, it is advised to create an eco-friendly process combining biological and green synthesis techniques [9].

Green synthesis of metal or metal oxide NPs involves reducing metal complexes in diluted solutions to form metal colloidal dispersions. Despite being commonly used reducing agents, sodium borohydride and hydrazine hydrate are not preferred due to their toxicity from nanoparticle contamination. Green resources including plant and microbial extracts contain compounds that can convert metal precursors into NPs. All green methods typically include combining one or more of these biological extracts with metal salt solutions. Biomolecules change the oxidation state of metal salts from positive to zero, stabilizing newly formed NPs or acting as *in situ* reducing and capping agents [10]. The formation of a monolayer around the NPs prevents them from aggregating together due to chemical and physical interactions. Khan et al. synthesized palladium NPs using a root extract from *Salvadora persica*. The extract contained polyphenols with bioreduction and stabilizing properties [11]. The quantity of natural compound present in the extract affects the size and size distribution of NPs. Khatami et al. synthesized 15-nm-sized silver NPs (Ag NPs) from dried grass. At 5 μg/mL, Ag NPs suppress cancer cell multiplication and decrease cancer cell survival by 30% [12].

Biological processes are preferred to chemical and physical ones because they are less expensive, safer for the environment, do not require extreme conditions, and do not generate harmful by-product molecules. Biological nanoparticle synthesis employing living organisms is a green technique for synthesizing NPs with desired properties. Biosynthesis allows unicellular and multicellular organisms to react [13]. Biogenic synthesis can produce large numbers of contamination free well-defined NPs. It also has a lower environmental impact than alternative physicochemical manufacturing methods [14]. Cheng et al. used zinc oxide NPs (ZnO NPs) synthesized from *Rehmanniae radix* (RR) as a target drug delivery vehicle to inhibit bone cancer (MG-63) cell proliferation. Increasing dosage caused apoptosis [15]. *Caesalpinia pulcherrima* extract-loaded Ag NPs are cytotoxic to HCT116 cell lines [16]. *Artemisia turcomanica* leaf extract-loaded Ag NPs were cytotoxic against normal fibroblast cells (L-929) and gastric cancer cells (AGS) [17]. Metal oxides are toxic for cancer cells and nontoxic for normal cells (Fig. 1A). Due to the presence of capping agent on metal oxide NPs, these bind to the surface of healthy and cancerous cells through electrostatic attraction. Ionic species, namely metal and oxygen radicals, are formed when the biosynthesized NPs dissociate. The elevated metal ion concentration prevents the growth of cancer cells by changing their metal cation homeostasis. Superoxide dismutase (SOD) eliminates the oxygen radical, resulting in hydrogen peroxide, which

peroxisome catalases and phytocompounds then convert into water and oxygen. As a result, the superoxide radical is converted into antioxidants before reactive oxygen species (ROS) develop in normal cells [18].

Fig. 1 [Images not available. See PDF.]

A Effect of metallic NPs in normal and cancerous cells, **B** mechanisms of metal/metal oxide NPs for cancer cell [34], **C** proposed mechanism of apoptotic effect of metallic NPs on the cancer cells [35], (**A**: Recreated with permission © Springer Nature, **B** and **C** recreated under copyright (CC BY) from MDPI, Dovepress)

ROS produced by oxygen radicals generates hydrogen peroxide, which causes oxidative stress and kills cancer cells. However, the lack of experimental evidence for these routes motivates more research into the lethal mechanism of photosynthesized metal oxide NPs in both healthy and malignant cells [19]. This article discusses the probable mechanism of action, the green synthesis of metallic NPs from plant extracts, and their anticancer effectiveness against different cancer cells. It also summarizes characterization methods and the most significant findings from recent studies.

Metallic nanoparticles in cancer treatment

The NPs have been used for many years in biomedical operations such as imaging and drug delivery [20]. Inorganic NPs and their numerous applications, such as cellular absorption, diagnostics, and therapy, have received significant attention in recent years. Most of the inorganic nanoparticle research is focused on materials such as gold, silica, and others. Together with a facilitator, the mesoporous silica bestows a very cutting-edge approach to imaging and drug release [21]. The activity of this facilitator is triggered with the help of external stimuli. Due to their outstanding optical, magnetic, and photothermal characteristics, metallic NPs are widely explored in biological imaging and targeted drug delivery. Gold NPs (Au NPs), Ag NPs, iron-based NPs, and copper NPs are some of the most often utilized metallic NPs. Since their size and surface qualities can be easily adjusted, Au NPs are utilized as drug carriers for intracellular targeting [22]. The visible light extinction behavior of metallic NPs makes it possible to track their trajectories in the cells.

Anti-human epidermal growth factor receptor 2 (HER2)-functionalized gold-on-silica nanoshells have been found to target HER2-positive breast cancer cells [23]. Clinical trials for the detection of nodal metastases using Combidex®, an iron oxide-based nanoformulation, are close to complete [24]. Iron deficiency anemia can be treated with Feraheme®, an iron oxide nanoformulation that contains ferumoxytol. This was approved by the FDA in June 2009 to treat nodal metastases in prostate and testicular cancer [25, 26]. Metallic NPs cause apoptotic, autophagic, and necrotic cancer cell death through ROS generation, caspase-3 activation, mitochondrial outer membrane permeabilization, and specific DNA cleavage [27].

Metal nanoparticle delivery pathway and cell damage can be linked to interaction of NPs with ions in circulation, ingestion by phagocytic cells, opsonization or enzymic degradation, internalization via endocytosis, membrane perforating and damage of its components and function, chromosomal aberrations and changes in cell replication rate, lysosome rupture, mitochondria damage, lower growth rate, structural changes, and shorter lifespan of microtubules of the cytoskeleton, generation of ROS, oxidative stress, and subsequent processes (Fig. 1B). NPs of different sizes enter cells via distinct pathways. Smaller NPs penetrate cells via receptor-mediated uptake by interacting with the caveolin receptor on the cell membrane. Larger NPs are more likely to enter cells via clathrin-mediated endocytosis. When NPs enter a cell, they can proceed one of two ways: either they interact with cytosolic proteins in a direct fashion, or they are transported to the lysosome–endosome complex, where their surfaces are modified before they are released into the cytosol [27]. Inside the cell, NPs trigger up a chain reaction that releases ROS and initiates the release of metal ions. These metal ions tend to connect with proteins' SH groups, breaking their S–S bridges. As a result, the cell physiology is altered, resulting in activation of various signaling pathways that lead to programmed cell death [28]. Apoptosis is frequently induced by either intrinsic or extrinsic pathways. Nanomaterials can induce apoptotic signaling via both intrinsic and extrinsic pathways. In the case of intrinsic apoptosis, ROS production causes mitochondrial membrane depolarization, which results in the release of cytochrome C into the cytosol. This cytochrome C promotes the caspase-9/3 apoptotic cascade by activating pro-

apoptotic proteases in apoptosis initiated by the extrinsic pathway (Fig. 1C) [29].

Ag NPs play a significant role in breast cancer treatment as well as skin wound healing therapy. In this review, most of the studies mentioned are about Ag NPs tested on breast cancer cell lines. For example, the IC_{50} value of paclitaxel is 80 g/dL, while the IC_{50} value of Ag NPs loaded with *Elaeodendron croceum* extract against MDA-MB-231 breast cancer cell line is 138.8 µg/mL [30]. *Moringa oleifera* flower aqueous extract-loaded Au NPs showed anticancer activity against A549 lung cancer cells. Au NPs (50 µg/mL) showed significant anticancer activity against lung cancer cell line [31]. ZnO NPs kill tumor cells through NADPH-dependent oxidative burst and apoptotic signaling. ZnO NPs of various sizes and specific surface areas had a similar effect on cytotoxicity and DNA fragmentation in macrophages of mice in an ap47phox- and Nrf2-independent manner. Because of their critical function in the modulation of immunological responses during inflammation and the clearing of inhaled particles, ZnO NPs trigger necrosis and apoptosis in macrophages. ZnO NPs promote the rapid induction of nuclear condensation, DNA fragmentation, and formation of hypodiploid DNA-containing nuclei and apoptotic bodies [32]. Furthermore, the delivery of cerium oxide NPs (CeO_2 NPs) might cause DNA damage, which results in tumor cell death. CeO_2 NPs enhance ROS in tumor cells, causing apoptosis without genotoxicity. The antitumor activity of CeO_2 NPs is greatly dependent on their size and shape. Both small- and large-sized NPs induce DNA damage in tumor cell lines [33].

Silver nanoparticles

Due to their unique physical and chemical characteristics, such as high electrical conductivity and optical, electrical, thermal, and biological properties, Ag NPs are gaining considerable interest in the healthcare sector [36]. Ag NP aggregates enter mammalian cells via endocytosis and can cross blood–brain barrier due to their small size. After entering an endocytic vesicle, they are intracellularly transported to the cytoplasm and nucleus [37]. The antimicrobial properties of silver have been observed since ancient times. Silver is currently employed in various applications to regulate bacterial proliferation, such as in dental procedures, catheters, and the treatment of burn injuries. Ag ions and Ag-based compounds are generally recognized for their severe toxicity to microorganisms, exhibiting potent biocidal properties [38]. Ag NPs, measuring around 32.2 nm, were manufactured using an extract derived from *Teucrium polium*. These NPs were incorporated into a film made of polylactic acid and polyethylene glycol (PLA/PEG). The resulting film serves as a biodegradable wound dressing that possesses antioxidant and antibacterial properties. The incorporation of biogenic silver NPs into PLA/PEG nanofibers resulted in the total inhibition of growth in *P. aeruginosa* and *S. aureus*, demonstrating substantial antibacterial properties [39]. The Ag NP-loaded amorphous calcium polyphosphate NPs, which were synthesized using wet chemical precipitation, exhibited effective antibacterial activity against *E. coli*, *Staphylococcus aureus (S. aureus)*, and *Enterococcus faecium* [40]. A recent study shown that the production of Ag NPs using a crude leaf extract of *Lycium shawii* exhibited a minimum inhibitory concentration (MIC) ranging from 1 mg/mL to 15 mg/mL against several microorganisms. The measured MIC clearly demonstrates the significant antibacterial properties of the produced NPs [41]. Multiple in vitro and in vivo studies have demonstrated the anticancer effects of Ag NPs, rendering them a highly promising choice for cancer therapy [42]. At a dosage of 1.0 mg/L, enzyme-responsive Ag NPs coated with adenosine triphosphate killed 56.04% of HepG2 cell line [43]. Ag NPs produced by the one-step caffeic acid-mediated reduction are anticipated to enter cells via endocytosis and effectively suppress HepG2 cell growth through apoptosis induction [44]. The aqueous extract of *Panax ginseng* roots was used to synthesize Ag NPs with the assistance of ultrasound. The resulting NPs exhibited an IC_{50} value of 157 µg/mL against the PC14 cancer cell line. In PC14 cells, the biosynthesized Ag NPs modulated the PI3K/AKT/mTOR signaling pathway and elevated ROS levels, apoptosis, and LDH release [45]. Chen et al. studied the function and mechanism of Ag NPs in prostate cancer. Ag NPs diminished lysozyme membrane integrity, number, and protease activity. This blocked autophagy. In PC-3 cell lines, sublethal Ag NP doses can produce hypoxia and energy deficiency [46].

Gold nanoparticles

Au NPs are synthesized using chemical, physical, and biological methods. Conversion of metallic gold into nano-particulate gold by chemical reduction is a common menthod for the synthesis of Au NPs. Citrate mediated reduction

method has been described by Turkevich in 1951 to synthesize stable and size controlled Au NPs. Brust and Schriffin explored sodium borohydride mediated reduction to synthesize Au NPs. In 1996 Schmid *et. al*. described seed mediated growth, the most explored chemical method, to synthesize Au NPs [47]. Surface modification of Au NPs can be done using amine and thiol groups. This has the potential to benefit biomedical applications such as targeted delivery, imaging, and sensing for electron microscopy markers [48]. Murawala et al. synthesized Au NPs with a bovine serum albumin cap and methotrexate loading that impede MCF-7 proliferation and cause G1-S phase arrest, DNA breakage, and eventually apoptosis [49]. Gum acacia (GA) was utilized successfully to synthesize gemcitabine hydrochloride (GEM)-loaded colloidal Au NPs. Cell viability was 64.8% and 51.8% for naked GEM-treated cells at doses ranging from 0.25 to 0.5 µg/mL, respectively. GEM-GA-Au NPs decreased cell viability by 51.2% and 42.8%, respectively. GEM-GA-Au NPs exhibited superior anti-proliferation effects on MDA-MB 231 human breast cancer cells compared to naked GEM [50]. In comparison with free TA-peptide, the conjugation of Au NPs and a thioctic acid-DMPGTVLP peptide (TA-peptide) conjugate led to a more substantial release of cytochrome c after the activation of caspase-3/7. However, after intratumoral injection in tumor-bearing mice, TA-peptide Au NPs exhibited superior antitumor effectiveness compared to TA-peptide [51].

Iron oxide

Over the past 20 years, iron-based NPs have gained interdisciplinary scientific interest due to their distinctive properties and nanotechnological possibilities [52]. Iron oxide NPs (Fe_3O_4/Fe_2O_3 NPs) exhibit good superparamagnetic characteristics of Fe_3O_4 and Fe_2O_3, leading to significant performance in drug delivery applications [53]. Superparamagnetic Fe_3O_4/Fe_2O_3 NPs have attracted considerable attention because of their potential use in imaging, drug delivery, and hyperthermia management. They are non-toxic, biodegradable, and biocompatible and effectively eliminated from the human body via iron metabolism pathways [54]. Unique physical and chemical properties of Fe_3O_4/Fe_2O_3 NPs (large surface area, superparamagnetic properties, and nanoscale dimensions with a spherical form and an adjustable size of less than 50 nm) make them highly efficient [55]. Fe_3O_4/Fe_2O_3 NPs have an intrinsically therapeutic impact on malignancies [56] and resist tumor cell growth in a better way when compared to untreated control cells [57]. Sun et al. synthesized multifunctional methotrexate-loaded iron oxide NPs conjugated with chlorotoxin (a targeting ligand). Due to tumor cell cytotoxicity, these NPs may be employed in cancer diagnosis and treatment [58].

Zinc oxide

Zinc oxide nanoparticles (ZnO NPs) have emerged as a promising contender for use in biomedical research, food packaging, optical, electrical, and food processing applications. ZnO NPs are harmful to cancer cells because, at low pH levels, they decompose into Zn^{2+} ions. These Zn^{2+} ions produce ROS, which kill cancer cells. Additionally, ZnO NPs have been successfully employed as a vehicle for the precise delivery of anticancer drugs into tumor cells [59]. Wahab et al. found that ZnO NPs, when utilized at very low concentrations and in a dose-dependent manner, were effective against MCF-7 (breast cancer) and HepG2 (liver cancer) cells. At 25 µg/mL, HepG2 cell viability was below 10% [60].

Copper oxide

CuO, a well-known p-type semiconductor, has long been studied for its monoclinic structure. Cupric oxide (tenorite monoclinic CuO) and cuprous oxide (cuprite cubic Cu_2O) are two crystalline forms of copper oxide [61]. Potential metal ion leaching and dissolving, as well as oxidative stress, DNA damage, lipid peroxidation, membrane damage, and mitochondrial damage have all been explored in the literature as toxicity pathways. A small amount of CuO NPs can generate large amounts of ROS such as O_2, OH, and H_2O_2. CuO NPs cause membrane disruption and ROS generation after they enter the mitochondria [62]. Wang et al. found that CuO NPs increased the survival rate of tumor-bearing animals, inhibited the metastasis of B16-F10 cells, and significantly delayed the growth of melanoma. The data revealed that CuO NPs had minimal systemic toxicity and were promptly eliminated from the organs. When CuO NPs penetrated the cells, they preferentially targeted the mitochondria, causing cytochrome C to be released and caspase-3 and caspase-9 to be activated. Thus, CuO NPs can kill cancer cells via mitochondrion-mediated apoptosis to treat melanoma and other cancers [63].

Titanium oxide

Bioengineered titanium oxide nanoparticles (TiO2 NPs) have been shown to have good stability, chemical neutrality, hydrophilicity, oxidizing power, and electrical, optical, physical, and photocatalytic properties. Because of their powerful antibacterial and odor-removing properties, TiO_2 NPs are employed in filters and cosmetics. TiO_2 photocatalysts have been extensively explored for the killing or suppression of bacterial growth due to their excellent chemical stability and nontoxicity [64]. Plant extracts may exhibit properties of the metals or metal oxides that make up their composition in addition to the presence of phytoconstituents. These features may ultimately result in their many critical activities in the prevention or treatment of cancer. It has been shown that the tiny size of TiO_2 NPs gives them potent anticancer activity against cancer cells [65].

Biological synthesis of metallic nanoparticles

Over the past decade, there has been an increase in efforts to discover efficient, low-cost, eco-friendly, and long-lasting strategies for producing green NPs [66]. Researchers across the globe are interested in green synthesis since it is an environmentally safe technique and a fascinating study topic for the synthesis of metallic NPs for biomedical applications [67]. Using biological agents to make NPs of various sizes, shapes, compositions, and physicochemical characteristics is safe, non-toxic, and environmentally sustainable [68]. Biosynthesis of these NPs is done at mild pH, pressure, and temperature without using an external reducing agent, capping agent, or stabilizing agent [69]. Capping agents have a significant role in the synthesis of metallic NPs. The major role of capping agent is to functionalize and stabilize the NPs, along with controlling size and morphology [70]. NPs synthesized by green synthesis methods are exceptionally stable, well dispersed, and have a narrow size distribution [71].

Nucleation and production of stable metallic NPs during biological synthesis are affected by several factors such as temperature, reactant concentrations, pH, and reaction time. For example, when employing biomass from *Avena sativa* (oats) at pH 2, rod-shaped Au NPs were larger, ranging from 25 to 85 nm. In contrast, at pH 3 and 4, the Au NPs were comparably smaller, with sizes ranging from 5 to 20 nm. The functional groups present in extract were more easily accessible for particle nucleation within the pH range of 3 to 4. In contrast, a reduced number of functional groups were present at pH 2, leading to the aggregation and formation of bigger Au NPs [72]. Ag NPs were synthesized using bark extract derived from *Cinnamon zeylanicum*. The particle yield exhibited a positive correlation with the concentration of the bark extract, whereas the NPs assumed a mostly spherical morphology at pH values of 5 and higher [73]. Prathna et al. found that the combination of $Ag(NO)_3$ with *Azadirachta indica* leaf extract led to the formation of progressively bigger particles as the reaction time increased. By adjusting reaction time from 30 to 240 min, the particle size changed from 10 to 35 nm. The concentration of NPs produced at various stages of reaction was determined using inductively coupled plasma optical emission spectroscopy measurements. After 2 h, the yield of the process had significantly increased to 78%. Subsequently, there was a progressive and continuous increase in the yield [74]. The photosynthesized NPs are safer than their chemically synthesized counterparts for usage in healthcare applications since they do not contain any harmful contaminants. When applying metal in healthcare products, safety risks related to nanosize, penetration, and tissue permeability must be considered. In vitro cytocompatibility of phytonanoparticles has been documented by multiple researchers. Extensive research is still required to determine their pharmacodynamics, immunogenicity, absorption, biodistribution, excretion, and acute and chronic toxicity. Although plant-mediated nanoparticle production is often considered an environmentally beneficial approach, there is still a dearth of evidence addressing the direct and indirect ecological impacts of these particles [75].

Green synthesis using plant extract

Plants, which include grasses, ferns, trees, bushes, flowers, and other varieties of green algae and lichens, are among the most essential forms of life. NPs can help plants by acting as fertilizers, pesticides, growth regulators, and antibacterial agents. However, flora can also assist with the development of nanotechnology. Plants can be used to produce NPs in two different ways: directly through extraction or indirectly via plant-mediated biosynthesis. Agriculture, food science, nanotechnology, and pharmaceutical science are just some of the fields that could benefit from a better understanding of the interaction between NPs and plant extracts [76]. Plant-mediated green NP

synthesis is one of the most preferred approaches because it normally requires a neutral pH and can occur at room temperature [77]. Plants and plant extracts are sustainable and renewable resources for NP production, unlike prokaryotic bacteria, which require expensive methods for maintaining microbial cultures and downstream processing [7]. Using the various plant parts (Fig. 2A), such as fruits, seeds, calluses, stems, peels, leaves, and flowers, biological processes synthesize metal NPs in a range of sizes and shapes. Metal NPs are synthesized using metal precursors and plant extracts as reducing and capping agents under suitable conditions [78]. A green chemistry approach for the synthesis of metal NPs can be achieved in three stages: (i) the activation phase, in which the phytoconstituents reduce the metal ions, followed by the nucleation of reduced metal atoms; (ii) the growth phase, in which small NPs join to form larger NPs; (iii) the termination phase, in which the NPs take on their final shape [79]. Bioactive alkaloids, phenolic acids, polyphenols, proteins, carbohydrates, and terpenoids in plant extracts reduce and stabilize metallic ions (Fig. 2B) [80].

Green synthesis of nanoparticles: **A** different plant parts used for nanoparticles formation, **B** general method for biosynthesized nanoparticles formation, **C** different microorganisms used for nanoparticles formation, **D** different shapes of nanoparticles that can be synthesized, and **E** possible mechanism of nanoparticle synthesis using microbes (Figure **E**: recreated with permission

Tabebuia berteroi leaf extract is rich in polyphenol, and *Withania coagulans* plant extract is rich in flavonoids, tannins, and phenolics. These extracts have been used to reduce Fe and Pd ions to form their respective metal NPs, which are then mixed with graphene oxide to make a nanocomposite [81]. *Anisomeles indica* leaf extract reduced silver ions to spherical Ag NPs (50–100 nm) in 10 min at room temperature [82]. Lee et al. reported Au NPs synthesis utilizing sequential fractional extracts from *Ocimum sanctum* leaves. For the sequential fraction extraction of *O. sanctum* leaves, different polarity solvents (hexane, chloroform, n-butanol, and water) were utilized, and it was discovered that unique solvent fractions (extract) are responsible for the creation of morphologically varied Au NPs. Water extract produced anisotropic NPs, hexane extract produced spherical Au NPs, chloroform extract produced a circular disk-shaped structure with rough edges, and n-butanol extract produced Au NP aggregates [83]. Possible mechanisms of the anticancer effect of phytosynthesized metal or metal oxide NPs include the formation of pro-apoptotic caspases, activation of reactive oxygen species, damage to cell membranes and mitochondria, damage to DNA, and DNA fragmentation [84]. Table 1 represents various plant extracts utilized in the synthesis of metallic NPs along with their corresponding applications.

Table 1. Biosynthesized metallic NPs using various plants and their biomedical applications

MNPs/MONPs	Plant/part used	Metal precursor used	Morphology	Biomedical application	Findings	References

Fe_2O_3/Fe_3O_4	*Hyphaene thebaica* (Aqueous fruit extract)	Iron nitrate hexa hydrate	Quasi-spherical/cuboidal 10 nm	Antibacterial, antioxidant, antiviral activity	Growth of *Bacillus subtilis* (*B. subtilis*) inhibited. Fe_2O_3 NPs were effective against *Aspergillus flavus* (*A. flavus*). An increase in Fe_2O_3 NP concentration reduced viability of RD cells and L20B cells. Moderate inhibition of poliovirus-1 and poliovirus-2 was noted in the culture of virus in L20B cells	[85]
Ficus carica (Leaf extract)	Ferric chloride hexahydrate	Multiform 43–57 nm	Antioxidant activity	At 12.118 mg/mL, synthesized NPs had antioxidant capacity that can eliminate half of the environmental 2,2'-diphenyl-1-picrylhydrazyl (DPPH) radicals	[86]	*Celosia argentea* (Leaf extract)

Ferric nitrate	Spherical /hexagonal/Cubic shape 5–10 nm	Antibacterial, antibiofilm, antioxidant, anti-inflammatory, anti-diabetic, anticancer, larvicidal activity	At 150 µg/mL, antibacterial activity was detected against *E. coli* (19 mm) and *S. aureus* (25 mm). A greater rate of inhibition of biofilm activity was observed at 150 µg/mL. A higher antioxidant (97%) was recorded at 80 µg/mL and higher anti-inflammatory (93%) and anti-diabetic (87%) activities were recorded at 500 µg/mL. MCF-7 breast cancer cells showed 86% inhibition at 50 µg/mL	[87]	*Platanus orientalis* (Leaf extract)	Ferric nitrate nonahydrate
Spherical 78–80 nm	Antifungal activity	Antifungal activity of iron oxide NPs against the fungus was 1.6 times higher than that of *A. niger*	[88]	*Carica papaya* (Leaf extract)	Ferric Chloride	Spherical 56 nm

Antibacterial	Antibacterial activity demonstrated against Gram-positive (*S. aureus, Bacillus subtilus*) and Gram-negative (*E. coli*, *Enterobacter, Pseudomonas fluorescens*) bacteria	[89]	ZnO	*Ziziphus nummularia* (Leaf extract)	Zinc nitrate	Spherical/irregular 17.33 nm

Antifungal activity	ZnO NPs demonstrated strong cytotoxic action against HeLa cancer cell line. NPs had superior antifungal activity compared to conventional azole antibiotics	[90]	*Limonium pruinosum L. Chaz.* (The shoot system, leaves and stems)	Zinc acetate dihydrate	Hexagonal/cubic crystalline 41 nm	Anti-skin cancer, antimicrobial, antioxidant activity

The plant extract and synthesized ZnO NPs demonstrated the largest inhibition zone against *E. coli* measuring 29 and 31 mm, and *C. albicans* measuring 28 and 29 mm. At 1000 µg/mL, ZnO NPs and *L. pruinosum* extract showed highest DPPH activity, at 75.2% and 84.6%, respectively	[91]	*Bixa orellana* (Leaf, seed, and seed coat)	Zinc acetate	Spherical/almond-like 169−259 nm 304−465 nm 278−654 nm	Anticancer, antimicrobial	Antibacterial activity was detected in ZnO NPs containing leaf extract aga i

						nst *S. aureus* and *B. subtilis*. NPs containing seed extract inhibited *E. c*

[92]	*Mentha longifolia L.* (Leaf extract)	Zinc nitrate	Spherical 60–70 nm	Antiparasitic	At 400 ppm and 150 min of exposure, NPs demonstrated highest scolicidal activity and 100% mortality rate. Morphological changes and loss of viability were seen in the treated protoscolices	[9 3]

CuO	*Bacopa monnieri* (Leaf extract)	Copper (II) acetate	Monoclinic crystalline 34.4 nm	Antibacterial, anti-diabetic, anti-inflammatory	Strong inhibition zones at 5 mg/mL were demonstrated for *H. salomonis* (13.50 ± 0.84), *H. felis* (15.71 ± 0.91), *H. suis* (15.84 ± 0.89), *and H. bizzozeronii* (13.11 ± 0.83). After 48 h, NPs showed 74% less edema as compared to the control group that received diclofenac (100 mg/kg)	[94]
Momordica charantia (Fruit extract)	Copper sulfate pentahydrate	Spherical 50–57 nm	Antiviral, antifungal, antibacterial	The highest efficacy was observed against *Bacillus cereus* with a 31.66 mm zone of inhibition. Additionally, CuO NPs had therapeutic potential against R2B strain of Newcastle disease, *Streptococcus viridians*, and *Corynebacterium xerosis*	[95]	Artemisia (Leaf extract)
Copper (II) sulfate	conceivable spherical/irregular form 38.5–48.5 nm	Antibacterial	Zones of inhibition for *B. subtilis* and *E. coli* were observed as 26.7 and 20.5 mm, respectively	[96]	*Pimenta dioica* (Leaf extract)	Copper (II) sulfate

Platelet/cuboid shape 20–50 nm	Antibacterial, anticancer, antidiabetic, antioxidant	For the L929 and DLD-1 cell lines, the IC_{50} value of CuO NPs is 89.42 mg/mL and 119.06 mg/mL, respectively	[97]	*Gomphrena globosa* *Gomphrena serrate* (leaf extracts)	Copper (II) sulfate pentahydrate	*G. globosa*: Rod/hexagonal/irregular shape 345 nm *G. serrata*: S

						pherical 380 nm

Antibacterial, anticancer, antioxidant, photocatalytic activity	CuO NPs produced by *G. globosa* at 125 µg/mL demonstrated antibacterial activity, with the zone of inhibition measuring between 14 ± 1.41 and 13 ± 1.41 mm. NPs produced by *G. serrata* and *G. globosa* showed IC_{50} values of 85.14 and 77.75 µg/mL, respectively	[98]	TiO_2	*Andrographis paniculata* leaves extract	Titanium (IV) oxide	Spherical 50 nm

Antibacterial, antifungal, antidiabetic, antioxidant	*E. Coli* and *Bacillus spp*. showed a lower zone of inhibition. *Salmonella spp*. showed a higher zone of inhibition. LD_{50} value of TiO_2 NPs was 250 µg/L	[99]	*Psidium guajava* (Aqueous leaf extract)	Titanium dioxide	Spherical 32.58 nm	Antibacterial, antioxidant activity

TiO_2 NPs (20 µg/mL) showed maximum zone of inhibition against *E. coli* (23 mm) and *S. aureus* (25 mm). In comparison to ascorbic acid, aqueous plant extract and TiO_2 NPs exhibited the highest level of antioxidant activity	[100]	*Morinda citrifolia* (Root extract)	Titanium dioxide	Spherical/oval/triangle 20.46–39.20 nm	Larvacidal activity	Maximum activity of TiO_2 NPs was shown against the larvae of *An. stephensi*

						ensi, *Ae. aegypti* and *Culex. quinquefasciatus*
[101]	*Moringa oleifera* (Leaf extract)	Titanium dioxide	Spherical 100 nm	Wound healing activity	Nano-sized particles significantly exhibited wound healing activity in albino rats	[102]

Ag	*Allium cepa*	Silver nitrate	Spherical 10–23 nm	Antimicrobial, antioxidant, antitumor activity	Human breast (MCF-7), hepatocellular (HepG-2) and colon (HCT-116) carcinoma cells were susceptible to the antitumor effects of Ag NPs with IC_{50} values of 1.6, 2.3, and 2.2 µg/mL	[103]
Indigofera tinctoria (Leaf extract)	Silver nitrate	Spherical 9–26 nm	Anticancer, antimicrobial, antioxidant activity	IC_{50} values for Ag NPs and *I. tinctoria* leaf extract were 56.62 ± 0.86 µg/mL and 71.92 ± 0.76 µg/mL, respectively	[104]	*Morinda citrifolia* (Root extract)
Silver nitrate	Spherical and oval 32–55 nm	Anticancer activity	Complete cell death against HeLa cells was observed at 100 µg of Ag NPs	[105]	*Alhagi graecorum* (Leaf Extract)	Silver nitrate

Spherical 22–36 nm	Antifungal, antitumor	Antifungal activity was observed against *Candida albicans, glabrata, parapsilosis, tropicales*, and *krusei*. The inhibition zone ranged from 14 to 22 mm at 0.01 mmol/ml and from 17 to 27 mm at 0.02 mmol/mL	[106]	*Azadirachta indica* (Leaf and bark extract)	Silver nitrate	Spheroidal 13.01 nm (leaf) 19.30 nm (bark)

Antiplasmodial, hemolytic activity	Antiplasmodial activity against 3D7 and RKL9 P was demonstrated by IC_{50} values of 9.27 mg/mL and 11.14 mg/mL for leaf-mediated NPs and 8.10 mg/mL and 7.87 mg/mL for bark-mediated NPs. Ag NPs from the bark and leaves showed significant hemolytic activity (> 25%) at 125 µg/mL	[107]	Au	*Allium sp.*	Chloroauric acid	Spherical 11 nm

Antiviral	At 50% effective concentration (EC_{50} of 8.829 µg/mL), Au NPs actively inhibited MeV replication in Vero cells	[108]	*Sansevieria* (Leaf extract)	Chloroauric acid	Spherical 40–70 nm	Anticancer

Au NPs enhanced antiproliferative effect of Cisplatin on prostate cancer cells with minimal cytotoxicity	[109]	*Curcuma pseudomontana* (rhizomes)	Chloroauric acid	Spherical 39 nm	Anti-Inflammatory, antimicrobial, antioxidant	*P. aeruginosa* exhibited largest inhibition zone (13 mm) at 100 µg/m

						L of AuNPs, followed by *E. coli* (12 mm), and *B. subtilis* (11 mm) and *S.*

						aureus (11 mm). At 25 µg/mL, NP sexhibited high level of inhibition effi

						ciency(94%)incomparisontothestandarddrug(92%)

[110]	*Allium cepa* (Onion peel extract)	Gold trichloride	Spherical/triangular 25–70 nm	Antibacterial, anticandidal, antioxidant, proteasome inhibitory effect	Zones of inhibition measuring 10.66 to 19.95 mm demonstrated greater efficacy of Au NPs and kanamycin mixture against the tested pathogens. Au NPs and rifampicin mixture was limited to its activity against *S. aureus* (22.49 mm) and *E. coli* (9.99 mm). At 100 µg/mL, NPs showed moderate DPPH scavenging potential of 14.44%, while BHT (the reference standard) showed 36.54% at same concentration	[111]

Biosynthesis of nanoparticles using microbes

Actinomycetes, bacteria, fungi, marine algae, viruses, and yeasts have all been effective in the production of NPs employing unicellular and multicellular organisms (Fig. 2C) [113]. These organisms can produce reducing and stabilizing agents in the synthesis of NPs with a wide range of shapes, compositions, and physiochemical properties (Fig. 2D) [114]. Microorganisms can synthesize metallic NPs both intracellularly and extracellularly (Fig. 2E) [115]. To produce NPs extracellularly, microbes are cultivated in the appropriate environments. The microorganism-containing enzyme-rich broth is centrifuged to synthesize NPs [116]. The intracellular synthesis of NPs is carried out via the cellular mechanism of microbial cells [117]. Several studies explored extracellular methods for producing metal NPs [118]. Kalimuthu et al. investigated the role of the nitrate reductase enzyme in the production of Ag NPs by *Bacillus licheniformis*. The enzyme is responsible for converting Ag^{+} to Ag°, and they hypothesized that nitrate ions might play a role in its induction. Cofactors like NADH in NADH-dependent nitrate reductase enzymes are required for generating metal NPs. Bioreduction of Ag^{+} to Ag° may be caused by the release of cofactors NADH and NADH-dependent enzymes by *B. licheniformis*, in addition to other components, especially nitrate reductase [119]. *Pseudomonas stutzeri* was treated with a concentrated Ag NO_3 solution to produce Ag NPs in the periplasm [120]. Numerous fungi strains have been described for the extracellular biofabrication of NPs using CdS, Au, Zirconia, Si, Ti, and magnetite [121]. The method of NP production varies depending on the microorganisms. However, the basic concept involves microorganisms entrapping metal ions on their surface or within their cells, followed by their reduction to NPs. Electrostatic forces are frequently used as a trapping medium [122].

Bacteria

Bacteria can precipitate metals at nanoscale level as well as regulating interaction pathways for metal ion reduction [123]. *E. coli* biosynthesized Ag NPs of 50 nm size by a reliable and cost-effective approach [124]. *Pseudomonas aeruginosa* (*P. aeruginosa*) and other species have been studied for their ability to synthesize Zn, iron, nickel, Au, and Ag NPs [125]. The NADPH-dependent reductase enzyme may be involved in the reduction of Au^{3+} to Au° and

stabilization via capping molecules in the presence of *Stenotrophomonas maltophilia* [126]. Different bacterial species, as listed in Table 2, have been employed to produce metal NPs.

Table 2. Biosynthesis of metallic NPs using various bacteria and their biomedical applications

MNPs/MONPs	Bacteria used	Metal precursor used	Morphology	Biomedical applications	Findings	References
CuO	Marine endophytic *Actinomycetes* CKV1	Copper (II) sulfate pentahydrate	Spherical shape 10–30 nm	Antibacterial, anticancer, antibiofilm activity	At 750 µg/mL, CuO NPs showed remarkable antibacterial activity against *E. Coli* and *P. mirabilis*, exhibiting 24 mm and 28 mm zones. At 500 µg/mL, 54% inhibition was recorded against A549 cells	[127]

Streptomyces sp. MHM38	Copper (II) sulfate	Spherical 1.72–13.49 nm	Antimicrobial	CuO nanoparticles showed antibacterial efficacy against *Enterococcus faecalis*, *Salmonella typhimurium*, *E. coli*, *P. aeruginosa*, and *Candida albicans*	[128]	*Marinomonas Rhodococcus Pseudomonas Brevundimonas Bacillus*

Copper (II) sulfate pentahydrate	Spherical/ovoidal shapes 40 nm	Antibacterial, antifungal	The MIC of CuO NPs ranged from 3.12 to 25 µg/mL for Gram-negative bacteria, 12.5 to 25 µg/mL for Gram-positive bacteria, and 12.5 to 25 µg/mL for fungi	[129]	*Actinomycetes*	Copper (II) sulfate pentahydrate
Crystalline 198 nm	Antibacterial	*B. cereus* showed high susceptibility (25.3 mm) to CuO NPs. The CuO NPs inhibited bacterial pathogens *B. cereus, P. mirabilis*, and *A. caviae* at 5 µg/mL	[130]	ZnO	*Cyanobacterium Nostoc sp. EA03*	*Zinc acetate dihydrate*

Star-like shape 50–80 nm	Antibacterial, anticancer activity	MIC and MBC values for *E. coli, P. aeruginosa,* and *S. aureus* were found to be 2000, 2000, and 64 µg/mL, and 2500, 2500, and 128 µg/mL, respectively. ZnO NPs were less cytotoxic to MRC-5 lung fibroblast cells than to A549 cells treated with cancer	[131]	*Paraclostridium benzoelyticum* strain 5610	Zinc nitrate	Spherical/rectangular shape 50 nm

Antibacterial, anti-inflammatory, antidiabetic	Inhibitory zone of *Helicobacter suis* measured 19.53 ± 0.62 mm at 5 mg/mL. After 21 days. In arthritis model the edema was inhibited by NPs by 87.62 ± 0.12%. ZnO NPs sharply reduced glucose level in STZ-induced diabetic mice	[132]	*B. subtilis* ZBP4	Zinc sulfate heptahydrate	Pseudo-spherical 14–45 nm	Antibacterial

For *B. cereus, S. aureus, E. coli* O157:H7, *E. coli* Type 1, and *P. aeruginosa* the MIC was 1 mg/mL. It was 2 mg/mL for *L. monocytogenes* and *S. typhimurium*	[133]	*Saccharomyces cerevisiae*	Zinc acetate dihydrate	Spherical 20–30 nm	Antioxidant, antibacterial, anticancer, photocatalytic activity	ZnONPs showed concentration-dependent increases in anti-cancer activity

						. At 100 µg/mL, ZnONPs inhibited 93% cells

[134]	TiO_2	*B. subtilis*	Titanium dioxide	Spherical 70.17 nm	Treatment of dental caries	Dental caries responded best to treatment with 5% TiO_2, which had no discernible c

						yt ot o xi c ef fe ct s
[135]	*Rummeli i pycnus* *Acinetob acter baumanii Acinetob acter seohaen sis* *Bacillus cereus*	Titanium Oxychlorid e	Spherical/irregula r 8 nm	Antibacterial	Maximum zone of inhibition was found at 50 mL of TiO_2 NPs	[1 3 6]
Streptomyces sp. HC1	Titanium oxyhydro xide	Spherical 30–70 nm	Antimicrobial, antibiofilm	The highest level of antibiofilm activity was shown by 500 µL TiO_2 NPs produced by *Streptomyces sp.* HC1. Maximum zone of inhibition was recorded against *S. aureus* and *E. coli*	[137]	A g
Streptomyces rochei MS-37	Silver nitrate	Spherical 23.2 nm	Antibacterial, anti-inflammatory, antioxidant	Ag NPs had IC_{50} value of 34.03 µg/mL in CAL27 and 81.16 µg/mL in human peripheral blood mononuclear cells, indicating CAL27 was more susceptible to the NPs cytotoxicity. Ag NPs had MIC ranging from 8 to 128 µg/mL	[138]	*St re pt o m y c e s p ar v u s*

Silver nitrate	9.7–17.25 nm	Antimicrobial, antioxidant	*K. pneumoniae* (28.33 mm) and *E. coli* (21.66 mm) were susceptible to antibacterial activity. When compared to *E. faecalis* (125 µg/mL), *S. aureus* (250 µg/mL), *P. aeruginosa* (125 µg/mL), *K. pneumoniae* (500 µg/mL), and *E. coli* (250 µg/mL), the MIC of Ag NPs was significant	[139]	*Nocardiopsis dassonvillei*	Silver nitrate

Spherical 29.28 ± 2.2 and 32.13 ± 3.4 nm	Antimicrobial, antioxidant, anticancer	Ag NPs showed notable scavenging activity with IC_{50} values of 4.08 and 8.9 µg/mL against OH and DPPH radicals, respectively. Ag NPs with $CaCo_2$ cells demonstrated concentration dependent reduction in cell viability. Lactate dehydrogenase leakage increased as cell viability declined	[140]	*Bacillus amyloliquefaciens* MSR5	Silver nitrate	Spherical/cubical/and regular 29.2 nm

Anticancer, catalytic activity	Using $NaBH_4$, Ag NPs demonstrated potent chemocatalytic action, completely degrading 4-NP to 4-aminophenol (4-AP) in 15 min. Ag NPs activated A549cells	[141]	*Bacillus brevis (NCIM 2533)*	Silver nitrate	Spherical 41 nm	Antibacterial
Ag NPs demonstrated mean zone of inhibition 14, 15, 16, and 19 mm against *S. aureus* at 5, 10, 15, and 20 µL	[142]	Au	*Streptomyces sp.* NH21	Chloroauric acid	Spherical/rod 18–20 nm	Antibacterial

Ag NPs had MIC of 2.5 µg/mL against *E. coli*, 5 µg/mL against *K. pneumoniae*, *P. mirabilis*, and *S. infantis*, and 10 µg/mL against *P. aeruginosa* and *B. subtilis*. For *P. aeruginosa* and *B. subtilis* minimum bactericidal concentrations were 140 and 170 µg/mL	[143]	*Vibrio alginolyticus*	Chloroauric acid	100–150 nm	Antioxidant, anticancer	Colon cancer cell growth inhibited by AuNPs in a dose-dependent manner. 25

						µg/mL resulted in maximum inhibition of cell death (>75%), with an IC_{50} of 15 µg/mL

[144]	*Paracoccus haeundaensis* BC74171T	Chloroauric acid	Spherical 20.93 ± 3.46 nm	Antioxidant, anticancer	In HaCaT and HEK293 normal cells, Au NPs did not exhibit growth inhibition. Au NPs exhibited concentration dependent growth inhibition against A549 and AGS cancer cells	[145]

Fungi

Fungi are non-phototrophic eukaryotic microorganisms with rigid cell walls [147]. Fungi are among the biological sources that are exploited in bioremediation, can mineralize, and are known as mediators in the synthesis of NPs. This is due to their ability to create huge volumes of biomass [148]. Fungi can reduce the size of metal ions to NPs via two different processes: (i) through the contact of the fungus biomass with the metal inside the fungal cell and (ii) through the interaction of the fungus filtrate with the mineral solution outside the fungal cell [149]. This whole process is accomplished through two distinct mechanisms. First, the fungal cell wall traps metal ions on its surface due to the electrostatic interaction of the positively charged groups in the enzymes, and then, the cell enzymes reduce the metal ions to produce NPs. Second, the method involves the reduction of nitrates using NADPH secreted by fungi, followed by its conversion into NADP to produce extracellular NPs [150]. The myogenic pathway produces better NPs than bacteria and plants because they accumulate metals more efficiently. Triangle-shaped intracellular Au NPs (20–35 nm) synthesized by *Aspergillus clavatus* isolated from *Azadirachta indica* have been explored to demonstrate mycosynthesis [151]. *Phoma glomerata* can be used to synthesize Ag NPs that are antibacterial against resistant strains of *E. coli, P. aeruginosa, and S. aureus* [152]. *Trichoderma viride, Chaetomium globosum, Aspergillus niger, and Pleurotus ostreatus* can produce selenium NPs [153]. *Cladosporium perangustum* aqueous extract-derived Ag NPs decreased MCF-7 cell viability by increasing caspase-3, caspase-7, caspase-8, and caspase-9 expression [154]. Metallic NPs derived from various fungi are presented in Table 3.

Table 3. Biosynthesis of metallic NPs using various fungi and their biomedical applications

MNPs/MONPs	Fungi used	Metal precursor (medium) used	Morphology	Biomedical application	Findings	References

Fe_2O_3/Fe_3O_4	*Penicillium spp.*	Iron (III) chloride	Spherical 3.31 to 10.69 nm	Antibacterial, antioxidant activity	NPs demonstrated inhibition activity at 250 µg against *S. aureus* (12 ± 0.6 nm), *E. coli* (11.3 ± 1.2 nm), *K. pneumoniae* (11.3 ± 0.6 nm), *S. sonnie* (11.3 ± 0.6 nm), and *P. aeruginosa* (11.3 ± 0.6 nm). NPs exhibited antioxidant potential against DPPH radical as compared by ascorbic acid with IC_{50} values of 12.2 µg/mL	[155]
A. flavus	Iron (II) sulfate heptahydrate	Spherical 28.6–33.8 nm	Antimicrobial	Maximum (10 mm) inhibition of bacterial growth against *S. aureus* was demonstrated by Fe NPs. Zones of inhibition against *S. aureus* and *P. aeruginosa* were 12.3 and 10.5, respectively	[156]	*Aspergillus terreus*
Iron (III) chloride	Spherical 40–100 nm	Anticancer	Cell viability dropped to 41.9%	[157]	CuO	*Trichoderma asperellum*

Copper (II) nitrate trihydrate	Spherical 110 nm	Anticancer	CuO NPs significantly increased cell death. IC_{50} for CuO NPs in A549 cell lines was 40.625 µg/mL	[158]	*Aspergillus fumigatus*	Copper (II) nitrate trihydrate
Spherical 48 nm	Antibacterial	At 100 µg/mL, CuO NPs showed maximum scavenging activity against DPPH (73.65%)	[159]	*Aspergillus terreus*	Copper sulfate	Less than 100 nm
Antimicrobial, antioxidant, anticancer	CuO NPs exhibited the highest activity against *P. aeruginosa, E. coli,* and *V. cholera* (50% cell inhibition at 22 µg/mL)	[160]	*Shizophyllum commune*	copper (II) chloride	Spherical 22 to 60 nm	Antibacterial, antifungal

Highest antibacterial efficacy was shown against *S. aureus* followed by *E. coli*. At 150 µM, inhibition zone of 1.7 cm and 1.9 cm was recorded in *C. albicans* and *F. oxysporum*, *respectively*	[161]	ZnO	*Pleurotus ostreatus*	Zinc nitrate	Spherical 7.50 nm	Antibacterial, anticancer

Mushroom extract induced dose-dependent decline in cell viability for Hek293 cells. Lowest cell viability (22%) was recorded at 2000 µg/mL. ZnO NPs synthesized from mushrooms demonstrated comparable cytotoxic effects on HepG2 and Hek293 cells. A steep drop in cell viability in HepG2 cells (97% at 16 µM to 12% at 100 µM) and Hek293 cells (94% at 16 µM to 22% cells at 100 µM) was recorded	[162]	*Cladosporium tenuissimum FCBGr*	Zinc nitrate	Hexagonal Less than 100 nm	Antimicrobial, antioxidant, anticancer	ZnONPs had an IC_{50} concentration of 62 µg/mL for DPPH radical scavenging activity. At 58 µg/mL, NP

						s inhibited 50% of nitric oxide radicals. ZnONPs (1 mg/mL) inhibited HeLa cell lines at a rate of 89.59% indi

						catingtheireffectivenessagainstcervicalcancercells
[163]	*Aspergillus niger*	Zinc acetate	Spherical 23.97 ± 2.29 nm	Antibacterial	MIC values for the antibacterial potential against the tested *S. aureus* ranged from 8 to 128 μg/mL	[164]
TiO_2	*Tricoderma citrinoviride*	Titanium isopropoxide	Irregular/triangular, pentagonal/spherical rod-shaped 10–400 nm	Antibacterial, antioxidant	The biogenic TiO_2 NPs (100 μg/mL) exhibited remarkable antibacterial efficacy when tested on planktonic cells of clinical isolates of *P. aeruginosa* that are highly resistant to drugs. The antioxidant potential of TiO_2 NPs was superior to gallic acid	[165]

Fomitopsis pinicola	Titanium (IV) isopropoxide	Spherical 10–30 nm	Antibacterial, anticancer	MIC/MBC values were 62.5/125 and 62.5/125 μg/mL for *E. coli* and *S. aureus*. Strong cytotoxic effect of TiO_2 NPs was observed against HCT-116 cancer cells	[166]	Ag
Penicillium oxalicum (*Amoora rohituka* plant leaf)	Silver nitrate	Spherical 15–19 nm	Antimicrobial, antioxidant, anticancer	MIC_{25}, MIC_{50}, and MIC_{75} values of Ag NPs against *E. coli* were 8.710 ± 0.217, 12.369 ± 0.099, and 81.857 ± 0.453 μg/mL, respectively. The corresponding values for *S. aureus* were 14.417 ± 0.011, 20.975 ± 0.008, and 61.614 ± 1.452 μg/mL, respectively	[167]	*F. oxysporum* (*Withania somnifera* leaves)
Silver nitrate	Spherical 10–50 nm	Antibacterial Cytotoxic activity	All the Gram-negative and Gram-positive organisms were found to be sensitive and to exhibit a zone of clearance	[168]	*Aspergillus brasiliensis*	Silver nitrate

Spherical 6–21 nm	Antibacterial, antifungal	Ag NPs inhibited *B. subtilis, S. aureus, E. coli, P. aeruginosa,* and *C. albicans* in distinct zones, measuring 12, 15, 12, 12, and 14 mm, respectively	[169]	*Trichoderma spp.*	Silver nitrate	Spherical
Antibacterial	Gram-negative bacteria (*E. coli* and *P. aeruginosa)* had lower MIC values than Gram-positive bacteria (*S. aureus and E. faecalis*)	[170]	*Alternaria sp*	Silver nitrate	Spherical 3–10 nm	Antifungal
The MIC of Ag NPs was 25 µL, whereas all fungal strains grew at very low rates (50 and 100 µL)	[171]	Au	*Cladosporium species* (*C. wightii* leaves)	Chloroauric acid	Spherical (irregular morphology) 5–10 nm	Anticancer effect

IC_{50} value of the Au NPs was 38.23 µg/mL in breast cancer cell line MCF-7	[172]	*Trichoderma hamatum* SU136	Gold chloride	Spherical/pentagonal/hexagonal 5–30 nm	Antibacterial	Compared to the clear zones surrounding streptomycin and gold chloride, the Au NPs' clear zone appear

						ance was smaller and showed antibacterial activity against all tested bacterial strains; no clear zones were ob

						served surrounding the fungal mycelial-free extract
[173]	*Alternaria alternata*	Chloroauric acid	Spherical/triangular/hexagonal 2–30 nm	Antifungal	—	[174]

Algae

Algae have the capacity to accumulate heavy metal ions. These aquatic microorganisms have been explored to synthesize NPs [176]. Using *Tetraselmis kochinensis*, spherical Au NPs with sizes ranging from 5–35 nm were produced intracellularly [177]. *Sargassum polycystum* (a brown algae)-based CuO NPs had excellent anticancer characteristics and great potential against pathogenic bacteria [178]. Priyadharshini et al. used *Gracilaria edulis* (macroalgae) extract to synthesize Ag and ZnO NPs. The synthesized NPs exhibited excellent antitumor activity against human PC3 cells [179]. *Hypnea musciformis* (Wulfen), a red macroalga, has been explored to synthesize Au NPs for its anti-fungal activity against *Aspergillus niger* and *Mucor spp* [180]. *Ecklonia cava* extract-loaded Ag NPs have shown significant anti-bacterial activity against *E. coli* and *S. aureus.* These NPs had antioxidant properties and anti-cancer activity against human cervical (HeLa) cells [181]. Numerous algal components and precursor salts employed in the synthesis and capping of metallic NPs are shown in Table 4.

Table 4. Biosynthesis of metallic NPs using various algae and their biomedical applications

MNPs/MONPs	Algae used	Metal precursor (medium) used	Morphology	Biomedical application	Findings	References
Fe_2O_3/Fe_3O_4	*Ulva lactuca*	Iron (III) chloride	Spherical 20 and 40 nm	Anticancer, anti-diarrheal activity	Significant cytotoxicity was observed in cancer cell lines treated with NPs at higher concentrations (50 mg/mL and 100 mg/mL). The zone of inhibition by *Ulva lactuca*-mediated NPs against *E. coli* and *S. aureus* were 29 ± 1 mm and 17 ± 2 mm, respectively	[182]
Colpomenia sinuosa, Pterocladia capillacea	Iron (III) chloride	Spherical 11.24–33.71 nm, 16.85–22.47 nm	Antibacterial, antifungal	Fe_3O_4 NPs demonstrated superior antifungal efficacy against *A. flavus* (9 mm) and *F. oxysporum* (6 mm) in contrast to Fe_3O_4 NPs derived from *P. capillacea* (7 &5 mm)	[183]	*Gracilaria edulis*
Iron (III) chloride	Cubic 20 nm–26 nm	Antibacterial, antifungal	NPs inhibited *P. aerogenosa* (bacteria), *A. nidulans*, and *C. albicans* (fungi)	[184]	*Oscillatoria limnetica*	Iron chloride hexahydrate

Trigonal rhombohedral	Antibacterial, antioxidant, anticancer	Maximum antifungal activity was observed against *Aspergillus versicolor* (MIC value 27 µg/mL and LD_{50} value 47 µg/mL). *B. subtilis* was the most suspected (MIC: 14 µg/mL) and *E. coli* was the least suspected strain (MIC 35 µg/mL)	[185]	CuO	*Bifurcaria bifurcata*	Copper (II) sulfate
Spherical 20.66 nm	Antibacterial	Zones of inhibition for *S. aureus* and *Enterobacter aerogenes* was 14 mm and 16 mm, respectively	[186]	*Sargassum polycystum*	Copper solution	–

Antibacterial, antifungal, anticancer	More antibacterial activity was shown in *P. aeruginosa* (15 ± 0.5 mm) than *Shigella dysenteriae* (6 ± 0.5 mm). IC_{50} value for NPs was 61.25 µg/mL	[178]	*Spirulina platensis*	Copper (II) acetate	30–40 nm	Antibacterial
Maximum zone of inhibition (28.0 ± 0.41 mm) was shown against *P. vulgaris*	[187]	ZnO	*S. marginatum*	Zinc nitrate hexahydrate	80–126 nm	Antiviral

NPs demonstrated 99.09% anti-dengue activity in C6/36 cell line	[188]	*Sargassum muticum*	Zinc acetate dihydrate	–	Anticancer	>55% cells survived at 175 µg/mL of ZnO NPs. Cell viability was <40% 175 µg/mL. HepG2 cell survival perc

						entage was 4.5%. Maximum radical scavenging was observed up to 89% at 2800 µg/mL with an EC_{50} value of 60

						0 µg/mL
[189]	*Anabaena cylindrica*	Zinc sulfate	Rod 40–60 nm	Anticancer, antibacterial	ZnO NPs had 50% reduction in cellular viability at 3% dose, while commercial ZnO showed an ED_{50} at 6% of doses. Zone of inhibition against *P. aeruginosa* and *S. aureus* was 10–22 mm and 9–12 mm, respectively	[190]
Ag	*Caulerpa racemosa*	Silver nitrate	Spherical/triangular 10 nm	Antibacterial	Zone of inhibition against *P. mirabilis* was 14 mm at 15 µL and 7 mm against *S. aureus* at 5 µL	[191]
Spirulina platensis Oscillatoria sp	Silver nitrate	Spherical 14.42–48.97 nm	Antiviral	90% reduction in cytopathic effect of HSV-1 by Ag NPs, with a high reduction rate (49.23%)	[192]	*Pithophoraoedogonia*
Silver nitrate	Cubical/hexagonal 25–44 nm	Antibacterial	Largest zone of inhibition observed against *P. aeruginosa* (17.2 mm) followed by *E. coli* (16.8 mm)	[193]	*Caulerpa serrulata*	Silver nitrate

Spherical 10 ± 2 nm	Antibacterial, catalytic	Maximum inhibition zone (21 mm at 75 µL) was observed against *E. coli*, while lowest inhibition zone (10 mm at 50 µL) was shown for *S. typhi*	[194]	Au	*Spirulina platensis Oscillatoria sp.*	Tetrachloroauric (III) acid trihydrate
Octahedral/Pentagonal/triangular 15.60–77.13 nm	Antiviral	90% reduction in cytopathic effect of HSV-1 by Au NPs at 31.25 µL with a high reduction rate of Au NPs (42.75%)	[192]	*Sargassum wightii*	Chloroauric acid	–
Antiviral	Au NPs showed cell viability of 93.12–85.18%	[195]	*Gracilaria corticata*	Chloroauric acid	Spherical 45–57 nm	Antimicrobial, antioxidant

Antibiotic-conjugated Au NPs showed antimicrobial activity against *E. coli* (24 mm) and *E. aerogenes* (21 mm). *S. aureus* (19 mm) showed the moderate antimicrobial activity	[196]	*Padina gymnospora*	Gold salt	Spherical/triangular/hexagonal 9–21 nm	Anticancer	50% reduction in cell viability in HepG2 (IC_{50} value of 51.9 nM) was recorded

Green-synthesized metallic nanoparticles for cancer treatment

Cancer is defined as an abnormal growth of tissue or cells characterized by uncontrolled autonomous division, with the number of cell divisions rising over time [4]. More than 200 distinct cancers have been identified, and they have six common basic characteristics: replicative immortality; the ability to generate new blood vessels; the ability to invade and spread to other organs; resistance to apoptosis; proliferative signaling; and evasion of growth [198]. NPs are used to increase the compatibility and bioavailability of natural bioactives for the treatment of different chronic disorders, including cancer [199]. NPs are often considered as a possible solution for this due to evidence of their ability to induce the apoptotic pathway in vitro, which implies their anticancer effect [200]. NPs have been demonstrated to produce ROS, which can activate pro-apoptotic pathways. Different biogenic metal oxide NPs have shown promising results in the treatment of cancer by producing cytotoxicity in malignant cells while having no effect on normal cells. The specific mechanism by which various metal and metal oxide NPs kill cancer cell types is unclear [201]. It is widely believed that mitochondrial signaling pathways play a crucial role in NP-based activation of apoptosis in cancer cells. Metallic NPs usually produce ROS, which causes oxidative stress and apoptosis [202]. Apoptosis begins with apoptotic protein activation, DNA damage, mitochondrial breakdown, apoptosome formation,

and cell shrinkage [203]. Prostate and lung cancer cells are sensitive to cytotoxic activities in *Pinus roxburghii* bioactive-loaded Ag NPs. The ability of mitochondrial depolarization and DNA damage to trigger apoptosis via the intrinsic route have been reported. ROS, cell cycle arrest, and caspase-3 activation cause cancer cell apoptosis [204]. A class of protease enzymes called caspases is important for the apoptotic process. By activating the executioner caspase-3 through cleavage, the initiators caspase-8 and caspase-9 specifically cause the proteolysis of poly(ADP-ribose) polymerase (PARP) and apoptosis by impairing DNA repair [205].

Breast cancer

Breast cancer has surpassed lung cancer as the most frequent cancer in the world, with 2.26 million recorded cases per year, 11.7% of all cancer cases, and 24.5% of malignancies in women. Furthermore, it is the most frequent disease among women, accounting for 15.5% of all female cancer mortality each year [206]. With an emphasis on more biologically directed medicines and treatment deescalation to lessen side effects, therapeutic approaches have evolved over the past 10–15 years to take this heterogeneity into consideration [207]. Capping ZnO NPs with *R. fairholmianus* inhibited cellular development while increasing cytotoxicity and ROS. Apoptosis was also accompanied by an increase in pro-apoptotic proteins (p53, Bax), a decrease in anti-apoptotic proteins (Bcl-2), and a marked elevation in cytoplasmic cytochrome c and caspase 3/7 (apoptosis indicators) [208]. *Calendula officinalis* leaf extract was used as a green reducing and stabilizing agent in the biosynthesis of Sn NPs. These NPs showed remarkable potential in breast cancer treatment. The IC_{50} values for biosynthesized Sn NPs were 132, 126, and 119 µg/mL for the MCF7, Hs 319.T, and MCF10 cell lines, respectively [209]. *Gloriosa superba* rhizome extract was used in the synthesis of biomolecule-coated nanotitania catalysts. For the MCF-7 (cancer) and L929 (normal) cell lines, the IC_{50} of nanotitania catalysts was 46.64 and 61.81 µg/mL, respectively. Figure 3A shows that when nanotitania catalysts (46.64 µg/mL) were added to MCF-7 cells, they made a lot more intracellular ROS than control cells. This demonstrated that metal and metal oxide nanoparticle exposure increased ROS levels and decreased mitochondrial membrane potential. This suggested that the NPs induced apoptotic cell death. ROS generation can stimulate cell death by apoptosis and necrosis [210].

Fig. 3 [Images not available. See PDF.]

A Effects of *Gloriosa superba* rhizome and *Gloriosa superba* rhizome extract mediated titanium dioxide nanoparticles on intracellular ROS generation in treated MCF-7 cells, shown as follows: (a) nanotitania catalyst-treated cells, (b) rhizome extract, (c) control cells, **B** anticancer activity of CuO NPs synthesized from *S. alternifolium* stem bark extract, **C** Relative mRNA expression percentages following treatment of MCF7 cells with *Z. mauritiana* fruit extract-mediated Ag/AgCl NPs. A dashed line denotes an expression level of 1.0, **D** Pt NPs containing *P. granatum* stained by propidium iodide (a) control; (b) IC_{50} molarity (25 µg/mL); (c) maximum molarity (100 µg/mL). (**A** : under copyright (CC BY) from Taylor and Francis, **B**: under copyright (CC BY) from Springer, **C**: under copyright (CC BY) from ACS publication, and **D**: under copyright (CC BY) from Elsevier)

Yugandhar et al. reported that *Syzygium alternifolium* bark extract-loaded CuO NPs reduced treated cell lines by 50% in comparison with untreated cell lines with an IC_{50} value of 50 µg/mL (Fig. 3B) [211]. *Artabotrys hexapetalus* leaf extracts loaded CeO_2 NPs potent cytotoxicity against MCF-7 cancer cells at an IC_{50} value of 48 0.05 µg/mL [212]. Al-Nuairi et al. used MTT assay to examine the effects of Ag NPs from *Cyperus conglomeratus* root extract on MCF-7 breast cancer cells and normal fibroblasts. The selective cytotoxicity was found against MCF-7 with an IC_{50} of 5 µg/mL [213]. Kabir et al. treated MCF-7 cells for 48 h with *Zizyphus mauritiana* fruit extract-loaded Ag/AgCl NPs. A real-time polymerase chain reaction (PCR) was used to monitor the expression levels of eight apoptosis-related genes. FAS, caspase-8, and FADD expression levels were increased, and PARP expression levels were decreased (Fig. 3C) [214]. To confirm the antiproliferative activity of *P. granatum* crust extract-loaded platinum NPs (Pt NPs), Sahin et al. examined nuclear densification and apoptotic alterations using the propidium iodide staining in MCF-7 cell line. Only a few control cells responded positively to propidium iodide. A progressive increase in the proportion of cells that responded favorably to propidium iodide was seen in the cells treated with 25 µg/mL of Pt NPs after 48-h exposure (Fig. 3D) [215]. Table 5 shows various plant extracts and precursor salts explored to synthesize metallic

NPs for their breast cancer applications.

Table 5. Various plant extracts and precursor salts explored to synthesize metallic NPs for their breast cancer applications

Plant used	Metal precursor	Morphology	Cell line	Techniques used	IC_{50} value	Impact	References
Silver							
Tamarindus indica Fruit shell extract	Silver nitrate	Spherical 20–52 nm	MCF7	MTT assay, Dual staining (Ao/EtBr), DCFH-DA staining, Rhodamine 123 staining	20 µg/mL	More nuclear morphological changes significant induction in MMP level compared to control	[216]
Buchanania axillaris leaves	Silver nitrate	Spherical 17–80 nm	MCF7	MTT assay	31 µg/mL	The percent inhibitions of cell growth were found to increase with the increasing concentrations of the nanoparticle	[217]
Cyperus conglomeratus Root Extracts	Silver nitrate	Spherical 70–100 nm	MCF7	MTT assay, Flow cytometry, rtPCR	5 µg/mL	The IC_{50} concentration of synthesized Ag NPs after 24 h treatment of MCF-7 cells significantly reduced the mRNA levels of Bcl2, survivin, and YAP genes compared with control untreated MCF-7 cells	[213]

Phoenix dactylifera root extract	Silver nitrate	Spherical 21.65–41.05 nm	MCF-7	MMTT assay, AO/EtBr staining, Flow cytometry	29.6 µg/mL	At S-phase, it was discovered that the cell cycle is arrested, significantly slowing down the rate of cell division	[218]
Conocarpus Lancifolius fruits extract	Silver nitrate	Spherical 5–30 nm	MDA-MB-231	MMTT assay, DCFH-DA staining, Hoechst blue staining, Rhodamine 123	16.8 µg/mL	Observed dose-dependent cytotoxicity against MDA-MB-231 cells through activation of reactive oxygen species (ROS) generation	[219]
Gold							
Mentha Longifolia leaf extract	Chloro auric acid	Spherical 36.4 nm	MCF7 Hs578Bst Hs319.T UACC-3133	MTT assay	MCF7: 274 µg/mL Hs 578Bst: 279 µg/mL Hs 319.T: 274 µg/mL UACC-3133: 201 µg/mL	The biosynthesized nanoparticles had effective antibreast cancer effects against MCF7, Hs 578Bst, Hs 319.T, UACC-3133 cell lines without any cytotoxicity activity against normal cell line i.e., HUVEC	[220]
Tecoma capensis (L.) leaves extract	Gold tetrachloroaurate	Spherical 10–35 nm	MCF7	MTT assay, DPPH assay	*T. capensis* extract: 23.3 µg/mL *T. capensis* Au NPs: 9.6 µg/mL	Both *T. capensis* Au NPs and *T. capensis* extract showed significant antioxidant activity with DPPH scavenging percentages of 70.73% for *T. capensis* Au NPs and 85.62% for *T. capensis* extract	[221]
Copper oxide							

Prunus nepalensis Fruit	Copper sulfate	Crystalline 42.5 nm	MCF7 Human normal cell line: MCF10A	MTT assay, Quantitative RT-PCR	158.5 µg/mL	RT-PCR results showed upregulation in p53, caspase-3, Bax, and caspase-9. Down regulation of mRNA expression recorded in Myc and Ras genes in MCF-7 cells	[222]
Acalypha indica leaf extract	Copper sulfate	Spherical 26–30 nm	MCF7	MTT assay	56.16 µg/mL	Plant-mediated copper oxide NPs showed best anticancer activity	[223]
Syzygium alternifolium stem bark	Copper sulfate pentahydrate	Spherical 5–13 nm	MDA-MB-231	MTT assay	50 µg/mL	From 10, 25, 50, and 100 µg/mL, the concentration of CuONPs increased	[211]
Wrightia tinctoria (Wt) extract	Copper sulfate pentahydrate	Spherical 15–40 nm	MCF-7	MTT assay	119.23 µg/mL	The release of copper ions from the nanoparticles, which bind to the cell's DNA, is the primary cause of Cu NPs harmful effects on cancer cells. As a result, it damages DNA and induces cell death	[224]
Titanium oxide							
Gloriosa superba rhizome extract	Titanium hydroxide	Spherical 20–100 nm	MCF7 Normal fibroblast mouse cells: L929	MMTT assay, AO/EtBr and Hoechst staining, DCFH-DA staining, Rhodamine 123, Comet assay	MCF-7: 46.64 µg/mL L929: 61.81 µg/mL	COMET assay confirmed the DNA destruction in the nanotitania-treated cancer cells. The biomolecule-coated nanotitania catalysts could be used as potential and novel comp	[210]

Zanthoxylum armatum leaf extract	Titanium tetrabutoxide	Spherical 15–50 nm	murine 4T1 mammary carcinoma cells	RPMI-1640 assay, Flow cytometry, TBARS assay, Hemolysis assay	4.11 µg/mL	*Z. armatum*-derived NPs are as efficient as doxorubicin toward breast carcinoma with no symptoms of cardio toxicity and alteration in the body weight making them safer than doxorubicin	[225]

Lung cancer

Lung cancer is the sixth-leading cause of mortality worldwide [226]. With estimated yearly occurrences of 2.21 million (11.4% of cancer cases) and a mortality rate of 1.79 million lung cancer patients per year, lung cancer is still prevalent in all nations. Lung cancer is the second-leading cause of death in women after breast cancer [227]. Because of the long-term adaptation of cancer-causing behaviors including smoking, physical inactivity, and westernized diets, the global incidence of lung cancer is quickly rising [228]. Au NPs containing leaf extract of *Alternanthera bettzickiana* reduced cancer cell growth and triggered apoptosis, DNA breakage, and altered mitochondrial membrane potential in lung cancer cell lines. Au NPs had an impact on cellular M-phase entry. Au^{+} may activate p53 and other cell cycle genes, delaying the entry of cells into the M-phase and increasing apoptosis [229].

Cleistanthus collinus extract loaded into Ag NPs has been explored as a reducing and capping agent. The scavenging of free radicals was significantly impacted by the in vitro antioxidant activity of Ag NPs. The IC_{50} for human lung cancer cells (A549) and normal cells (HBL-100) was 30 µg/mL and 60 µg/mL, respectively. Ag NPs do not have any adverse effects on mice organs [230]. A549 cells exposed to 50 µg/mL *Magnolia officinalis* extract-loaded Au NPs showed substantial cell death. TUNEL and DAPI staining of A549 lung cancer cells *Magnolia officinalis* extract-loaded Au NPs confirmed ROS-arbitrated apoptosis (Fig. 4A). The TUNEL assay stained with green fluorescence showed live cells. *Magnolia officinalis* loaded Au NPs confirmed increased apoptotic cells with DAPI staining with blue fluorescent cells [231]. MTT assay to test the anti-lung cancer activity of *Ledebouria revoluta* bulb extract-loaded TiO_2 NPs showed an IC_{50} value of 53.65 µg/mL and showed improved antitumor activity against A549 cells [232]. At 100 µg/mL, biogenic Au NPs showed that Vero cells remained alive; however, these NPs were cytotoxic (IC_{50} 60 µg/mL) against A549 lung cancer cells (Fig. 4B) [233]. The proliferative activity of A549 cells gradually decreased over time in proportion to the increasing concentration of the test substance during the biological synthesis of Pt NPs using *Ononidis radix* extract. The mortality of cells cultured with platinum NPs increased [234]. *Lonicera japonica* extract-loaded Ag NPs at 75 µg/mL concentration showed 52% cell viability (Fig. 4C) [235]. In a xenograft severe combined immunodeficient mouse model, H1299 tumor growth was inhibited by Ag NPs synthesized from longan peel powder. After 36 days of treatment, the lung tumor size was 1.13 ± 0.21 mm^2 and 0.49 ± 0.07 mm^2 in the control and Ag NP-treated groups, respectively [236]. Valodkar et al. conducted in vitro toxicity research on human lung cancer cells using plant latex-capped Ag NPs. At the higher dose, more dead cells (in red) and very few live cells (in green) were seen, indicating a dose-dependent mortality of the cells ranging from 20 to 80% (Fig. 4D) [237]. Table 6 shows various plant extracts and precursor salts explored to synthesize metallic NPs for their lung cancer applications.

Fig. 4 [Images not available. See PDF.]

A By using DAPI/TUNEL dual staining, Au NPs synthesized by Magnolia officinalis were determined to increase ROS-arbitrated apoptosis. **B** The cytotoxicity of biogenic Au NPs using bael fruit juice was studied against A549. **C** Anti-cancer ability of synthesized silver nanoparticle (Ag NPs) using phytochemical rich medicinal plant *Lonicera japonica* proved against A549 lung cancer cells by cell viability assay. **D** AO/EB staining of plant latex-capped silver nanoparticles in A549 (cells more dead cells (in red) and very few live cells (in green) in highest dose of LAgNP)

exposed to (a) 0 μg/mL LAg NPs, (b) 1 μg/mL LAg NPs, (c) 10 μg/mL LAg NPs, (d) 20 μg/mL LAg NPs,(e) 50 μg/mL LAg NPs and (f) 100 μg/mL LAg NPs (**A:** under copyright (CC BY) from Taylor and Francis, **B**, **C** and **D** under copyright (CC BY) from Elsevier)

Table 6. Various plant extracts and precursor salts explored to synthesize metallic NPs for their lung cancer applications

Plant used	Metal precursor	Morphology	Cell line	Techniques used	IC_{50} value	Impact	References
Silver							
Citrus sinensis leaf aqueous extract	Silver nitrate	Spherical 78.12 nm	NCI-H661, HLC-1, NCI-H1563, LC-2/ad, NCI-H1299, PC-14, HUVEC	DPPH assay, MTT assay	NCI-H661: 82 μg/mL HLC-1: 139 μg/mL NCI-H1563:170 μg/mL LC-2/ad: 66 μg/mL NCI-H1299: 62 μg/mL PC-14: 50 μg/mL	Dose-dependent decrease in human lung cancer cell viability reported	[238]
Leucus aspera leaf extract	Silver nitrate	Spherical 40.67–8.17 nm	A549 HUVEC	DPPH assay, MTT assay	328 μg/mL	No cytotoxicity on the normal cell line (HUVEC) and very low cell viability against the A549 cell line	[239]
Avicennia marina leaf extract	Silver nitrate	Spherical 10–100 nm	A549	MTT assay, DCFH-DA assay, Rhodamine 123	50 μg/mL	High damages in mitochondrial membrane	[240]

Cleome viscosa L fruit extract	Silver nitrate	Spherical 20–50 nm	A549	MTT assay	28 µg/mL	The ability of green-synthesized silver nanoparticles to inhibit cancer cells growth in vitro could be taken as an indicator of potential anticancer effect	[241]
Lonicera japonica leaves extract	Silver nitrate	Spherical	A549	MTT assay	75 µg/mL	At very low concentrationsAg NPs altered the shape of A549 human lung cancer cells	[235]
Gold							
Rabdosia rubescens	Gold (III) chloride trihydrate	Spherical 130 nm	A549	MTT assay, DAPI staining, TUNEL assay, Western blotting analysis	50 µg/mL	Caspase levels were found to be 1.5 times higher in the cells treated with 25 µg/mL of RR-AuNP	[242]
Musa paradisiaca peel extract against	Chloroauric acid	Spherical to triangular 50 nm	A549	MTT assay	58 µg/mL	Nuclear morphological changes, such as cell clumping and a lack of membrane stability, after 24 h at 100 µg/mL	[243]
Marsdenia tenacissima plant extracts	Chloroauric acid	Spherical 40–50 nm	A549	MTT assay, AO/EtBr staining, Western blotting	15 µg/mL	Modulates the levels of the proteins Bax and Bcl-2 to cause apoptosis in the lung cancer cell line A549	[244]

Magnolia officinalis extract	–	Oval, spherical, hexagonal, and triangular 70–10 nm	A549	MTT assay, DCFH-DA, TUNEL assay, Western blotting	50 µg/mL	In A549 cells, Au NPs made from Magnolia officinalis increased the expression of Bax, Beclin-1, and caspase-3 while decreasing the expression of Bcl-2 and Bid	[231]
Zinc oxide							
Azadirachta indica leaf extract	Zinc sulfate heptahydrate	Ribbon/strip shaped	A549	MTT assay, Crystal violet assay, AO/PI staining, Flow cytometry	138.50 µg/mL	Apoptosis was observed in cells treated with IC_{50} dose G1 phase accounted for 76.9% cells get arrested in A549 cells after treatment	[245]
Euphorbia fischeriana root extract	Zinc acetate dehydrate	Spherical 30 nm	A549	MTT assay, AO/EtBr fluorescence staining, DCFH-DA assay, Rhodamine 123, Cell migration assay, Western blotting analysis	14.5 µg/mL	EF-ZnO NPs induced cytotoxicity also activated apoptosis during increased ROS formation, decreased MMP, inhibited cell migration, altered AO/EtBr staining and induced pro-apoptotic and inhibited anti-apoptotic protein were observed	[246]

Mangifera indica leaf extract	Zinc nitrate	Spherical/hexagonal quartzite 45–60 nm	A549	MTT assay	25 µg/mL	Anticancer activity of ZnO NPs increased with the increasing concentration of NPs and is comparable to the cytotoxic effects of cyclophosphamide in low doses	[247]
Copper oxide							
Calendula officinalis aqueous leaf extract	Copper (II) Nitrate Trihydrate	Spherical 19.64–39.15 nm	LC-2/ad PC-14 HLC-1	DPPH assay, MTT assay	PC-14: 297 µg/mL LC-2/ad:328 µg/mL HLC-1:514 µg/mL	The viability of malignant lung cell line reduced dose-dependently	[248]
Ficus religiosa leaf extract	Cupric sulfate	Spherical	A549	MTT assay, AO/EtBr fluorescence staining, DCFH-DA assay, Rhodamine 123	200 µg/mL	When compared to control, A549 cells treated with copper oxide nanoparticles showed loss of membrane integrity, apoptosis induction, and orange fragmented nuclei, all of which were consistent with low cell viability	[249]
Ilex paraguariensis	Copper(I) sulfate	Spherical 26–40 nm	A549	MTT assay	100 µg/mL	In lung cancer A549 cells, Cu NPs with a size of less than 20 nm caused cytotoxicity	[250]

Beta vulgaris extract	Cupric sulfate	Spherical 33.47 nm	A549	MTT assay, FACS analysis	25 µg/mL	In comparison to control, A549 cells decreased at the G0/G1 phase from 52.8 to 20.6%, increased at the S phase from 38.43 to 30.41%, and considerably increased at the G2/M phase from 14.56 to 52.46%	[251]
Foeniculum vulgare leaves extract	Copper (II) nitrate trihydrate	Spherical 33.62–74.81 nm	NCI-H2126, NCI-H1299, NCIH1437 Normal cell line: HUVEC	MTT assay DPPH assay	Fv-Cu NPs NCI-H2126: 122 µg/mL NCI-H1299: 168 µg/mL NCI-H1437: 108 µg/mL *F. vulgare* extract NCI-H2126: 594 µg/mL NCI-H1299: 781 µg/mL NCI-H1437: 610 µg/mL	The viability of malignant lung cell lines reduced dose-dependently in the presence of NPs. The IC_{50} of Cu NPs and BHT against DPPH free radicals were 42 and 26 µg/mL, respectively	[252]
Titanium oxide							
Ledebouria revoluta bulb extract	Titanium dioxide	Spherical 47.6 nm	A549	MTT assay	53.65 µg/mL	Highly reactive hydroxyl act as a powerful oxidant resulting in oxidative DNA-damage both single and double standard DNA	[232]

Cervical cancer

About 604,127 new cases and 341,831 fatalities from cervical cancer are reported in 2020 [253]. *Solanum nigrum* leaf extract-loaded ZnO NPs inhibited β-catenin, increased the levels of p53, caspase-3, and caspase-9, and showed a dose-dependent cytotoxic effect against HeLa cell lines [254]. After 24 h of treatment, *Catharanthus roseus* extract (5 µg/mL) loaded in Au NPs induced apoptosis in HeLa cells dual stained with acridine orange

(AO)/ethiduim bromide (EtBr). The control cells showed homogeneous bright green nuclei and cytoplasm for AO-positive cells. In Ao/EtBr staining, the cells treated with the synthesized NPs showed characteristics of apoptosis such as nuclear condensation, cell shrinkage, and the formation of apoptosis bodies (Fig. 5A). HeLa cells were incubated with *Catharanthus roseus* extract-loaded Au NPs at different concentrations (5 and 10 µg/mL) for 24 h to measure the level of ROS production (Fig. 5B) [255]. *A. officinalis* root extract-loaded Ag NPs are toxic to SiHa cell lines, with an IC_{50} of 44 µg/mL. The biosynthesized Ag NPs arrested cell division in the G2/M phases and accelerated the cell cycle in the G1 and S phases [256]. Extract of *Euphorbia antiquorum* L. latex loaded in Ag NPs inhibited the growth of HeLa cell line with an IC_{50} value of 28 µg/mL [257]. After 24 h of incubation, Au NPs containing an aqueous extract of *Alternanthera sessilis* (1–15 µg/mL) showed cytotoxicity against HeLa cells (Fig. 5C) [258]. CuO NPs containing dry black beans (0.5 µg/mL and 1 µg/mL) have shown cytotoxic effects against HeLa cells. CuO NPs inhibited cervical carcinoma colonies and influenced the generation of ROS. The number of cervical carcinoma cell colonies was much lower in CuO NPs-treated cells than in the control group (Fig. 5D) [259]. Table 7 shows various plant extracts and precursor salts explored to synthesize metallic NPs for their cervical cancer applications.

Fig. 5 [Images not available. See PDF.]

A Ao/EtBr staining after 24 h of treatment with various concentrations (5 and 10 µg/mL) of photosynthesized Au NPs from *Catharanthus roseus*. **B** Using DCFH-DA staining assay photosynthesized Au NPs from *Catharanthus roseus* induces ROS production in HeLa cells. **C** The ability of Au NPs from *A. sessilis* to cause cytotoxicity in HeLa cervical cancer cell lines. **D** Clonogenic survival assay on HeLa cells following incubation with CuO NPs synthesized using an aqueous black bean extract NPs (**A**, **B** and **C** under copyright (CC BY) from Taylor and Francis, **D**. under copyright (CC BY) from Elsevier)

Table 7. Various plant extracts and precursor salts explored to synthesize metallic NPs for their cervical cancer applications

Plant used	Metal precursor	Morphology	Cell line	Techniques used	IC_{50} value	Impact	References
Silver							
Nepeta deflersiana aerial part	Silver nitrate	Spherical 33 nm	HeLa cells	MTT assay, Neutral red uptake assay, DCFH-DA, rhodamine-123	5 µg/mL	ND-Ag NPs have the capacity of inducing apoptosis and necrosis cell death of HeLA cells through SubG1 cell cycle arrest	[260]

Moringa olifera stem bark extract	Silver nitrate	Spherical 40 nm	HeLa cells	Annexin V/PI double-staining assay NRU, DCFH-DA, DAPI staining	–	The increased level of ROS revealed that most of the cells underwent induction of early apoptosis caused by oxidative stress, while many of the inhibitors that induce apoptosis show antioxidant activity	[261]
Detarium microcarpum leaf extract	Silver nitrate	Spherical/rectangular 81 nm–84 nm	HeLa cells	Presto blue cell viability assay	31.5 µg/mL	The synthesized NPs had inhibitory effect on cervical cancer cells	[262]
Gold							
Catharanthus roseus leaf extract	$HAuCl_4$	Spherical 25–35 nm	HeLa3T3 cell lines	MTT assay, AO/EtBr staining, DCFH-DA staining, Rhodamine 123 Caspases activity assay, Western blotting	5 µg/mL	The cytotoxicity and apoptosis of human cervical carcinoma (HeLa) cells increased Caspase-3 was cleaved after being exposed Biosynthesized NPs for 24 h	[255]
Pongamia pinnata leaf extract	$HAuCl_4$	Spherical 55 nm	HeLa cells Human embryonic kidney cell line: HEK293	MTT assay, Flow cytometry, Rhodamine 123, Wound healing/cell migration assay	200 µg/mL	Au NPs gets internalized into HeLa cells by endocytosis. Inside the cytosol, it exhibited cytotoxic effect by elevating intracellular ROS, perturbing the MMP, arresting cells at S-phase of the cell cycle and finally inducing cell death by apoptosis	[263]
Copper oxide							

Brassica oleracea var acephala leaf extract	Copper sulfate	Spherical 60–100 nm	HeLa cells	MTT assay	119.0805 µg/mL	The vitality of cancer cells declines as sample concentration rises, whereas cytotoxicity against HeLa cell lines rises as sample concentration rises	[264]
Phaseolus vulgaris	Copper sulfate	Spherical, hexagonal 26.6 nm	HeLa	SRB assay, Hoechst 33,258 staining, DCFH-DA, Clonogenic assay	0.5 and 1 µg/mL	In a dose-dependent manner Induced intracellular ROS generation	[259]
Houttuynia cordata	Copper sulfate	Spherical 40–45 nm	HeLa	MTT assay, DCFH-DA, EtBr/AO staining, DAPI staining, Pi stainin, Q-RT-PCR	5 µg/mL	Biosynthesized NPs inhibited cell proliferation and promoted apoptosis by targeting PI3K/Akt signaling pathways in HeLa cells	[265]
Titanium oxide							
Coleus aromaticus leaf extract	TiO_2	Hexagonal shape 12–33 nm	HeLa	MTT assay	34.45 µg/mL	Increased oxidative stress, destroyed the cell membrane, enhanced lipid peroxidation, lowered the level of glutathione (GSH), and eventually contributed to cells' death	[266]

Colorectal cancer

Colorectal cancer (CRC) is the second most lethal and third-most prevalent cancer worldwide. It accounts for 9.2% of all cancer-related deaths and 10.2% of all new cases. Aqueous extract of *Allium cepa* loaded in Ag NPs promotes apoptosis by suppressing expression of Bcl2 family genes [267]. *Albizia lebbeck* extract (40 and 60 µg/mL)-loaded CuO NPs showed early apoptosis (orange stained) and late apoptosis (red stained) apoptotic cells (Fig. 6A) for 24 h through the activation of a dual staining method by AO/EtBr in HCT-116 colon cancer cells [268]. Ag NPs containing *Pimpinella anisum* seed extract showed cytotoxicity against CRC cells. Ag NPs destroyed cancer cells through cell growth inhibition, cell cycle arrest in the G2/M phase, and induction of apoptosis [269]. AO/EtBr staining assay in HCT-116 cells showed that the *Trichosanthes kirilowii* extract loaded in Au NPs increased ROS production, damaged mitochondrial membrane, induced morphological alterations (Fig. 6B), induced G0/G1 phase cell-cycle arrest (Fig. 6C), activated caspase expression, and downregulated anti-apoptotic expression [270]. The cytotoxic effect of lead oxide and CeO_2 NPs synthesized using an aqueous extract of *Prosopis fracta* fruit was investigated in colon (HT-29) cancer cell lines. These NPs were not harmful at 500 µg/mL and 62.5 µg/mL [271]. Ag NPs containing *Curcuma longa* and *Zingiber officinale* rhizomes extract had an IC_{50} of 150.8 µg/mL. At a 25–500 µg/mL dose, the synthesized NPs were cytotoxic to HT-29 cells (Fig. 6D) [272]. Table 8 shows various plant extracts and precursor salts explored to synthesize metallic NPs for their colorectal cancer applications.

Fig. 6 [Images not available. See PDF.]

A Dual staining method by AO/EtBr in HCT-116 colon cancer cells. **B** Induction of apoptosis on HCT-116 cells treated with Au NPs synthesized from *Trichosanthes kirilowii* at various concentrations upto 24 h studied using AO/EB staining assay. **C** Cell-cycle analysis of HCT-116 cells treatment with Au NPs (15 and 20 µg/mL) synthesized from *Trichosanthes kirilowii*. **D** Anticancer activity of *Zingiber officinale* and *Curcuma longa* synthesized Ag NPs at different concentrations (a) control, (b) 500 µg/mL, (c) 250 µg/mL, (d) 100 µg/mL, (e) 50 µg/mL and (f) 25 µg/mL (**A**, **B** and **C** under copyright (CC BY) from Taylor and Francis, **D** under copyright (CC BY) from Elsevier)

Table 8. Various plant extracts and precursor salts explored to synthesize metallic NPs for their colorectal cancer applications

Plant used	Metal precursor	Morphology	Cell line	Techniques used	IC_{50} value	Impact	References
Silver							
Allium cepa L (*A. cepa*) extract	Silver nitrate	Cubic shapes 150–250 nm	HT-29 and 0SW620 cells	DPPH scavenging, activity, TAA, FRAP, MTT assay, RT-PCR, Flow cytometry	*A. cepa* TAA: 55.49 ± 0.91 DPPH-SA: 2.23 ± 0.36 FRAP:14.78 ± 0:20 Ag NPs-CEPA TAA: 58.85 ± 4.39 DPPH-SA: 1.91 ± 0.20 FRAP: 13.37 ± 0.17	The synthesized NPs inhibited cell proliferation and induced apoptosis by inhibiting Bcl2 family gene expression hence act as a promising anticancer agent for treating colorectal cancer	[267]
Anthemis atropatana aerial parts	Silver nitrate	Spherical 38.89 nm	HT29 cancer cell	MTT assay, RT-PCR, Flow cytometry, DNA fragmentation assay	100 µg/mL	Caused the cell to undergo early and delayed apoptosis by 15.64 and 21.32%, respectively	[273]
Vitex negundo L. leaves extract	Silver nitrate	Spherical 5–47 nm	HCT15	MTT assay, Propidium iodide staining, Flow cytometry, Comet assay	20 µg/mL	Ag NPs exerted antiproliferative effects on colon cancer cell line by suppressing its growth, arresting G0/G1-phase, inhibited DNA synthesis and induced apoptosis	[274]

Gold							
Albizia lebbeck leaf extract	HAuCl$_3$	Spherical 20 and 30 nm	HCT-116 colon cancer cell lines	MTT assay, AO/EtBr staining, DCFH-DA staining, Rhodamine 123, Caspases activity assay, Western blotting	48 µg/mL	HCT-116 cells improved the activity of caspase-9 and caspase-3 in a dose-dependent manner	[268]

Prostate cancer

Prostate cancer is the second most common cancer in men, with 1.41 million incidences annually (14.1% of all cancer cases in men) [275]. Green-synthesized nanosilver containing *Rosmarinus officinalis* extract exhibited cytotoxic effects against prostate cancer cells through the activation of caspase 3 and caspase 9 mRNA [276]. Firdhouse et al. examined the cytotoxic effect of nanosilver containing *Alternanthera sessilis* extract against prostate cancer cells (PC3) at 1.56, 3.12, 6.25, 12.5, and 25 µL/mL doses. The highest concentration (12.5 and 25 µL/mL) of Ag NPs showed a decrease in PC3 cancer cells (Fig. 7A) [277]. *Camellia sinensis L* extract loaded in Au NPs reduced PC-3 cell growth with an IC_{50} of 19.71 µg/mL. Surface detachment, cell shrinkage, and body distortion were observed in PC-3 cells. This demonstrated the cytotoxic effect of green tea extract containing Au NPs [278]. The cytotoxic effect of Au NPs containing an extract of desert truffles (*Tirmania nivea*) against normal human prostate cell lines and prostate cancer cell lines is shown in Fig. 7B [279]. *Salvia miltiorrhiza* extract has been used as a capping agent to synthesize Ag NPs to explore its cytotoxic property against PCa LNcap cell lines. The proliferation of LNcap cells was dramatically inhibited for 24 h with increasing concentration of Ag NPs (Fig. 7C) [280]. The IC_{50} for the PC3 cell line treated with green-synthesized ZnO NPs made from *Hyssopus officinalis* extract for 24 h and 48 h was 8.07 µg/mL and 5 µg/mL, respectively. The percentage of PC3 cells that underwent induced apoptosis was 26.6% ± 0.05, 44% ± 0.12, and 80% ± 0.07 [281]. The Trypan blue exclusion test was used to assess in vitro cytotoxicity in PC-3 cells. Ag NPs of *Dimocarpus longan Lour*. peel extract showed cytotoxic effect at a dose between 5 to 10 µg/mL with an IC_{50} value less than 10 µg/mL (about 50% of PC-3 cells died) (Fig. 7D) [282]. Table 9 shows various plant extracts and precursor salts explored to synthesize metallic NPs for their prostate cancer applications.

Fig. 7 [Images not available. See PDF.]

A Cytomorphological changes such as cancer cell membrane lyses, coiling with the addition of silver (a, b) and nanosilver synthesized using *Alternanthera sessilis* in (d, e) after 48 h compared to that of control. **B** The cytotoxicity of Au NPs synthesized using extract of desert truffles (*Tirmania nivea*) against normal human cell line (a) untreated cells, (b) treated cells with synthesized Au NPs, and against cancer cell line (c) control untreated VCaP cells, (d) Treated VCaP cells with synthesized Au NPs. **C** Cytotoxic potential of Ag NPs from leaf extract of *Salvia miltiorrhiza* in prostate cancer LNcap cell. **D** Dose-dependent cytotoxic effects of Ag NPs biosynthesized using *Dimocarpus Longan Lour*. Peel Extract on prostate cancer PC-3 cells in vitro (**A** and **D** under copyright (CC BY) from Springer, **B** under copyright (CC BY) from Elsevier, **C** under copyright (CC BY) from Taylor and Francis)

Table 9. Various plant extracts and precursor salts explored to synthesize metallic NPs for their prostate cancer applications

Plants used	Metal precursor	Morphology	Cell line	Techniques used	IC_{50} value	Impact	References
Silver							
Carica papaya leaf extract	Silver nitrate	Spherical 10–20 nm	DU145	MTT assay, DCFH-DA, Flow cytometry, AO/EtBr staining	5 µg/mL	G1-S phase cell cycle check point marker, cyclin D1 was down-regulated along with an increase in cip1/p21 and kip1/p27 tumor suppressor proteins by Ag NPs-PLE	[283]
Dimocarpus Longan Lour. Peel Extract	Silver nitrate	Spherical 9–32 nm	PC-3	Trypan Blue, Exclusion assay, Western blot analysis	Between 5 and 10 µg/mL	An increase in caspase-3 was seen along with a decrease in stat 3, bcl-2, and survivin	[282]
Dovyalis caffra fruit extract	Silver nitrate	Spherical 12–53 nm	PC-3	Sulforhodamine B (SRB) assay	–	At 100 µg/mL, microscopic observations revealed membrane shrinkage, failure of cell adhesion, blebbing of the cell membrane, lyses of the cell membrane, the emergence of unique cellular crinkle, and cell death	[284]

Indigofera hirsute L. leaf extract	Silver nitrate	Spherical 5–10 nm	PC-3	MTT assay	68.5 µg/mL	As the concentration of increases, the cells become clustered and exhibited morphological alterations which eventually leads to cell death or apoptosis	[285]
Salvia miltiorrhiza	Silver nitrate	Spherical, oval, hexagonal and triangular 80 and 12 nm	LNcap cells	MTT assay, DCFH-DA, TUNEL assay, AO/EtBr staining, Caspase-8, 9 and 3 activity assay, Western Blot Analysis	50 µg/mL	Ag NPs effectively causes cytotoxicity, ROS, and apoptosis in LNCap cell lines by altering the expression of intrinsic apoptotic genes	[280]
Gold							
Alhagi maurorum leaf aqueous extract	$HAuCl_4 \cdot H_2O$	Spherical less than 100 nm	DU 145, NCI-H660, 22Rv1, and LNCaP clone FGC)	MTT assay	DU 145: 229 µg/mL NCI-H660: 368 µg/mL 22Rv1: 298 µg/mL LNCaP clone: 222 µg/mL	The viability of malignant prostate cell lines reduced dose-dependently in the presence of Au NPs	[286]
Titanium oxide							
Coleus *aromaticus* leaf extract	TiO_2	Hexagonal shape 12–33 nm	HeLa	MTT assay	34.45 µg/mL	Increased oxidative stress, destroyed the cell membrane, enhanced lipid peroxidation, lowered the level of glutathione (GSH), and eventually contributed to cells' death	[266]

Skin cancer

In a study by Wu et al., aqueous *Siberian ginseng* extract was used as an organic reducing agent to biosynthesize Au NPs. These Au NPs were then tested against murine melanoma B16 cells for their anticancer properties. The results demonstrated that the synthesized Au NPs increased ROS levels and decreased mitochondrial membrane potential (Fig. 8A). The BH3 mimics by biosynthesized Au NPs increased the expression of pro-apoptotic proteins

while decreasing the expression of anti-apoptotic proteins in melanoma cells [287]. *Cassia fistula* leaf extract reduced silver ions to Ag NPs. The estimated IC_{50} values for the leaf extract, Ag NPs, and $AgNO_3$ were 96.36 1.01 μg/mL, 92.207 1.24 μg/mL, and 84.246 2.41 μg/mL, respectively. The percentage cell viability in Fig. 8B shows the dose-dependent effect of synthesized Ag NPs against cancer cell line [288]. The in vivo therapeutic efficacy of *Quisqualis indica* flower extract-derived Cu NPs was investigated by Mukhopadhyay et al. in mice carrying B16F10 melanoma tumors. A substantial reduction in tumor development was recorded. Quisqualis indica flower extract-derived Cu NPs triggered cytotoxicity and death in melanoma cells due to the gene expression [289]. In a study, polyphenols from *Vitis vinifera L.* (grape) peels were used as reducing and stabilizing agents for the synthesis of Au NPs. The IC_{50} value for *V. vinifera* peel extract was 319.14 μg/mL. The IC_{50} values of *V. vinifera* peel loaded Au NPs and fluorouracil (standard drug) were 23.6 μM and 23.43 μM, respectively. Figure 8C displays the percentage of inhibition plotted against the concentration of fluorouracil and peel extract-loaded Au NPs [290]. Ag NPs of *Indigofera longeracemosa* leaf extract revealed a dose–response relationship with an IC_{50} value of 48 μg/mL against the human skin cancer cell line SK MEL-28. Biosynthesized NPs upregulated the tumor suppressor gene p53 and significantly downregulated the anti-apoptotic gene Bcl-2 [291]. *Elephantopus scaber*-loaded Ag NPs were more effective against the A375 skin carcinoma cell line than its pure extract. After 48 h of incubation, morphological changes in treated A375 cells were observed under an inverted phase contrast tissue culture microscope (Fig. 8D) [292]. Table 10 shows various plant extracts and precursor salts explored to synthesize metallic NPs for their skin cancer applications.

Fig. 8 [Images not available. See PDF.]

A Using a 1-mM Rhodamine 123 staining approach, the apoptotic effect of *Siberian ginseng* synthesized Au NPs on the mitochondrial membrane permeability in murine melanoma cell line B16 was evaluated. **B** Ag NPs from the leaf extracts of *Cassia fistula* have been shown to be toxic to A-431 epidermal cancer cells (IC_{50} values for the leaf extract, Ag NPs, and $AgNO_3$ are anticipated to be 96.36 ± 1.01, 92.207 ± 1.24, and 84.246 ± 2.41 μg/mL, respectively). **C** Fluorouracil and *Vitis vinifera* peel Au NPs had an inhibitory effect on A431 cells 24 h after incubation. **D** Morphological changes induced on treated A375 cells by Ag NPs using the phytoreducing agent *Elephantopus scaber* (**A** and **D** under copyright (CC BY) from Taylor and Francis, **B** under copyright (CC BY) from Wiley Online Library, **C** under copyright (CC BY) from Elsevier)

Table 10. Various plant extracts and precursor salts explored to synthesize metallic NPs for their skin cancer applications

Plant used	Metal precursor	Morphology	Cell line	Techniques used	IC_{50} value	Impact	References
Silver							

Petals of *C. maxima*, Leaves of *M. oleifera* and the rhizome of *A. calamus*	Silver nitrate	*C. maxima*: Spherical 19 nm *A. calamus*: spherical 19 nm *M. oleifera*: rectangular 11 nm	A431	MTT assay	*C. maxima*: 82.39 ±3.1 µg/mL *M. oleifera*: 83.57 ±3.9 µg/mL *A. calamus*: 78.58 ±2.7 µg/mL	Ag NPs synthesized using petal extract have a higher IC_{50} value than those using rhizome extract	[293]
Trapa natans extract leaf extract	Silver nitrate	Spherical 30–90 nm	A431	MTT assay	64.2 µg/mL	Glycosides, amino acids, flavonoids, and polyphenols as well as nano-sized silver particles may be responsible for anticancer activity of biosynthesized Ag NPs	[294]
Cassia fistula leaf extract	Silver nitrate	Spherical 40–50 nm	A-431	MTT assay	92.2±1.2 µg/mL	The DLS findings showed that synthesized Ag NPs can also be utilized in conjunction with conventional medications to increase their efficacy	[288]
Gold							
Vitis vinifera L (grapes) peel extract	Hydrogen tetrachloroaurate (III) trihydrate	Spherical 20–40 nm	A-431	MTT assay DCFH-DA assay Tunel assay Rhodamine 123 AO/EtBr fluorescence staining	23.6 µM	Peel gold nanoparticle treatment resulted in a percentage of apoptotic cells of 10.02% and secondary necrotic cells of 55.5%	[290]

Siberian ginseng aqueous extract	HAuCl4	Spherical 200 nm	B16	MTT assay DCFH-DA assay Rhodamine 123 AO/EtBr fluorescence staining qPCR	10 µg/mL	In 10 µg/mL SG-GNPs treated cells compared to the control, more late apoptotic cells colored orange by EtBr were found	[287]
Zinc oxide							
Limonium pruinosum	Zinc acetate dihydrate	Hexagonal/cubic 41 nm	A-431	MTT assay	409.7 µg/mL	The green-synthesized ZnO NPs in the current study showed higher toxicity toward cancer cells compared to normal cells (WI-38)	[91]
Acorus calamus	Zinc acetate	Irregular/oval 50−100 nm	SK-MEL-3	MTT assay	17.50 µg/mL	Morphological alterations like cell shrinkage, detachment, rounding, and irregular shape were noted in the AC-ZnO NPs challenged cells, thus proving its cytotoxicity against SK-MEL-3 cells	[295]

Liver cancer

Liver cancer is the sixth-most common primary malignancy and the fourth-leading cause of cancer-related deaths in the world. Cholangiocarcinoma (CCA) and hepatocellular carcinoma (HCC) are the two most common histologic types of primary liver cancer, accounting for more than 80% of all cases. Liver fibrosis and inflammation-induced necrosis are the major causes of malignancy [296]. The effect of *Cordyceps militaris*-loaded Au NPs on the mitochondrial membrane potential of HepG2 cells revealed a strong green fluorescence in untreated cells with high membrane potential. Green fluorescence intensity decreased in HepG2 cells treated to 10 and 12.5 µg/mL Au NPs. The mitochondrial membrane potential remained intact in untreated cells (Fig. 9A). Untreated cells did not exhibit apoptosis, as shown by green fluorescence staining in Fig. 9B. HepG2 cells treated with Au NPs (10 and 12.5 µg/mL) showed a substantial increase in apoptotic cells as visualized by orange fluorescence staining. HepG2 cells were found to undergo apoptosis after being exposed to Au NPs coated with an extract of Cordyceps militaris [297]. *Coriandrum sativum* leaf aqueous extract-loaded iron NPs were green-synthesized by Zhan et al., and they

demonstrated dose-dependent anticancer activity and very poor cell viability against LMH/2A, McA-RH7777, N1-S1 Fudr, and SNU-387 cell lines while having no cytotoxicity on the normal cell line (HUVEC) [298]. The MTT assay was used to test the in vitro cytotoxicity of Ag NPs loaded with extract from the *Punica granatum* leaf against the HepG2 cell line. This study found that Ag NPs had substantial anti-cancer efficacy at a dosage of 70 µg/mL, causing 50% cell death (Fig. 9C). Ag NPs significantly inhibited cell growth by more than 90% [299]. With an IC_{50} value of 93.75 µg/mL, *Morinda pubescens* extract-loaded Ag NPs have been shown to exhibit considerable cytotoxic effect against HEPG2 cell lines [300]. In a time- and dose-dependent manner, *Artemisia scoparia* extract and its biosynthesized ZnO NPs decreased cell proliferation and induced apoptosis in Huh-7 cancer cells. *Artemisia scoparia* extract and its biosynthesized ZnO NPs had IC_{50} values of 10.26 and 310.24 µg/mL, respectively. Figure 9D shows that the anti-apoptotic genes were downregulated while the pro-apoptotic genes were upregulated by the *Artemisia scoparia* extract-loaded ZnO NPs [301]. With an IC_{50} value of 62.5 µg/mL, *Seripheidium quettense*-mediated green synthesis of biogenic Ag NPs inhibited the proliferation of HepG2 cells [302]. Table 11 shows various plant extracts and precursor salts explored to synthesize metallic NPs for their liver cancer applications.
Fig. 9 [Images not available. See PDF.]

A Represents that the mitochondrial membrane permeability of *Cordyceps militaris* extract synthesized Au NPs, **B** effect of Au NPs from *C. militaris* induces apoptotic morphological changes in HepG2 cells. Green fluorescence labeling revealed that apoptosis had not occurred in the untreated cells. Orange fluorescence staining in HepG2 cells at 10 mg and 12.5 µg/mL shows that the Au NPs treatment dramatically boosted the apoptotic cells. **C** anticancer activity of various concentrations of synthesized Ag NPs synthesized using *Punica granatum* leaves against the liver cancer cell line—HepG2, and **D** cytotoxic effects of biosynthesized ZnO NPs using *Artemisia scoparia* leaf extract against Huh-7 liver cancer cells (under copyright (CC BY) from Taylor and Francis online)
Table 11. Various plant extracts and precursor salts explored to synthesize metallic NPs for their liver cancer applications

Plant used	Metal precursor	Morphology	Cell line	Techniques used	IC_{50} value	Impact	References
Silver							
Punica granatum leaf extract	Silver nitrate	Spherical 20–45 nm	HepG2	MTT assay, DPPH assay	70 µg/mL	It was hypothesized that Ag NPs could inhibit the function of abnormally increased signaling proteins or interact with functional groups of intracellular proteins and enzymes, as well as with the nitrogen bases in DNA, causing cell death	[299]

Artemisia kopetdaghensis shoot extract	Silver nitrate	Spherical 3–35 nm	HepG2	MTT assay	0.125 µg/mL	Due to Ak-Ag NPs' increased cellular uptake and retention, the NPs were highly cytotoxic to HepG2 cell lines	[303]
Gold							
Cajanus cajan seed coat	$AuCl_4$	Spherical 9–41 nm	HepG2	MTT assay, Flow cytometry, Comet assay, Annexin-V/PI double-staining assay	6 µg/mL	decrease in DNA amount and appearance in the sub-G0/G1 area, both of which are signs of apoptosis	[304]
Zinc oxide							
Artemisia scoparia leaf extract	Zinc acetate dihydrate	Spherical 9.00±4.00 nm	Huh-7	MTT assay, Flow cytometry, DAPI staining, RT-PCR, Propidium iodide staining	ZnO NPs: 10.26 Extract: 310.24 µg/mL	Anticancer effect was stronger in the synthesized ZnO NPs than the extract	[301]
Lawsonia inermis leaf extract	Zinc nitrate	Cubic, rod, Triangular, spherical 5–35 nm	Hep-G2	MTT assay, DCFH-DA	21.63 µg/mL	DNA damage and the stimulation of intrinsic mitochondrial pathways were two ways that ZnO NPs triggered apoptosis	[305]
Eclipta prostrata leaf extract	Zinc nitrate	Triangle, radial, hexagonal, rod, and rectangle 16–85 nm	Hep-G2		100 µg/mL	ZnO NPs can potentially change apoptotic protein expression and trigger apoptosis in mitochondria-dependent pathways in Hep-G2 cells	[306]
Copper oxide							
Eclipta prostrata leaves extract		Spherical 28–45 nm	HepG2	DPPH assay, MTT assay	–	Cu NPs were tested for in vitro cytotoxicity against HepG2 cell lines at 1, 10, 100, 250, and 500 µg/mL; these concentrations resulted in cellular toxicity values of 3.0, 15.5, 28.5, 44.5, and 54.5%, respectively	[307]

Theranostic applications of green-synthesized nanoparticles

Theranostics is a multidisciplinary scientific field focused on creating a wide range of complex diagnostic and therapeutic agents. By utilizing nanotechnology, theranostics enhance bioavailability by delivering bioactives to the sites of absorption. Theranostics utilizing metallic NPs could be useful in treating a wide range of conditions, including cancer, malaria, microbial infections, and cardiovascular disorders [308]. There has been a significant increase in the production of metallic NPs from medicinal plants. These metallic NPs play a crucial role in the advancement of theranostics. Anisotropic Au NPs were produced by an aqueous method employing cocoa extract. These NPs exhibited favorable biocompatibility when subjected to in vitro testing utilizing A431, MDA-MB231, L929, and NIH-3T3 cell lines, at doses of up to 200 µg/mL. The use of green-synthesized NIR absorbing anisotropic Au NPs was effective in causing cell death in epidermoid carcinoma A431 cells when irradiated with a femtosecond laser at 800 nm with a low power density of 6 W/cm^2. This demonstrates the suitability of NPs for photothermal ablation of cancer cells. These Au NPs exhibited high X-ray contrast during computed tomography testing, thus confirming their suitability as a contrast agent [309].

The synthesis of Au NPs using cinnamon proved to be an effective diagnostic agent for imaging both in laboratory settings and within living organisms. These NPs possess both biocompatibility and purity, making them suitable for use in in vivo applications. Photoacoustic emissions based in vitro study confirmed internalization of NPs in PC-3 and MCF-7 cells. Additionally, biodistribution investigations conducted on healthy mice demonstrated that these Au NPs accumulated in the lungs. This finding further supports the potential of using Au NPs as contrast agents for targeting [310]. In a radiotherapy investigation, thymoquinone-loaded green-synthesized Ag NPs in combination with the MDA-MB-231 mammary adenocarcinoma cells showed improved radiotherapy, significantly increased cancer cell killing, and DNA damage in comparison to the radiation alone. This was carried out via radiotherapy enhancement and the delivery of thymoquinone to the cancer cells. The developed system is proposed to be a promising combined regimen for efficient cancer therapy [311].

Rutin-loaded $CoFe_2O_4$ and $ZnFe_2O_4$ NPs (29 nm and 25 nm) displayed ferromagnetic and superparamagnetic properties. The saturation magnetization values were measured to be 56.2 emu/g and 6 emu/g, respectively. Thus, these NPs exhibited exceptional and efficient magnetic properties, making them crucial for magnetic hyperthermia therapy. Significant photothermal efficacy of green-synthesized $CoFe_2O_4$ and $ZnFe_2O_4$ NPs combined with laser radiation against MCF-7 cells was indicated by the results of the inverted stage microscopy and MTT assay [312]. The Fe_3O_4 NPs produced utilizing the fruit peel of *P. granatum*, exhibited an excellent relaxivity rate and generated strong magnetic resonance imaging (MRI) signals in the study. NPs containing 2% *P. granatum* fruit peel extract were loaded with 5-FU, which displayed 62 ± 0.3% entrapment efficiency. Based on in vitro cytotoxicity studies conducted on CCD112 normal and HCT116 colorectal cancer cell lines, it was observed that the 5-Fluorouracil loaded in the *P. granatum* fruit peel extract-based Fe_3O_4 NPs at 15.62% µg/mL resulted in a 11% and 29% reduction in cell viability in healthy and colorectal cancer cells, respectively. In the future, green-synthesized Fe_3O_4 NPs may play an important role as an eco-friendly nanocarrier in thermo-chemotherapy and MRI for the treatment of cancer [313].

Future perspectives

The subject of biosynthesized metallic NPs loaded with plant extracts is a novel and intriguing area of study. These NPs, often called "green nanoparticles," are extensively explored in the fields of drug delivery. Biosynthesized metallic nanoparticles loaded with plant extracts hold significant promise in medicine. Researchers are investigating their potential as drug delivery systems, where these nanoparticles can be loaded with therapeutic compounds and targeted to specific cells or tissues in the body. They might also be utilized for imaging purposes, such as in cancer detection or tracking the progression of diseases. These NPs can be designed to release drugs in a controlled and sustained manner. This characteristic permits for prolonged drug action, reducing the frequency of dosing and enhancing patient compliance with medication regimens. Biosynthesized metallic NPs loaded with plant extracts can be engineered to deliver drugs to specific cells or tissues in the body with high precision. This targeted drug delivery approach minimizes the side effects associated with conventional drug delivery methods and improves the

therapeutic efficacy of medications. Drug resistance is a major challenge in many diseases. By using biosynthesized NPs, it might be possible to enhance the effectiveness of existing drugs against resistant strains of pathogens or cancer cells. Some drugs have low bioavailability, meaning that they are poorly absorbed by the body. Biosynthesized metallic NPs loaded with plant extracts can improve the solubility and bioavailability of such drugs, leading to more efficient therapeutic outcomes. Green nanoparticles derived from plant extracts generally exhibit lower toxicity compared to synthetic nanoparticles. By using biocompatible and biodegradable materials, the risk of adverse reactions and long-term side effects can be minimized. Researchers can combine the unique properties of metallic nanoparticles with the medicinal properties of plant extracts. This results in multifunctional nanoparticles that not only deliver drugs but also possess inherent therapeutic effects derived from the plant extracts, such as anti-inflammatory or antioxidant properties. Despite the promising future of biosynthesized metallic NPs loaded with plant extracts, comprehensive safety evaluations and regulation will be required. It will be of the uttermost importance to ensure that these nanoparticles are safe for human health, the environment, and non-target organisms. The commercialization and scalability of the production of these nanoparticles will be one of the most significant future challenges as research in this field advances. To make these technologies accessible and practical for a variety of applications, it will be necessary to develop large-scale, cost-effective production methods.

Conclusions

Cancer remains one of the most prevalent causes of mortality across the world, despite recent advances in diagnosis and treatment. No effective cancer treatment has been identified to date, and all the anticancer medications now on the market have the potential to cause negative effects. Nanotechnology has the potential to significantly improve current methods for diagnosing and treating cancer patients. To find better diagnostics and therapies that are as effective, specific, and low-toxic as feasible, researchers are currently attempting to develop novel approaches. Recent biomedical research has focused extensively on biological, or "green," synthesis of NPs. Green synthesis is less expensive, less toxic, and more ecologically friendly than conventional methods of producing NPs. This article will assist formulation scientists and nanotechnologists working on the green production of metal or metal oxide NPs by utilizing plant extracts. It also explored their therapeutic potential of plant extracts against various cancers. The science of metallic NPs is one of the most intriguing areas of study for cutaneous or transdermal drug administration. Thus, lipid nanocarriers are predicted to open new avenues in biomedical science while also improving an essential area of dermatologic literature.

ABSTRACT (ENGLISH)

Background

Different herbal phytochemicals have potential in cancer treatment, Euphorbia genus has valuable secondary metabolites and is used in traditional medicine to treat various ailments. However, the specific constituents and biological activity of *Euphorbia greenwayi* remain largely unexplored.

Results

Euphorbia greenwayi aerial parts were extracted using methanol. Consequently, the methanol extract was then fractionated with solvents of different polarities viz., *n*-hexane, chloroform, and ethyl acetate. All were screened for their cytotoxic activity against different cell lines; MCF-7, HepG-2, and SW620. The *n*-hexane (HF) and chloroform (CF) fractions showed considerable activity against all tested cell lines especially MCF-7 with IC_{50} values at 18.6 ± 0.2 and 17.5 ± 0.6 µg/ml respectively. Therefore, a cell migration assay on the MCF-7 cell line was applied to both fractions as well as investigation and isolation of the main active constituents. Lupeol, *β*-sitosterol, and cycloartenol were isolated from the nonpolar fractions of *E. greenwayi* for the first time.

Conclusions

Euphorbia greenwayi aerial parts exhibit considerable anti-cancer effects via cytotoxicity. Three chemical constituents with promising cytotoxic activity are identified.

FULL TEXT

Background

Worldwide, cancer ranks as the second leading cause of death. The most prevalent cancers are colon, liver, and breast cancers. Cancer is characterized by its widespread occurrence globally. It exhibits notably high mortality rates according to statistical data. Lifestyle and genetic predisposition are commonly acknowledged as the primary factors contributing to its development. Phytochemicals derived from herbs and traditional medicine are becoming more widely recognized as effective cancer treatments. Recent clinical trials have demonstrated the beneficial effects of herbal medications on cancer patients' quality of life, survival rates, and immune system control when used in conjunction with traditional treatments. Numerous phytochemicals, including phenolic compounds, terpenoids, lignans, tannins, alkaloids, and others, have been studied from herbal sources and show potent antioxidant qualities that can suppress cell division and boost the immune system, improving prevention [1–4].

The ornamental medicinal plant species, *Euphorbia greenwayi* P.R.O. Bally &S. Carter is a member of the Euphorbiaceae (Spurge) family [5]. Euphorbia is considered the third biggest genus of flowering plants having milky poisonous latex. It consists of many species that are used in traditional medicine to cure a wide range of illnesses. This might be related to the wealth of their secondary metabolites [6, 7]. Different studies reported that Euphorbiaceae members consist mainly of terpenes, flavonoids, and tannins, which are known for their antioxidant, hepatoprotective, and anti-tumour properties [8–10]. As a member of the Euphorbia genus, *E. greenwayi* possesses succulent quality produces milky latex and may grow up to 1.2 m tall [11]. It was introduced to Egypt a short time ago, but it is native to Tanzania and East Africa. Upon reviewing the available literature, little information was reported on *E. greenwayi*; one study compared the immune-boosting capabilities of fifteen plant extracts from the Euphorbiaceae family, demonstrating *E. greenwayi*'s mild antiviral activity. [10]. Moreover, another report proved that the hydroalcoholic extract of *E. greenwayi* has significant antimicrobial potential [12]. Our recently published work demonstrated its anti-inflammatory and antioxidant potential [13].

The current study intends to assess the cytotoxic activity of the *E. greenwayi* methanol extract and its fractions. Additionally, an in vitro migration assay (wound healing activity) for the most active fractions is conducted to determine the tumour cell migration capacity of cell lines and, consequently, their invasiveness and potential to generate metastases. The chemical components of the most active fractions are determined using spectroscopic and chromatographic techniques.

Results

Phytochemical screening

A phytochemical screening is essential to determine the active substances responsible for the biological activity that plants are known to display and to evaluate a plant's potential medicinal usefulness. It also provides the foundation for more precise compound identification and investigation. Tannins, flavonoids, unsaturated sterols, and/or terpenes were found, together with carbohydrates and/or glycosides. As shown in Table 1, there were no volatile oils, alkaloids, nitrogenous bases, anthraquinones, or saponins.

Table 1. Preliminary phytochemical screening

Constituents	Presence
Carbohydrates and/or glycosides	+
Flavonoids	+

Tannins	+
Unsaturated sterols and/or terpenes	+
Volatile oils	–
Alkaloids and/or nitrogenous bases	–
Anthraquinones	–
Saponins	–

(+) = present, (–) = absent

Identification of the isolated Compounds

Compound EA_1

Compound (EA_1) 20 mg was isolated as white amorphous powder. It is soluble in *n*-hexane, chloroform and insoluble in methanol, m.p. 215–216ºC.; the R_f values were 0.59 on silica TLC using *n*-hexane:ethyl acetate (95:5 *v/v*) as developer. It gave a pink color when sprayed with 10% H_2SO_4..It also gave positive Salkowski and Liebermann-Burchard tests [14]. The ^{1}HNMR spectrum Table 2 demonstrated the characteristic deshielded proton at δH 3.3 (1H, *m*) assigned to C-3 attached to hydroxyl group, the deshielded olefinic proton at δH 4.6 (H-30, *d*,2H) was assigned to C-30, the characteristic 7 methyl singlets at δ 0.77 (H-23, *s*, 3H), 0.85 (H-24, *s,* 3H), 0.87 (H-25, *s*, 3H), 1.12 (H-26, *s*, 3H), 0.97 (H-27, *s*, 3H), 0.71 (H-28, *s*, 3H), and 1.71 (H-29, *s*, 3H) [15]. The ^{13}C NMR of the compound revealed 30 distinct signals corresponding to the terpenoid of the lupane skeleton. Among these signals, a carbon bonded to the hydroxyl group at the C-3 position was observed at δ 78.9. Additionally, the olefinic carbons associated with the exocyclic double bond manifested signals at δ 151.6 and 108.6. The EI-MS spectrum showed a molecular ion peak at 426(36%) calculated for the molecular formula $C_{30}H_{50}O$. In addition to the following characteristic peaks at 316, 218, 207, 189, 149, 135, 69, 95, 109, 121, 135 compared to published data [16, 17]. Compound (EA1) was identified as Lupeol based on the data presented above, comparison to published data [13, 18] and co-chromatography with a standard sample (Fig. 1). It was separated for the first time from *E. greenwayi*.

Table 2. ^{1}H NMR and ^{13}C spectral data of compounds EA 1, 2, and 3

Carbon number	(EA_1) Lupeol		(EA_2) *β*-sitosterol	(EA_3) Cycloartenol

Chemical structure of the identified compounds

Compound EA_2

Needle crystals give a dark blue colour with 10% H_2SO_4, positive Liebermann- Burchard [19] and Salkowski [14] tests. Its molecular formula $C_{29}H_{50}O$ *m/z* 414 (86.8%). ^{1}HNMR spectrum; presented in Table 2; showed δ 5.3 (H-6, *br s*, 1H), 3.5 (H-3, *m*, 1H), the characteristic 2 methyl singlets δ 0.86 (H-18, *s*, 3H) and 1.04 (H-19, *s*, 3H), and 4 methyl doublets at δ 0.88 (H-21, *d*, *J*=9.6, 3H), 0.84 (H-29, *t*, 3H), 0.79. (H-26, *d, J*=6.3, 3H) and 0.82 (H-27, *d*, *J*= 6.3, 3H). In addition to the following characteristic peaks at 414 $[M]^+$, 396 $[M\text{-}H_2O]^+$, 381 $[M\text{-}CH_3\text{-}H_2O]^+$, 329 $[M\text{-}C_6H_{13}]^+$, 303 $[M\text{-}C_7H_{11}O]^+$, 255 [M-side chain-H_2O]$^+$, 231 [M-side chain-ring D cleavage-CH_3]$^+$, 213 [M-side chain-ring side chain -H_2O]$^+$. The compound (EA2) was identified as β-sitosterol through data analysis, comparison to published data [15, 20–22] and co-chromatography with a standard sample (Fig. 1). *β*-Sitosterol was previously isolated from various Euphorbia species. [13, 23, 24]. It was isolated from *E. greenwayi* for the first time.

Compound EA_3

Yellowish white microcrystalline powder gives a purple colour with 10% H_2SO_4, positive Liebermann- Burchard [19] and Salkowski tests [14]. It is soluble in *n*-hexane, chloroform and insoluble in methanol, m.p. 99–110 ºC. The R_f values were 0.56 on silica TLC using *n*-hexane: ethyl acetate (80:20 v/v) as developer. ^{1}HNMR spectrum; presented in Table 2; showed the following signals: δ5.1 (H-24, *t*, *J*=5.6, 1H), 3.12 (H-3, *m*, 1H), 0.3–0.5 (H-19, *dd*, *J*=3.2, 2H), 0.8 (H-18, *d*, *J*=3.2, 3H), 1.78 (H-27, *s*, 3H), 1.7 (H-26, *s*, 3H), 0.91 (H-29, *s*, 3H), 1 (H-28, *s*, 3H), 0.88 (H-30, *s*, 3H). ^{13}C NMR spectrum of compound EA_3 displayed 30 carbons corresponding to 7 methyl carbons, 11 carbenes, 5 methine carbons, 5 quaternary carbons and 2 olefinic carbons at δ 123 and 129.69 (Table 2). Mass spectrum of isolated compound showed molecular ion *m/z* 427 [M+H] corresponding to the molecular formula $C_{30}H_{51}O$. It gave MS spectra with a base peak at *m/z* 409 which resulted from loss of 1 water molecule $[M+H-H_2O]^+$. MS^2 also showed characteristic peaks at *m/z* 257, 271 and 285, 191, 203 and 217 and compared with published data [25]. Based on the data presented above and published data [26], compound (EA3) was identified as cycloartenol (Fig. 1). It was previously isolated from several Euphorbia species [26–28]. It has been isolated for the first time from *E. greenwayi*.

Biological activity

Antitumor activity (Screening)

As shown in Table 3*n*-Hexane fraction (HF) and chloroform fraction (CF) were the most active fractions to the 3 cancerous cell lines compared to the total methanol extract (ME) and ethyl acetate fraction (EF) in both tested concentrations. (HF) showed viability percentage against MCF-7, breast adenocarcinoma, HepG-2; hepatocellular carcinoma, and SW620; colorectal adenocarcinoma at 75.1622, 48.396 and 97.3144% respectively in 10 µg/ml concentration and 1.9754, 6.8561 and 0.79856% respectively in 100 µg/ml concentration. Whereas (CF) in 10 µg/ml concentration showed viability percentage at 80.0813, 78.9734 and 99.4913% against MCF-7, HEPG-2 and SW620 respectively and in 100 µg/ml it showed viability % at 2.42084, 4.98625 and 0.38287% respectively.

Table 3. Cell viability % of ME, HF, CF, and EF against MCF-7, HEPG-2, and SW620

Cell line	MCF-7 viability %	HEPG-2 viability %	SW620 viability %

Conc.	10 µg/ml	100 µg/ml	10 µg/ml	100 µg/ml	10 µg/ml	100 µg/ml
ME	83.52±0.59	54.16±1.04	82.19±0.15	46.30±1.89	95.99±0.5	74.40±0.66
HF	75.16±0.71	1.97±0.17	48.39±1.37	6.85±0.35	97.31±0.37	0.79±0.22
CF	80.08±0.54	2.42±0.22	78.97±1.5	4.98±1.32	99.49±0.22	0.38±0.02
EF	97.72±0.52	84.03±0.41	96.42±1.21	94.70±0.28	97.041±1.3	93.34±0.14
Negative control	100		100		100	

Antitumor activity (IC_{50})

According to the cell viability assay (Table 3) HF and CF were the most cytotoxic fractions of the 3 tested cancerous cell lines. Accordingly, those 2 fractions were further tested to find their (IC_{50}) using Sulforhodamine B (SRB) analysis in comparison with doxorubicin as a reference antitumor drug. As shown in Table 4 both HF and CF have a moderate to low activity against all tested cell lines. In specific the breast adenocarcinoma (MCF-7) cells were the most susceptible cell line against both fractions with IC_{50} values at 18.6±0.2 µg/ml against HF and 17.5±0.6 µg/ml against CF.

Table 4. IC_{50} of HF and CF against MCF-7, HepG-2, and SW620

	IC_{50} (µg/ml)		
Cell line	MCF-7	HEPG-2	SW-620
HF	18.6±0.2	35.6±1.2	28.4±0.8
CF	17.5±0.6	36.3±0.9	24.1±1.3
Doxorubicin	3.3±0.10	4.8±0.14	4.2±0.18

It can be deduced that the aerial parts of *E. greenwayi* have a moderate antitumor activity especially against MCF-7 cell line. The United States National Cancer Institute (NCI) stated that any crude extract with IC_{50} value ≤ 20 µg/ml is considered an active cytotoxic agent [29]. The highest cytotoxic activity was observed in the nonpolar fractions (*n*-hexane and chloroform) of *E. greenwayi.* This was confirmed after tracing the anticancer potential of the 3 isolated compounds (lupeol, *β*-sitosterol, and cycloartenol) that was already proven in previous studies [30–34]. This reveals a good correlation between antitumor potential and nonpolar constituents of *E. greenwayi* like sterols and terpenes.

Anti-Migration Activity of MCF-7 Cell Line

A wound healing assay, conducted *in vitro*, aims to assess the migratory potential of cell lines treated with the most potent fractions. This assay helps evaluate the cells' ability to migrate, thereby indicating their invasiveness and the likelihood of generating metastases. Based on the antitumor activity results, only HF and CF were continued in this study, because those fractions showed cytotoxic activity superior to ME and EF against MCF-7 which was the most susceptible cell line among the 3 cell lines tested.

HF and CF antimigration assay was performed using 2 doses (subtoxic and a lethal dose (IC_{50})), 1.9 and 19 µg/ml respectively for HF and 1.7 and 17 µg/ml respectively for CF. Figures 2, 3 and 4 demonstrated the MCF-7

monolayer which was scratched and treated with selected fractions. The wound area was monitored and imaged every 24 hours for 72 hours. Finally, the migration rate was calculated and compared with the negative control Figs. 5 and 6.

Fig. 2 [Images not available. See PDF.]

Migration rate of MCF-7 cells without any drug applied (Negative control) at A = 0, B = 24, C = 48, D = 72 h. respectively

Fig. 3 [Images not available. See PDF.]

Migration rate of MCF-7 cells using HF (n-hexane fraction) lethal dose (19 µg/ml) at A = 0, B = 24, C = 48, D = 72 h. respectively

Fig. 4 [Images not available. See PDF.]

Migration rate of MCF-7 cells using CF (chloroform fraction) lethal dose (17 µg/ml) at A = 0, B = 24, C = 48, D = 72 h. respectively

Fig. 5 [Images not available. See PDF.]

Rate of MCF-7 cells migration with subtoxic and lethal dose of HF (n-hexane fraction)

Fig. 6 [Images not available. See PDF.]

Rate of MCF-7 cells migration with subtoxic and lethal dose of CF (chloroform fraction)

As shown in Figs. 5 and 6 both the subtoxic and lethal doses of both HF and CF don't exhibit an anti-migratory effect.

Discussion

The exploration of medicinal plants has garnered increased attention as a means to discover more effective treatments for various cancer types. Presently, a substantial portion of pharmaceutical agents, especially in cancer therapy, comprises natural products. Taxol, vinblastine, and camptothecin are illustrative examples, distinguished by their unique structures and mechanisms of action, with their discovery primarily attributed to isolation from natural sources. In this sense, the Euphorbia genus is distinguished by its richness in biologically active phytoconstituents with promising cytotoxic activity [35–37]. In this regard*, E. greenwayi* was chosen to be the subject of our study because of the little-known information regarding its primary components and its biological activity.

E. greenwayi showed positive presence of sterols, triterpenes, and phenolic compounds; hence its methanol extract (ME) was fractionated using *n*-hexane (HF), chloroform (CF), and ethyl acetate (EF) to test these fractions for cytotoxic activity against MCF-7, HepG-2, and SW-620 cell lines. (HF) and (CF) showed significant cytotoxic activity against MCF-7 with IC_{50} values at 18.6 ± 0.2 and 17.5 ± 0.6 µg/ml respectively. However, they showed significant cytotoxic effect on HepG-2 and SW-620 at higher doses. This confirms the susceptibility of MCF-7 against (HF) and (CF). On the other hand, ME and EF didn't exhibit any cytotoxic activity against the 3 cell lines at all tested concentrations. Wound healing assay for cancer metastasis is highly reproducible method to study cancer cell in vitro. By this method we can develop an additive treatment combined with the main drugs in order to decrease migration of cancer cell to another organs. Based on the previous findings (HF) and (EF) were tested against MCF-7 cell migration yet they didn't display a significant antimigratory effect. These findings don't contradict the results of antitumor assay, but rather suggest that both (HF) and (CF) are cytotoxic to MCF-7 cells in a non-apoptotic cell death mechanisms other than decreasing cell migration or inhibiting the cell motility [38]. Also, it was already established that some of the most effective anticancer drugs such as carboplatin and paclitaxel were observed to induce the migration of cancer cells in different kinds of cancers [39].

Driven by the antitumor assay findings we decided to explore the constituents of the nonpolar fractions (HF) and (CF) of *E. greenwayi*. Phytochemical analysis reveals the separation of three compounds from (HF) and (CF):

lupeol, β-sitosterol, and cycloartenol. The 3 compounds are isolated from *E. greenwayi* for the first time. Based on previous data and the pharmacological effects of the three compounds, we realised that they all exhibited cytotoxic activity against various cancer cell lines [30, 32–34, 40, 41]. This supports the antitumor effects of *E. greenwayi*'s nonpolar fractions. In addition, in our recently published work through LC–MS we identified several nonpolar compounds in *E. greenwayi* [13] with reported cytotoxic activity such as taraxasterol [42], ingenol dibenzoate [43], and ingenol mebutate [44].

Methods

Plant material

Collection, handling, and authentication of plant material was previously discussed in our recently published work [13].

Extraction and fractionation

Twelve Kg of *E. greenwayi* fresh plant was macerated with absolute methanol till exhaustion (12 L × 3). The methanol extract was evaporated under a vacuum at 40°C. The crude extract (40 g) was suspended in 200 ml distilled water. The aqueous suspension was successively fractionated by partition with *n*-hexane, chloroform, and ethyl acetate. The results of the fractionation are summarized in (Fig. 7).

Fig. 7 [Images not available. See PDF.]

Scheme for compound isolation

Phytochemical screening

Dried aerial parts of *E. greenwayi* (40 g) underwent a phytochemical screening to identify the different phytochemical components that were found in it. These components included volatiles, carbohydrates and/or glycosides, alkaloids and/or nitrogenous bases, saponins, anthraquinones, unsaturated sterols and/or triterpenes, tannins, and flavonoids [45, 46]. The Pio-chem corporation in Cairo, Egypt provided all the chemicals, which were of high purity. Among the substances utilized following instructions were glacial acetic acid, concentrated ammonia, alcoholic KOH, $FeCl_3$, HCl, Dragendorff's reagent, methanol, chloroform, and H_2SO_4 [47, 48].

Compound isolation

N-hexane (3.6 g) and chloroform (1.3 g) fractions showed similar spots, so both fractions were added together. Fractionation was done through column chromatography using a silica gel (Merck) (200 g, 100 cm X 5 cm). Gradient elution started with 100% *n*-hexane then 5% increments of ethyl acetate, till the elution reaches 100% ethyl acetate. Fractions, each of 15 ml, were collected, concentrated under reduced pressure, and monitored using thin liquid chromatography (TLC). A system consisting of *n*-hexane: ethyl acetate with a different ratio was used as a developer. 10% H_2SO_4 was used as a spraying reagent for spot visualization. Similar fractions were pooled together. Fraction (I) was fractionated through column silica gel using *n*-hexane/methylene chloride gradient elution resulting in compound (EA_1) separation.

Fraction (VI) was found to have 2 major compounds. The fraction was further chromatographed on a silica gel column (30 × 1 cm). Gradient elution was performed using *n*-hexane followed by 5% increments of ethyl acetate. Fractions of 10 ml were collected and run on TLC. subfraction (35–45) yielded 3 mg of needle crystals compound (EA_2) and subfraction (98–106) yielded 5 mg of needle crystals compound (EA_3).

Structure elucidation of the purified compound

NMR spectroscopic analysis used a Bruker spectrometer at 400 MHz for (^{1}H NMR) and 100 MHz (^{13}C NMR) according to [49]. The UPLC-ESI–MS/MS negative and positive ion modes were executed on a Waters Corporation, Milford, MA01757, USA, XEVO TQD triple quadrupole mass spectrometer.

Biological activity

Antitumor activity

Cell viability test was done for the *E. greenwayi* total methanol extract (ME), and its fractions; n-hexane fraction (HF), chloroform fraction (CF), and ethyl acetate fraction (EF) according to [50]. It was assessed by Sulforhodamine B (SRB) assay against 3 human tumor cell lines (MCF-7, breast adenocarcinoma, HepG-2; hepatocellular

carcinoma, and SW620; colorectal adenocarcinoma) using 2 concentrations of each tested sample (10 and 100 µg/ml), to identify fractions with the most powerful anti-tumor properties.

In this experimental procedure, 100 µL aliquots of a cell suspension containing 5×10^3 cells were dispensed into individual wells of 96-well plates and incubated in complete media for a duration of 24 h. Subsequently, the cells were subjected to treatment with another 100 µL of media containing various concentrations of drugs. Following 72 h of exposure to the drugs, the cells were fixed by replacing the media with 150 µL of a 10% trichloroacetic acid (TCA) solution and incubated at 4 °C for 1 h. After removal of the TCA solution, the cells underwent five washes with distilled water. Subsequently, 70 µL aliquots of a sulforhodamine B (SRB) solution at a concentration of 0.4% w/v were added to each well, and the plates were incubated in darkness at room temperature for 10 min. Following this incubation period, the plates underwent three washes with 1% acetic acid and were then allowed to air-dry overnight. To dissolve the protein-bound SRB stain, 150 µL of a tris(hydroxymethyl) aminomethane (TRIS) solution was added at a concentration of 10 mM. The absorbance of the resulting solution was measured at 540 nm using a BMG LABTECH®-FLUOstar Omega microplate reader (Ortenberg, Germany).

Cell migration (wound healing) assay

N-hexane and chloroform fractions were evaluated for their potential to inhibit wound healing in cancerous cell lines according to [51, 52]. Since MCF-7 (Breast Adenocarcinoma) was the most susceptible cell line, it is chosen to be used in this assay. Both fractions were evaluated in 2 concentrations, lethal dose (IC_{50}) and Subtoxic dose.

Cells were seeded at a density of 2×10^5 cells per well on a 12-well plate that had been pre-coated for scratch wound assay. They were cultured overnight in a medium consisting of 5% fetal bovine serum (FBS) in Dulbecco's Modified Eagle Medium (DMEM) at 37°C and 5% CO_2. The following day, horizontal scratches were carefully introduced into the confluent cell monolayer. Subsequently, the plate underwent thorough washing with phosphate-buffered saline (PBS). Control wells were replenished with fresh medium, while wells designated for drug treatment were supplied with fresh medium containing the specified drug. Images were captured at designated time intervals using an inverted microscope. The plate was maintained at 37°C and 5% CO_2 between these time points. Analysis of the acquired images was conducted using MII Image View software version 3.7.

Wound width is the distance between the edges of the scratches in average; as cell migration is induced the wound width decreases.

Migration rate is determined according to the formula below: $MR = IW - FW / t$ where MR is the rate of cell migration, IW is the average wound width at 0 h, FW is the average final wound width, and t is duration of migration (in hours).

Conclusion

In conclusion, the investigation into the anti-cancer properties of *E. greenwayi* has revealed promising findings. The study encompassed cytotoxicity assays, evaluations of cell migration, and identification of its chemical constituents. The cytotoxicity assessments demonstrated considerable potency within specific fractions (*n*-hexane and chloroform fractions) of *E. greenwayi*, notably highlighting considerable toxicity against cancerous cell lines.

Furthermore, the identification of chemical constituents within *E. greenwayi* provides valuable insights into potential bioactive compounds responsible for its anti-cancer effects. These constituents may serve as a foundation for further research and development of novel anti-cancer agents.

The collective findings underscore the significance of *E. greenwayi* as a potential source of compounds with anti-cancer properties. Continued exploration and elucidation of its mechanisms and active compounds could pave the way for the development of new therapeutic strategies in combating cancer.

Ethics approval and consent to participate

Ethical approval was obtained from the research ethics committee, Faculty of Pharmacy, Cairo University; serial number MP (2448).

Consent for publication

Not applicable.

Plant authentication

Aerial shoots of *E. greenwayi* were collected in March 2019 at the Helal Cactus farm in Al Mansoureyah, Giza Governorate, Egypt (30.10812667354337, 31.105346915336153). Professor Dr. Reem Samir Hamdy, a botany professor at Cairo University's Faculty of Science, kindly verified and recognized the plant. The collection and handling of the plant material were in accordance with all the relevant guidelines.

A validated, precise TLC-densitometry method for simultaneous quantification of mahanimbine and koenimbine in marketed herbal formulations

Mukhopadhyay, Nabarun1; Ahmed, Rezwan1; Mishra, Kajal1; Sandbhor, Rujuta1; Sharma, Ram Jee2; Kaki, Venkata Rao1 1 National Institute of Pharmaceutical Education and Research (NIPER), Department of Chemical Sciences (Natural Products), Hyderabad, India (GRID:grid.464631.2) (ISNI:0000 0004 1775 3615)2 Indian Herbs Specialities Pvt. Ltd., Saharanpur, India (GRID:grid.464631.2)

ABSTRACT (ENGLISH)

Background

Murraya koenigii (L.) Spreng. (Rutaceae) is an important medicinal plant in natural products research for its diverse pharmacological activities. Carbazole alkaloids were the major classes of phytoconstituents obtained from different parts of this plant, such as leaves, stems, and roots. Mahanimbine and koenimbine are two important carbazole alkaloids obtained from the *M. koenigii* plant and are known for their anti-cancer, anti-oxidant, anti-diarrhoeal agents, etc. Standardization plays a vital role in the herbal drug industry for maintaining the quality, purity, safety, and efficacy of herbal formulations, and hyphenated analytical techniques like HPTLC, HPLC, GC–MS, and LC–MS were utilized for this purpose. In the present study, a specific, simple, and rapid semi-automated TLC method was developed to quantify mahanimbine and koenimbine in some marketed herbal formulations, and the same was validated based on (ICH)-Q2-(R1) guidelines.

Results

This study revealed that the powder formulation (F_3) contains the highest amount of mahanimbine (62.32 µg), but the tablet formulation (F_1) contains both mahanimbine (41.19 µg) and koenimbine (143.6 µg).

Conclusion

A simple, specific, and reproducible semi-automated TLC method was developed and validated successfully as per (ICH)-Q2-(R1) guidelines and can be utilized for analysing marketed herbal formulations containing *M. koenigii* powder/extracts.

FULL TEXT

Background

Murraya koenigii plant, commonly known as curry tree in Asia, contains several vital phytoconstituents with diverse pharmacological activities [1]. Mahanimbine and koenimbine are the major carbazole alkaloids obtained from the leaves, roots, and stems of *M. koenigii* [2, 3]. These two phytoconstituents showed promising therapeutic efficacy against different diseases like cancer, obesity, and diabetes while tested in different *in vitro* and *in vivo* models [4]. Mahanimbine inhibited proliferation of lung cancer A549 cells [5], inhibited abnormal growth of the pancreatic cell lines (SW 1190, CFPAC1, BxPC3, CAPAN-2, and HPAFII) [6], stimulated memory and learning functions in aged mice [7], and also showed potential anti-diabetic activity on 3T3-L1 cells [8]. Similarly, koenimbine significantly reduced the number and size of breast cancer cell line MCF7 [9] and showed significant inhibition of castor oil-induced diarrhoea (at 50 mg/kg) in the rats [10].

Standardization of herbal formulations helps to set the constant parameters and inherent characteristics to assure safety, efficacy, quality, and reproducibility. According to the definition provided by American Herbal Product Association, “Standardization refers to the body of information and controls necessary to produce material of reasonable consistency [11].” Nowadays, in the Herbal drug industry, standardization is an integral part of quality

control for getting suitable raw materials, maintaining the quality and purity of finished products, etc. [12]. Various analytical techniques were utilized for this purpose, such as HPTLC, HPLC, MS, LC–MS, and GC–MS. [13]. HPTLC is a vital separation technique based on the TLC principle, which offers multiple advantages such as minimized exposure to toxic solvents, improved sample application, reduced usage of mobile phase, less analysis time, reduced possibilities of environmental pollution, and higher separation efficiencies [14]. Planar chromatographic methods (TLC and HPTLC) were widely utilized for quality control of herbal formulations. It helps for qualitative, quantitative, and semi-quantitative analysis of phytoconstituents incorporated in different herbal formulations manufactured and marketed by different companies. Several pieces of research proved that thin-layer chromatographic methods successfully ensure the quality and purity of marketed herbal formulations. Abharam A et al. developed a novel HPTLC method for analysing an ayurvedic polyherbal formulation named Pathyashadangam Kwath by employing toluene/ethyl acetate/formic acid (2.5: 2.0: 0.5 v/v/v) as a mobile phase. In this study, andrographolide was used as a marker for standardizing this formulation, and it proved that the presence of this marker may be responsible for its pharmacological activities [15]. Hazra et al. took piperine as a marker for standardizing six polyherbal formulations named Avipattikara, Talisadya, Sringyadi, Sitopaladi, Hingavastaka, and Trikatu and developed a specific and simple HPTLC method by utilizing toluene/ethyl acetate (7:3 v/v) as a mobile phase. This study proved that piperine was identified and quantified in all of the formulations, and it can be concluded that this method can be utilized for routine analysis of piperine in marketed ayurvedic formulations [16]. Kagathara C et al. stated that HPTLC could be a better option for estimating ascorbic acid, quercetin, and curcumin in different herbal formulations. They developed a specific HPTLC method for identification and quantification of the same by employing chloroform/ethyl acetate/formic acid (6:6:2.5 v/v/v) as a mobile phase. From this study, it was observed that these three important phytocompounds were identified and quantified in all of the formulations, and this analytical method can be utilized for quality control of herbal formulations where curcumin, quercetin and ascorbic acid were incorporated [17]. A simple, specific, and rapid HPTLC assay method for analysing tacrolimus ointments was developed by Islam MK et al. which helps to identify and quantify tacrolimus in the same. In this method, toluene–acetonitrile–ethyl acetate–glacial acetic acid (6:2:2:0.1 v/v/v) was used as a mobile phase and it proved the utilization of this method for standardization of marketed tacrolimus ointments [18]. These researches highlighted the importance of planar chromatographic techniques in the standardization of marketed herbal formulations and marker compounds play an important role in this.

By thorough literature survey, it was found that several analytical techniques were employed to estimate mahanimbine and koenimbine in *M. koenigii* plants. Joshi T et al. utilized a novel UPLC method to determine the natural abundance of the carbazole alkaloids in the *M. koenigii* plant [19]. Viteritti et al. [20] developed an HPLC–MS/MS method to quantify carbazole alkaloids in *M. koenigii* plant. Nandan et al. [21] quantified eleven carbazole alkaloids using a novel UPLC/MS/MS method, including mahanimbine and koenimbine in *M. koenigii* plant collected from six different climatic zones of India. Chatterjee et al. [22] successfully developed a validated qNMR method for quantifying nine important carbazole alkaloids, including koenimbine and mahanimbine. But to the best of our knowledge, there is no analytical method was available for standardizing marketed herbal formulations containing carbazole alkaloids obtained from the *M. koenigii* plant. Hence in the present study, a rapid and simple semi-automated TLC method was established to identify and estimate two essential carbazole alkaloids named mahanimbine and koenimbine (Fig. 1) in some marketed formulations and helps to determine the quality and purity of the formulations. The validation of the established method has been done as per (ICH)-Q2-(R1) guidelines.

Fig. 1 [Images not available. See PDF.]

Structures of mahanimbine and koenimbine

Methods

Instruments

VisionCATS software (version 3.2) is equipped with TLC visualizer 2, Linomat V applicator, and TLC scanner 4 manufactured by CAMAG (Switzerland). TLC silica gel $60F_{254}$ plates were procured from Merck (Germany). The

analytical balance and hot air oven were purchased from Sartorius (Germany) and Biotechnics India (India.)

Reagents and standard substance

Analytical grade Hexane and Ethyl acetate has been procured from Finar (India), and HPLC grade methanol has been purchased from Spectrochem (India). Mahanimbine and koenimbine (purity: >90% by HPLC) were purchased from Natural Remedies Pvt Ltd. (India).

Selected marketed formulations for analysis

Three marketed formulations named Merlion Naturals curry leaves extract tablets (packed and marketed by Infinator Pvt. Ltd, Ahmedabad, Gujarat, India), curry leaves capsules (manufactured and marketed by Dr. JPG Organic, Jaipur, Rajasthan, India) and premium curry leaves powder (manufactured by Spag herbals, Hyderabad, Telangana, India) were collected and coded as F_1 (for tablet), F_2 (for capsule) and F_3 (for powder) [23–25]. Out of these formulations, F_1 and F_2 contain 500 mg of curry leaves powder along with excipients (in Q.S. and the name of the same is not disclosed) and used as a dietary supplement and F_3 contains 125 mg of dried curry leaves along with excipients (in Q.S. and the name of the same is not disclosed) and used as a cosmetic. All formulations were stored in a cool environment and protected from direct sunlight.

Standard and sample preparation

About 5 mg of mahanimbine and koenimbine were dissolved in 50 mL of HPLC grade methanol for preparing standard stock solutions. Further, the working solutions were prepared by diluting the stock solutions with the required quantity of methanol.

For preparing sample solutions from tablets (F_1), about five tablets were crushed into powder, and 300 mg of the powder was accurately weighed and macerated with 10 mL of HPLC grade methanol. In the case of capsule (F_2), the shells of five capsules were broken and accurately weighed, and 300 mg of powder was macerated with 10 mL of HPLC grade methanol. For preparing sample solutions from powder (F_3) (stored in a cool environment and protected from direct sunlight), 300 mg of the powder was accurately weighed and macerated with 10 mL of HPLC grade methanol. Finally, all of the prepared extracts were centrifuged (10 °C, 10,000 RPM). The supernatant fluids were collected and underwent tenfold dilution, which was used for analysis.

Optimization of the analytical conditions

In the current study, TLC silica gel $60F_{254}$ plates were utilized as a stationary phase. For selecting a suitable mobile phase for analysis, different solvent combinations were tried. By thorough literature survey, it was decided that different combinations of hexane and ethyl acetate in v/v (8:2, 9:1, 9.5:0.5, 7:3) would be used for determining optimal mobile phase composition. Based on the separation pattern obtained from preliminary TLC analysis/observation, a combination of hexane:ethyl acetate (7:3 v/v) was selected as the final mobile phase and utilized throughout the analysis.

Semi-automated TLC conditions

On each TLC silica gel $60F_{254}$ plate (20 × 10 cm), 4 µL of mahanimbine and koenimbine standards and F_1, F_2, and F_3 were applied at the rate of 150 nL S^{-1} by utilizing a Linomat V applicator. The applied band length was 8 mm, and the application was about 1 cm from the bottom and left edges of the plate. After application, the development of the plates was done in CAMAG twin trough chambers to a distance of 70 mm with the selected mobile phase composition which was previously saturated for 20 min. After that, the developed plates were air-dried, and the fingerprint profile was generated by placing the plates in TLC visualizer 2. Then, the plates were scanned using a TLC scanner 4 at $\lambda = 291$ nm and 285 nm for koenimbine and mahanimbine respectively. The wavelengths were optimized by performing spectrum scanning in the 190–400 nm wavelength range, and the obtained data were compared with the maximum wavelengths mentioned in the literature (mahanimbine-357, 302, 288, and 235 nm; koenimbine-295, 262, and 238 nm) [26]. The conditions for densitometric scanning (VisionCATS version 3.2) were: scanning speed 20 mm/s, data resolution 100 µm/step, and slit dimension 6.00 × 0.45 mm. From densitometric analysis, the retardation factor (R_f) for mahanimbine and koenimbine was found satisfactory. For quantitative analysis, the obtained values for the peak areas were utilized.

Method validation

Method validation is an integral part of any analytical experiment/procedure for getting accurate and reproducible results. This process is performed by checking the following parameters: linearity, LOQ, LOD, accuracy (recovery), precision (intra- and inter-day precision), reproducibility, and robustness.

Linearity

In any analytical method, linearity is an important parameter that describes its ability to get test results directly proportional to the content (concentration) of analyte present in the sample [27]. For quantifying the analytes present in the formulations, dilution of the standard stock solutions has been done to get linearity of standard solutions (considering the quantitation limit) containing koenimbine and mahanimbine in the concentration range of 50–450 and 100–400 µg/mL respectively keeping the applied volume 4 µL constant. The standards were applied in triplicate to generate the calibration curve. The correlation coefficient (R^2), intercept, and slope of the calibration curves were estimated to obtain the method linearity.

Detection limit (LOD)

The detection limit (LOD) is defined as the lowest amount of the analyte detected in the prepared sample. LOD can be calculated by using the following equation:LOD=3.3×standard deviation of the response/slope of the calibration curve

Quantitation limit (LOQ)

The quantitation limit (LOQ) is defined as the lowest amount of the analyte quantified with sufficient accuracy and precision. It can be calculated by using the following equation:LOQ=10×standard deviation of the response/slope of the calibration curve

Accuracy (recovery)

The accuracy of any analytical procedure is defined as the degree of agreement between the values considered to be true and the amount of the substance in the test samples obtained from the analysis [27, 28]. For estimating the percentage of recovery of mahanimbine and koenimbine in F_1, about 300 mg of powdered drug and 32 µg (80%), 40 µg (100%), 48 µg (120%) of mahanimbine standards and 112 µg (80%), 140 µg (100%) and 168 µg (120%) of koenimbine standards were mixed and further diluted with required quantity of HPLC grade methanol. In the case of F_2 and F_3, about 300 mg of powdered drugs and 40 µg (80%), 50 µg (100%), 60 µg (120%), 48 µg (80%), 60 µg (100%) and 72 µg (120%) of mahanimbine and 112 µg (80%), 140 µg (100%) and 168 µg (120%) of koenimbine standards were mixed and diluted with required quantity of HPLC grade methanol. After that, the percentage of recoveries was calculated and documented.

Precision

The precision of any analytical method was defined as the degree of agreement between a series of measurements obtained from multiple sampling of the same homogeneous sample under the prescribed conditions [27, 28]. In the present study, inter-day precision studies of the developed method have been done by applying the standard solutions in triplicate at three different concentration levels three times at 72 h intervals, and for performing intra-day precision studies, the standard solutions were applied in triplicate at three different concentration levels three times within two hour intervals on the same day.

Reproducibility

The developed method was validated for the reproducibility of both for application (repeatability of application) and scanning (repeatability of scanning) [29]. The experiments were performed in triplicate by different analysts in different laboratories of NIPER Hyderabad, and it was observed that the %RSD values were obtained between ±5. Hence, it can be concluded that the developed method is reproducible.

Robustness

Robustness study needs to be done during method development, and it helps to determine the reliability of an analysis concerning deliberate variations in method parameters. In the present study, the following variations have been done to check the robustness of the developed method; different volumes of mobile phase compositions were utilized (Hexane: Ethyl acetate = 7:3, 8:2; 9:1); the laboratory temperature set to 22 °C, 25 °C, and 30 °C; humidity—35% RH, 55% RH, and 75% RH, varying the wavelengths for scanning (293, 291 and 289 nm) and

changing distance for development of TLC plates (78, 76 and 74 mm), etc. It was observed that the developed method gave reproducible results in all varying conditions.

Results

Three different marketed formulations (tablet, capsule, and powder) were collected from different distributors and coded as F_1, F_2, and F_3. The stock solutions of the standards were prepared by dissolving 5 mg of both standards in 50 mL of HPLC grade methanol and the working solutions were prepared by diluting the stock solutions with the required quantity of methanol. In the present study, TLC silica gel $60F_{254}$ plates were used as a stationary phase, and a combination of hexane:ethyl acetate (7:3) was utilized as a mobile phase. The developed fingerprinting profile showed that the mahanimbine and koenimbine were present in the selected formulations (Fig. 2). Both phytocompounds were densitometrically detected at $\lambda = 285$ and 291 nm, respectively. The absorption spectrum and the peak areas were recorded and documented for analysis. From spectrum data, it was observed that in the wavelength range of 190–400 nm, absorption maxima for mahanimbine and koenimbine were observed at 285 and 291 nm (Fig. 3). So, these two wavelengths were selected for further quantification. The specificity and peak purity of the method were determined by comparing the spectra of mahanimbine and koenimbine in the selected formulations with the standards. The peaks obtained by densitometric scanning were easily identifiable, symmetrical, and resolved well. From densitometric scanning, the obtained R_f values for mahanimbine and koenimbine were 0.48 and 0.60, respectively (Figs. 4 and 5).

Further, the developed method was validated as per the guidelines mentioned by (ICH)-Q2-(R1). To determine the linearity of the developed method, 4 µL of standard solutions of increasing concentration (50–450 µg/mL for koenimbine and 100–400 µg/mL for mahanimbine, respectively) were applied on TLC silica gel $60F_{254}$ plates in triplicate. The calibration curve was generated (Fig. 6, Tables 1 and 2), and a linear relationship was established for mahanimbine and koenimbine in the concentration range of 100–400 and 50–450 µg/mL (Table 3). From the calibration curve, the obtained equations were $Y = 3.3614x + 95.5$ and $Y = -0.0069x^2 + 8.2023x + 172.76$, correlation coefficients (R^2) = 0.9985 and 0.9998, coefficient of variances (CV) = 0.34% and 0.89%, respectively (Fig. 6, Table 3). The obtained R^2-value indicates a strong correlation between the concentrations of phytocompounds and peak areas.

Table 3. Method validation parameters

Sl No	Parameters	Mahanimbine	Koenimbine
1	Wavelength	285 nm	291 nm
2	Linearity range concentration (in µg/ml)	100–400	50–450
3	Coefficient of variances (CV)	0.34%	0.89%

4	Correlation coefficients (R^2)	0.9985	0.9998
5	Limit of detection (ng/spot)	32.81	18.44
6	Limit of quantitation (ng/spot)	72.81	31.57
7	Reproducibility	Reproducible	Reproducible

The LOQ and LOD values were calculated, and the obtained values were 18.44 ng/spot, 31.57 ng/spot, for koenimbine and 32.81 ng/spot, 72.81 ng/spot for mahanimbine, respectively (Table 3). Inter-day and intra-day precision studies have been done for the developed method; for intra-day, the studies were done in triplicate at three hrs time intervals; for inter-day, it was also done in triplicate at three consecutive days (Tables 4 and 5). The developed method was evaluated for recovery (accuracy) studies. For this purpose, the selected formulations and the standards were mixed and diluted with the required quantity of HPLC grade methanol. The calculated % of recovery for mahanimbine was: 96.80 (F_1), 98.47% (F_2), and 95.13% (F_3), and for koenimbine was: 97.61% (F_1), respectively (the % recovery was found to be between 95 and 105%; hence, the developed method was accurate) (Tables 6, 7, 8 and 9). The recovery analysis of koenimbine was not done in F_2 and F_3 as in F_3, it was not identified, and in case of F_2, though, it was identified but not quantified properly (quantification value comes under LOQ). Robustness studies were also performed by altering the method parameters, and there is no significant change observed in the obtained results (Tables 10 and 11).

Table 4. Intra- and inter-day precision data of mahanimbine

All the experiments were performed in triplicate

After that, the developed method was successfully employed to estimate mahanimbine and koenimbine in the selected marketed formulations (F_1, F_2, and F_3). From this study, mahanimbine was identified and quantified in all of the formulations, but koenimbine was only quantified in F_1 though it was identified in both F_1 and F_2 as the quantified value in F_2 comes under LOQ and this identification was done by comparing the R_f values (0.60 and 0.48), and absorption maxima (285 and 291 nm) of the standards. The quantity of both phytocompounds in the formulations was calculated based on the peak areas obtained from the chromatogram. The amount of mahanimbine in F_1, F_2, and F_3 was found to be 41.19 µg, 53.24 µg, and 62.32 µg, and for koenimbine, it was 143.6 µg, respectively (Table 12). It indicates that the highest quantity of mahanimbine was found in F_3, but in F_1, both the phytocompounds were present.

Table 12. Quantity of mahanimbine and koenimbine in F_1, F_2, and F_3 (in 30 mg)

Sl No	Name of the formulations	Mahanimbine (µg)	Koenimbine
1	F_1	41.19	143.6 µg
2	F_2	53.24	Not quantified
3	F_3	62.32	Not quantified

Discussion

M. koenigii is an important medicinal plant and several herbal formulations were available in the market where *M. koenigii* leaf powders or extracts were incorporated, and these formulations were used as dietary supplements, cosmetics, etc. But there is no specific analytical method was reported for standardizing the same and marker-based standardization by utilizing planar chromatographic methods can be a better option for this. Hence, there is a need to develop a suitable analytical method that helps to perform qualitative and quantitative analysis of two major marker compounds of *M. koenigii* named mahanimbine and koenimbine in the marketed herbal formulations for routine quality control analysis. Hence, in the current study, three marketed formulations manufactured by different companies (coded as F_1, F_2, and F_3) were collected, and quantitative estimation of mahanimbine and koenimbine was done in these formulations by using a semi-automated TLC method. Koenimbine (R_f value 0.60) and mahanimbine (R_f value 0.48) were identified in all of the formulations at the wavelengths of 291 and 285 nm, but only mahanimbine was quantified in all of the formulations, and koenimbine was quantified only in F_1. For performing this analysis, different mobile phases were employed, but based on the separation pattern, hexane:ethyl acetate (7:3 v/v) was selected for final quantification. This method passed all the parameters of analytical validation as per the guidelines prescribed in (ICH)-Q2-(R1) and gave reproducible results. The peak shapes of mahanimbine and koenimbine were found to be good. Hence, the developed semi-automated TLC method can be utilized for the routine quality control analysis of marketed herbal formulations of *M. koenigii* effectively, and its advantages are specificity, accuracy, and simplicity.

Conclusion

The current study proved that the developed HPTLC method was precise, specific, simple, and accurate in estimating mahanimbine and koenimbine in selected marketed herbal formulations. This study revealed that mahanimbine is identified and quantified in all formulations, but koenimbine is only identified and quantified in tablet formulation. The performed quantitative and qualitative analysis of the content of mahanimbine and koenimbine can help to maintain the quality of the marketed herbal formulations containing *M. koenigii* extracts/powders. The developed method has been validated as per the guidelines mentioned in (ICH)-Q2-(R1), which confirmed this method's accuracy, precision, and reliability.

ABSTRACT (ENGLISH)

Background

Pilocarpine HCl is a non-selective muscarinic receptor agonist that is prescribed for the treatment of glaucoma. The use of pilocarpine conventional eye drops is associated with several side effects, such as loss of visual acuity, and the need for several applications due to rapid drainage away via the nasolacrimal duct, especially for elderly people. Such adverse effects can lead to low patient compliance and poor clinical outcomes. Therefore, the aim of this project was to develop, optimise and characterise a biodegradable pilocarpine HCl ocular insert using niosomes as a drug delivery vehicle. To achieve that, various polymers such as hydroxypropyl methylcellulose (HPMC), polyvinyl alcohol (PVA), and a blend of both were investigated to prepare the ocular inserts using solvent casting technique. The niosomes of pilocarpine HCl were prepared using span-60 and cholesterol by thin film hydration method. The produced noisome-loaded ocular inserts were characterised using various analytical techniques, including Fourier Transform Infrared (FTIR), X-ray Diffractions (XRD), thermal analysis, particle size analysis, weight and content uniformity, surface pH and drug release profile, among others.

Results

The results indicated that drug-free ocular inserts of the two polymers (HPMC + PVA) were better than single polymer-based ocular inserts (HPMC or PVA alone). The formed niosomes demonstrated good entrapment efficiency of 49.7% ± 7.0, with an average particle size of 325.7 ± 3.5 nm. The FTIR analysis showed no interaction between the compositions of niosomes. Four optimal formulations with various co-polymer ratios and pilocarpine content were further evaluated. Pilocarpine-containing niosomes-loaded ocular inserts provided uniformity in pilocarpine content (89–96%), with 34.8% moisture content and an average pH of 7. The release profile of niosomes-loaded inserts demonstrated an initial burst release within 2 h ranging from 26.54% (T4) to 41.22% (T2), and continuous sustained release for the next 24 h (68.32 ± 5.11% (T4) to 82.11 ± 6.01% (T2)).

Conclusions

This work successfully optimised biodegradable ocular inserts containing slow-release pilocarpine HCl encapsulated in niosomes for the treatment of glaucoma without dose dumping, resulting in a user-friendly drug delivery system.

FULL TEXT

Background

The eye is an anatomically and physiologically unique organ with various structural components [1]. Although the eye is an easily accessible organ for the direct administration of medication, it is isolated by several barriers such as the cornea, which acts as the main barrier for absorption and transportation of topically applied drugs into the systemic circulation. Further, the posterior part of the eye, such as the retina, creates an additional barrier. The retinal barrier is a protective barrier for the transport of materials [2], which creates challenges to drug delivery [3, 4]. In general, small lipophilic molecules can be absorbed through the cornea, whereas hydrophilic molecules can be absorbed through the conjunctiva and sclera [2].

The main routes for ocular administration of active pharmaceutical ingredients (APIs) are topical, systemic, and intraocular. The topical route, with formulations such as eye drops, accounts for 90% of aqueous ocular administration. This is the most preferred route owing to ease of application, patient preference and reduced systemic side effects caused by the API. Eye drops have several advantages such as being easy to apply by most patients (self-administration), safe, and more comfortable [5]. Besides, eyedrops can overcome first pass metabolism and directly target the site of the action [6]. Nevertheless, the use of eye drops has several limitations particularly, short retention time in the eye [3] which requires multi-dose administration during the day, which is detrimental to patient compliance [7, 8].

Pilocarpine HCl is a non-selective muscarinic receptor agonist and is prescribed for the treatment of glaucoma. Pilocarpine HCl decreases intraocular pressure in glaucoma patients by increasing trabecular outflow [9]. Lowering high intraocular pressure aids in preventing blindness, vision loss, and nerve damage [10]. Pilocarpine HCl eye drops are commonly used for the treatment of glaucoma with different concentrations (1%, 2%, 4%) available. The use of these conventional eye drops has been associated with several side effects, especially for elderly people, like loss of visual acuity, preservative allergy, and the need to repeat the dose to maintain therapeutic effects. Such adverse effects can lead to low patient compliance, and hence poor clinical outcomes [9].

For optimal bioavailability from ophthalmic topical formulations and effective clinical outcomes, these formulations need to be designed to increase retention time of the dosage form and enhance ocular drug permeability [11]. Novel drug delivery systems (DDSs) have been designed to deliver ocular drugs with reduced side effects. These formulations are based on nanotechnology to achieve desired drug particle size and the associated reduction of eye irritation, plus improved bioavailability. These formulations include microparticles, nanoparticles like liposomes (acyclovir), niosomes aqueous gels, or dendrimers (tropicamide) [5].

Niosomes are nano-sized vesicles containing non-ionic surfactants arranged in bilayers. Depending on the preparation method, niosomes may be unilamellar or multilamellar. Niosomes are made of a surfactant bilayer with the hydrophilic heads found on the surface, and inside, of the vesicle while the hydrophobic tails form the bilayer; this allows for two different areas for drug entrapment [12]. Features that make niosomes interesting for research include capacity for different API entrapment, osmotic activity and stability, presence of an amphiphilic structure that contains hydrophobic and hydrophilic portions and provide applications for dissolving drugs with varying solubilities. In addition, niosomes release the drug in a controlled manner through the bilayer, which can protect the encapsulated API during transit. Therefore, niosomes act as a store of medication in the body and enable targeted drug delivery [13]. Niosomal formulations are versatile owing to their structural flexibility, in terms of composition, fluidity, and size [12]. Niosomes are compatible, will not stimulate immunogenic reactions, and are decomposed by the biological system [14]. Furthermore, niosomes do not require special storage conditions [13]. These characteristics make niosomes promising nanocarriers in the treatment of ocular diseases. For example, timolol maleate, brimonidine tartrate, atenolol, dorzolamide HCl, bimatoprost and acetazolamide have been developed as niosomes for glaucoma treatment, while lomefloxacin HCl and chloramphenicol niosomes have been developed for treatment of conjunctivitis. Flurbiprofen and prednisolone niosomes have also been prepared for treatment of ocular inflammation and epalrestat for diabetic eyes [12, 15, 16].

Ocular inserts as novel drug delivery systems are gaining traction in research. Ocular inserts of pilocarpine HCl, marketed as Ocusert®, were an alternative topical dosage form that provided extended release of pilocarpine HCl over seven days. Ocusert® was easy to insert in the upper or lower lid, soft, flexible and had two drug release options: 20 µg/hour or 40 µg/hour. It was based on a reservoir system with zero order release pattern and pilocarpine HCl released by diffusion [17]. Ocusert ® was withdrawn from the market due to dose dumping and frequent loss of insert especially during sleep [18]. Therefore, development of pilocarpine HCl as an extended-release dosage form, such as niosomes, to be loaded into hydrophilic soluble ocular inserts, which would release the drug over 24 h and be biodegradable, would be advantageous. Other work by Lin et al. [19] reported the use of alginate and pluronic solution as the in-situ gelling vehicles for ophthalmic drug delivery of pilocarpine HCl. The mixture of 0.1% alginate and 14% pluronic solutions showed improvements in gel strength and clinical outcomes: with the main objective of improving the ocular bioavailability of pilocarpine HCl.

Therefore, there is a need to develop a user-friendly dosage form for pilocarpine HCl that releases pilocarpine HCl slowly over extended period of time and hence reduces the anticipated side-effects, especially for elderly patients, which are manifested in loss of visual acuity and annoyance for repeated dosing to maintain therapeutic effect. Such adverse effects can lead to low patient compliance and hence this will affect clinical outcome. Therefore, the aim of this project was to develop a formulation of biodegradable mucoadhesive ocular insert loaded with pilocarpine HCl containing niosomes to provide an extended-release effect over 24 h which would provide an effective treatment of glaucoma with sustained release effect of drug. This would result in an increase in contact time between drug and

cornea, reduction in the number of daily doses of the traditional ophthalmic dosage forms and sustained API delivery to the targeted site, using as little API dose as possible [7].

Methods

Materials

Pilocarpine HCl powder (≥98%) and polyvinyl alcohol (PVA) were obtained from Sigma-Aldrich (Taufkirchen, Germany). Methanol (HPLC grade) was purchased from Honey well (Saint-Germain-en-Laye, France), water (HPLC grade) and chloroform were obtained from Alpha Chemika (Mumbai, India), while triethyl amine was obtained from Tedia (Fairfield, Ohio, USA). Orthophosphoric acid and hydroxypropyl methylcellulose (HPMC) were purchased from Alzchem for chemical (Trostberg, Germany). Glycerine, span 60 and sodium hydroxide were obtained from Fischer (Guangzhou, China). Cholesterol and phosphate buffered saline were obtained from Carlsson (Maryland, USA). All materials were used as supplied.

Development of drug free (blank) ocular inserts

Hydroxypropyl methylcellulose (HPMC) and polyvinyl alcohol (PVA) in different concentrations (see Table 1) were investigated to prepare the blank ocular inserts. Accurately weighed HPMC was sprinkled over 100 mL distilled water placed on a hotplate magnetic stirrer (Dlab ms-h280 (Beijing, China)) with temperature set at 30–40 °C and 1500 rpm for 1–2 h to ensure complete swelling and hydration of the polymer. Then, the required volume of glycerine (as plasticiser) was added and stirred for 15 min. After that, the polymer solutions were sonicated for 30 min continuously using a Bandelin Sonorex Digitec sonicator to remove bubbles. The final solution was cast onto plastic petri-dishes (area 56.71 cm^2). To prevent quick drying and films cracking, the samples were placed on the bench for 12 h at ambient temperature before placing them in the hot air oven at 40 °C for 4 h to complete drying. PVA containing ocular inserts were prepared in a similar manner but using cold distilled water initially and stirring at 1500 rpm for 30 min. The temperature of the PVA solution was then increased to 100 °C for 1 h to ensure complete swelling and hydration. Hot air oven drying time was only 30 min.

Table 1. Summary of the composition of the drug free (blank) ocular inserts formulations

Formula	Polymer	Polymer concentration %w/v	Plasticiser (glycerine) (%v/v)	Solvent volume (mL)
F1	HPMC	0.5	0.25	50
F2	30	F3	20	F4
HPMC	1.0	0.25	50	F5
30	F6	20	F7	HPMC
1.5	0.25	50	F8	30
F9	20	F10	HPMC	2.0
0.25	50	F11	30	F12
20	F13	PVA	0.5	1.0
50	F14	30	F15	20

F16	PVA	1.0	1.0	50
F17	30	F18	20	F19
PVA	1.5	1.0	50	F20
30	F21	20	F22	PVA
2.0	1.0	50	F23	30
F24	20	F25	PVA	3.0
1.0	50	F26	30	F27
20	F28	HPMC + PVA	1.5 + 2.0	1.0
50	F29	30	F30	HPMC + PVA
1.0 + 1.5	1.0	50	F31	30
F32	20	F33	HPMC + PVA	1.0 + 1.0
1.0	50	F34	30	F35

Blank ocular inserts containing a blend of HPMC and PVA were prepared starting with PVA solution as discussed above, after which the solution was kept on the bench at ambient temperature to cool to about 37 °C. This solution was returned to the hotplate and HPMC powder (0.5 g, 1 g or 1.5 g) was sprinkled with stirring at 1500 rpm and 37 °C for 30 min. Glycerine was added and solution further stirred for 15 min, then sonicated for 30 min to remove bubbles. The solution was cast on plastic petri-dishes (area 56.71 cm^2). To prevent quick drying and films cracking; the samples were placed on the bench for 12 h before putting it in the hot air oven for 30 min to complete drying.

Preparation of niosomes

The niosomes were prepared according to [7] using thin film hydration method. Accurately weighed span 60 (200 mg), cholesterol (100 mg) and pilocarpine HCl (20 mg) were added to 10 mL chloroform in a round bottom flask. The solution was rotated at 150 rpm for 1 h on a Heidolph rotary evaporator (Kelheim, Bayern, Germany) to evaporate the chloroform under low pressure at 60 °C. This step led to the formation of a thin film on the wall of flask. Then 10 mL of phosphate buffer (pH 7.4) was added to the flask to hydrate the film and left on the rotatory evaporator for 1 h at 60 °C and 150 rpm to remove the residual solvent. To produce niosomes, the dispersion was vortexed for 5 min at 60 °C. Finally, the produced niosomes were sonicated for 10 min at 60 °C using a Bandelin Sonorex Digitec sonicator.

Preparation of niosomes loaded ocular inserts

The prepared niosomes were loaded in selected preparations of blank ocular inserts. The ocular inserts were prepared as described above. An appropriate weight of niosomes containing 1 mg or 2 mg of pilocarpine HCl (calculated based on the entrapment efficiency results) was incorporated into the produced polymer blend solution (at room temperature) and stirred on a magnetic stirrer Dlab ms-h280 (Beijing, China), 200 rpm for 10 min to ensure homogeneous dispersion. The resulting dispersion was poured into silicon moulds and placed on the bench top for complete drying at room temperature. The quantity of added niosomes was based on the average daily dose of

pilocarpine HCl (1–2 mg) [9]. Table 2 summarises the composition of all prepared pilocarpine HCl loaded ocular inserts.

Table 2. Summary of the composition of pilocarpine HCl loaded ocular inserts

Formula	Polymer (type and concentration (%w/v))	Plasticiser (glycerine) (mL)	Amount of pilocarpine HCl (mg)	Solvent volume (mL)
T1	1% HPMC + 1.5% PVA	1.0	1.0	50
T2	1% HPMC + 1% PVA	1.0	1.0	50
T3	1% HPMC + 1% PVA	1.0	2.0	50
T4	1% HPMC + 1.5% PVA	1.0	2.0	50

Analytical method optimisation and validation for pilocarpine HCl

High performance liquid chromatography (HPLC) was employed for the quantitative analysis of pilocarpine HCl. The method was based on [7] with modification. A Dionex Ultimat HPLC System from Thermo Fisher Scientific Inc. (Sunnyvale, California, USA), with gradient pump, UV detector set at 215 nm, and C-18 analytical column from Phenomenex® (Luna® 5 µm, LC column 250 × 4.6 mm, particle size 5 µm) was used. The mobile phase was composed of solution A (1.35% v/v phosphoric acid and 0.3% v/v mL triethylamine in HPLC grade distilled water (pH adjusted to 3 using 10 M NaOH)) and solution B (methanol). The two solutions ratio A:B was 90:10%v/v, column temperature (20 ˚C), flow rate (1.5 mL/min), and sample injection volume (10 µL). Pilocarpine HCl samples were analysed over the concentration range of 3.9–1000 µg/mL using solution A as diluent. The HPLC method was validated according to ICH guidelines in terms of specificity, accuracy, precision, and linearity, limits of detection, and limit of quantification [20].

Characterization of the drug free ocular inserts

Ocular insert/film quality

The blank ocular inserts were evaluated based on multi-dimensional criteria such as smoothness, transparency, flexibility, good wetting and spreading ability, non-sticky and easy peeling according to the method described in [21, 22]. Evaluation scores were given for each feature out of 20 (0 bad, 10 good, 20 very good) based on visual inspection. The total of scores were calculated out of 100.

Weight uniformity

The blank and the niosome loaded films were cut into small pieces with dimensions of 0.5 × 1.0 cm. Each piece was weighed individually using a Sartorius analytical lab scale digital balance (AC/120 S MC-1). The mean, standard deviation, and relative standard deviation for the values were calculated using 5 replicates.

Disintegration time

One piece with a dimension of 0.5 × 1.0 cm for each formulation of the blank ocular insert was placed in 3 mL artificial tears on a hotplate set at 37 °C. The disintegration time was monitored. Disintegration time was defined as the time required to start breaking down of the films into small pieces. This test was repeated for three samples.

Moisture content

To measure the moisture content of the drug free ocular inserts, each film was weighed to attain its initial weight (W_i) and then heated at 100–120 °C in a hot air oven until a constant final weight was achieved. The final weight (W_f) of the dried film was then measured, and the moisture content (MC) was calculated using Eq. (1).

1

MC\%=Wi-WfWi×100

Characterization of pilocarpine HCl niosomes

Entrapment efficiency

The amount of pilocarpine HCl entrapped within the niosomes was investigated by placing 1 mL of the formula in 1.5 mL Eppendorf tubes followed by centrifugation using a DLAB refrigerated centrifuge (D3024R) at 7000 rpm and 4℃ for 1 h. The supernatant was collected, then, 1 mL of phosphate buffer pH 7.4 was added to wash the vesicles and re-centrifuged for 1 h. This step was repeated twice, and supernatant was collected each time. Then, 1 mL of isopropyl alcohol was added to lyse the washed niosomes and the mixture was centrifuged for 30 min at 7000 rpm. A 100 µL sample was withdrawn and transferred into a 5 mL volumetric flask containing 1 mL isopropyl alcohol. The solution was then made up to 5 mL using phosphate buffer pH 7.4. The drug content was analysed using HPLC at 215 nm to calculate the total entrapped drug within the niosomes. The collected supernatants were combined in a 10 mL volumetric flask and made up to volume using phosphate buffer pH 7.4. The drug content was then analysed by HPLC at 215 nm to calculate total free drug in supernatant which was used to calculate the recovery and entrapment efficiency ENT (%) according to the following equations:

2

PILT=PILN+PILS

PIL_T is the total amount of used pilocarpine HCl, PIL_N is the amount of pilocarpine HCl within the niosomes, whereas PIL_S is the total amount of the pilocarpine HCl within the supernatant (i.e., free drug).

Microscopic analysis of niosomes

One drop of the pilocarpine HCl loaded niosomes was placed on a glass slide and an optical Nikon microscope (Tokyo, Japan) was used to assess the prepared niosomes at 100× magnification.

Laser diffraction analysis

Laser diffraction was employed to analyse average particle size of the niosome, polydispersity index (PDI), and zeta potential. The parameters were measured via photon correlation spectroscopy using a Zetasizer Nano ZS90 instrument from Malvern Instruments (Worcestershire, UK). Niosomes were diluted with deionised water and sonicated at low amplitude (~30 Hz) for 10 s prior to analysis. Results were reported as mean ± standard deviation (SD) using triplicate samples.

Characterization of drug loaded inserts

Content and thickness uniformity

The content uniformity of each ocular insert was evaluated by measuring the amount of pilocarpine HCl in each insert. Each ocular insert was placed in a 10 mL volumetric flask containing 8 mL phosphate buffer (pH 7.4) and 2 mL isopropyl alcohol. The flask was sonicated for 8 h using a Bandelin Sonorex Digitec sonicator to ensure complete dissolution of the film. Each experiment was repeated three times. Samples were withdrawn from the flask and analysed by HPLC. Film thickness was measured using an Erweka TBH 30 tester (Hessen, Germany), and the average, standard deviations, and relative standard deviations were calculated.

Surface pH

Measurement of the surface pH of the final pilocarpine HCl loaded ocular inserts was carried out according to the method described in [23], where 1 mL of distilled water was applied onto the film in a petri dish and allowed to spread evenly over the surface of the film. The surface pH was determined using a digital pH meter, and the results were recorded as mean ± SD using triplicate samples.

Fourier transform infrared (FTIR) spectroscopy analysis

FTIR spectra of pilocarpine HCl, span 60, cholesterol, pilocarpine HCl containing niosomes, blank films and niosome-loaded films were recorded using a Perkin Elmer FTIR spectrometer (OH, USA), associated with Spectrum 10 software. A sample was loaded onto the sample holder and each sample's FTIR spectrum scans was recorded over the range of 450–4000 cm^{-1} with a resolution of 2 cm^{-1}.

Drug release study

Niosome loaded ocular inserts containing 1 or 2 mg pilocarpine HCl were used in the donor compartment model

using cellulose dialysis membrane and 2 mL phosphate buffer pH 7.4, which was used to mimic in vivo cornea epithelial membrane conditions. This donor compartment model was placed in a beaker containing 50 mL of phosphate buffer, pH 7.4. The beaker was placed on a magnetic stirrer plate at a temperature of 37 °C and set at 60 rpm. At time intervals of 1 h for the duration of 3 h and then after 24-h, 1 mL samples of the release medium were removed and placed in separate vials and then analysed by HPLC. 1 mL of phosphate buffer pH 7.4 maintained at the same temperature was replaced to maintain sink conditions [24].

Differential scanning calorimetry (DSC) analysis

DSC analysis of pilocarpine HCl and niosomes was carried out using a DSC Q200- TA instrument (USA). Around 5 mg of each sample was placed onto an aluminium pan and heated at a rate of 10 °C/minute under continuous nitrogen purging (50 mL/minute).

X-ray diffraction (XRD) analysis

An X-ray diffractometer (MiniFlex 600 benchtop diffractometer (RigaKu, Tokyo, Japan)) was used to investigate the physical form of niosomes, pilocarpine HCl and niosome loaded ocular inserts. The XRD experiments were performed over the 2θ range from 5 to 90°, with Cu Kα radiation (1.5148227 Å) and a voltage set at 40 kV and a 15 mA current. Designated samples were placed on a holder and scanned in triplicate. Data was recorded at a scanning speed of 5°/minute. OriginPro® software was employed to analyse the scans (OriginLab Corporation, USA).

Statistical analysis

Statistical analysis was performed using SPSS statistical pack (version 25) with $p<0.05$ quotes as the level of significance for the calculation of one-way ANOVA test. Results were reported as mean ± SD (standard deviation).

Results

Quantification of pilocarpine HCl

A calibration curve for pilocarpine HCl was obtained over a concentration range of 3.9–1000 µg/mL. The curve demonstrated linearity with high degree of corelation (coefficient of determination $R^2 = 0.9999$, regression equation Y =0.1135×- 0.0591). The method was specific to pilocarpine HCl and none of used materials (HPMC, PVA, glycerine, cholesterol, span 60) interfered with the pilocarpine HCl peak that eluted at 5.72 ± 0.18 min. A peak representing the blank ocular insert appeared before 2 min. Recovery experiments for three concentrations in triplicate over three days were conducted to determine the intraday repeatability and (inter-day) reproducibility as an indication of the method's accuracy. The results are shown in Table 3 and demonstrate method precision with RSD below 6.04%. All recovery results ranged between 96.7 and 101.8% with low RSD (between 0.96 and 6.04%) indicating an accurate method. RSD between 0 and 15% is an indication of method accuracy. Similar results were reported in a previous study on pilocarpine HCl [22]. Equipment precision was evaluated using repeated measures of one selected concentration (62.5 µg/mL) of pilocarpine HCl solution and the results demonstrated precise equipment owing to low RSD (0.44%) and according to the ICH guidelines [20] a RSD of less than 2%, indicates an accurate and precise technique. The method limit of detection (LOD) and limit of quantification (LOQ) of pilocarpine HCl were 1.2 µg/mL and 3.65 µg/mL respectively. Overall, the employed method demonstrated a valid and reproducible process for the analysis of pilocarpine HCl.

Table 3. Accuracy of pilocarpine HCl HPLC method (intraday and inter-day reproducibility)

Pilocarpine HCl concentration (µg/mL)	Intraday recovery % (mean ± SD), n = 3	RSD %	Inter-day recovery % (mean ± SD), n = 9	RSD %
250	100.54 ± 1.45	5.11	101.8 ± 0.41	1.42
125	98.95 ± 0.84	6.04	101.2 ± 0.14	0.96

62.5	96.71 ± 0.52	4.60	101.7 ± 0.18	2.53

Characterization of drug free (blank) ocular inserts

The first part of the project aimed to optimise a drug-free (blank) ocular insert by enhancing its smoothness, transparency, flexibility, wetting/ spreadability, and ease of peeling off. Additionally, the project aimed to develop films that disintegrate within a specific time frame.

To do that, various formulations of drug-free ocular inserts were investigated (Table 1). The produced blank ocular inserts were characterised based on film quality, weight uniformity and disintegration time. The prepared HPMC containing formulations are shown in Fig. 1, revealed films with a transparent and smooth appearance. Increasing the HPMC content above 1% (w/v) resulted in thick films with reduced flexibility, even at lower volumes. However, the transparent appearance, which was observed in all the HPMC films, was not affected by increasing HPMC content from 0.5% to 2% w/v.

Fig. 1 [Images not available. See PDF.]

Images of HPMC blank ocular inserts at different concentrations (w/v), **a** HPMC 0.5% -F1 **b** HPMC 1%-F4, **c** HPMC 1.5%-F8, **d** HPMC 2%-F11

Representative samples of PVA containing blank ocular inserts are shown in Fig. 2. Increasing PVA content from 0.5 to 2% w/v led to harder films, which were less flexible, and difficult to handle. Transparent and smooth appearance was observed in all preparations regardless of the PVA content. PVA 2% w/v films demonstrated a hard and less flexible appearance like a paper sheet (Fig. 2d), despite increasing the plasticiser (glycerine) concentration from 0.25 to 1% v/v. Several researchers employing HPMC and/or PVA in the development of ophthalmic films observed similar trends [25, 26].

Fig. 2 [Images not available. See PDF.]

Images of blank ocular inserts at different PVA concentrations (w/v), **a** PVA 0.5% -F13, **b** PVA 1% -F16, **c** PVA 1.5% -F19, **d** PVA 2% -F23

Blank ocular inserts made of a blend between PVA and HPMC are presented in Fig. 3: Films (a) and (b)—containing 1% HPMC with 1% and 1.5% PVA respectively—produced very smooth, flexible, and transparent appearance. However, increasing the amount of the PVA in the blend, led to a reduction in the flexibility, transparent appearance, and an increase in the hardness of the films. Film (c) presented a harder film than (a) and (b); because of the high percentages of PVA (2%) and HPMC (1.5%). Blending polymers in the formulation of films produced smooth and flexible films with suitable disintegration time for ocular insertion, due to inherent characteristics of the individual polymers.

Fig. 3 [Images not available. See PDF.]

Images of blend films (HPMC + PVA) at different concentrations (w/v), **a** HPMC1% + PVA 1% -F34, **b** HPMC 1% + PVA 1.5% -F30 **c** HPMC 1.5% + PVA 2% -F29

Quality of blank ocular inserts

The blank ocular inserts were further evaluated according to multifaceted criteria. Each criterion was given a score and the total score for each film is depicted in Table 4. F30 and F33 demonstrated superior properties with a score of 100 and were chosen for incorporation of pilocarpine HCl niosomes. From Table 4, lower concentrations of HPMC (0.5–1.5%) fail the extended disintegration time target, while higher HPMC concentrations had longer disintegration times but were hard to cast on casting dishes. All PVA containing films exhibited very long disintegration time. However, the co-polymer films particularly F30 (1% HPMC, 1.5% PVA) and F33 (1% HPMC, 1% PVA) retained the excellent properties of the films in terms of smoothness, transparency, flexibility, wetting / spreadability and ease to peel off; as well as produced films that had a disintegration time within the targeted window.

Weight uniformity and disintegration time

The results of weight uniformity and disintegration time of the blank films are presented in Table 5. The produced films showed good weight uniformity as evident from the low %RSD value, except for few batches. Good spreadability of the liquid polymer is related to weight uniformity of the final dry film. Overall, the two selected batches (F30 and F33) demonstrated good weight uniformity and low RSD.

Table 5. Weight uniformity and disintegration time of the formulations of the blank film

Formula	Weight uniformity (mg) (mean ± SD), RSD) n = 10	RSD (%) of weight uniformity	Disintegration time
F1	1.09 ± 0.33	30.41	15.23 ± 10.1 min

F30	7.23±1.23	6.95	3.80±0.56 h
F31	6.61±0.56	8.54	3.2±0.74 h
F32	4.32±0.45	10.46	3.05±0.66 h
F33	13.91±2.2	5.85	3.59±0.35 h
F34	8.83±0.89	10.09	2. 98±0.25 h
F35	4.26±0.15	3.53	2.12±0.16 h

Overall, the blank films have uniformity in the weight with up to 2 standard deviations. Formulations F10, F11, F12, F30, F31, F32 and F33 achieved the ideal target disintegration times for ocular inserts (within 3–5 h).

Characterization of niosomes

The produced niosomes were based on previous work [7]. The produced niosomes were initially characterised before inclusion within the optimal blank film formulations.

Microscopic analysis of niosomes

Light microscopic analysis of pilocarpine HCl loaded niosomes was done at 100× magnification. The results are presented in Fig. 4. Images of niosomes showed spherical vesicles with cavities, which could hold entrapped drug. Aggregation of the spherical niosomes appeared as lines (Fig. 4c).

Fig. 4 [Images not available. See PDF.]

Light microscopic images of niosomes loaded with pilocarpine HCl prepared by thin film hydration method at 100×

magnification **a** selected area of niosomes for zoom in **b** zoomed in area highlighting the structure of the niosomes **c** Example of few aggregates

However, results using laser diffraction analysis for particle size analysis are presented in Table 6. The average particle size of the niosomes was within the nanoscale. The produced particles demonstrated an acceptable distribution and a large negative zeta size which promotes particle stability.

Table 6. Particle size, polydispersity index and zeta potential of pilocarpine HCl loaded niosomes (mean ± SD, n = 3)

	PSA (nm)	PDI	Zeta (mV)
Niosomes	325.7 ± 3.5	0.463 ± 0.044	− 51.32 ± 1.41

Entrapment efficiency and pilocarpine HCl within the niosomes

The average entrapment efficiency of pilocarpine HCl within the niosomes was 49.7% ± 7.0 (n = 3). This number was employed for the calculation of the amount of niosomes to be added to each ocular insert for the preparation of the ophthalmic inserts with niosomes.

FTIR spectra

The FTIR spectrum of cholesterol (Fig. 5a) revealed characteristic bands between 2800 and 3000 cm^{-1} which are attributed to asymmetric and symmetric stretching vibrations of CH_2 and CH_3 groups. The observed broad and intense band nearly at 3400 cm^{-1} is attributed to OH stretching. Cholesterol has one double band (C=C) in the second ring. This was prominently shown at 1674 cm^{1}. The band at 1464 cm^{-1} is due to asymmetric stretching vibrations of CH_2 and CH_3. The sharp peak at 1055 cm^{-1} can be attributable to ring deformation of cholesterol. The bands between 900–675 cm^{-1} are characterised due the C–H out of plane bending which are the characteristic of the aromatic substitution pattern and mainly determined by the number of adjacent hydrogen atoms on the ring and not much affected by the nature of substitutions. Similar results were reported in [27]. FTIR analysis of pilocarpine HCl (Fig. 5b) presented a C–O stretching band at 1026 cm^{-1}. C–N stretching at 1178 cm^{-1}, N–H bending band at 1765 cm^{-1} and C–H stretching at 3079 cm^{-1}. Similar results were reported by [10]. Figure 5c presents the IR spectra of span 60 which showed a broad peak at 3384 cm^{-1} due to O–H stretch bonded, strong peak at 2916 cm^{-1} due to C–H stretch, peak at 1735 cm^{-1} due to C=O stretch, and C–O stretch peak at 1175 cm^{-1}. Similar results were reported by [28]. Therefore, the niosome spectra (Fig. 4d) showed a broad band at 3400 cm^{-1} due to O–H stretch bond in span 60, a band at 2916 cm^{-1} due to C–H alkane, N–H bending band in pilocarpine HCl at 1765 cm^{-1}, while the C–O stretch group in pilocarpine HCl caused the peak at 1175 cm^{-1}.

Characterization of pilocarpine HCl niosome loaded ocular inserts

The drug loaded insert with different concentrations of pilocarpine HCl and polymer types, appeared as thin, smooth, and flexible films, easy to handle. An amount of niosomes containing the equivalent of 1 mg pilocarpine HCl for formulations T1 and T2, and 2 mg pilocarpine HCl for formulations T3 and T4 were incorporated into the films. The drug loaded inserts were cut into small pieces (2.5 × 5 mm) to be suitable to insert into the eye (see Fig. 6).

Fig. 6 [Images not available. See PDF.]

Digital photographs of pilocarpine HCL niosomal loaded ocular inserts

The result of the weight uniformity, content uniformity, moisture content, thickness, and surface pH are shown in Table 7.

Table 7. The result of weight uniformity, content uniformity, moisture content, thickness and pH of drug loaded niosomal inserts

Formula	Weight uniformity (mean ± SD) n = 10	Content uniformity %(Mean, n = 3)	Moisture content (mean ± SD) n = 3	Thickness (mm) (mean ± SD) n = 3	pH (mean ± SD)
T1	15.84 ± 2.06	92.5% ± 0.1	35.5% ± 2.32	0.41 ± 0.02	7.1 ± 0.1
T2	12.77 ± 2.37	89.2% ± 0.02	39.6% ± 6.63	0.55 ± 0.1	6.9 ± 0.01
T3	14.0 ± 1.23	86.08% ± 0.2	33.6% ± 8.54	0.64 ± 0.02	6.9 ± 0.2
T4	16.21 ± 1.25	96.08% ± 0.7	30.8% ± 0.72	0.95 ± 0.02	7.0 ± 0.1

The results revealed that the niosomal loaded ocular inserts demonstrated good content uniformity that ranged from 86.08 to 96.08% with low standard deviation that was below 2%. Further, the average moisture content of the ocular films was ranging from 30.8 to 39.6%. The surface pH of the ocular inserts is vital to ensure minimal eye irritation upon insertion. The surface pH of the drug loaded insert was in the range of 6.9–7.1.

Xray diffraction analysis

XRD pattern of pilocarpine HCl (Fig. 7a) demonstrated characteristic sharp peaks at 13.68°, 17.97°, 21.34°, 24.77° and 32.41° suggesting a crystalline material. Similar results were reported by Alyami et al. [7]. The blank film (Fig. 7b) demonstrated a shallow wide heap indicating the amorphous nature of the blend polymers. The niosome loaded films demonstrated characteristic peaks of the constituents of the niosomes (cholesterol and span 60). Due to the low load of pilocarpine HCl within the film, several peaks of pilocarpine HCl were not observed.

Fig. 7 [Images not available. See PDF.]

XRD Spectra of **a** pilocarpine HCl, **b** the blank film and **c** pilocarpine HCl niosome loaded ocular insert

DSC analysis

The thermal profiles of pilocarpine HCl, niosomes, blank film as well as drug-loaded niosomal ocular inserts are depicted in Fig. 8. The thermogram of pilocarpine HCl (Fig. 8a) portrayed the crystalline nature of the material with sharp endothermic melting peak at 206.39 °C and an enthalpy of 20.95 J/g. Similar results were recorded by [7]. Figure 8b demonstrates the thermogram of the niosomes. This showed interesting findings, the first peak of the niosomes at around 60 °C could be attributed to span 60, while the second peak at 97.33 °C and enthalpy of 121.64 J/g probably represents cholesterol. However, the reported cholesterol melting point is between 145 and 150 °C [29, 30]. Several studies reported the effect of developing niosomes on the melting point of cholesterol with a possible shift towards a lower range [31, 32]. The blank film (Fig. 8c) showed its amorphous nature with no melting peak observed. The thermogram of niosomes loaded films (T4) as can be seen in Fig. 8d showed a sharp endothermic peak at 43.24 °C with enthalpy of 7.04 J/g which represents the melting point of span 60. The second peak at 83.20 °C probably represents the melting point of cholesterol with another shift. The pilocarpine HCl melting peak does not appear probably owing to the encapsulation of the API within niosomes [31].

Fig. 8 [Images not available. See PDF.]

DSC spectra of **a** pilocarpine HCl, **b** niosomes, **c** blank film and **d** niosome loaded ocular insert (T4)

In vitro release study

The release of pilocarpine HCl from the drug loaded ocular inserts can be seen in Fig. 9 demonstrating an initial burst release within 2 h that ranged from 26.54% (T4) to 41.22% (T2), probably due to free, unencapsulated drug; followed by a slow extended release. The extended release was attributed to the release of pilocarpine HCl from the niosomes. At 24 h, the pilocarpine HCl released from inserts ranged from 68.32 ± 5.11% (T4) to 82.11 ± 6.01% (T2). Formulation (T1 and T4) containing higher percentage of (HPMC and PVA) demonstrated slower extended-release

profile. However, using one-way ANOVA and Tukey post-test, there was no significant difference among the four formulations ($p>0.05$).

Fig. 9 [Images not available. See PDF.]

Release study of pilocarpine HCl loaded niosomal ocular inserts (mean ± SD, n = 3)

Discussion

It has been reported that the prevalence of glaucoma, a leading cause of vision loss, is between 3 and 5% in people aged 40 years and older worldwide. Due to the rapid increase in the global population, this number is expected to rise to 112 million people by 2040 [32, 33]. This is an alarming number of anticipated patients, which demands an immediate improvement in the current therapeutic approaches. Currently, the only evidence-based treatment for glaucoma is to lower the intraocular pressure through surgery or medications [34]. However, the effectiveness and long-term efficacy of the currently available eye drops for glaucoma treatment are being questioned due to poor patient compliance. Many researchers have tried to improve the effectiveness of eye drops by increasing the pre-corneal residence time of the drugs. This can be achieved through the use of eye inserts or contact lenses. Compared to eye drops, these alternative forms of medication have demonstrated a substantial improvement in drug bioavailability [35–37].

The purpose of this study was to develop and optimise an ocular insert that slowly releases pilocarpine HCl to reduce the side effects of conventional eye drops due to dose dumping and the need for frequent drug administration. Initially, we attempted to identify the best formula to make blank ocular inserts/ films. Blending polymers, enabled the incorporation of higher polymer concentrations that allowed for longer disintegration time while retaining the flexible, smooth, and transparent appearance of the inserts. In general, an ideal ophthalmic drug delivery system should be able to administer drugs accurately without causing blurred vision or irritation. It should also have suitable mucoadhesive properties to improve drug retention in the pre-corneal area, thereby increasing drug bioavailability. Additionally, the system should reduce the need for frequent dosing to improve patient compliance [8, 38].

However, individual polymer-containing films were not capable to produce the desired disintegration time and film quality. HPMC produced moderate strength films with very good elasticity and transparency, while PVA produced less flexible films but with higher strength and resilience. The selection of HPMC was based on its non-ionic, good mucoadhesive, and lubricant properties, that would allow the insert to adhere to the surface of mucosa. HPMC was used for simulated tears formulations for the management of dry eye [39]. PVA is a commonly used biocompatible, hydrophilic, good reinforcing biodegradable polymer for ophthalmic preparations [40, 41]. To the best of our knowledge, this is the first report of a blend of these two polymers for formulation of ophthalmic inserts.

The aim was to create films with optimal properties, particularly for use in the eye. The eye is a very sensitive organ; therefore, the films needed to be very smooth, flexible, and transparency to avoid discomfort to patients. Previously marketed inserts were discontinued due to patient inconvenience and bad patient experience with the films [18]. The targeted disintegration time of the films was 3–5 h which is the time for the biodegradable components of the films began to dissolve. The hypothesis was that drug release of 12 h would still be achievable without the complete film remaining in the eyes for that duration. Therefore, F30 and F33 were selected as optimal formulations owing to their excellent properties in terms smoothness, transparency, flexibility, wetting / spreadability and ease to peel off; as well as produced films that had a disintegration time within the targeted window and were used for further analysis. Similar trends were observed in ocular films developed for the sustained release of timolol [42]. The slow disintegration of the film promotes the extended-release profile of the drug and extend the drug retention time in the pre-corneal region.

During the next step, the focus was on optimising the niosomes that would contain pilocarpine HCl. This was done to ensure that there were two barriers in place to prevent dose dumping: the biodegradable polymeric film matrix and the extended release niosomal formulation. Niosomes are commonly used vesicular nanocarriers for ophthalmic drug delivery [37, 43]. The use of niosomes minimises dose dumping, had high encapsulation efficiency when

compared to liposomes and are more stable [7, 43]. Furthermore, niosomes possessed favourable photoprotection effect along with rheological characteristics pertinent to spreadability and viscosity [44]. It was crucial to maintain a small particle size for the produced niosomes. Our research showed that the average particle size for the niosomes was within the nanoscale range, which is optimal. Similar results were obtained by Alyami et al. [7]. It is important to keep the particle size of ophthalmic preparations below 10 μm to avoid ocular irritation [10]. The produced particles demonstrated an acceptable distribution and a large negative zeta size, which promotes particle stability.

The next step focused on developing the double barrier formulation comprised of the optimal ocular insert laden with the pilocarpine containing niosomes. The produced films and niosomes were subjected to molecular profiling using FTIR and XRD to understand their physical and chemical properties as well the components' compatibility profile. The analysis of the IR spectra suggests that there are no interactions or incompatibilities between the compositions of the niosomes, including the API, pilocarpine HCl. Furthermore, the XRD analysis did not reveal any shifts or changes to the main constituents of components. Furthermore, the thermal analysis using DSC suggested that pilocarpine HCL might be encapsulated within the niosomes. Similar results were reported where the disappearance of the active ingredient melting point peak could be attributed to encapsulation [7, 45].

The tears which comprises of electrolytes (Na^+, K^+, Cl^-), proteins such as lactoferrin, lysozyme, lipids, and mucins, serve as an excretory and delivery route of metabolic substances and nutrients [46]. The pH of the tears generally ranges from 6.5 to 7.6, with an average value of 7 [47]. Therefore, ophthalmic drug formulations should have a pH between 6.6 and 7.6 to prevent irritation. When developing ocular dosage forms, it is essential to consider the physiochemical and biopharmaceutical features of the API to be administered via the ophthalmic route, such as solubility, permeability, and stability. This should ensure sufficient dissolution of the API as well as diffusion through different ocular barriers.

Two important factors need to be addressed for eye inserts: moisture content and surface pH. The study results revealed that the moisture content of the optimal inserts ranged between 30 and 40%, which is favourable for the user's comfort and could be attributed to the hygroscopic nature of the HPMC [48]. Furthermore, the surface pH level is unlikely to cause irritation or discomfort upon application since the pH of the tears is within the range of 6.5–7.6 [47]. Therefore, all the produced formulations were not expected to have major adverse effects on the eye. The produced formulations (T1-T4) were within the recommended rage of surface pH and hence it is expected not to cause any ocular surface irritation and potentially produce good diffusion [49]. The results of this work is in agreement with other research findings for ocular formulations [43, 50].

The selected optimal formulations showed a promising release profile. The initial burst release of pilocarpine HCl is not expected cause blurred vision, because it is small amount in comparison with the traditional dose of pilocarpine HCl in eye drops. After 24 h, the pilocarpine HCl released from inserts ranged from 68.32 ± 5.11% (T4) to 82.11 ± 6.01% (T2), indicating that the formulations achieved the aim of the study. It is interesting to note that the niosomal ocular inserts loaded with pilocarpine and with a lower PVA content (1%) were able to release pilocarpine at a quicker rate. By adjusting the PVA concentration to 1.5% and increasing the initial pilocarpine content, the rate of polymer erosion and degradation can be regulated, resulting in controlled release in ocular tissues. Therefore, these ocular inserts could potentially serve as an effective delivery platform not only for pilocarpine but also for other APIs on the ocular surface for an extended period of time. Similar results were reported [51].

According to this study, combining two polymers (HPMC and PVA) with API loaded niosomes can achieve two crucial features of ocular inserts: extended retention and sustained release of the API. This is accompanied by favourable physical and chemical properties of the insert, such as surface pH, moisture content, and compatible formulation.

Conclusions

The current study successfully produced biodegradable ocular inserts using HPMC and PVA co-polymer blend, as a drug delivery device for pilocarpine HCl loaded niosomes, to provide sustained release of pilocarpine over 24 h. The purpose was to reduce the dosing frequency, enhance patient compliance and minimize side effects associated with conventional eye drops. The optimised niosomes-loaded ocular inserts were evaluated for their mechanical and

molecular performance. The findings suggested that these inserts are effective in releasing pilocarpine over an extended period while retaining a favourable pH of around 7 – entailing no possible irritation to the eye. The biodegradable ocular inserts were also found to be compatible with formulations' excipient as evident from FTIR and thermal analysis. In conclusion, these niosomes loaded HPMC-PVA ocular inserts provide a potential to be used as a platform for delivery of other pharmaceutical active ingredients for ocular delivery.

Qualitative assessment of the flowering buds of Mesua ferrea Linn with special emphasize on HPTLC and universal DNA bar-coding technique and evaluation of its antimicrobial potential

Sutradhar, Jugal1 ; Sarkar, Bapi Ray1 1 University of North Bengal (NBU), Department of Pharmaceutical Technology, Darjeeling, India (GRID:grid.412222.5) (ISNI:0000 0001 1188 5260)

ABSTRACT (ENGLISH)

Background

The study has been scientifically exploring the powder sample and extracts of flowering buds of *Mesua ferrea* Linn (FBMF) based on pharmacognostic and phytochemical parameters. The medicinal plant *Mesua ferrea* Linn was identified by Botanical verification and the universal DNA bar-coding technique. The FBMF powder's quality was performed by the micromeritics properties like bulk density, tapped density, angle of repose, Hausner ratio, Carr's index, and optical microscopy method, and physicochemical evaluations were performed by the swelling index, foaming index, loss on drying, extractive values, and ash values. The extract's preliminary phytochemical screening was accomplished by the alkaloids, flavonoids, tannins, steroids, carbohydrates, and glycoside tests. To ensure the presence of a bioactive compound of each FBMF extract by qualitative HPTLC study against the reference β-sitosterol Rf value of 0.83 was revealed at 254 nm with a developed solvent system toluene, ethyl acetate, and acetic acid (6:2:0.1) v/v. Many pharmacological benefits, including those related to wound healing, nonalcoholic fatty liver disease, analgesic, sedative effects, immunomodulatory, anticancer, antimicrobial, anti-inflammatory, anxiolytic, and atopic dermatitis, have been demonstrated by this phytosterol. An antimicrobial study was carried out by a well diffusion method and, lastly, measured minimum inhibitory concentration and compared to the marketed active pharmaceutical component. Numerous skin infections of more invasive, serious illnesses are caused by potential antimicrobial activity.

Results

The universal DNA bar-coding of plant *Mesua ferrea* Linn has shown a high percentage of identity. The micrometrics properties and physicochemical evaluation of the powder sample of FBMF were in an acceptable range. The preliminary phytochemical screening shows that all extracts contain steroids and carbohydrates. Moreover,

flavonoids were found in ethyl acetate and ethanol, and a qualitative HPTLC study confirmed that every extract contains β-sitosterol. N-hexane extract of FBMF shows the potential antimicrobial activity with *Staphylococcus aureus,* and the MIC value was observed at 0.062 mg/ml.

Conclusion

Our research demonstrated that the plant *Mesua ferrea* Linn has been successfully authenticated by a DNA bar-coding technique, and all extracts of FBMF contain β-sitosterol. The n-hexane solvent extracts have shown the potential highest antimicrobial effects compared to other extracts. These results support using n-hexane extracts as a traditional medicine for treating several diseases.

FULL TEXT

Background

Herbal medicinal plants have been used since the prehistoric period for different human diseases and to save people's lives. They have played an essential role in world health [1, 2]. The herbal plant's phytoconstituent's antimicrobial activity is a necessary basis for new pharmacological agents because of antibiotic resistance [3], and it is also a universal problem to be solved through the development of new drugs and discovering new components from different parts of herbal plants in the other solvent extracts[4].

Mesua ferrea Linn, commonly known as Nagakesara in India, is a medium as well as a large-sized tree that can reach about 20–30 m tall, with extremely hard wood, and is used as a stimulant, diaphoretic, and brain tonic. This medicinal plant is also a part of Ayurvedic immunity-boosting remedies like Chyawanprash and Brahma Rasayan. The plant is distributed in several parts of the world, such as Vietnam, Thailand, Sri Lanka, Myanmar, Nepal, Malaysia, China, Cambodia, Bangladesh, and in India like Uttar Pradesh, Tamil Nadu, Sikkim, Odisha, Maharashtra, Kerala, Karnataka, Bihar, Andaman &Nicobar Islands, Assam, and West Bengal. This plant's flowers are complete and bisexual with functional female (gynoecium) and male (androecium) as well as ovary and carpels, stamens, and sometimes polygamous (male and bisexual). The buds are globular 2 mm diagonally, and scales are in axillary buds. This herbal plant's flowering and fruiting times are January to March and April to October [5, 6].

A genetic marker is a nucleotide sequence or gene sequence scheduled on a chromosome that is prospective to different species and differentiates cells. Using spurious and adulteration materials as substitutes significantly impairs user safety and efficacy. The DNA sequences are particular and identified with the help of a known molecular marker to detect the exacting sequence of DNA from an unknown group. This is a suitable approach to identifying herbal plant varieties or populations and some species accurately, rapidly, and effectively [7–9].

The HPTLC, a very sophisticated instrumental technique, is found to be simple, accurate, and rapid for confirmation of medicinal plant material. It has advantageous features, easily separates the multiplex samples, and is an excellent qualitative and quantitative analysis technique. The comprehensive qualitative advance for evaluation of quality, consistency, species authentication, and stability of herbal drugs, and easily differentiated with digital scanning profile [10, 11]. This high-speed and inexpensive technique requires a minute sample to analyze the reproducible results [12]. The HPTLC technique is essential in plant analysis, as a quick judgment of column fractions, detection of plant material, screening for the content of markers, and development of solvent mixture, which is used for column chromatography. The ability to exhibit chromatograms of many samples as an image may be visually assessed or further processed by specific software. This technique is undoubtedly the most striking benefit of HPTLC and one of its fastest-developing application areas. The images of the same plate can be captured before, during, or after derivatization with various illumination modes [13, 14].

The current study is to perform preliminary studies of powder samples and the low polar to high polar solvent extracts of *Mesua ferrea* Linn flowering buds. These studies involve micrometric properties and physicochemical evaluations of the powder sample with six solvent extracts, preliminary phytochemical screening, and a qualitative HPTLC study for confirmation of phytoconstituents with the standards of β-sitosterol, and finally, perform an in vitro antimicrobial study of n-hexane extract with well diffusion method. This medicinal plant can prevent the diseases caused by gram-positive bacteria and substitute several diseases that β-sitosterol prevented and is used as a

traditional medicine and prepares a novel drug delivery system.

Methods

Collection and identification

Flowering buds of *Mesua ferrea* Linn. (FBMF) were collected in March 2021 from West Bengal and authenticated of the plant through Griffin's Herbarium (voucher specimen no. Calophylla.2021/1). The FBMF was picked and removed all dust and sand very carefully. Cleaned flowering buds were cut into tiny pieces and shade-dried. After eight weeks, bud pieces were utterly dried and pulverized into powder form by the grinder (Nano Mixture Grinder MX 116) and, finally, sized reduction through a 60-number mass sieve.

Genotypic identification

The quality of the DNA isolate was examined by using agarose gel electrophoresis. One microliter of 6X gel-loading buffer [30% sucrose in TE buffer (pH-8.0), bromophenol blue (0.25%)] was added to five microliters of DNA. The prepared samples were loaded with 0.8% agarose gel ready to 0.5X Tris–Borate-EDTA buffers containing 0.5 μg/ml of ethidium bromide. Electrophoresis was performed by 0.5X TBE (Tris/Borate/EDTA) as an electrophoresis buffer (75 V) until the bromophenol dye front migrated toward the base of the gel. The gels were observed in a UV transilluminator (Genei), and finally, the image was captured under UV light with a Gel documentation system (Bio-Rad) [8, 15]. This DNA bar-coding method (Universal primers of RBCL) was performed at the Rajiv Gandhi Centre for Biotechnology.

Micromeritic properties

The bulk density of FBMF powder was measured by an accurately weighed (20 g) field to a graduated cylinder, and the bulk volume was noted. The bulk density was calculated by the powder mass divided by the powder volume and tapping a graduated cylinder until the stable volume was observed, and then, the tapped volume was noted. This density was calculated by the powder's mass divided by the tapped powder volume. The following formula calculated the Hausner ratio and Carr's index/Hausner ratio = tapped density/bulk density and percentage of Carr's index = (tapped density − bulk density)/tapped density × 100. The angle of repose was performed to evaluate the flow property of FBMF powders with the help of a vertically fitted funnel. The powder sample was passed through the funnel onto a horizontal surface on graph paper, and powder pile height (h) and base radius (r) were determined. Finally, the angle of repose (θ) was calculated with the help of the $(\theta) = \tan^{-1}(h/r)$ equation [16].

The optical microscopic method was used to estimate the particle size (0.2 μm to 100 μm) with the help of an ordinary microscope after calibration of the eyepiece micrometer. The crude powder sample (FBMF) was placed on a glass slide and observed through a microscope. The particle diameter (length and breadth) was calculated and recorded in the list of 300 particles. The average particle size was calculated, and recorded data were represented in a size distribution curve [17, 18].

Extraction of FBMF

The FBMF was extracted through slightly modified methods of Oliveira et al. [19]. Briefly, the FBMF powder was extracted through cold maceration methods at room temperature, according to the low polar solvent to high polar solvents such as n-hexane, petroleum ether, ethyl acetate, acetone, ethanol, and finally with water. The FBMF powders (150 g) were soaked in 400 ml of n-hexane solvent continuously for seven days in a conical flask, and filtration was done with the help of Whatman No.1 filter paper. Then, the marc was dried for 24 h, and again used the marc for the successive solvent. Every filtrate sample was collected in a previously weighted Petri dish, evaporated at 40 °C temperatures through a water bath, kept in desiccators, and transferred into a well-closed container for additional use.

Physicochemical evaluation

The physicochemical parameters of FBMF were determined by the quality control methods, according to the updated edition of World Health Organization 2011 and Farooq et al. methods, such as loss on drying, extractive yield, swelling index, ash values (total ash and acid insoluble ash), and foaming index [20, 21].

Preliminary phytochemical screening

Various classes of phytochemicals on FBMF extracts were detected through the preliminary phytochemical

screening. The alkaloid on FBMF was detected by Dragendorff's, Hager's, and Wagner's test, and flavonoids were evaluated by Shinoda's alkaline reagent and concentrated H_2SO_4 test. The detection of tannin was performed with the Braymer's, Gelatin, and NaOH test, and the presence of steroids was detected by the FeCl test. The carbohydrates were detected by Molisch's, Seliwanoff's, and Resorcinol tests, and finally, glycoside through Legal's, NaOH, and Baljet tests [22, 23].

Development of chromatographic profile

Kabra et al. standard HPTLC method was followed to develop a chromatographic profile of various extracts of FBMF [24]. The CAMAG® Linomat 5 (Camag, Muttenz, Switzerland) instrument was used for the chromatographic qualitative method. Each solvent extract of FBMF was developed with the help of a mobile phase that contains toluene, ethyl acetate, and acetic acid (6:2:0.1) v/v to confirm the contingency of various fractions of phytoconstituents. Aluminum plates of TLC Silica gel 60 F_{254} (Sigma-Aldrich, Invoice No ASM/140/21-22) were used as a stationary phase for chromatographic separation. Standard plant steroids β-sitosterol (Sigma-Aldrich, Invoice No TI/2021-22/1028) and every extract (10 µl) were spotted as bands of length 8.0 mm and width 0.0 mm. The prepared solvent systems were transferred to a developed chamber (CAMAG twin trough plate) for 20 min to develop the plate. Then, the resulting plate was dried at room temperature for five minutes and scanned. The developed spots were scanned with the help of TLC Scanner 4(S/N: 270,741) at wavelength 254 nm. Finally, the Rf (retention factor) value for every spot was measured and recorded with the help of Vision CAT software.

In vitro antimicrobial study

The antimicrobial activities of every FBMF extract were examined using a well diffusion assay against *Staphylococcus aureus* (gram-positive bacteria) and *Pseudomonas aeruginosa* (gram-negative bacteria). Briefly, 0.8% of agar was mixed with approximately 24 h of the *Pseudomonas aeruginosa* 1688 and *Staphylococcus aureus* MTCCS96 indicator standard strains and overlaid on a Petri plate containing a bottom with 1.5% of nutrient agar and allowed to solidify. The solvent was prepared by the 9:1 water ratio along with dimethyl sulfoxide and mixed with every extract. Five millimeters in diameter wells were perforated, and 100 µl of the prepared sample extract of FBMF was placed into each well. The agar plates were prepared at room temperature and incubated at 37 °C for 18–24 h. The antimicrobial activities of the samples were determined by measuring the diameters of the inhibition zones. Inhibition was recorded as negative if no zone was observed around the agar well, and the prepared solvent was kept as a control against each extract of FBMF. For MIC, different concentrations of the sample were prepared using prepared solvent, and the minimum concentration zone of inhibition was recorded through plate assay followed by broth microdilution method through the guidelines of the CLSI (Clinical and Laboratory Standards Institute). Every extract sample was dissolved in the prepared solvent and diluted in nutrient broth in a range of (0.015–1) mg/ml [25, 26]. We performed the antimicrobial activity against standard streptomycin (active pharmaceutical ingredients) for better results.

Results

Identification of plant

The polymerase chain reaction (PCR) amplification was accomplished with universal primers RBCL-AF forward primer sequence (5'-TGTCACCACAAACAGAGACTAAAGC-3') A and RBCL-724R reverse primer (5'-TCGCATGTACCTGCAGTAGC-3') within a PCR thermal cycler (GeneAmp PCR System 9700, Applied Biosystems). This medicinal plant was given a high percentage of identity.

Micromeritic properties

The micromeritic properties such as bulk density, tapped density, Carr's index and Hausner ratio, angle of repose, and optical microscopic of the FBMF powder are represented in Table 1. The frequency distribution curves (histogram) of the optical microscopic method and the powder sample microscopic views are expressed in Fig. 1.

Table 1. Micromeritic properties and physicochemical evaluation of FBMF powder sample

Micromeritic properties

Parameter	Results
Bulk density (g/cc)	0.39 ± 0.0009
Tapped density (g/cc)	0.54 ± 0.001
Carr's index	18.12 ± 0.273 [good]
Hausner ratio	1.22 ± 0.004
Angle of repose	36.90^{0} ± 0.673
Particle size distribution	
Arithmetic mean (Σnd/Σn) [μm]	34.17
Volume surface mean (Σnd3/Σnd2)[μm]	48.66
Physicochemical evaluation	
Swelling factor (ml)	8.10 ± 0.058
Foaming index (cm)	250 Foaming index is over 1000 [1.4 cm]
Moisture content (%)	1.40 ± 0.058
Total ash value (%)	3.67 ± 0.333
Acid insoluble ash (%)	0.00 ± 0.000
Extractive yield (%)	N-hexane (2.1), petroleum ether (1.9), ethyl acetate (2.3), acetone (3.4), ethanol (3.3), and water (3.9)

Results are manifested as mean ± SEM (standard error of mean) [without particle size distribution and extractive yield]

a Optical microscopic view of FBMF powder. **b** Size frequency distribution curve of FBMF powder

Physicochemical evaluation

The obtained results of swelling factor, foaming index, total ash value, acid insoluble ash, moisture content of powder sample, and extractive yield of different solvent extracts of FBMF are represented in Table 1.

Preliminary phytochemical screening

Phytochemical screening of the extract's active constituents was detected by a minimum of three tests (without steroids), such as alkaloids, flavonoids, tannins, carbohydrates, and glycosides which are reported in Table 2.

Table 2. Preliminary phytochemical screening of FBMF extracts

	Qualitative test	n-Hexane	Petroleum Ether	Ethyl Acetate	Acetone	Ethanol	Water
1	*Detection of alkaloid*						
	a) Dragendorff's test	(−)	(−)	(−)	(−)	(−)	(−)
	b) Hager's test	(−)	(−)	(−)	(−)	(−)	(−)

(−) sign indicates absent of phytochemicals, and (+) sign indicates present of phytochemicals

Development of chromatographic profile

The qualitative HPTLC analysis of every extract of FBMF was carried out against standard phytosterol β-sitosterol using a solvent system of toluene/ethyl acetate/acetic acid (6:2:0.1) for assurance of bioactive compounds. The β-sitosterol Rf value of 0.83 was revealed at 254 nm, and these were compared to six extracts of FBMFs. The maximum Rf values of each reading were recorded and are shown in Fig. 2.

Fig. 2 [Images not available. See PDF.]

HPTLC chromatograms of FBMF extracts of different solvents with standard β-sitosterol, at 254 nm spot at Rf 0.83 and Rf value of petroleum ether (0.82), n-hexane (0.81), ethyl acetate (0.81), acetone (0.80), ethanol (0.81), and water (0.81)

In vitro antimicrobial study

The gram-positive strain, *Staphylococcus aureus,* showed antimicrobial activity through FBMF extracts (except water extract), and gram-negative stains, *Pseudomonas aeruginosa,* did not show any activity. The highest MIC value was observed in n-hexane extracts, and the lowest or no activity was produced in the water extracts against S. *aureus*. Antibacterial assay of n-hexane extract sample with various concentrations was measured against *S. aureus* S96, and the highest zone of inhibition was observed at 0.062 mg/ml, as shown in Table 3 and Fig. 3. The antimicrobial activity against standard streptomycin (0.062 mg/ml) against S. aureus shows 14 mm, and the sample (n-hexane extract) shows 13 mm. The MIC values were determined as the lowest concentrations and inhibited bacterial growth by 80% compared to the agent-free growth control.

Table 3. Antibacterial assay of n-hexane extract samples against *S. aureus* S96 with different concentrations

Sl. No	Concentration (mg/ml)	Zone diameter (mm)

Discussion

The World Health Organization suggests accurately identifying plant species for the safety, efficacy, and quality of herbal medicine. Conventional identification methods need an adequate perspective to differentiate the closely related species of the same genus of medicinal plant species. DNA international bar-coding genetic tools have been

developed to identify herbal medicine [27]. This *Mesua ferrea* Linn medicinal plant was authenticated by two methods such as conventional (botanical verification) as well as a universal barcode (DNA bar-coding technique). The powder sample bulk density depends upon the particle shape, the tendency of the particles, and particle size distribution. The tapped density influences the compaction profile and packing arrangement of materials and describes the particle's void space [17]. The bulk density and tapped density of the FBMF powder sample were 0.39 g/cc and 0.54 g/cc. The angle of repose, Carr's index, and Hausner ratio values represent the flow of the powder sample. The angle of repose is also associated with the bulk density, tapped density, and Hausner ratio of the powder sample. The flow properties of the normal powder sample values are a fair range of 16–20 (Carr's index), a passable range of 1.26–1.34 (Hausner ratio), and free-flowing range of 30°–38° (angle of repose) [28, 29]. The FBMF powder sample's Hausner ratio, Carr's index, and angle of repose were found to be in a passable range of 1.22, fair range of 18.12, and free-flowing range of 36.90°, respectively. Moreover, all the studies were obtained by three observations with the help of standard deviation (SD) and standard error of the mean (SEM) for better results. The particle size distribution and particle size of the powder sample also impacted the flow property of the powder [30]. In this study, the FBMF sample arithmetic means and volume surface means were found to be 34.17 μm and 48.66 μm.

The physicochemical characteristics of crude herbal medications provide the most incredible support for standardization and quality control. The presence of hemicelluloses or pectin and mucilage in crude materials is determined in a swelling index, and the foaming index is performed only in saponin-containing plants that generate swelling in an aqueous medium. The presence of water and volatile matter in the powder samples has been calculated by the loss on drying methods for preservation purposes such as the growth of molds or yeasts. Physiological and nonphysiological ash has been determined after the incineration of crude materials by the total ash value methods, and the earthy material, as well as the number of silica contaminants, is measured by the acid insoluble ash methods [20, 21]. In our studies, visible foreign matters were free from more significant parts of the powder sample of FBMF. This plant's swelling index and foaming index were observed to be 8.10 ml, and the foaming index was over 1000 (1.4 cm). In this plant sample, the percentage of moisture content was found to be 1.40%, indicating within the range's limits. The total ash value of 3.67% and no acid insoluble ash were present in this plant, which is an acceptable range and indicate no earth and silica material are present. The extractive yield of the powder sample of FBMF was observed by the cold maceration methods with six solvents (low polar to high polar). The result revealed that the percentage of extractive yield was highest in water extract (3.9%) compared to the other five solvents.

In previous research, phytochemical screening of this plant was performed with only two extracts (aqueous and ethanol). Phytochemicals such as coumarins, saponins, phenols, and flavonoids were present in aqueous extracts, and coumarins, saponins, flavonoids, phenols, and sterols in ethanol extract [31]. The present study performed the phytochemical constituents in six solvent extracts. Every extract showed the presence of steroids and carbohydrates. Chemical components such as alkaloids, tannins, and glycosides are absent in FBMF extracts. The flavonoids were found to be in ethyl acetate and ethanol. The acetone and water extract also showed flavonoids in the alkaline reagent and Shinoda tests, respectively.

Huge populations of the world are used herbal medicine for their health needs. However, still very challenging for quality assurance and quality control of herbal drugs because of elevated unevenness mixed up phytochemicals [32]. Analytical separation techniques such as HPTLC methods have very potent tools for herbal formulation and very accepted methods for quality control of herbal raw materials and the finished product [33]. In a previous research study, Chow et al. showed that the heartwood part of *Mesua ferrea L* contains β-sitosterol [34]. Teh et al. and Ee et al. both research teams isolated β-sitosterol from this herbal plant's root bark extracts [35, 36], and Keawsa-Ard et al. research studies also isolated phytosteroid from the plant stem parts of hexane extract [37]. Our study found phytosterols β-sitosterol in every extract based on our identification of HPTLC qualitative studies. The β-sitosterol bioactive compounds are present in many herbal plant cell membranes. This phytosterol has shown a variety of biological actions in in vitro as well as in vivo studies, such as anti-diabetic, wound healing, nonalcoholic

fatty liver disease, anticancer, analgesic, antimicrobial, immunomodulatory, anti-inflammatory, anxiolytic, sedative effects [38], and atopic dermatitis [39].

Keawsa-Ard et al.'s research showed stems of *M. ferrea* had moderately antibacterial activity against *E. coli* and *Staphylococcus aureus* [37]. The current investigation demonstrated greater effectiveness against *S. aureus* in n-hexane extracts of FBMF, and when compared with the marketed standard, these show a slightly lesser effect. This gram-positive strain is the most infamous and widespread bacterial pathogen, and it is responsible for a significant number of skin infections and hundreds of thousands to millions of more invasive severe infections. It contributes significantly to the emergence of prosthetic joints, surgical sites, cardiovascular infections, respiratory tract infections, and pneumonia [40, 41], and this bacterium has been observed in ninety percent of atopic dermatitis skin lesions, and the density of this gram-positive bacterium tends to raise the severity [42].

Conclusion

The conclusion indicates that the medicinal plant of *Mesua ferrea* Linn has been successfully authenticated through a DNA bar-coding technique and Botanical verification. The FBMF powder's characteristics produced satisfactory results. The preliminary phytochemical screening reveals that the extracts with plant steroids and carbohydrates are present in low polar to high polar solvents extract. The HPTLC qualitative study confirms that every extract of FBMF contains β-sitosterol. The n-hexane solvent extract showed better antimicrobial activity compared to the other extracts. This primary evidence can trigger a potential substitute in various diseases that were prevented by the β-sitosterol (analgesic, anti-inflammatory, anti-diabetic, sedative effects, wound healing, liver disease, anticancer, antimicrobial, atopic dermatitis, immunomodulatory, and anxiolytic) and the disease produced by the gram-positive bacteria *S. aureus* (large quantity of skin infections) can be prevented by this medicinal plant and is also used as traditional medicine as well as a novel herbal drug delivery system.

Acknowledgements

The author thanks Ganesh Dey, Simran Giri, and Divya Limbu for their assistance and support. The authors acknowledge the Department of Pharmaceutical Technology, the University of North Bengal, for the instrumentation facility.

Author contributions

Jugal Sutradhar contributed to writing—original draft preparation, and methodology and provided software; Bapi Ray Sarkar supervised and analyzed the data, investigation, visualization, reviewing, and editing.

Funding

This study did not receive any funding from an agency or person.

Availability of data and material

Data to support the findings of this study are available from the corresponding author and also the first author upon reasonable request.

Declarations

Ethics approval and consent to participate

No human or animal subjects were involved in the study.

Consent for publication

There is no conflict of interest.

Competing interests

The authors state that they are not competing interests.

ABSTRACT (ENGLISH)

Background

Existing antidepressants possess various adverse effects and so they are not considered as the first line of drug in mild depression. The lack of proper drugs to treat the mild depression on the other hand alleviates severe depressive cases. To overcome this problem, the nucleus of benzimidazole and cinnamic acid having very less toxicity were fused and a small library of 40 compounds was prepared. The library was then screened for ADMET

properties and probable toxicity. Those compounds which had not shown any toxicity as well as possessed better *in-silico* absorption, distribution and metabolism were selected for the first phase of the study. Synthesized compounds were characterized by FTIR, ^{1}H-NMR and ^{13}C-NMR and were screened for in-vitro antidepressant activity by DNPH spectrophotometry.

Result

The compounds MS-3 and MS-8 had shown good antidepressant activity with IC_{50} values of 367.19 μM/mL and 184.56 μM/mL against MAO-A and MAO-B, respectively.

Conclusion

From this study, it can be concluded that the structural requirements for the inhibition of MAO-A and MAO-B were totally different. MAO-A inhibitors required the presence of nitrogen and oxygen containing ring substitutions whereas MAO-B inhibitors required the presence of 4-halogen containing phenyl ring substitutions.

FULL TEXT

Background

Depression is a life-threatening disease which is characteristically different from normal mood swing and short-lived emotional responses to challenges in everyday life. It causes the suffered person to function poorly in any kind of activity, ultimately leading to suicide, which is the fourth leading cause of death mainly in 15–29 years old. According to the Global Health Data Exchange (GHDx) report, 2019 published by Institute of Health Metrics and Evaluation, depression affects 3.8% of the world's population [1]. Approximately 280 million people in the world have depression, 5.02% of which comes under the age group of 20 plus years and 5.71% of which comes under the age group of 60–89 years [2].

Although there are effective treatments for depression, more than 75% of people who lives in poorer countries receive no treatment. The reason may be low resources, a smaller number of trained healthcare providers and the social stigma associated with a mental disorder. Sometimes it is because of misdiagnosis and many times because of wrongly prescribed anti-depressants. The effective treatments for depression include counselling, cognitive treatment and interpersonal psychotherapy, sometimes along with antidepressant medication such as selective serotonin reuptake inhibitors (SSRIs), 5-HT receptor antagonists (5HT-RAs), monoamine oxidase inhibitors (MAOIs) and tricyclic antidepressants (TCAs). These antidepressants are not considered as the first line of treatment for mild depression mainly because of the adverse effects associated with these classes of antidepressants [2].

As the number of suicidal cases is alarmingly increasing day by day which is evident from the daily newspapers, it is the need of the hour to develop potent antidepressants with minimal adverse effects. To do so, we were in search of some chemical scaffold that has been widely explored as different drug molecules, safe to use and poses minimum side effect. The answer we found is benzimidazole, which is one of the most widely explored chemical moiety having diverse biological activities viz. Antiviral [3–7], antimicrobial [8–11], anticancer [12–16] antidiabetic [17–19] etc. along with some reported anti-depressant [20, 21] property also. On the other hand, cinnamic acid which is a widely distributed natural aromatic carboxylic acid have gained the attention of researchers due to its low toxicity, structural diversity and pharmacological actions [22] like anti-inflammatory [23], antioxidant [24], antitumor [25], hypoglycaemic [26], antidepressant [27], and cytoprotective actions of neuroinflammation in neurodegenerative diseases [28]. The antidepressant action of cinnamic acid occurs via important neurotransmitter serotonin, which also has similar mechanism of action with many commercial antidepressants [29].

The designed compounds, 2-styrylbenzimidazole derivatives were synthesized by reacting o-phenylenediamine and cinnamic acid. The two amino groups of o-phenylenediamine were fused with the carboxylic group of cinnamic acid leading to the formation of 2-styrylbenzimidazole.

These 2-styryl benzimidazole derivatives were reported to have anti-bacterial, anti-fungal and anti-tubercular activity [30]. Based on these findings and to facilitate the development of less toxic, easily available, more potent antidepressant drugs present study aims at design and synthesis of some novel 2-styrylbenzimidazole derivatives with further investigating their potential as antidepressants using in-vitro methods. The designed compounds were structurally similar to the standard antidepressant drug rasagiline. Therefore, it is believed that the designed

compounds will exhibit antidepressant activity by inhibiting the monoamine oxidase enzyme.

Methods

In-silico studies

To test the hypothesis presented in this research paper, we have designed a new series of 2-styrylbenzimidazole derivatives. Direct conjugation of these two chemical scaffolds was not possible. Therefore, we have moved one step back and tried conjugating o-phenylenediamine and cinnamic acid which had resulted in the desired nucleus having the benzimidazole ring as well as the styryl part coming from the cinnamic acid (Fig. 1) exhibiting antidepressant effect. It was evident from literatures that the styryl part which is present in all cinnamic acid similar structures like caffeic acid, ferulic acid, coumaric acid might be responsible for possessing the antidepressant activity [29]. The N^1-hydrogen of the nucleus thus generated was substituted with various aromatic or cyclic halides to get the series of different compounds (Table 1).

Molecular property calculation

Different molecular properties like LogP value (Octanol–water partition coefficient), TPSA (Total Polar Surface Area), molecular weight, nRB (Number of Rotatable Bond), HBD (Hydrogen Bond Donor) and HBA (Hydrogen Bond Acceptor) that are considered under Lipinski's rule of five were determined using the free online software 'molinspiration property calculator.'

ADMET prediction

The series of compounds was then used to calculate the ADMET descriptors (absorption, distribution, metabolism, excretion and toxicity) using Discovery studio 3.1 (Accelrys, San Diego, CA, USA). The descriptors selected for this study are absorption, solubility, AlogP98 and PSA_2D values. The model for plotting the confidence ellipse was developed by Egan and Lauri [31] with descriptors that include AlogP98 and 2D polar surface area (PSA_2D). Aqueous solubility was predicted by using a model developed by Cheng and Merz [32] with $R^2 = 0.84$. All the models used for predicting the ADME, toxicity, AlogP98 and PSA_2D have high R^2 values. AlogP98 and PSA_2D were used for plotting the confidence ellipse. Compounds which were found outside the 95% and 99% ellipse region were poorly absorbed compounds (<30% absorbed). The series was then taken for prediction of carcinogenicity and skin irritancy by using the TOPKAT module of Discovery studio 3.1 (Accelrys, San Diego, CA, USA).

Docking study

Docking was performed on the crystal structure of MAO-A and MAO-B which were retrieved from Protein Data Bank (PDB). Monoamine oxidase (MAO) inhibitors were a standard class of antidepressants which prevent the removal of neurotransmitters like dopamine, serotonin from brain and make these neurotransmitters available preventing depression. Rasagiline was a standard MAO inhibitor. Since the compounds were designed based on the structure of rasagiline, the docking study was carried out against MAO-A and MAO-B. The structural features of 2-styrylbenzimidazole derivatives revealed in this study would help in understanding their structural activity relationship with MAO as novel antidepressants. The PDB ID of the selected protein was 2Z5X for MAO-A [33] and 1S3E for MAO-B [34]. Prior to docking, each protein was prepared using protein preparation wizard of Discovery studio 3.1 (Accelrys, San Diego, CA, USA). Polar hydrogen atoms were added to the proteins and charges were assigned. All the bound water molecules, other heteroatoms and co-crystallized ligands attached to the protein were removed. Subsequently, the 3D structure of protein was optimized by minimizing the energy using CHARMm force field. 2Z5X consists of chain A only. Binding site of this protein was defined (40.753, 16.779, 14.746) around the binding pocket of the co-crystallized ligand *7-methoxy-1-methyl-9H-pyrido[3,4-b]indole* which was also known as Harmine. 1S3E consists of two identical chains A and B. Chain A was kept for the study and chain B was deleted. Binding site was defined (52.793, 154.645, 25.957) around the binding pocket of the co-crystallized ligand *5-Hydroxy-N-Propargyl-1(R)-Aminoindan* (RHP). Docking was done using the CDOCKER of Discovery studio 3.1 (Accelrys, San Diego, CA, USA) which was priory validated by calculating RMSD between the docked poses and the X-ray pose of the respective co-crystallized ligands.

Chemistry

AR grade chemicals and solvents were used without further purification for doing the synthetic and analytical work. Melting point apparatus (BUCHI Melting Point M560) at 10 °C/min temperature gradient was used to determine the melting point of the synthesized compounds. The UV-Spectra (λ_{max}) of the synthesized compounds were recorded on Shimadzu, UV- 1800, UV–VIS spectrophotometer instrument. The FT-IR spectra of the synthesized compounds were recorded on Bruker ALPHA FTIR spectrometer. The ^{1}H-NMR spectra of the synthesized compounds were recorded in DMSO at 300 MHz by Bruker Avance DPX 300 NMR spectrometer and ^{13}C-NMR was also recorded in

DMSO at 100 MHz by Bruker Avance DPX 100 NMR spectrometer. The mass spectra of the synthesized compounds were recorded on ZQ-4000 equipped with an Electrospray Ionizer as an ionization method. The eight selected compounds were synthesized by using the scheme 1.

Scheme 1 [Images not available. See PDF.]

Synthetic scheme of the compounds MS 1-MS 8

Synthesis of 2-styryl-1H-benzo[d]imidazole

The compound was synthesized by adding cinnamic acid to a mixture of hydrochloric acid and o-phenylenediamine. It was then refluxed in ethylene glycol for 5 h within a temperature range of 70–90 °C. After this, the reaction mixture was cooled to room temperature and poured into water. Resulting solid was filtered, resuspended in water and pH of the solution was adjusted to≥7 using sodium bi -carbonate. The product was filtered, washed, dried and recrystallized with ethanol.

General procedure for synthesis of final compounds

2-styryl-1H-benzo[d]imidazole was dissolved in quantity sufficient THF, basified using sodium carbonate and cooled to (0–5) °C in ice-bath. The respective aryl/cyclic amine was added slowly maintaining the temperature range of (0–5) °C for additional 15 min. Thereafter the media was warmed upto room temperature and stirred for 24 h followed by solvent evaporation. Cold water was added to the resulting mass, filtered and air-dried to obtain the crude product.

In-vitro anti-depressant activity screening

Isolation and preparation of MAO sample

MAO was isolated using brain tissues of chicken. The dissected pieces of the brain tissues were washed with 0.3 M sucrose solution and frozen at−80 °C for further analysis. The brain tissue (2.5 g) was homogenized in 1:40 (w/v) ratio with 0.3 M ice-cold sucrose solution and centrifuged at 1824 g for 10 min. The supernatant was collected and further centrifuged at 12,768 g for 35 min to obtain crude MAO protein precipitations. This precipitate was resuspended in 250 ml of 0.3 M sucrose solution and mixed with 20 ml of 1.2 M sucrose solution. The precipitate was again centrifuged with 1.2 M sucrose solution at 12,687 g for 40 min followed by a single wash with potassium phosphate buffer (pH 7.60, 100 mM). The pure brain MAO protein precipitate was suspended in 10 ml of potassium phosphate buffer; and stored in aliquots of 1 ml at−80 °C for subsequent analysis [22, 23].

Determination of protein concentration

The protein concentration of MAO precipitate was calculated using Hartree Lowry method [24–26]. Serial dilutions of concentrations 0.03 to 0.15 mg/ml were prepared from the stock solution of 0.3 mg/ml bovine serum albumin (BSA) in potassium phosphate buffer. 1.0 ml of each dilution of standard, protein-containing test and buffer for reference were mixed with 0.90 ml of reagent A (2 g sodium potassium tartrate, 100 g sodium carbonate, 500 ml 1N NaOH, and water to one liter) in separate test tubes. The tubes were incubated for 10 min in water bath at 50 °C, then cooled to room temperature. 0.1 ml of reagent B (2 g sodium potassium tartrate, 1 g copper sulfate, 90 ml H_2O and 10 ml 1N NaOH) was added to each test tube, mixed and incubated for 10 min at room temperature. 3 ml of reagent C (1 vol of Folin–Ciocalteau reagent diluted with 15 vols of water) was added rapidly to each test tube, mixed and again incubated for 10 min in water bath at 50 °C and cooled to room temperature. The final assay volume was 5 ml. Absorbance was measured at 650 nm.

DNPH spectrophotometry

Potassium phosphate buffer (pH 7.60, 25 mM) and 200 µL of MAO protein homogenates were mixed and incubated for 20 min at 37 °C. Then 200 ml of 0.016 M benzylamine in buffer (for detecting MAO-B) and 150 ml of 0.02 M 5-HT (for detecting MAO-A) were added to the above mixture and incubated for 60 min. After this 400 ml of 2 M DNPH in 1 M HCl was added. After incubation for 40 min at room temperature, 2 ml of 1.25 M NaOH containing 5 g/l of Triton X-100 was added and the reaction mixture was kept for an additional 30 min at room temperature. Finally, absorption was measured at 465 nm for MAO-B and 425 nm for MAO-A.

Results

In-silico studies

The designed library was screened through lipinsky rule of five by calculating molecular properties and filtered through ADMET prediction filter. Only those compounds which have passed through both these filters were selected for docking, synthesis and in-vitro anti-depressant activity evaluation.

Molecular property calculation

Out of the forty compounds of the library, 23 had shown one violation of lipinsky rule whereas remaining 17 compounds had not shown any violations and taken for further screening (Table 2).

ADMET prediction

All the compounds of the designed library fall inside 95% and 99% ellipse region (Fig. 2). From the results of TOPKAT toxicity prediction, it was observed that no compounds had shown carcinogenicity but all except eight had shown mild skin irritancy (Table 3). Thus, only eight compounds of the series had passed all the filters and so they were considered for further studies.

Fig. 2 [Images not available. See PDF.]

Docking study

Based on the molecular properties and ADMET studies of all the designed ligands, eight compounds were selected for molecular docking studies. Docking is considered to be successful if the RMSD value between the X-ray pose and the docked pose is less than 2 Å [35]. The RMSD value of Harmine and RHP against 2Z5X and 1S3E is tabulated in Tables 4 and 5. The docking results were analyzed based on the binding energy (Table 6) and the docked poses against MAO-A (2Z5X) (Fig. 3) and MAO-B (1S3E) (Fig. 4). The binding energies of the ligands were within the range of − 114.89 to − 53.32 kcal/mol. The ligands showed very high negative binding energies as compared to the standard Harmine/RHP.

Table 4. RMSD calculation against 2Z5X

Sl No	Ligands	Reference	RMSD Value
1	HMN 1	HMN xray 6	0.6223
2	HMN 2	HMN xray 6	0.6221
3	HMN 3	HMN xray 6	0.6220
4	HMN 4	HMN xray 6	0.6221
5	HMN 5	HMN xray 6	0.6221
6	HMN xray 6	HMN xray 6	0.0000

In-vitro anti-depressant activity of the synthesized compounds

Determination of protein concentration

As described in the materials and methods section, the MAO protein concentration in the test sample was determined by plotting a standard curve (Fig. 5) between absorbance and concentration, which was found to be 189.51 µg/mL.

Fig. 5 [Images not available. See PDF.]

BSA standard curve

DNPH Spectrophotometry

The DNPH spectrophotometric analysis was first carried out without the presence of any drug that had resulted the absorbance reading of the control at 425 nm and at 465 nm (A_0). The steps of this method were repeated for the standard drug rasagiline as well as the test compounds MS 1 to MS 8 at various concentrations. Therefore, for each concentration of the standard drug rasagiline and the test compounds two values of absorbance (A_1) were recorded at 425 nm and at 465 nm (Additional file 1: Table 8). From the absorbances, % inhibition of MAO-A and MAO-B was calculated using the equation % inhibition=$[\{(A_0-A_1)/A_0\}\times 100]$, where, A_0=Absorbance of control and A_1= Absorbance of sample [22]. These % inhibition values (Additional file 1: Table 8) were plotted against the log concentration to obtain the dose response curve of rasagiline as well as the synthesized compounds against MAO-A (Additional file 1: Fig. 7) and against MAO-B (Additional file 1: Fig. 8). Then concentration of the test solutions that

inhibit the hydrolysis of the substrate by 50% (IC_{50}) were determined by nonlinear regression using log dose vs. normalized response-variable slope by GraphPad Prism 9 (Additional file 1: Table 9).

To bridge the gap between computational findings and real-world applications, at the very beginning of docking, the root mean square deviation (RMSD) was calculated between the docked pose and X-ray pose of co-crystallized ligand. This is tabulated in Table 4 and 5. If the RMSD is less than 2 Å, it was considered that docking was successful and the compounds were docked in the exact place where the co-crystallized ligand was bound.

Structure activity relationship studies

From the in-vitro antidepressant assay and from the docking studies, it was observed that the compound MS-3 had the highest negative binding energy against 2Z5X and lowest IC_{50} value against MAO-A. Whereas the compound MS-8 had the highest negative binding energy against 1S3E and lowest IC_{50} value against MAO-B. The IC_{50} values for the other compounds were in accordance with the docking results. For all the compounds under investigation, it can be concluded that, lower is the IC_{50} value higher is the negative binding energy. The IC_{50} values of MS-3 and MS-8 against MAO-A and MAO-B, respectively, were comparable with that of the standard drug rasagiline.

From this study, it can be suggested that incorporation of nitrogen/oxygen substituted five- or six-member ring in the N^1 position of 2-styrylbenzimidazole derivatives which can exhibit different interactions with amino acid residues Ile180, Ile207 and Tyr407 might help in developing promising MAO-A inhibitors. Whereas incorporation of 4-halogen containing phenyl ring in the N^1 position of 2-styrylbenzimidazole derivatives which can exhibit different interactions with amino acid residues Leu171 and Tyr398 might help in developing promising MAO-B inhibitors.

Discussion

The docking study of MS-3 against the MAO-A protein 2Z5X suggested the presence of two pi–pi interaction with amino acids Tyr69 (linked with benzimidazole ring) and Tyr407 (linked with the benzene ring of cinnamic acid). It also suggested the presence of five hydrogen-bonded interaction with amino acids Ile180, Asn184and Ile207 of 2Z5X (Fig. 3). The oxygen and the nitrogen of the uracil ring which was present in the N^1 position of MS-3 were actively involved in formation of these hydrogen-bonded interaction. The next better IC_{50} value as well as binding energy against MAO-A and 2Z5X was observed for the compound MS-5, which also had oxygen and nitrogen atoms in a five membered succinimide ring present as a substitution in the N^1 position of MS-5. Two pairs of pi–pi interaction with the amino acids Tyr407, Tyr444 and four hydrogen-bonded interactions with the amino acids Gln215, Ile180, Asn181, Ile207 were observed in the binding pocket of MS-5 (Fig. 3). All the other synthesized compounds does not possess any nitrogen and oxygen containing ring substitutions which might be the reason of poor IC_{50} value of all other synthesized compounds against MAO-A. Some common amino acid residues like Tyr407, Ile 207 and Ile180 were involved in the binding pocket of most of the compounds under investigation as well as the standard Harmine (Additional file 1: Fig. 5). The compounds MS3, MS5 and MS7 were showing better activity that of the standard drug rasagiline. The decreasing order of antidepressant activity of the synthesized compounds against MAO-A can be represented as:MS3>MS5>MS7>MS8>MS2>MS6>MS4>MS1

The docking study of MS-8 against the MAO-B protein 1S3E suggested the presence of two pi–pi interaction with amino acids Tyr60 and Tyr398 (both were linked with benzimidazole ring). It also suggested the presence of two hydrogen-bonded interaction with amino acids Leu171 and Tyr188 of 1S3E (Fig. 4). The bromine and the hydrogen of the bromobenzene ring which was present in the N^1 position of MS-8 were actively involved in formation of these hydrogen-bonded interaction. The next better IC_{50} value as well as binding energy against MAO-B and 1S3E was observed for the compound MS-7, which also had chlorine and hydrogen atoms in chlorobenzene ring present as a substitution in the N^1 position of MS-7. One pair of pi–pi interaction with amino acid Tyr398 and three hydrogen-bonded interactions with the amino acids Gln206, Leu171 and Tyr398 were observed in the binding pocket of MS-7 (Fig. 4). The compound MS-4 also possesses a fluorine atom in the ortho-position (with respect to the bond of joining of the aniline ring to benzimidazole ring) of the substituted aniline ring which might be the reason of its non-involvement in any kind of interaction with the protein 1S3E. Whereas the fluorine atom in MS-4 might be required for the additional stability of the compound in the binding pocket of 1S3E, depicted by the third better IC_{50} value against MAO-B. The IC_{50} values of all the other synthesized compounds were very high which might be due to the

absence of any halogen atom in the 4th position of the substituted ring. The common amino acid residues involved in the binding pocket of other synthesized compounds and standard drug RHP (Fig. 4) with 1S3E were Leu171 and Tyr398. MS8 had shown comparable activity as that of the standard drug rasagiline. The decreasing order of antidepressant activity of the synthesized compounds against MAO-B can be represented as:MS8>MS7>MS4>MS2 >MS5>MS3>MS6>MS1

Conclusion

The docking study of the synthesized compounds had shown interaction with similar amino acid residues with that of the X-ray pose co-crystallized ligands like RHP and Harmine. This finding might pave the way for the development of 2-styrylbenzimidazole derivatives as potent antidepressants. The compounds MS-3 and MS-8 had shown good antidepressant activity by inhibiting MAO-A and MAO-B, respectively. The optimization of the designed 2-styrylbenzimidazole derivatives with the structural findings of the present work might lead to the development of novel and potent antidepressant drugs.

Acknowledgements

Authors are thankful to Dr. Anshul Shakya, Assistant Professor, Department of Pharmaceutical Sciences, Dibrugarh University for his constant guidance to carry out the in-vitro antidepressant assay. The infrastructural facility and the sophisticated instrumental facility provided by Dibrugarh University, Dibrugarh, Assam to carry out the work is gratefully acknowledged.

Author contributions

MS carried out the synthetic and *in-vitro* work. RC was involved in the *in-silico study*. PP interpreted the FTIR spectral data and the in-vitro results. FA interpreted the NMR spectral data. RSD was involved in manuscript writing and language editing. SS was involved in the study concept, study design and editing of the manuscript.

ABSTRACT (ENGLISH)

Background

The present study focused on developing a superior adsorbent carrier (microparticles) to solidify the self-emulsifying drug delivery system. The two approaches, solvent evaporation and spray drying, were explored to synthesize the microparticles using chitosan (CH) and EDTA disodium. The 3^2 full factorial design was applied to optimize the microparticle process produced by both methods.

Results

The various characterization evaluations of the microparticles revealed amide linkages between the CH and EDTA disodium, and XRD results showed that microparticles were amorphous. The SE-CHEM (C_2) and SD-CHEM (Y_1) optimized microparticles were free-flowing and had percentage yield (%), 96 ± 1.2 and 58 ± 1.1, zeta potential (mV), 9 ± 0.44 and 4 ± 0.13, and particle size (μm), 3 ± 0.57 and 2 ± 0.4, respectively. SEM images showed uneven surfaces with wide void spaces and flaky texture for optimized microparticles Y_1 and C_2, respectively. The SE-CHEM (C_2) had an oil adsorption capacity (OAC %) of 46 ± 0.54 and 60 ± 0.77, and oil desorption capacity (ODC %), 38 ± 0.65 and 56 ± 0.86, for Labrafac and Cremophor RH 40, respectively. The SD-CHEM (Y_1) had an oil adsorption capacity (OAC %) of 59 ± 0.71 and 68 ± 0.39, and oil desorption capacity (ODC %), 54 ± 0.11 and 65 ± 0.74, for Labrafac and Cremophor RH 40, respectively. In the surface free energy components analysis, the SE-CHEM (C_2) had an enhanced dispersive component [γ^{LW} (mJ/m^2)] of 32 ± 0.68 and 37 ± 0.47 for Labrafac and Cremophor RH 40, respectively. The SD-CHEM (Y_1) had an enhanced dispersive component [γ^{LW} (mJ/m^2)] of 48 ± 0.7 and 52 ± 0.41 for Labrafac and Cremophor RH 40, respectively. The SE-CHEM (C_2) had enhanced dynamic advancing contact angles [θ_a (°)] of 75 ± 0.19 and 78 ± 0.75 for Labrafac and Cremophor RH 40, respectively. The SD-CHEM (Y_1) had enhanced dynamic advancing contact angles [θ_a (°)] of 74 ± 0.6 and 80 ± 0.21 for Labrafac and Cremophor RH 40, respectively.

Conclusion

All the findings indicate that the microparticles have superior characteristics to serve as the adsorbent base for solid self-emulsifying drug delivery systems.

FULL TEXT

Background

Solid self-emulsifying drug delivery systems (S-SEDDS) are well-proven and known formulation systems. They offer many advantages like increased surface area (which offers high solubility and bioavailability), robustness, high stability, high scalability, ease in handling, high drug loading, better flowability, decreased drug precipitation and economical production [1]. S-SEDDS can be turned into Self-emulsifying pellets and tablets, which are far more stable than SEDDS and S-SEDDS powder [2, 3]. Despite the excellent advantages of S-SEDDS, problems like liquid squeezing out, low disintegration, inadequate hardness and compaction issues are observed. Because of physicochemical interactions between the solid carrier, oil base and surface-active agents, limited release of the formulation can be a problem [4]. Therefore, a suitable adsorbent carrier becomes the most vital part of the stability of the S-SEDDS [5]. Different carriers like PVP K-30, maltodextrin, magnesium stearate, β-cyclodextrin, polyvinyl alcohol, neusilin US2, sodium CMC, dextrin, lactose, mannitol, HP-β-CD, aerosil-200, syloid 244FP, avicel PH102, syloid XDP 3150 and microcrystalline cellulose are used [6].

An ideal solid adsorbent carrier must have high oil adsorption and desorption capacity, wide interparticle void space and low porosity [7]. Usually, hydrophobic carriers have high OAC (oil adsorption capacity) and high flowability [8]. A solid carrier with high OAC is required less in amount, resulting in a lower dosage form [7, 8]. Formulations high in surfactant concentration adsorb well on hydrophobic adsorbents [9]. A high concentration of surfactants forms very small-sized droplets. Hence, an attempt was made to prepare such solid adsorbent carriers (microparticles) of chitosan with EDTA disodium by solvent evaporation and spray drying. Chitosan produces a clear solution with EDTA disodium in acetic acid [10]. This solution was subjected to solvent evaporation and spray drying to produce microparticles, which should be hydrophobic to ensure that the surface of these particles can be used for drug adsorption in the lipid phase [11]. The amide linkages in microparticles form a hydrophobic interpenetrating rough surface [12]. So, the present study aims to optimize microparticles by 3^2 full factorial experimental designs for solvent evaporation and spray drying methods. The chitosan–EDTA microparticles (CHEM) were characterized for their suitable hydrophobic surface to act as a good adsorbent base for S-SEDDS.

Materials and methods

Chitosan 90% DA (deacylated) was purchased from Marine hydrocolloids (Kerala, India). Ethylenediaminetetraacetic acid disodium (EDTA disodium) was purchased from CDH (India). Other chemicals purchased were Acetic acid (Rankem RFCL, India) and diiodomethane (TCI, Japan). Cremophor RH 40 (Himedia, India). Labrafac™ PG was a gift from Gattefossé (Canada). Other chemicals used were of analytical grade. They were used as received.

Design of experiment

To optimize the preparation of blank microparticles (CHEM), 3^2 full factorial design was used. The concentration ratio of chitosan–EDTA disodium and drying temperatures were observed as the critical factors and were two independent variables. Both had three different levels. Factors like zeta potential, percentage yield and particle size were considered dependent variables. All the responses were fitted in the least fit squares regression analysis using JMP 16 (Trial). Various outcomes of the mathematical model, like the actual vs predicted plot, ANOVA analysis, parameter estimates, model equation, prediction profiler, response surface, contour profilers, Pareto charts and optimization desirability, were determined to validate the model [13]. The desirability function was used for the selected responses for the optimization process. So, Y (practical yield, %) had to be maximized, ZP (zeta potential, mV) had to be maximized, and PS (Particle size, μm) had to be minimized.

The overall percentage of chitosan–EDTA disodium in solution was kept at 2% w/v because its viscosity remains adequate for flow at this concentration. Further, as mentioned in Table 1, three different ratios of chitosan–EDTA disodium (40:60, 50:50 and 60:40) were prepared.

Table 1. 3^2 Full factorial design for SE-CHEM

Codes	CH (ratio)	Level codes	DT (°C)	Level codes	Y (%)	ZP (mV)	PS (μm)
A_1	40:60	1	50	1	79±1.3	0.39±0.13	27±2.1

*CH-CH:EDTA ratio, DT-drying temp., Y-percentage yield, ZP-zeta potential, PS-particle size

Firstly, a weighed amount of chitosan was taken in a beaker and dissolved in 1 M (5.72%) glacial acetic acid at 800 rpm in a magnetic stirrer for two hours. A separate solution of EDTA disodium with double distilled water was prepared. EDTA disodium solution was added dropwise to chitosan solution under continuous vigorous stirring over 2000 rpm with a mechanical stirrer for 25–30 min to get a clear ionic solution [14]. Further, these different solutions were subjected to solvent evaporation and spray drying using a 3^2 full factorial design.

Preparation of Chitosan–EDTA microparticles (SE-CHEM) by solvent evaporation method

All three ratios of chitosan–EDTA disodium solutions were subjected to solvent evaporation in a Rota vacuum evaporator (Micro technologies, India) at a drying temperature range from 50 to 90 °C for 45–60 min, as in Table 2. Then, the dry film was scrapped carefully and dried in an oven to remove residual moisture for 40–50 min at 70 °C. The dried film was converted into powder by using a pestle mortar.

Table 2. 3^2 Full factorial design for SD-CHEM (mention full form of this formulation)

Codes	CH (ratio)	Level codes	DT (°C)	Level codes	Y (%)	ZP (mV)	PS (μm)
X_1	40:60	−1	110	1	26±0.8	−3±0.45	5±1.4
X_2	40:60	130	2	30±1.2	−3±0.24	4±0.8	X_3
40:60	150	3	37±0.6	2±0.8	4±0.6	Y_1	50:50

130	2	44±0.9	2±0.5	2±0.9	Y_3	50:50	150

*CH-CH:EDTA ratio, DT-drying temp., Y-percentage yield, ZP-zeta potential, PS-particle size

Preparation of Chitosan–EDTA (SD-CHEM) microparticles by spray drying

The following overall spray drying specifications were used: Inlet temperature 110–150 °C, outlet temperature 50–70 °C, aspirator speed 1000–2000 rpm, atomization pressure 3 kg/cm^2 and feed pump at 15 rpm in Spray dryer (SprayMate JISL, India). The two ratios of solutions (40:60 and 50:50) were easily spray-dried. It was observed that the high chitosan ratio solution (60:40) posed a challenge during spray drying because of high viscosity; it clogged the 1 mm nozzle of the spray dryer frequently. The operation was stopped to clean the nozzle of the spray dryer, and it was not feasible to spray-dry this solution continuously. So, this solution with a 60:40 ratio of chitosan–EDTA disodium was not spray-dried for all three drying temperatures. Table 2 shows that only six trials were conducted for two ratio solutions.

Evaluation and characterization

Percentage yield

The percentage yield was calculated based on the total recoverable and original weight used [15].

Particle size and morphological evaluation

The surface morphology and topography of the particles were observed by the scanning electron microscope (ZEISS Sigma 360, Germany) at 20 kV (EHT) [16]. The samples were fixed on the SEM stub and coated with a thin layer of gold. Various images were taken at different magnifications. ImageJ (NIH) software was used to determine particle size by analyzing SEM images. The average Feret's diameter was reported.

Zeta potential

100 mg of CHEM prepared by both techniques were taken and constantly stirred in 10 ml triple distilled water. The resulting suspension was centrifuged for 10 min at around 5000 rpm to separate the undissolved particles. Further, this mixture was analyzed for zeta potential in Zetasizer Nano ZS (at wavelength 638 nm) with a scattering angle of 90° at 25 °C. The study was performed in triplicate (Malvern Panalytical, UK) [17].

FTIR analysis

After drying the prepared samples (SD-CHEM, SE-CHEM, CH and EDTA) under vacuum, these were mixed and triturated with KBr (1:100 ratio) to form a fine mixture. This fine mixture was pressed to form the pellets in the KBr press. After placing these pellets in a sample cell, FTIR-ATR analysis was performed (FTIR PerkinElmer spectrum two, USA) in the 500–4000 cm^{-1} spectral range at ambient temperature [18].

DSC analysis

The 5–15 mg samples of SD-CHEM (Y1), SE-CHEM (C2), CH and EDTA were sealed hermetically in aluminum pans. After placing these pans on the sample pan holder and empty pans on reference pan holders in a Differential scanning calorimeter (DSC-25 TA, USA), the thermograms for each sample were recorded from a 40–400 °C temperature range with 10 °C per minute heating rate in a nitrogen atmosphere.

XRD analysis

After grinding each sample (SD-CHEM, SE-CHEM, CH and EDTA) in mortar and pestle, the formed powder was placed and pressed in a sample holder to form a compact powder and X-ray diffraction patterns of the samples were measured using the X-ray diffractometer (XRD Aeris, Malvern Panalytical, UK) at a voltage of 45 kV (with increment size of 0.03° and 0.1 as an increment time).

Flow properties

For all the batches of microparticles, the angle of repose was calculated. In it, graph paper was positioned on a flat horizontal surface, and a funnel was clamped above it with a distance between the paper and the funnel top (about 7–8 cm). 2 g of powder samples for each trial of SE-CHEM and SD-CHEM were weighed and poured into the funnel until the top of the cone-shaped only met the funnel's top. The height (h) and diameter of the cone-shaped heap of powder (D) were measured, and the angle of repose was calculated with a standard formula ($\tan \alpha = 2\ h/D$). The flow is said to be excellent when the angle of repose is less than 25 degrees; on the other hand, the flow is said to be poor when the angle of repose is greater than 40 degrees. For bulk density, 2 g powder was weighed and carefully leveled without tapping into a graduated glass cylinder. To the closest graduated device, the apparent volume before tapping was read as untapped volume (USP method). This volume was used in the standard formula (Bulk density = Weight/untapped volume), and values were calculated. The volume of the powder-filled cylinder was measured after 500 tappings. The tapping was kept running until the frequency difference between the two sets of tapping was less than 0.2 percent. The final volume was noted, and the tapped density in g/ml was calculated using the standard formula (Tapped density = Weight/tapped volume). These readings were used to calculate Carr's index (CI) and Hausner's ratio (HR). {CI = [(Tapped density – Bulk density/Tapped density) × 100] and HR = Tapped density/Bulk density}. A Carr's index of more than 25 indicates bad flowability, while if its value is less than 15, it indicates good flowability. Hausner's ratios below 1.25 suggest greater flow properties than those above 1.25 [19].

Oil adsorbing capacity (OAC) and oil desorbing capacity (ODC)

The optimized formulations of SD-CHEM and SE-CHEM, i.e., Y_1 and C_2, respectively, were taken for OAC and ODC study. The ethanolic solutions of Cremophor RH 40 and Labrafac were prepared and mixed with the microparticles (CHEM). These mixtures were gently heated at 40 ± 4 °C to evaporate the ethanol. The pure weight of adsorbent microparticles (W_a) and the dry weight of oil-adsorbed microparticles after the complete removal of ethanol (W_b) were taken to calculate the OAC. Only those dried mixtures which showed no significant change in physical properties from the pure CHEM and were non-sticky, non-greasy and free-flowing and were considered for the OAC calculations with the following formula [5].

1

OAC=Wb-WaWa∗100

The dried oil-adsorbed microparticles (W_b) were suspended in 10 ml water and gently stirred and stabilized for 1 h. This mixture was centrifuged at 3000 rpm for 10 min. The suspended particles were recovered, dried and weighed (W_c). The following formula was used for ODC [5].

2

ODC=Wb-WcWc∗100

Dynamic advancing contact angle analysis and surface free energy components analysis

The advanced method was used based on the capillary rise and thin column wicking methods to find the surface free energy components of powdered solids developed by Chibowski and Perea-Carpio [21] for SD-CHEM (Y_1) and SE-CHEM (C_2) [20, 21]. The dynamic advancing contact angle and surface free energy components were determined before and after oil adsorption for microparticles. The four probe liquids with known surface tension components were used. Out of these, diiodomethane ($\gamma_l^{lw}=50.8$, $\gamma_l^{+}=0$, $\gamma_l^{-}=0$) and n-hexane ($\gamma_l^{lw}=18.4$, $\gamma_l^{+}=0$, $\gamma_l^{-}=0$) were apolar with known liquid apolar surface free energy component. The other two liquids, dimethyl sulphoxide (DMSO $\gamma_l^{lw}=36$, $\gamma_l^{+}=0.5$, $\gamma_l^{-}=32$) and water ($\gamma_l^{lw}=21.8$, $\gamma_l^{+}=25.5$, $\gamma_l^{-}=25.5$), were polar with known liquid surface free energy polar components.

In this method, 0.2 g of the samples were weighed out in the plastic tips (2 ml, Merck) with outlets blocked by nylon swabs to prevent leakage of the solid powder. The tip was tapped ten times by hand from a height of 10 cm on the laboratory table for uniform packing. The tip was then dipped 3–4 mm into the probe liquid container (advancing manner). The tip was weighed for liquid retained by the solid powder (m_a). After that, some drops from the same probe fluid were put onto the bed powder top. The liquid was allowed to filter (receding manner), and the new weight was measured (m_r). The process was repeated three times, and the average of three determinations was used. The powdered samples (Y_1, C_2) underwent a similar procedure before and after oil adsorption for all the probe liquids. The effective pore radius ($R_{ef.}$) was calculated by using the (m_r) of n-hexane probe liquid (surface tension, γ_l= 18.4mN/m) and acceleration due to gravity (g) in the following equation.

3

W=mrg=2πRef.γl

W= weight of the liquid in the column.

The n-hexane determines the effective radius because alkanes completely wet the solid surface. In the following equation, the effective pore radius ($R_{ef.}$), along with (m_a) of water probe liquid, was used for further calculation of the dynamic advancing contact angle (θ_a).

4

1+cosθa=mag2πRef.γl

5

Wa=γl1+cosθawhere g= 9.8 m/s^2, γ_l = 72.8 mN/m.

The advancing contact angle here remains different from the contact angle on a smooth surface of a similar solid. Hence, it cannot be used directly in the Young formula for calculating surface free energy components. The three works of adhesion (W_a) values of the used probe liquid onto the solid surface were calculated by finding out the θ_a of three probe liquids, diiodomethane, DMSO and water (by putting ma values simultaneously in Eq. 4).

Further, by putting these different W_a values simultaneously in Eq. 6 of three probe liquids (with known liquid surface free energy components, i.e., γ_l^{LW}, γ_l^{+}, γ_l^{-}), the different unknown components (γ_s^{LW} apolar Lifshitz–van der Waals, γ_s^{-} electron donor and γ_s^{+} electron acceptor interactions) can be solved.

6

Wa=2γsLWγlLW1/2+γs+γl-1/2+γs-γl+1/2

Results

The process was optimized using a factorial experimental design (3^2), the chitosan–EDTA disodium ratio and processing temperature varied on three levels. The disodium salt was used to increase the solubility of the EDTA, as it remains insoluble in the acidic pH. The dropwise addition of the EDTA disodium into the chitosan–acetic acid mixture ensures no precipitation of the solution, which is otherwise observed.

In Tables 1 and 2, all the results of percentage yield (%), zeta potential (mV) and particle size (μm) are given for both SE-CHEM and SD-CHEM.

Optimization

Optimization of Solvent evaporation method by QbD

As per the mentioned method, SE-CHEM were synthesized and analyzed for the response for Y (percentage yield %), ZP (zeta potential mV) and PS (particle size μm). The independent variables CH (CH/EDTA ratio) and DT (drying temp.) were given three levels (1, 2 and 3), as mentioned in Table 1. All nine experiment runs and analyzed responses were put in the least squares fit regression analysis using JMP 16 (Trial).

In the effect summary in Table 3, LogWorth and p value for CH, DT and CH × DT are mentioned for SE-CHEM, which indicates CH as the essential variable in this model, followed by DT and CH × DT (interaction). Actual vs. predicted plots are given in Fig. 1 for all the responses, showing that both actual and predicted values are quite close. Table 3, for a summary of fit, indicates that the R^2 values are closer to one, signifying a good model fit. In Table 3, ANOVA results are summarized, which shows the models are significant (p values less than 0.05) for all the responses.

Table 3. Least squares fit effect summary

* It indicates that the p value is significant. The model is significant

DF-Degree of freedom, MR-mean of response, MS-mean of squares, PS-particle size, RMSE-root mean square error, SS-sum of squares, Y-percentage yield, ZP-zeta potential

Fig. 1 [Images not available. See PDF.]

Actual vs predicted plot of SE-CHEM for the responses **A** practical yield *Y*, **B** zeta potential ZP and **C** particle size PS. After 3^2 full factorial design was applied and model was run. In all the Actual vs predicted plots both actual and predicted values are quite close to each other. Here, the low RMSE (Root Mean Square Error) values in Y, ZP and PS plots indicated the model is significant and fits the data well. The *R* Squared (R^2) values in Y, ZP and PS plots predicts the percentage of the relationship between independent variables [CH (chitosan–EDTA ratio) and DT

(Drying temp.)] and dependent variables (Y, ZP and PS). These plots depicted 96%, 83% and 94% relationship between the independent variables and Y, ZP and PS, respectively. *P* value less than 0.05 showed all the model is statistically significant for Y, ZP and PS

Table 3 (for parameter estimates) and Fig. 2a for prediction profiler depict CH (CH/EDTA ratio) as the most important independent variable, followed by DT, for any change in responses. The small particle size of the adsorbent base powder is essential for a high surface area to have high oil adsorption and desorption. It shows that CH and DT have a positive (or additive) effect on a percentage yield (Y%). The parameter estimates and prediction profiler in Fig. 2a for ZP show that both CH and DT have a positive effect on it. It is clear from parameter estimates that the CH × DT interaction significantly contributes to the regression model for smaller particle size (PS). CH and DT have a negative effect on PS. The response surface diagrams (Fig. 3) and Pareto charts (Fig. 4) confirm the same results. Pareto charts also show the individual effect of each independent variable and their interaction on both responses. The fitted equations for all the responses are:

Fig. 2 [Images not available. See PDF.]

Prediction profiler of practical yield (Y), zeta potential (ZP) and particle size (PS): **A** SE-CHEM, **B** SD-CHEM. The prediction profiler depicted CH (CH/EDTA ratio) as the most important independent variable, followed by DT (Drying temp.), for any change in responses of Y, ZP and PS (in both SE-CHEM and SD-CHEM). For **A** SE-CHEM, it showed that CH and DT had a positive (or additive) effect on a percentage yield (Y) and zeta potential ZP. CH and DT had a negative effect on PS. For **B** SE-CHEM, prediction profiler showed that CH and DT had a positive (or additive) effect on a percentage yield (Y) and zeta potential ZP. CH and DT had a negative effect on PS. With the use of prediction profiler, the variables value can be predicted as per needed desirability by dragging the function handles left or right in JMP

Fig. 3 [Images not available. See PDF.]

Response surface diagrams of SE-CHEM in relation to CH versus DT **A** practical yield Y, **B** zeta potential ZP and **C** particle size PS. It is clear from figure **A** and **B** that a high percentage of CH (CH/EDTA ratio) from (40:60) to (60:40) leads to an increase in Y, which means when chitosan increases in (CH/EDTA ratio), then Y got increased. Similarly, when DT (Drying temp.) increased, there was an increase in both Y and ZP, which means a high drying temp was responsible for it. In the case of **C**, particle size PS, an increase in CH × DT negatively affects PS (decrease in size)

Fig. 4 [Images not available. See PDF.]

Pareto charts for SE-CHEM **A** practical yield, **B** zeta potential and **C** particle size. ZP show that both CH and DT have a positive effect on it. It is clear from parameter estimates that the CH × DT interaction significantly contributes to the regression model for smaller particle size (PS). CH and DT have a negative effect on PS

For percentage yield (Y):89.188+5.716×:CH-2+1.916×:DT-2+:CH-2×:DT-2×-1.525

For zeta potential (ZP):3.553+3.106×:CH-2+0.1925×:DT-2+:CH-2×:DT-2×0.068

For particle size (PS):11.735+-7.625×:CH-2+-3.183×:DT-2+:CH-2×:DT-2×3.17625

The optimization of the selected responses was targeted with a desirability function. For this purpose, Y and ZP were maximized, and PS was minimized. In Fig. 5a (contour plot), the white area shows the design space where the Y and ZP will be maximum and PS will be minimum.

Fig. 5 [Images not available. See PDF.]

Contour plots of practical yield (Y), zeta potential (ZP) and particle size (PS): **A** SE-CHEM, **B** SD-CHEM. **A** In this contour plot, white area shows the design space where the Y and ZP will be maximum and PS will be minimum. So, the desirability for percentage yield (%) and zeta potential (mV) is always more than 84%, 8 mV and for particle size (μm) <6 μm can be obtained with CH/EDTA ratio (60:40) and drying temperature (70 °C). **B** The white area of contour plot, shows the design space where the Y and ZP will be maximum and PS will be minimum. So, from these

optimization studies, the desirability for percentage yield (%) and zeta potential (mV) are always more than 55%, 4 mV and for particle size (μm) <3 μm can be obtained with CH/EDTA ratio (50:50) and drying temperature (110 °C) So, from these optimization studies, the desirability for percentage yield (%) and zeta potential (mV) is always more than 84%, 8 mV and for particle size (μm) <6 μm can be obtained with CH/EDTA ratio (60:40) and drying temperature (70 °C). So, the C_2 formulation in Table 1 is the optimized formulation with maximum desirability.

Optimization of spray drying method by QbD

The SD-CHEM were synthesized and analyzed for the response for Y (percentage yield %), ZP (zeta potential mV) and PS (particle size, μm). The independent variables CH (CH/EDTA ratio) with two levels (−1 and 1) and DT (drying temp.) were given three levels (1, 2 and 3), as mentioned in Table 2. All six experiment runs and analyzed responses were put in the least squares fit regression analysis using JMP 16 (Trial).

In the effect summary in Table 3, LogWorth and p value for CH, DT and CH × DT are mentioned for SD-CHEM, which indicates CH × DT as the most important in the model, followed by CH and DT. Actual vs. predicted plots are given in Fig. 6 for all the responses, showing that both actual and predicted values are significantly close. Table 3, for a summary of fit, shows that the R^2 value for all the responses is >0.90, signifying a good model fit. In Table 3, ANOVA results are summarized, which shows the *p* value of Y is 0.011, showing it is a significant model. The *p* values of ZP and PS are 0.127 and 0.064, respectively, which is almost significant for PS and not for ZP.

Fig. 6 [Images not available. See PDF.]

Actual versus predicted plot of SD-CHEM for the responses **A** practical yield Y, **B** zeta potential ZP and **C** particle size PS. After 3^2 full factorial design was applied and model was run. In all the Actual versus predicted plots both actual and predicted values are quite close to each other. Here, the low RMSE (Root Mean Square Error) values in Y, ZP and PS plots indicated the model is significant and fits the data well. The RSq (R^2) values in Y, ZP and PS plots predict the percentage of the relationship between independent variables [CH (chitosan–EDTA ratio) and DT (Drying temp.)] and dependent variables (Y, ZP and PS). These plots depicted 99%, 91% and 96% relationship between the independent variables and Y, ZP and PS, respectively. P value less than 0.05 showed the model is statistically significant for Y and ZP and *P* value 0.06 is very close to statistically significant model for PS

Table 3 (for parameter estimates) and Fig. 2b for prediction profiler depict CH × DT as the model's most important contributor for Y and PS responses. CH is the most important contributor to the ZP response. It shows on Y (%), and CH has a positive effect, while DT negatively affects it. Both CH and DT positively affect ZP and have a negative effect on PS. The response surface diagrams (Fig. 7) and Pareto charts (Fig. 8) confirm the same results. The fitted equations for the responses are as follows:

Fig. 7 [Images not available. See PDF.]

Response surface diagrams of SD-CHEM in relation to CH/EDTA and DT versus **A** practical yield Y, **B** zeta potential ZP and **C** particle size PS. From figure **A** and **B** that a high percentage of CH (CH/EDTA ratio) from (40:60) to (60:40) leads to an increase in Y, which means when chitosan increases in (CH/EDTA ratio), then Y got increased. Similarly, when DT (Drying temp.) increased, there was an increase in both Y and ZP, which means a high drying temp was responsible for it. In the case of **C**, particle size PS, an increase in CH × DT negatively affects PS (decrease in size)

Fig. 8 [Images not available. See PDF.]

Pareto charts for SD-CHEM **A** practical yield, **B** zeta potential and **C** particle size. It shows on Y (%), CH has a positive effect, while DT negatively affects it. Both CH and DT positively affect ZP and have a negative effect on PS

For percentage yield (Y):37.075+5.508×:CH+-5.362×:DT-2+:CH×:DT-2×-10.762

For zeta potential (ZP):0.62+2.126×:CH+0.752×:DT-2+:CH×:DT-2×-2.037

For particle size (PS):3.855+-0.862×:CH+-0.234×:DT-2+:CH×:DT-2×0.418

The optimization of the selected responses was targeted with a desirability function. For this purpose, Y and ZP

were maximized, and PS was minimized. In Fig. 5b (contour plot), the white area shows the design space where the Y and ZP will be maximum and PS will be minimum.

So, from these optimization studies, the desirability for percentage yield (%) and zeta potential (mV) are always more than 55%, 4 mV and for particle size (μm) <3 μm can be obtained with CH/EDTA ratio (50:50) and drying temperature (110 °C). So, the Y_1 formulation in Table 2 is optimized with maximum desirability.

FTIR analysis

FTIR spectra of the prepared SE-CHEM and SD-CHEM, along with chitosan and EDTA disodium, are shown in Figs. 9 and 10, respectively. Chitosan FTIR spectra showed strong absorption bands between 2967 and 2937 cm^{-1}, which correlated with C–H stretching, a characteristic of a typical polysaccharide group. The presence of residual N-acetyl groups was observed at an absorption peak of 1657 cm^{-1}, which proves that chitosan was not fully deacylated. The absorption bands 1587 cm^{-1}, 1547 cm^{-1} and 1325 cm^{-1} confirmed N–H bending of primary amine, amide II and C-N stretching of amide III respectively [22]. The absorption bands 1437 cm^{-1}, 1395 cm^{-1} and 1030 cm^{-1} corresponded to CH_2 bending, symmetrical CH_3 deformation and C–O stretching, respectively [23]. The FTIR of EDTA disodium showed N–H stretching between bands 3027–2945 cm^{-1}, C–H stretching between 2879 and 2793 cm^{-1}. The absorption bands 1666–1607 cm^{-1}, 1474 cm^{-1} and 1394 cm^{-1} showed –C=O stretching, CH_2 bending and O–H bending, respectively [24]. The optimized microparticles C_2 (SE-CHEM) and Y_1 (SD-CHEM) showed absorption bands between 1676–1657 cm^{-1} and 1693–1667 cm^{-1} respectively, representing the amide linkage. Again, the optimized microparticles C_2 (SE-CHEM) and Y_1 (SD-CHEM) showed absorption bands between 2378 and 2373 cm^{-1}, which corresponds to free acetate moieties, and indicates that all the acetate moieties were not involved in the amide linkage. Similarly, FTIR spectra of other SE-CHEMs and SD-CHEMs confirm the same results.

Fig. 9 [Images not available. See PDF.]

FTIR spectra of chitosan (CH), EDTA disodium (EDTA) and SE-CHEM. The samples with KBr pellet were measured (at ambient temp.) for FTIR-ATR analysis in the 500–4000 cm^{-1} spectral range. The C_2 (SE-CHEM) showed absorption bands between 1676–1657 cm^{-1} and 1693–1667 cm^{-1}, representing the amide linkage. The absorption bands between 2378 and 2373 cm^{-1} correspond to free acetate moieties

Fig. 10 [Images not available. See PDF.]

FTIR spectra of chitosan (CH), EDTA disodium (EDTA) and SD-CHEM. The samples with KBr pellet were measured (at ambient temp.) for FTIR-ATR analysis in the 500–4000 cm^{-1} spectral range. The spectra of Y_1 (SD-CHEM) showed absorption bands between 1676–1657 cm^{-1} and 1693–1667 cm^{-1}, representing the amide linkage. The absorption bands between 2378 and 2373 cm^{-1} correspond to free acetate moieties

DSC analysis

Figure 11 shows the DSC analysis of the samples. The thermogram of chitosan, C_2 and Y_1 showed an endotherm transition near 100 °C due to the evaporation of moisture or the presence of acetic acid moieties. The exothermic transition around 311 °C corresponds to the degradation of the chitosan. The melting of the chitosan is not observable because of the amorphous regions present, so it remains near the degradation point [25]. In the EDTA thermogram, the sharp endotherm starting at 243.96 °C corresponds to the melting of it. The C_2 and Y_1 thermograms show an endothermic transition around 240 °C and exothermic transitions near 312–14 °C. This analysis confirmed the purity of the synthesized SE-CHEM and SD-CHEM.

Fig. 11 [Images not available. See PDF.]

DSC graphs of chitosan, EDTA disodium, C_2 and Y_1. The DSC thermograms were recorded in a Differential scanning calorimeter from 40 to 400 °C temperature range. The CH, C_2 and Y_1 showed an endotherm transition near 100 °C, 240 °C (C_2 and Y_1) and for EDTA near 243.96 °C. The CH showed exothermic transition around 311 °C and C_2 and Y_1 thermograms showed it at 312–314 °C

XRD analysis

XRD patterns of the prepared SE-CHEM and SD-CHEM, along with chitosan and EDTA disodium, are shown in Figs. 12 and 13, respectively. The XRD pattern for chitosan showed two diffraction peaks, one at 2θ=20.37°, which indicates the characteristic of semicrystalline regions for chitosan and the other at 2θ=29.57°, which relates to calcite region [26, 27]. The EDTA disodium XRD pattern showed the major diffraction peaks at 2θ=21.2°, 2θ=26.5°, 2θ=29.8°, 2θ=34.3° and 2θ=45.4°. All these diffraction peaks correspond to the characteristic crystalline region of EDTA disodium [28]. The SD-CHEM samples showed broad diffraction peaks at 2θ=21.2°, 2θ=23°, 2θ=26.5° and 2 θ=29.8°. Similarly, SE-CHEM samples showed that diffraction peaks at 2θ=21.2° and 2θ=23° almost disappeared, and diffraction peaks at 2θ=26.5° and 2θ=29.8° were very broad and broad, respectively. These results indicate that microparticles formed from the two methods are amorphous.

Fig. 12 [Images not available. See PDF.]

XRD graphs of chitosan (CH), EDTA disodium (EDTA) and SE-CHEM samples were measured using the X-ray diffractometer at a voltage of 45 kV. The XRD pattern for chitosan showed two diffraction peaks, one at 2θ=20.37° and 2θ=29.57°, while EDTA disodium diffraction peaks were at 2θ=21.2°, 2θ=26.5°, 2θ=29.8°, 2θ=34.3° and 2θ=45.4°. SE-CHEM samples showed diffraction peaks at 2θ=26.5° and 2θ=29.8°

Fig. 13 [Images not available. See PDF.]

XRD graphs of chitosan (CH), EDTA disodium (EDTA) and SD-CHEM samples were measured using the X-ray diffractometer at a voltage of 45 kV. The XRD pattern for chitosan showed two diffraction peaks, one at 2θ=20.37° and 2θ=29.57°, while EDTA disodium diffraction peaks were at 2θ=21.2°, 2θ=26.5°, 2θ=29.8°, 2θ=34.3° and 2θ=45.4°. SD-CHEM samples showed broad diffraction peaks at 2θ=21.2°, 2θ=23°, 2θ=26.5° and 2θ=29.8°

Surface characteristics

To understand the shape and surface morphology of the microparticles, the scanning electron microscope images of the chitosan, EDTA disodium, C_2 and Y_1 (shown in Fig. 14) were taken. In Fig. 14c, the SE-CHEM (C_2) microparticles had a flaky appearance with an uneven surface, providing a high surface area for the adsorption of liquid SEDDS. Figure 14d shows the SD-CHEM (Y_1) microparticles, which are much spherical with uneven surfaces and wide void spaces, leading to better oil adsorption and desorption.

Fig. 14 [Images not available. See PDF.]

Scanning electron micrographs **A** chitosan, **B** EDTA disodium, **C** C_2 and **D** Y_1. **C** The SE-CHEM (C_2) microparticles had a flaky appearance. **D** SD-CHEM (Y_1) microparticles were spherical

Flow properties

The angle of repose (Fixed funnel method), apparent bulk density, tapped density, Carr's index and Hausner's ratio were calculated for the flowing characteristic of the microparticles, and the results are shown in Table 4, which shows all the parameters were in acceptable limits [29]. The angle of repose values for all the microparticles were between 9 and 17. Both optimized microparticles, C_2 and Y_1, were free-flowing.

Table 4. Flow properties

Code	θ	ρ_b	ρ_t	CI	HR	Flowability

OAC and ODC

Cremophor RH 40 and Labrafac were used for the OAC and ODC study; Fig. 15 shows the results. The oil adsorption for both the microparticles was significant, but Y_1 has it slightly higher than C_2 for both Labrafac and Cremophor RH 40. These results relate to the surface morphology analysis, where Y_1 showed a much spherical structure with wide voids compared to C_2, with a flaky structure.

Fig. 15 [Images not available. See PDF.]

Oil adsorbing capacity (OAC) and oil desorbing capacity (ODC) for C_2 and Y_1. Cremophor RH 40 and Labrafac were used for the OAC and ODC study. The OAC of Y_1 was slightly higher than C_2 for both Labrafac and Cremophor RH 40

Dynamic advancing contact angle and surface free energy components analysis

For the adsorption and desorption phenomena to happen on the microparticle's surface, the surface free energy components, i.e., apolar or dispersive component [γ^{LW} (mJ/m^2)] and polar component [γ^{P} (mJ/m^2)] are very important to understand. The γ^{LW} component is related to the hydrophobic surface, and the γ^{P} component relates to the hydrophilic part of the surface.

In Fig. 16, the results of the surface free energy components and dynamic advancing contact angles [θ_a (°)] are shown. The γ^{LW} components of C_2 and Y_1 were enhanced after oil adsorption (for both Labrafac and Cremophor RH 40); this indicates that increased γ^{LW} components can reduce oil droplet size significantly after reconstitution of the nanoemulsion from the surface of the adsorbent microparticles. In contrast, the γ^{P} components were decreased after the oil adsorptions for both microparticles. This result is significant in understanding that the microparticles can give ample surface free energy for the stable nanoemulsion, leading to good oil desorption.

Fig. 16 [Images not available. See PDF.]

Surface free energy components (dispersive component, γ^{LW} and polar component, γ^{P}) and dynamic advancing contact angles (θ_a) for C_2 and Y_1. The γ^{LW} components of C_2 and Y_1 were enhanced after oil adsorption (for both Labrafac and Cremophor RH 40). The γ^{P} components were decreased after the oil adsorptions for both microparticles. The dynamic advancing contact angles (θ_a) were also significantly increased after the oil adsorption The dynamic advancing contact angles (θ_a) were also significantly increased after the oil adsorption. Increased θ_a indicates the hydrophobicity of the surface, which is vital for the development of stable nanoemulsion.

Discussion

The solid adsorbent base with an excellent hydrophobic surface, oil adsorption and desorption capacities will play a crucial role in developing the S-SEDDS [30]. Hence, an attempt was made to develop the microparticles of chitosan–EDTA disodium. Such adsorbent microparticles will allow the incorporation of poorly water-soluble and thermolabile drugs into the S-SEDDS [31]. The solvent evaporation and spray drying techniques were explored to synthesize and characterize SE-CHEM and SD-CHEM microparticles, respectively. In the preliminary study, it was evident that the chitosan–EDTA disodium ratio and processing temperature in the solvent evaporation and spray drying procedures play a crucial role in the various properties of the microparticles like water solubility, yield, particle size and zeta potential. So, optimization was required for the development of the CHEM. The process was optimized using 3^2 full factorial designs, which showed a CH/EDTA ratio (60:40) and drying temp. 70 °C for solvent evaporation method and inlet temp. 110 °C and CH/EDTA ratio (50:50) produced SE-CHEM (C_2) and SD-CHEM (Y_1), respectively, with highest yield, zeta potential and lowest particle size. The different characterization studies like DSC and FTIR analysis for both optimized microparticles confirmed the amide conjugation between the CH and EDTA and free acetate moieties' existence. XRD study confirmed the broadening of the diffraction peaks for both C_2 and Y_1, suggesting the amorphous character of the particles. The high oil adsorption and desorption were achieved for both microparticles, confirmed by OAC and ODC studies. The ODC is closer to the OAC, which signifies that the amount of oil adsorbed by the microparticles will be desorbed in a very close quantity to adsorption. Surface morphology analysis through SEM images confirmed the flaky appearance of C_2 and Y_1, showing a spherical shape with voids. Flowability analysis revealed that both the microparticles were free-flowing. The surface free energy component analysis before and after oil adsorption revealed the enhancement in the dispersive components for both microparticles; this property leads to a reduction in oil droplet size on reconstitution of S-SEDDS, whereas reduced polar components after oil adsorption suggest microparticle's ability to provide sufficient surface free energy for the stability of the nanoemulsion after reconstitution. The enhanced dynamic advancing contact angles for C_2 and Y_1 indicated the hydrophobic surface of the microparticles, which was evident in high OAC for both microparticles. All these results suggest that both the microparticles can serve as stable adsorbent base for solid SEDDS to produce stable nanoemulsion after reconstitution.

Conclusion

This study has reported development of superior adsorbent carrier (microparticles) by solvent evaporation and spray drying techniques. The development of the CH-EDTA disodium microparticles (adsorbent carriers) by the solvent evaporation and spray drying methods is simplistic and practical, with the potential to be adopted at an industrial scale. The results of improved OAC, ODC and surface free energy components were satisfactory. They will prove beneficial for these microparticles to fabricate them with the liquid self-emulsifying drug delivery systems. The microparticles developed with both techniques were superior in their qualities as an adsorbent base for the solidification of SEDDS. However, if we compare both techniques, the microparticles developed by the spray drying technique were better than those from the solvent evaporation technique. The SE-CHEM had the advantage of a greater percentage yield as no minimal loss occurred during production, while SE-CHEM suffered a more significant loss and had a low percentage yield during the process. Further, the fabrication of these microparticles with SEDDS (of suitable drugs) is required to form a solid self-emulsifying drug delivery system, whose analysis in *in vitro* and *ex vivo* conditions will give a clear image of these microparticle's ability to enhance the drug loading, dissolution and

bioavailability and to form a stable solid self-emulsifying drug delivery system.

ABSTRACT (ENGLISH)

Background

Liposome-mediated drug delivery systems have emerged as a promising avenue for enhancing cancer treatment strategies. This study aims to develop and assess liposomal carriers loaded with Brilliant Blue G-250 (BBG-250), a potent P2X7 receptor antagonist that shows potential as an anti-tumor agent. Specifically, two types of liposomal formulations were designed: conventional liposomes composed of hydrogenated soya phosphatidylcholine (HSPC) and cholesterol, and pH-sensitive liposomes consisting of dioleoylphosphatidylethanolamine (DOPE), distearoylphosphatidylethanolamine-methoxy polyethylene glycol (DSPE-mPEG), dipalmitoylphosphatidylcholine (DPPC), and cholesterol. The investigation focuses on understanding the morphological characteristics, size, stability, drug incorporation efficiency, drug release profiles, blood compatibility, and cytotoxicity of these liposomal formulations.

Results

Advanced photon correlation spectroscopy using the Nano Plus-3 instrument was employed to evaluate the liposomes. The optimized conventional liposomes (HSPC-cholesterol ratio 7:3) exhibited a size of 125 ± 0.3 nm with a polydispersity index (PDI) of 0.21, indicating uniformity. The pH-sensitive liposomes (DOPE:DPPC:DSPE-PEG2000: Cholesterol 4:3:3:0.3) demonstrated a size of 118 ± 1.2 nm with a PDI of 0.230. Zeta potential measurements confirmed the stability of both formulations under physiological conditions, with values of − 16.93 mV for conventional liposomes and − 25.21 mV for pH-sensitive liposomes. Higher drug-to-lipid ratios were found to enhance drug incorporation efficiency. pH-sensitive liposomes exhibited superior drug release characteristics, with 95% release over 24 h, compared to conventional liposomes, which released 70% of the drug. Blood compatibility assessments revealed the safety of both formulations for intravenous administration. Cytotoxicity studies conducted on A549 cell lines demonstrated the cytocompatibility of both liposomal types across a range of concentrations, with IC_{50} values surpassing those of the reference drug, docetaxel.

Conclusions

This study underscores the potential of liposomal carriers as effective vehicles for delivering BBG-250, highlighting their stability, biocompatibility, and controlled drug release properties. Despite being slightly less potent than the reference drug, docetaxel, these liposomal formulations hold promise for advancing anticancer strategies. The findings contribute to the evolving landscape of innovative cancer therapy drug delivery systems, offering a novel approach to improving treatment outcomes for cancer patients. The successful development and evaluation of these liposomal carriers pave the way for further investigations and potential clinical applications in the field of cancer therapeutics.

FULL TEXT

Background

Cancer, a complex and multifaceted group of diseases characterized by uncontrolled cell growth and division, continues to be a major global health challenge. It is responsible for an enormous burden of suffering and mortality, with nearly 10 million deaths attributed to cancer in 2020 alone. The intricate interplay of genetic, environmental, and lifestyle factors contributes to the initiation and progression of cancer, rendering it a formidable adversary that requires innovative and targeted therapeutic approaches. In the realm of cancer, lung cancer occupies a particularly sinister position. It stands as one of the most prevalent and lethal forms of malignancy, causing an alarming number of deaths annually. In 2020, lung cancer accounted for a staggering 1.80 million fatalities, thereby solidifying its grim distinction as the leading cause of cancer-related death worldwide. The statistics paint a stark picture of the devastating impact of this disease on individuals, families, and societies at large (ACS, 2020, 2022, 2023). Among the spectrum of lung cancers, non-small cell lung cancer (NSCLC) emerges as the dominant subtype, encompassing a majority of cases. The etiology of NSCLC is intricately linked to diverse factors, including smoking, exposure to environmental pollutants, genetic predisposition, and aging. Its insidious nature often results in diagnosis at advanced stages, significantly hampering treatment success and patient prognosis. Central to addressing the challenge of lung cancer is an understanding of the critical role that cancer stages play in shaping outcomes. Stage of cancer refers to the extent to which it has progressed within the body, ranging from localized disease confined to its site of origin to invasive cancer that has spread to distant regions. This staging system provides valuable insights into the potential for disease eradication, recurrence, and overall survival. In the context of lung cancer, early detection and treatment significantly improve patient outcomes. Unfortunately, a substantial proportion of cases are diagnosed at later stages, severely limiting therapeutic interventions.

Traditional treatments for lung cancer, including surgery, radiation therapy, and chemotherapy, have made strides in extending survival and improving the quality of life[1]. However, the pursuit of more effective and targeted therapeutic strategies remains paramount. The advent of molecular and genetic insights into cancer biology has unveiled novel opportunities for precision medicine. Targeted therapies, immunotherapies, and combination regimens are reshaping the landscape of lung cancer treatment, offering hope for improved outcomes and personalized care [2, 3]. One intriguing avenue of research in the pursuit of innovative lung cancer therapies is the exploration of purinergic receptors, specifically P2X and P2Y subfamilies[4, 5]. These receptors, widely distributed throughout the body, are pivotal players in cellular signaling and communication. Of particular interest is the P2X7 receptor, which exhibits distinct expression patterns in both normal and cancerous lung cells. This receptor not only influences cell proliferation but also plays a crucial role in the delicate balance between cell survival and apoptosis, a programmed cell death mechanism. Importantly, in the context of lung cancer, alterations in P2X7 receptor activity have been implicated in disease progression. The intriguing interplay between the P2X7 receptor and lung cancer opens up an avenue for therapeutic intervention [6]. One compound of interest in this context is Brilliant Blue G-250 (BBG-250), a known antagonist of the P2X7 receptor [7]. Previous studies have demonstrated its ability to modulate receptor activity and impact cellular responses. Harnessing the potential of BBG-250 as a targeted therapy could pave the way for a more nuanced and effective approach to tackling lung cancer. To enhance the precision and efficacy of therapeutic interventions, nanotechnology has emerged as a transformative tool. Liposomes, with their minuscule dimensions and unique physicochemical properties, offer a platform for targeted drug delivery and controlled release. The concept of encapsulating therapeutic agents within nanocarriers holds the promise of minimizing systemic toxicity, maximizing drug accumulation at tumor sites, and ultimately improving treatment outcomes [8]. Liposomes, a well-established type of nanovesicle, have garnered considerable attention in drug delivery applications. Comprising a lipid bilayer surrounding an aqueous core, liposomes offer versatility in encapsulating a wide range of molecules, including hydrophilic and hydrophobic drugs [9]. Their potential to traverse biological barriers, selectively accumulate in tumor tissues, and release their cargo in a controlled manner has spurred interest in their use for cancer therapy. The present research endeavors to explore the computational screening approaches, such as homology modeling molecular docking and ADMET analysis, which were used to

evaluate binding affinity between the target (P2X7) and Ligand (BBG-250). The potential interaction of BBG-250 with crucial amino acid residues within target binding pockets has been a subject of investigation in this study. Afterward, pharmacokinetic parameters were checked via an in silico ADMET study. Then after the potential of liposomal formulations encapsulating BBG-250 for targeted therapy in lung cancer. The overarching objective is to harness the unique attributes of liposomes to enhance the delivery and efficacy of BBG-250 while minimizing adverse effects[10]. By delving into the formulation, characterization, and performance of these liposomal carriers, this study seeks to contribute to the growing body of knowledge aimed at advancing precision medicine strategies for lung cancer treatment. The subsequent sections of this research paper delve into the intricate details of this investigation, encompassing the methodology, results, and discussions that underpin the pursuit of innovative and effective lung cancer therapeutics. Through meticulous analysis and comprehensive assessment, this research endeavors to shed light on the potential of liposomal BBG-250 as a promising avenue for enhancing lung cancer treatment outcomes[11, 12].

Material

The selection and procurement of materials form the foundation of any scientific investigation. Each component contributes to the precision and reliability of experimental outcomes. The following section outlines the various materials employed in this study, including their sources and roles in the research process.

In silico study

Homology modeling

Comparative or homology protein modeling is a powerful 3D protein modeling tool that can predict the conformation of experimentally unavailable protein structure that has amino acid sequences similar to template protein sequence due to the unavailability of P2X7 receptor 3D structure in the PDB. It is difficult and time-consuming to establish the 3D structure of a P2X7 protein using experimental techniques including NMR, X-ray crystallography, and cryo-electron microscopy. Therefore, P2X7 protein structure determination is crucial for planning and evaluating biological research in this scenario. Homology modeling has proven to be the most effective method for building a reliable 3D model of a P2X7 protein from its amino acid sequence. The Ramachandran plot, Errat score, and other validation metrics are indicators of the quality of the protein structural geometry. The following list of tools was used for homology modeling:

Homology modeling by different tools

Homology modeling by MODELLER 10.2 module

To create constraints on atomic distances, dihedral angles, and other parameters, MODELLER employs the query structures. These constraints are then paired with statistical distributions determined from several homologous structure pairings in the PDB. Sequences and structures are combined by MODELLER to create a comprehensive alignment that may be manually altered and inspected with molecular graphics software. There are five consecutive steps to comparative modeling using the MODELLER 10.2 module. The very first step of modeling involves searching for the 3D structure of proteins related to the target. For this, we have used the site (www.ncbi.nlm.nih.gov) and downloaded the P2X7 receptor sequence in FASTA file format. The second step denotes the selection of templates for alignment with the target. Here, we run BLAST for getting similar sequences and selected ten sequences (PDB_ID:3H9V,4DW0,4DW1,5FLC,5SVH,5SVJ,5U11,5XW6,5YVE,6AH4) as templates based on maximum identity related to the P2X7 protein sequence from a list of generated sequences in Table 1. Out of a total of ten PDB structures, PDB ID_5SVH was found to be more perfect than others. The third step involves aligning the target protein with the template (PDB_5SVH). The fourth step is the model-building step which automatically calculates the 3D model of the target using an auto model class of the module. In this step, a total of 20 homology models have been generated with different conformations. The fifth step is the evaluation step, in this the models were evaluated using the Ramachandran plot and Errat score as Table 2. Again, out of 20 homology models after evaluation model number 10 (**qsec.B99990010.pdb**) was found to be a more accurate model than others[13].

Homology modeling by SwissModel module

SwissModel is a web server that accepts a sequence and delivers the model via email. It follows standard protocols for homologue identification, sequence alignment, core backbone determination, and modeling loops and side chains. SwissModel searches a protein database using BLAST and attempts to build a model for any PDB hits. In comparative modeling, a 3D protein model of a P2X7 receptor sequence is generated by extrapolating experimental information from an evolutionary-related protein structure that serves as a template. In SwissModel, the default modeling workflow consists of the following main steps: (1) **Input data:** The target protein amino acid sequence in FASTA format as a plain text from the NCBI database. (2). **Template search:** Data provided in step 1 serve as a query to search for evolutionary-related protein structures against the SWISSMODEL template library SMTL that is 6u9v, 6u9w, 5u2h, and 5u1u. (3) **Template selection:** Templates are ranked according to GMQE and **6u9v** were used for further model building as shown in Table 3. (4). **Model building**: Selected template(6u9v), a four-3D protein model (Table 4) is automatically generated by first transferring conserved atom coordinates as defined by the target template alignment. (5) **Model quality estimation**: To quantify modeling errors and give estimates on expected model accuracy the Ramachandran plot and Errat score provide estimates of the expected quality of the resulting model at the tertiary and quaternary structure level[14].

Table 3. Templates with the highest degree of similarity to the P2X7 protein sequence

S. No	PDB hits	Identity (%)	Resolution

Homology modeling by I-tasser module

A homology model, based on the Amino acid sequence (NCBI database) of the Homo sapience, corresponding to the P2X7 receptor obtained using the I-TASSER server, and five different models were generated as mentioned in Table 5. The confidence of each comparative model obtained by I-TASSER is quantitatively measured by the C-score which is typically in the range of [−5 to 2]. The best-identified 3D model (out of five comparative models) obtained a C-score value of−2.52. The quality of the raw homology model was assessed by the Pro-check server[15, 16].

Table 5. List of generated models and their Validation of I-Tasser server

Generated model	Ramachandran Plot (%)	Errat
Model 1	74.5	88.81
Model 2	74.1	84.32
Model 3	53.0	69.96
Model 4	**75.9**	**89.84**
Model 5	46.4	70.37

Bold value indicates the best model

Our criteria for model selection were stringent, with a significant emphasis on accuracy as reflected in the Ramachandran favored regions. Following this thorough validation process, Model.4 emerged as the most optimal choice for subsequent docking studies. A detailed account of the validation parameters, encompassing factors such as Ramachandran favored outcomes, is thoroughly documented and presented in Table 7. This transparent documentation underscores the robustness of our model selection process, establishing a solid foundation for the reliability of the chosen receptor model in our study.

Molecular docking

Molecular docking studies of Brilliant Blue G250 dye (Fig. 1) were performed with receptor protein designed by homology modeling method by using Glide module software (Schrodinger Maestro v13.1). The protein was further processed through ‘protein preparation wizard’ (Maestro wizard v13.1). The generating states and refinement step were used for improving the protein structure including optimization of H-bonded groups, dehydration, and restrained minimization by using default force field OPLS_3. The minimized protein structure was used for the generation of a grid around ligand molecules. Molecular docking studies were performed by the Glide module of Schrodinger Maestro v13.1 on Brilliant Blue G250 Dye. The protein structure was obtained from the homology modeling by SwissModel (Fig. 1C) which passed various evolution tests (Fig. 1A and B) and was pre-processed by using protein preparation wizard in Maestro v13.1. Generating states and refinement step automatically added hydrogen atoms and some essential bonds at the missing sites of the protein molecule. The refinement step has several functions like optimization of hydrogen-bonded groups, removal of water, and restrained minimization using the default force field OPLS_3. After the optimization process, receptor grid generation was processed to locate the binding pocket in

the receptor and in the last ligand docking was performed. The activity of the dye (Ligand) depends on the possible interactions of the ligand with various amino acid residues of the targeted protein (P2X7 receptor) as shown in Fig. 2 [17, 18].

Representation of Docking Interaction Between P2X7 Homology Model and BBG-250

Validation of docking results

The docking analysis of BBG250 revealed a notable docking score of -9.597. This outcome suggests a high affinity and favorable binding interaction of BBG250 within the target site. Importantly, these results indicate superior activity levels when compared to the reference compound (Docking score: −4.621), docetaxel, a well-established agent in previous anticancer studies (refer to Table 7). And also validated by the both positive controls (standard inhibitors) and negative controls (known non-inhibitors) within our docking analysis. BBG250 displayed a higher binding affinity when compared to the positive control and negative control compounds. This outcome strongly suggests that BBG250 may indeed exhibit superior activity levels compared to previously reported compounds (Table 7). Our research findings substantiate the enhanced potential of BBG250 as a promising candidate in the context of anticancer therapeutics.

Prediction of ADME properties

Nowadays, several online tools and offline software programs are available which help us in predicting the ADME behavior of the drug candidate. In this study, the SwissADME prediction tool (http://www.swissadme.ch/) was used. The compound selected for the ADME study was BBG-250. The compounds were then converted into their canonical ‘SMILE’ format and put in the ‘SwissADME’ in the section mentioned as ‘Enter a list of SMILES here.’ The server predicts the physicochemical properties, lipophilicity, water solubility, pharmacokinetics, druglikeness, lead likeness, and synthetic accessibility of the compounds.

Brilliant blue G-250

The key pharmaceutical agent under scrutiny is BBG-250, a potent antagonist of the P2X7 receptor[10]. This compound, which holds promise for targeted lung cancer therapy, was procured from HIMIDIA Laboratories Ltd, Mumbai, India. Its specialized properties make it an indispensable element in the formulation and subsequent evaluations of liposomal carriers.

Lipids

Lipids are fundamental components of liposomal formulations, providing the structural basis for these liposomes. The lipids used in this study were acquired from distinct sources, each contributing unique attributes to the formulation. mPEG-DSPE, a critical ingredient, was generously provided as a gift sample from Lipoid Germany. This lipid, known for its amphiphilic nature, facilitates the formation of stable liposomes and influences their surface properties. HSPC (hydrogenated soya phosphatidylcholine), a lipid renowned for its biocompatibility and stability, was also a gift sample from Lipoid Germany. Its inclusion in the formulations contributes to the structural integrity of liposomes, enabling efficient encapsulation of BBG-250. DOPE (dioleoylphosphatidylethanolamine), another vital lipid component, was likewise obtained as a gift sample from Lipoid Germany. DOPE presence imparts fluidity and flexibility to the lipid bilayer, optimizing the liposome's ability to encapsulate and release therapeutic agents [19].

Cholesterol

Cholesterol sourced from HiMedia, Mumbai, is a quintessential component of the lipid bilayer. Its role in maintaining membrane integrity, modulating fluidity, and enhancing the stability of liposomal carriers is indispensable [20]. The inclusion of cholesterol in the formulations contributes to the structural integrity and performance of liposomes.

Solvents and filters

Chloroform and methanol, vital solvents in the formulation process, were procured from Department. These solvents

play a pivotal role in dissolving lipids and facilitating the formation of thin lipid films, which serve as the foundation for liposomal encapsulation. To ensure the purity and clarity of the formulations, filtration steps were implemented. Nylon filters (AXIVA syringe filters) were employed for this purpose, effectively removing particulate matter and ensuring the quality of liposomal suspensions [21].

Dialysis membrane

For the evaluation of drug release profiles, dialysis membranes are indispensable tools. The dialysis membrane used in this study, sourced from Sigma-Aldrich, boasts a 14 kDa molecular weight cutoff. This semi-permeable barrier allows for controlled diffusion of molecules, facilitating accurate measurement of drug release from liposomal formulations.

The research demanded a range of other chemicals, each contributing to various aspects of the experimental process. These chemicals, all of the highest commercial grade, played roles in diverse procedures, from pH determination to characterization analysis. Their quality and consistency ensured the reliability of the research outcomes. The selection and procurement of materials underpin the scientific rigor and validity of this investigation. Each component, from the therapeutic agent BBG-250 to the lipids, solvents, filters, and membranes, plays a crucial role in formulating, characterizing, and evaluating liposomal carriers for targeted lung cancer therapy.

Preparation of conventional and pH-sensitive liposomes formulation

In the realm of targeted drug delivery, formulation and development of liposomal carriers play a pivotal role in enhancing therapeutic efficacy. This study undertook a systematic approach to engineer liposomal formulations tailored for the encapsulation of BBG-250, a potent P2X7 receptor antagonist with promising implications for lung cancer therapy. Two distinct formulations were meticulously crafted: conventional liposomes composed of hydrogenated soya phosphatidylcholine (HSPC) and cholesterol, and pH-sensitive liposomes consisting of dioleoylphosphatidylethanolamine (DOPE), dipalmitoylphosphatidylcholine (DPPC), DSPE-PEG 2000, and cholesterol [22]. The formulation process, a critical juncture in this research, was executed with precision and methodological rigor.

For the preparation of conventional liposomes, the thin-layer evaporation method was adopted, renowned for its capacity to generate liposomal structures with reproducibility. The process began with the precise weighing of HSPC and cholesterol in a 7:3 ratio ensuring the optimal composition. This lipid mixture was dissolved in a chloroform–methanol solution at a 9:1 ratio, creating an organic phase conducive to liposomal encapsulation [23]. The therapeutic agent BBG-250 was judiciously introduced into the organic phase and fortified with 3.5 mg of the compound to confer the desired therapeutic payload. After solvent evaporation under vacuum at a controlled temperature of 50 °C, a thin lipid film emerged. Hydration of the lipid film with the phosphate-buffered solution (PBS) at pH 7.4 revitalized the structure, forming a homogenous liposomal suspension through Rota evaporation at 50–55 °C and 200 rpm for one hour [24]. Further refinement involved probe sonication for uniformity and size optimization, followed by passage through Sephadex (G-50) column to attain the final liposomal formulation characterized by low polydispersity and targeted size distribution. The resulting liposomes, thus formed, were stored at a controlled 4 °C for subsequent stages of experimentation.

This comprehensive approach to crafting conventional liposomes ensured the creation of structurally sound carriers poised for targeted drug delivery. The subsequent segment will delve into the formulation of pH-sensitive liposomes, shedding light on their unique composition and the intricacies of their preparation.

Characterization of liposomes

FTIR analysis

FTIR (Fourier-transform infrared) analysis was performed to gain insights into the molecular interactions and structural changes present in the formulated liposomes and the Brilliant Blue G-250 (BBG-250) dye. The FTIR spectra of the HSPC liposomes (P11), pH-sensitive formulation (P5), and Brilliant Blue G-250 (BBG-250) were obtained using a Fourier-transform infrared spectrometer. The samples were prepared by depositing a thin film of each formulation on a suitable substrate, followed by scanning within the infrared range. The spectral data obtained were then analyzed to identify specific functional groups and molecular vibrations.

Vesicle shape, size, size distribution, and zeta potential

Vesicle characteristics play a pivotal role in determining the efficacy and behavior of liposomal formulations. Through the utilization of advanced analytical tools, the vesicle size (z-average), size distribution (polydispersity index), and zeta potential (ZP) were meticulously assessed. Using the Nano Plus-3 instrument, the formulations underwent thorough examination employing photon correlation spectroscopy (PCS). Before analysis, the formulations underwent meticulous filtration through a 0.25-micron syringe filter (1:9 v/v) to ensure accuracy. The resulting data were presented thoughtfully, offering a visual representation of these critical parameters [25].

Morphology and structure determination

A profound understanding of the morphology and structural characteristics of liposome preparations was sought through diverse microscopy techniques. Transmission electron microscopy (TEM) was employed to capture distinct features. Glass-mounted HSPC and pH-sensitive liposomes were meticulously examined under phase contrast microscopy, allowing detailed observations at optimal magnification. These observations were thoughtfully documented through photomicrographs, unveiling the distinctive visual attributes of each formulation. Furthermore, a comprehensive TEM study was conducted, involving the creation of thin films on carbon-coated copper grids. These grids, housing the liposome films, were meticulously air-dried and subjected to TEM analysis, providing valuable insights into their internal architecture at magnifications enabled by an accelerating voltage of 200 kV. The resulting images offered a deeper understanding of the structural organization of liposomes [26].

pH determination

The inherent pH values of both types of liposomal formulations were critically assessed, serving as a vital indicator of their stability and compatibility. Measurements were carried out using a precise Elico pH meter, maintaining a controlled temperature of 25 °C ± 0.5 °C. Ensuring the robustness of the findings, the pH determination was conducted in triplicate, reinforcing the accuracy and reliability of the obtained results [27].

Percentage entrapment efficiency

The encapsulation efficiency of the liposomal formulations was quantitatively determined to offer insights into their drug incorporation capabilities. Employing a meticulously designed protocol, liposome pellets underwent dissolution in PBS with 3% Triton X-100, followed by sonication and ultracentrifugation. The resultant process enabled the quantification of percentage entrapment efficiency (%EE). The centrifugation steps, conducted under precise conditions, contributed to accurating measurements. The derived values of %EE were calculated employing established formulas (Eq. 1), providing a quantitative assessment of the formulations' drug incorporation efficacy[28].

1

$$\%EE = \frac{Weightofinitialdrug - WeightoffreedrugWeightofinitialdrug}{} \times 100$$

In vitro drug release study

The in vitro drug release profiles of the formulations were meticulously examined, employing a well-established dialysis bag method. In this procedure, the formulations were introduced into dialysis bags, which were immersed in a controlled environment consisting of PBS with a pH of 6.4. Maintained under conditions of controlled temperature (37 °C ± 0.5 °C) and gentle stirring, the formulations' drug release was monitored over 24 h. At regular intervals, samples were withdrawn, and their drug release was quantified through UV spectroscopy. The cumulative drug release data provided valuable insights into controlled release kinetics of the liposomal carriers [29].

Blood compatibility analysis

Evaluating the formulations' compatibility with blood coagulation mechanisms, the PT (prothrombin time) and APTT (activated partial thromboplastin time) assays were deployed. Fresh blood samples, collected in ACD-containing tubes, underwent centrifugation to obtain platelet-poor plasma (PPP). This plasma was subsequently mixed with samples from the formulations, and after an incubation period, PT and APTT were assessed through coagulation analyzer reagent kits. The meticulous evaluation of coagulation parameters allowed for a comprehensive understanding of the formulations' impact on blood coagulation mechanisms, thereby ensuring their biocompatibility [30].

MTT assay: cell viability assessment

The cytotoxic potential of the optimized HSPC and pH-sensitive liposomes was evaluated through MTT [3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyl tetrazolium bromide] assay, a widely accepted method for gaging cell viability. Employing A549 cell lines as a model, cells were cultured in 96-well tissue culture plate with cell density of 104 cells/well and were allowed to adhere for 24 h. Following the cell adhesion, cell media was replaced with fresh media containing the treatment sample (2.5, 5, 10, 20, 40, 80 µg/mL) and was incubated for 24 h. Following the incubation, 20 µL of MTT solution (5 mg/mL) was added in each well and was incubated for 3 h. The media was aspirated and 100 µL of dimethylsulfoxide was accurately pipetted into each well to dissolve the formed formazan crystals. The optical density in each well was observed using ELISA microplate reader (M/s BioTek, Vermont, USA) at 550 nm. Thus, based on the optical density observed, % cell viability was calculated (Eq. 2)[31].

2

$$\%\text{Cellviability}=\frac{O.D_{\text{treatment}}-O.D_{\text{blank}}}{O.D_{\text{control}}-O.D_{\text{blank}}}\times 100$$

$O.D_{\text{treatment}}$, $O.D_{\text{blank,}}$, and $O.D_{\text{control}}$ are the optical densities observed for the treatment, blank (without cells), and the control (without treatment) group, respectively.

Incorporating a diverse array of methodologies, these characterization efforts contributed to a profound understanding of the structural, functional, and biocompatible attributes of liposomal formulations. Each subheading delved into specific facets of the formulations, offering valuable insights that collectively contribute to a holistic comprehension of their performance and potential applications.

Results

In silico analysis

A total of 29 protein structures were predicted using computational modeling tools, including MODELLER 10.2, I-Tasser, and SwissModel. Among these models, the SwissModel-generated model.4 exhibited superior accuracy, as evidenced in Fig. 1, thereby warranting its selection for subsequent docking analyses. Docking studies were conducted across five grid configurations to investigate the binding cavity of the P2X7 receptor, which was homology-modeled using SwissModel. The results are depicted in Fig. 1C, highlighting specific interactions, such as two hydrogen bonds and two Pi-Pi stacking interactions, depicted in distinct colors in Fig. 2. The ligand, Brilliant Blue G dye (BBG250), demonstrated binding interactions with amino acid residues Glu66, Phe97, Tyr111, and Pro112. The XP docking score for this interaction was determined to be −9.597, An estimated high binding affinity between the ligand (in this case, Brilliant Blue G dye or BBG250) and the P2X7 receptor is indicated by a docking score value of −9.597. The arbitrary negative sign simply denotes that a lower energy state is connected to a more stable complex. A result of −9.597 means that there is a strong and favorable binding interaction between BBG250 and the P2X7 receptor, indicating that there is a high probability of the ligand binding to the receptor and creating a stable complex. In comparison, the reference drug, docetaxel, exhibited a docking score of -4.921, indicating lower affinity than BBG250. The observed interactions between BBG250 and the P2X7 receptor, as outlined in Table 6, play a pivotal role in its inhibitory activity. These findings underscore the potential of BBG250 as a candidate for modulating the P2X7 receptor.

Table 6. Amino Acid residues interaction with BBG-250

Ligand	Protein	DOCK Score	H-bond	Pi-Pi stacking	Salt bridge
BBG 250	P2X7	−9.597	2	2	0

The results of the *In silico* ADME study are shown in Tables 7, 8, 9, 10, 11 The physicochemical properties of BBG-250 are reported in Table 7, indicating that BBG-250 possesses molecular weight>500, several hydrogen bond acceptors between 7, several hydrogen bond donors between 1, several rotatable bonds between 15, and a molar refractivity is 233.61. The lipophilicity profile of selected compounds is reported in Table 8, which suggested that BBG-250 possesses reasonable lipophilic character BBG-250 did not cross the blood–brain barrier. To check the

druglikeness parameter, Lipinski &Ghose filter is applied. BBG-250 violet the two Lipinski rule and four Ghose rules (Tables 11, 12, 13). It was observed from the above study that BBG-250 has high GI absorption (Table 10), does not cross the blood–brain barrier, has water solubility (Table 9), considerable lipophilic profile and moderate synthetic accessibility. BBG-250 did not follow the Lipinski rule because of its higher molecular weight (>500). The accessibility of the compound (BBG-250) was similar to that of the reference drug, docetaxel.

Table 7. Validation of docking result

FTIR spectrum

The FTIR spectrum of HSPC liposomes (P11) revealed characteristic peaks corresponding to various functional groups present in the formulation. Notably, the presence of strong absorption bands around 2920 cm^{-1} and 2850 cm^{-1} indicated the presence of CH stretching vibrations, typically found in lipid chains. The absorption bands around 1736 cm^{-1} indicated the presence of carbonyl (C=O) stretching vibrations, further confirming the presence of lipid components. Additionally, absorption peaks around 1230 cm^{-1} and 1100 cm^{-1} indicated the presence of phosphodiester groups in the formulation, which is consistent with the presence of phospholipids in liposomal formulations (Fig. 3a).

Fig. 3 [Images not available. See PDF.]

a FTIR spectrum of HSPC liposomes (P11); **b** FTIR spectrum of pH-sensitive formulation (P5); **c** FTIR spectrum of Brilliant Blue G-250 (BBG-250); **d** Particle size of formulation (P5) 118 nm; **e** Zeta potential of formulation (P5) − 25 mV; **f** Microscopic image of formulation (P5); **g** TEM image of formulation (P5); **h** In vitro drug release of formulation pH-sensitive (P5) and HSPC liposomes (P11) in phosphate buffer (pH 6.4); **i** Graph between % viability and concentration of formulation pH-sensitive (P5) and HSPC liposomes (P11), free dye, Docetaxel (DTX)

The FTIR spectrum of the pH-sensitive formulation (P5) exhibited distinct peaks corresponding to the specific functional groups present in the formulation. Notably, the absorption bands around 1736 cm^{-1} indicated the presence of carbonyl (C=O) stretching vibrations, characteristic of lipid components. The absorption bands around 1650 cm^{-1} indicated the presence of amide I bond, suggesting the incorporation of protein-like components, such as DSPE-PEG_{2000}, within the formulation. Furthermore, absorption peaks around 1100 cm^{-1} and 1050 cm^{-1} indicated the presence of P=O stretching vibrations, confirming the presence of phospholipids (Fig. 3b).

The FTIR spectrum of Brilliant Blue G-250 (BBG-250) showed distinct absorption bands characteristic of the dye molecule. Notably, the absorption peak around 1600 cm^{-1} indicated the presence of aromatic C=C stretching vibrations, confirming the aromatic nature of the dye. The absorption bands around 1300 cm^{-1} and 1200 cm^{-1} indicated the presence of aromatic C-N stretching vibrations, further confirming the structure of the dye (Fig. 3c).

FTIR analysis provided valuable insights into the molecular composition and interactions within the HSPC liposomes, pH-sensitive formulation, and Brilliant Blue G-250 dye. The characteristic peaks observed in the spectra confirmed the presence of specific functional groups and molecular vibrations, further supporting the formulation and

characterization of the liposomal delivery system and the dye.

Vesicle shape, size, size distribution, and zeta potential

The quantitative incorporation of BBG-250 into two distinct liposomal formulations was the focal point of the current study. One formulation comprised hydrogenated soya phosphatidylcholine (HSPC) and cholesterol, while the other featured dioleoylphosphatidylethanlamine (DOPE), DSPE-mPEG, DPPC, and cholesterol. A thin film method was employed to create these liposomes, with specific lipid ratios determining their properties. The HSPC and cholesterol ratio of 7:3 yielded liposomes with a vesicular size of 118 ± 1.2 and a polydispersity index (PDI) of 0.316. Similarly, the DOPE, DPPC, DSPE-PEG_{2000}, and cholesterol ratio of 4:3:3:0.3 resulted in liposomes with a vesicular size of 125 ± 1.6 and PDI of 0.165 (Fig. 3 d, e).

Morphology and structure determination

Transmission electron microscopy (TEM) examination revealed the morphology and structural attributes of the formulated HSPC and pH-sensitive liposomes. The TEM images showcased spherical vesicles with uniform size distribution for both formulations. HSPC liposomes exhibited sizes ranging from approximately 100–150 nm, while pH-sensitive liposomes displayed slightly larger sizes spanning 120–180 nm, potentially due to additional components. The lipid bilayer membrane of both liposomal types appeared intact and continuous, affirming their stability and suitability for drug encapsulation and delivery. The TEM results affirmed the successful formation of well-defined liposomal structures, underlining their potential for effective targeted drug delivery applications (Fig. 3f, g).

Analysis of pH levels

The pH values of formulated HSPC (P11) and pH-sensitive liposomes (P5) were measured and found to be 7.3 and 7.8, respectively. These pH values signify the intravenous safety of the liposomal formulations, highlighting their compatibility within physiological pH ranges.

Percentage drug efficiency

The entrapment efficiency of plain dye and HSPC liposome (P11) was determined to be 97% and 70%, respectively. In contrast, the pH-sensitive liposomes (P5) exhibited an entrapment efficiency of 95%. These findings underscore the formulations' capacity to encapsulate the drug effectively.

In vitro drug release studies

The In vitro drug release profiles of both optimized formulations were assessed using a dialysis tube method. The optimized HSPC formulation (P11) displayed a drug release profile of 84.95% over 24 h in PBS 6.4, while the optimized pH-sensitive liposomes (P5) exhibited a drug release of 95% over the same period. These release profiles are visually presented in Fig. 3h, providing a comprehensive depiction of the formulations'-controlled drug release kinetics (Table 14).

Table 14. Optimized formulation of conventional and pH-sensitive formulation

Formulation code	Lipid ratio	Drug (mg)	Sonication time	Particle size (nm)	PDI	Entrapment efficiency	Zeta potential
P1	3:2:3:0.3	4	4 min	325 ± 1.6	0.230	49%	−53
P2	3:3:3:0.3	4	4 min	370 ± 0.2	0.165	52%	−55
P3	3:4:3:0.3	4	4 min	390 ± 1.3	0.599	75%	−37

P6	4:4:3:0.3	4	4 min	290±0.8	0.599	65%	−47
P7	5:2:3:0.3	4	4 min	328±0.6	0.230	69%	−30
P8	5:3:3:0.3	4	4 min	425±1.2	0.165	70%	−22
P9	5:4:3:0.3	4	4 min	609±0.6	0.599	45%	−41
P10	8:2:0.3	4	4 min	425±0.6	0.215	**35**	−59
P11	**7:3:0.3**	**4**	**4 min**	**125±0.3**	**0.316**	**64**	**−28**
P12	6:4:0.3	4	4 min	356±0.9	0.366	**52**	−38

Lipid Ratio P1-P9 (DPPC: DOPE: Cholesterol: DSPE-PEG_{2000}); P10-P12 (HSPC: Cholesterol: DSPE-PEG_{2000})
Bold letters highlight the highest drug release in both formulations, whether HSPC or pH-sensitive

Blood compatibility analysis

The blood compatibility of the liposomal formulations was assessed through PT and APTT analyses, evaluating their impact on the extrinsic and intrinsic pathways of blood coagulation. The PT and APTT times for the optimized pH-sensitive formulation (P5) were 12 s and 43 s, respectively, while the HSPC liposomal formulation (P11) exhibited 14 s and 46 s, respectively. These times, slightly lower than the pH-sensitive formulation, demonstrated a normal safe margin compared to the negative control (saline). The findings as in Table 15 indicated that the liposomal formulations were not disrupted the blood coagulation pathways, thus confirming their biosafety.

Table 15. Coagulation assay by prothrombin time (PT) and activated partial thromboplastin time (APTT) assessment

S. No	Formulation	APTT Assay	PT assay
1	Normal patient value	45 s	15 s
2	P5	43 s	12 s
3	P11	46 s	14 s

MTT assay: cell viability assessment

The cytotoxicity of HSPC and pH-sensitive liposomes was assessed through an MTT assay on A549 cell lines. The results revealed that both liposomal formulations exhibited cytocompatibility across all concentrations tested. Notably, the MTT profiles illustrated that HSPC and pH-sensitive liposomes displayed significant toxicity toward A549 cell lines compared to blank media. The calculated IC_{50} values further emphasized the formulation's cytotoxic effects, with pH-sensitive formulation, conventional formulation, free drug, and docetaxel having IC_{50} values of 31.6181, 30.2012, 38.8108, and 4.72867, respectively (Fig. 3i, Table 16).

Table 16. Concentration, viability and IC_{50} of formulation pH-sensitive (P5) and HSPC liposomes (P11), free dye, Docetaxel (DTX)

Conc. (μg/mL)	P5		P11		Free Dye		DTX	
% viability	SD	% viability	SD	% viability	SD	% viability	SD	2.5
94.88542	4.718652	93.40623	4.654433	98.67076	1.0087	59.71	0.61	5
90.52881	5.725947	89.45039	5.152342	91.2	0.702183	57.6	0.85	10
86.21429	5.132336	86.23587	4.221246	90.0381	1.165957	51.95	0.87	20
79.00585	4.603671	77.53959	5.348681	83.30548	0.741875	38.04	1.27	40
54.26522	4.212066	54.25856	4.32278	58.35145	5.786023	32.16	1.74	80
43.68431	4.356637	44.89444	4.736364	46.88714	0.483777	26.85	0.57	IC_{50} (μg/mL)

The comprehensive experimental results elucidated the vesicular attributes, drug incorporation efficiency, drug release behavior, blood compatibility, and cytotoxicity profiles of the developed liposomal formulations. These findings collectively contribute to a comprehensive understanding of the formulation’s potential biomedical applications and safety considerations.

Discussion

The binding of BBG-250 to the inter-subunit allosteric pocket of the P2X7 receptor in a noncompetitive manner has been established as a safe approach for human administration. In this study, before doing the formulation study we proved interaction between P2X7 and BBG-250 through Docking Study (Fig. 1), and computational ADME study was observed from the above study (Tables 7, 8, 9, 10, 11, 12) that BBG-250 has high GI absorption, not crosses the blood–brain barrier, having water solubility, considerable lipophilic profile. BBG-250 did not follow the Lipinski rule because of higher molecular weight (>500), so due to this inference, we aimed to explore the potential of liposomal formulations for delivering BBG-250, focusing on formulation comparison, drug release, blood compatibility, and in vitro cytotoxicity. Our findings shed light on the effectiveness of liposomal encapsulation and its implications for antitumoral activity. Formulation optimization is crucial for successful drug delivery. We compared two liposomal formulations: a conventional one composed of HSPC and cholesterol in a 7:3 ratio, and a pH-sensitive formulation consisting of DPPC, DOPE, DSPE-PEG_{2000}, and cholesterol in a 4:3:3:0.3 ratio, both incorporating BBG-250. Microscopic analysis confirmed the vesicles' spherical morphology and uniform size distribution. Size plays a pivotal role in liposome behavior within biological systems. To ensure effective delivery and prevent undesirable accumulation, liposome size is typically maintained below 200 nm. In our study, the conventional and pH-sensitive

formulations exhibited sizes of 118 ± 1.2 nm and 125 ± 0.3 nm, respectively, optimizing their potential for tumor targeting while avoiding lung deposition and macrophage clearance. Zeta potential reflects the stability of liposomal suspensions under physiological conditions. The zeta potentials of the conventional and pH-sensitive formulations were − 25 and − 28 mV, respectively, suggesting adequate stability due to the repulsion between particles. The entrapment efficiency and drug loading of both formulations increased with higher drug-to-lipid ratios, indicative of the formulation's capacity to accommodate BBG-250. This finding supports the feasibility of tailoring drug loading based on therapeutic requirements. In vitro, drug release profiles are critical indicators of formulation performance. pH-sensitive and conventional liposomes exhibited superior drug release, reaching 95% and 74.95%, respectively, within 24 h, compared to the plain drug solution. This enhanced drug release kinetics in the pH-sensitive formulation aligns with its potential for controlled and targeted drug delivery.

Blood compatibility is a crucial factor for intravenous administration. Our study demonstrated the safety of both conventional and pH-sensitive liposomal formulations in terms of blood coagulation parameters. This highlights their potential for clinical translation and systemic administration. Cytotoxicity assessment using A549 cell lines revealed the effectiveness of both HSPC and pH-sensitive liposomes at various concentrations. The calculated IC_{50} values of 30.2012 ug/ml and 31.6181 ug/ml for HSPC and pH-sensitive liposomal formulations, respectively, indicate their significant toxicity compared to blank media. Notably, the IC_{50} values were approximately 7–eightfold higher than that of docetaxel, a reference drug. In conclusion, nanoscale liposomal formulations offer promising potential for cancer therapy due to their efficient drug delivery and tumor cell penetration capabilities. Our results indicate that liposomes composed of natural SL can serve as stable, biocompatible carriers for BBG-250 delivery, demonstrating the potential for cancer treatment, albeit with less potency compared to the reference drug, docetaxel. Future research could focus on further enhancing liposomal formulation characteristics to optimize antitumoral activity and clinical translatability.

Conclusion

In conclusion, this study establishes the safe and noncompetitively binding nature of BBG-250 to the inter-subunit allosteric pocket of the P2X7 receptor for human administration. Computational ADME analysis revealed favorable pharmacokinetic characteristics for BBG-250, while subsequent exploration into liposomal formulations demonstrated their potential as effective carriers for the compound. Both conventional and pH-sensitive liposomes exhibited promising characteristics, including uniform size distribution, stability, and controlled drug release. Notably, pH-sensitive liposomes demonstrated superior drug release kinetics. These findings underscore the potential of liposomal delivery systems for BBG-250, offering a viable avenue for enhancing cancer therapy. Further refinement of these formulations could lead to optimized treatment strategies in the future.

ABSTRACT (ENGLISH)

Background

People of Mediterranean descent are primarily affected by the autoinflammatory genetic condition known as familial Mediterranean fever (FMF). The disease is resistant to colchicine therapy in 10–20% of patients. Numerous recent animal studies showed promising results of extra virgin olive oil (EVOO) to control inflammation. The objective of this

study was to assess the effectiveness of combining EVOO with colchicine in the treatment of colchicine-resistant familial Mediterranean fever (CRFMF) patients.

Results

Both the frequency of episodes and inflammatory indicators significantly decreased after a three-month course of daily EVOO treatment with colchicine. The average erythrocyte sedimentation rate (ESR) of patients was 78.6 mm/h before the EVOO administration, and it dropped to 27.8 mm/h, after that. Additionally, after taking EVOO, the mean serum amyloid A (SAA) decreased from 123.82 mg/dl to 59.78 mg/L. Also, the average C-reactive protein (CRP) decreased from 34.22 to 7.84 mg/dl following its administration; the mean nucleotide-binding domain, leucine-rich-containing family, and pyrin domain-containing-3 (NLRP3) level decreased from 134.92 to 64.23 pg/ml. The mean caspase-1 level decreased from 7.8 to 4.98 ng/ml; and the mean levels of cytokines, interleukin 6 (IL-6), interleukin 1 beta (IL-1 β), and tumor necrosis factor-alpha (TNF-α) decreased from 9.8, 18.14, and 52.7 pg/ml, respectively, to 5.95, 12.51, and 29.39 pg/ml. Finally following the administration of EVOO, there was a notable overall improvement in the quality of life of (CRFMF) patients.

Conclusion

EVOO demonstrated a significant positive impact when paired with the tolerated dosage of colchicine in the management of CRFMF. Improvements were observed in both clinical and laboratory settings, including a reduction in the attack frequency and serum levels of inflammatory markers, such as NLRP3, caspase-1, ESR, CRP, IL-1β, IL-6, and TNF-α without any negative side effects.

FULL TEXT

Background

The autoinflammatory condition known as familial Mediterranean fever (FMF) is represented by repeated episodes of fever, polyserositis, arthritis, and skin manifestations as well as a strong acute-phase response lasting 12–72 h [1, 2]. It is the most prevalent autoinflammatory illness globally [3, 4]. In 1945, the illness was initially referred to as “benign paroxysmal peritonitis.” People in the Mediterranean region, such as Arabs, Greeks, Italians, and Turks, are primarily affected by the disease, but, throughout the twentieth century, migration and travel have increased its incidence [5, 6]. Prodromal signs of FMF include pain in the area where the flare is expected to occur one or two days before symptoms manifest. FMF fever is usually recurring and of a high degree (>38 °C). It usually rises quickly for one to three days, reaching a plateau then falls off [7].

Severe abdominal pain and stiffness are brought on by peritoneal inflammation (aseptic peritonitis), which starts locally and spreads throughout the body. It is possible to develop pericarditis or pleuritis, in the form of unilateral chest pain [8]. When FMF attacks occur in children, arthritis is frequently the accompanying symptom. It is usually monoarticular and commonly affects the big joints in the lower limbs such as ankles and knees. These arthritis symptoms can arise during FMF attacks and may also occur intermittently between episodes [9]. The dermatological manifestation of FMF is the skin lesions that resemble warm, painful erysipelas on the lower limb. Renal amyloidosis is the main FMF consequence that leads to end-stage renal failure [10, 11].

FMF arises from a mutation in the MEFV gene found on chromosome 16's short arm (p). This specific gene is responsible for producing pyrin protein, comprising 781 amino acids [12].

Over the past few years, evidence linking inflammation to FMF has grown. Pyrin is a member of the cytosolic pattern recognition receptors (PRRs) group expressed in neutrophils, eosinophils, monocytes, dendritic cells, and synovial fibroblasts. It is responsible for regulating innate immune responses upon detecting specific signals from pathogens or host-derived danger molecules, known as pathogen/danger-associated molecular patterns. When activated, pyrin, along with other receptors, forms inflammasomes, which are multiprotein signaling complexes. These inflammasomes recruit and activate caspase-1, an enzyme involved in promoting inflammation. Active caspase-1 facilitates the proteolytic maturation and secretion of cytokines, such as interleukin (IL)-1β that triggers a form of cell death characterized as pyroptosis, which is necrotic in nature [13, 14]. Mutation of MEFV genes disrupts pyrin protein and its function leads to unrestricted pyrin activity, causing excessive production of the NLRP3 inflammasome which in turn triggers the complete inflammatory cascade. This uncontrolled inflammation is

responsible for the characteristic febrile inflammatory episodes seen in FMF [15]. Therefore, addressing these inflammatory pathways can stop attacks from happening, return inflammation to normal in between episodes, and stop amyloidosis from developing [16].

The clinical presentation of FMF varies greatly, depending on the specific sequence variations found in the MEFV gene [17]. According to the European Alliance of Associations for Rheumatology (EULAR) recommendations, the objective of treating FMF is to achieve control over acute episodes, reduce chronic and subclinical inflammation, and prevent consequences, primarily renal amyloidosis that leads to renal failure [18].

Since 1972, colchicine has remained the primary treatment for FMF. This alkaloid compound inhibits a variety of cellular processes, including cell adhesion, microtubule assembly, and inflammasome activation. Administration of colchicine ultimately helps prevent FMF flare-ups in patients receiving this treatment [19]. However, approximately 10–20% of FMF patients exhibit resistance to colchicine. Colchicine resistance is typically described as experiencing one or more attacks per month even though receiving the maximum tolerated dose for six months, while others may only partially respond or be intolerant to high doses of colchicine. This poses a challenge for rheumatologists in managing such cases [20].

On the other hand, macrophages are crucial components of the immune system, playing a central role in the regulation of infections and inflammatory processes through their involvement in both innate and adaptive immune responses [21]. Regrettably, FMF patients with MEVF mutations experience an overabundance of macrophage activation. When macrophages are stimulated, they release pro-inflammatory cytokines such as IL-1β, IL-6, and TNF-α [22].

Extra virgin olive oil (EVOO) is commonly used as a dietary supplement or an over-the-counter remedy for various health benefits. EVOO comprises over 200 distinct chemical compounds, encompassing fatty acids, sterols, terpenoids, carotenoids, tocopherols, flavonoids, and olive polyphenols such as tyrosyl, hydroxytyrosol, oleuropein, oleacein, olive ligstroside, and oleocanthal (OC) [23]. Among these polyphenols, OC has garnered significant scientific attention due to its intriguing biological activities, despite representing only 10% of the olive's polyphenol content (100–300 mg/kg olive oil). This variability is influenced by various factors, including the type of olive cultivars, the environmental conditions in which the olives are grown, agricultural practices employed, the maturity of the olives, the methods used for processing the olives into oil, as well as the storage and heating conditions [24].

Research has revealed that OC exhibits potent anti-inflammatory properties [25]. Given that the development of numerous chronic diseases involves both inflammatory and oxidative components. OC was shown to be able to block catabolic genes like Matrix metalloproteinase-13 and ADAM Metallopeptidase with Thrombospondin Type 1 Motif (ADAMTS-5) as well as inflammatory genes like IL-6, IL-8, cyclo-oxygenase-2, nitric oxide synthase-2, macrophage inflammatory protein-1 alpha, TNF-α, and lipocalin-2 in osteoarthritis chondrocytes and macrophages studies. These findings demonstrated the compound's significance in the management of rheumatic and inflammatory disorders by controlling the NF-kB and mitogen-activated protein kinases pathways [26]. Additional recent data demonstrated that when EVOO polyphenolic extract OC and oleoresin were added to human synovial SW982 cell line, a substantial decrease in IL-1β-induced TNF-α and IL-6 production was observed [27].

Oleocanthal shows promise as a potential agent for preventing such conditions. It is worth noting that oleocanthal may work with other bioactive compounds present in EVOO to maximize its therapeutic potential. Additionally, several studies have suggested that combining colchicine with biological therapy targeting FMF inflammatory markers can be valuable for patients who do not respond adequately [28, 29]. However, the high cost associated with lifelong treatment using biological therapy and concerns about safety, [30] including an increased risk of cancer and infection, have prompted the need for alternative approaches [31]. Therefore, our study aims to investigate the effect of using extra virgin olive oil, which is rich in polyphenols, in combination with colchicine to achieve better control of attacks in FMF patients who have not responded to colchicine treatment alone clinically and laboratory, furthermore to determine the molecular mechanisms by which EVOO exerts its effect if found.

Patients and methods

This study was a single-center prospective single-arm study design. A total of 50 patients were assessed for

eligibility in this single-arm study, 20 patients were excluded (17 patients did not meet the inclusion criteria, and three patients refused to consume olive oil due to taste preferences). Then, 30 FMF patients continued the study. Among the participants, there were 14 males and 16 females who were being monitored at the Pediatric Rheumatology Outpatient Clinic of Children's Hospital (Pediatrics Specialized Hospital) at Cairo University. The study has lasted three months, starting in October and concluding at the end of December. The patients included in the study were children ≤ 16 years old, diagnosed with FMF based on the Yalcinkaya new FMF criteria [32] and showing +ve MEFV gene mutation who had at least one attack per month despite adhering to the maximum tolerated dose of colchicine treatment (up to 2 mg/day). The researchers assessed the participants' compliance by asking them and their relatives, and by counting the number of the remaining medication in the strip inside the package with the patient at each visit. It was observed that despite the patients taking their medications correctly, their response to colchicine was still limited, and hence, they were classified as colchicine resistance FMF patients [33].

Patients over 16 years old or those with conditions that could impact compliance with the treatment protocol were excluded from the study. Patients receiving concurrent medications with biological or disease-modifying antirheumatic drug (DMARD), systemic steroids, or those with various autoimmune and other autoinflammatory diseases that could affect FMF activity, such as systemic lupus or juvenile idiopathic arthritis, Crohn's disease, ulcerative colitis, diabetes mellitus, gastrointestinal diseases, active ischemic cardiovascular disease, congestive heart failure, renal amyloidosis, or chronic renal failure, were also excluded.

Following the protocol's (N.320.2023) approval by Clinical Research Ethics Committee and the acquisition of informed consent from each patient's parents. A thorough history was obtained of each patient, including the age at which symptoms first appeared, the age of diagnosis, the length of the illness, the characteristics of attacks (frequency, duration, and clinical signs), and the dosage of colchicine the patient had taken. Quality of life (QOL), baseline data, and a physician checkup were completed during the first visit and evaluated again at the end of the study. The patient data confirmed the MEFV gene alterations.

Intervention and assessment

Over three months, the patients in the study received the maximum tolerated dose of colchicine (COLCHICINE OPO CALCIUM, France) along with a daily oral dose of (15–30 ml) of EVOO [34]. The specific EVOO used was chosen by an expert based on its high content of polyphenolic compounds, which are recognized by their characteristic smell and strong taste on the back of the tongue. The selected EVOO was obtained from ELSALHYA company at the Ministry of Agriculture outlet in Dokki, Cairo. To preserve the phenolic compounds, EVOO was stored in dark glass containers to protect it from light.

The patients were given instructions to maintain diaries, recording any concomitant medications used, and FMF attacks experienced, including their duration and affected sites, the need for analgesics, hospital visits during attacks, and the number of school days missed due to pain or FMF-related attacks. Additionally, one of the investigators was responsible for contacting the patients to ensure treatment compliance and to assist in interpreting symptoms as true attacks or not.

To evaluate QOL, the patients' pre- and post-treatment assessments were conducted using the Arabic-translated version of the PedsQL 4.0 Generic Core Scales (Mapi Research Trust, Lyon, France) [35]. This self-report scale covered physical functioning (eight items), emotional functioning (five items), social functioning (five items), and school functioning (five items). The scale items were scored on a 5-point Likert response scale ranging from “never a problem” to “almost always a problem.” The scores were reverse scored and linearly transformed to a 0–100 scale, where higher scores indicated a better quality of life.

Blood samples were collected from the patients at the beginning and the end of three months. ESR was measured, and then, samples were allowed to clot before being centrifuged at 10,000 rpm for 20 min. The separated serum was frozen and stored at -80°C until further analysis. The laboratory tests conducted on the serum samples included CRP screening using the latex agglutination test [36] and confirmation via nephelometry analysis, serum amyloid A (SAA) analysis using ELISA kits catalog no. CSB-E08589h supplied by (Cusabio, USA) according to the

manufacturer's instruction [37]. IL-1β levels catalog no. MBS012415, IL-6 levels catalog no. MBS355306, TNF-α levels catalog no. MBS2502004, NLRP3 levels by NACHT, LRR, and PYD domains-containing protein 3 (NLRP3/C1orf7/CIAS1/NALP3/PYPAF1) catalog no. MBS917009, Caspase-1 catalog no. MBS264676. All kits of IL-1β, IL-6, TNF-α, NLRP3, and Caspase-1 were ELISA kits supplied by (MyBioSource, S, USA) according to manufacturer instructions.

Statistical analysis

Sample size calculation

To obtain a two-sided 95% confidence interval, a total of 30 patients were required based on a previous study [38]. Initially, thirty-three FMF patients were included but three patients discontinued their participation, resulting in a dropout rate of 1%. The sample size estimation was conducted using the Epi info7 statistical package, with a power of 95% and a type I error of 0.05. The data collected at the end of the study were coded and entered into the Statistical Package for the Social Sciences (SPSS) version 26 (IBM Corp., Armonk, NY, USA). Quantitative data were summarized using measures such as mean, standard deviation, median, minimum, and maximum, while categorical data were summarized using frequency (count) and relative frequency (percentage). For comparing serial measurements within each patient (before and after), a paired t test was used for normally distributed quantitative variables, whereas the nonparametric Wilcoxon signed-rank test was employed for non-normally distributed quantitative variables [39]. *P* values less than 0.05 were considered statistically significant.

Results

Participant characteristics

All participants in this study showed genetic mutation as the following: The allelic frequency of MEFV mutations was M694V (36.6%), M694I (30%), E148Q (20%), and M680I (13.3%).

As illustrated in Fig. 1 ($n=30$), patients were included in this study, 16 females (53.3%) and 14 males (46.7%) with a mean age of 6.25 ± 3.07 years at diagnosis, and a mean disease duration of 5.54 ± 3.19 years.

The percentage of male and female participants

Clinical presentation data

The main symptoms of the studied group during periods of active disease were abdominal pain (100%), arthralgia (80%), fever (53.3%), and pleurisy (46.7%) Fig. 2.

Fig. 2 [Images not available. See PDF.]

The percentage of the main symptoms observed within the studied group

Numbers of attacks before and after receiving EVOO

All participants were taking the maximum tolerated dose of colchicine that was not enough to control the attacks and they were in need for frequent intake of analgesics. However, they exhibited resistance to these treatments, experiencing frequent attacks at varying intervals. These ranged from two attacks every two weeks (four attacks per month) for 6.7% of participants, to two attacks every four weeks (two attacks per month) for 23.3% of participants. Most participants experienced one attack every two weeks (33.3%) or one attack every three weeks (33.3%) before starting a daily regimen of extra virgin olive oil (EVOO), as shown in Fig. 3A. After three months of daily EVOO consumption, a reduction in the number of attacks was observed. Specifically, 40% of participants had one attack every four weeks, while 36.7% experienced one attack every six weeks, as depicted in Fig. 3B.

Fig. 3 [Images not available. See PDF.]

A and **B** Comparison between numbers of attacks before and after EVOO administration

Inflammatory markers

Analysis of acute-phase reactants and cytokine levels, which indicate the presence of inflammation, before and after the administration of extra virgin olive oil (EVOO), demonstrated a significant reduction in all inflammatory markers.

Before receiving EVOO, the mean ESR was 78.6 mm/h, which decreased to 27.8 mm/h. after treatment with a *P* value less than 0.001. The mean SAA level decreased from 123.82 to 59.78 mg/L after EVOO administration, also with a *P* value less than 0.001. The mean CRP level decreased from 34.22 to 7.84 mg/dl after EVOO treatment, with a *P* value of 0.007. Furthermore, the mean concentrations of NLRP3 dropped from 134.92 to 64.23 pg/ml with a *P* value less than 0.001 (Fig. 4A–D).

Fig. 4 [Images not available. See PDF.]

A–D Comparison between levels of acute-phase reactants (A: ESR; B: SAA; C: CRP and D: NLRP3 before and after EVOO administration in the study group. ESR: Erythrocyte sedimentation rate; SAA: serum amyloid A; CRP: C-reactive protein; NLRP3: nucleotide-binding domain, leucine-rich-containing family, pyrin domain-containing-3 (n = 30). # # (*p* value: <0.001) Significantly different as compared to the patient in the group before EVOO administration, using a paired t test for normally distributed quantitative variables, whereas using Wilcoxon signed-rank test for the nonparametric data

Additionally, the mean caspase-1 level decreased from 7.8 to 4.98 ng/ml with a *P* value less than 0.001. The mean levels of IL-6, IL-1β, and TNF-α were also reduced from 9.8, 18.14, and 52.7 pg/ml, respectively, to 5.95, 12.51, and 29.39 pg/ml, respectively, with a *P* value less than 0.001. These findings indicate a significant difference after the administration of extra virgin olive oil (EVOO), (Fig. 5A–D).

Fig. 5 [Images not available. See PDF.]

A–D Comparison between inflammatory markers (**A**: Caspase-1; **B**: IL-6; **C**: IL-1β; &**D**: TNF-α) before and after EVOO receiving by the study group. IL-6: Interleukin-6; IL-1 ß: Interleukin-1 beta; TNF-α: Tumor Necrosis Factor Alpha. (n = 30). ** (*p* value: <0.001) Significantly different as compared to the patient in the group before EVOO administration, using a paired t test for normally distributed quantitative variables, whereas using Wilcoxon signed-rank test for the nonparametric data

Quality of life (QOL)

The subjects were assessed using the Arabic version of the PedsQL 4.0 Generic Core Scales before and after receiving olive oil. The administration of EVOO led to a significant enhancement in the overall quality of life, as evidenced by significantly higher mean scores in school, emotional, social, and physical domains (*p* value: <0.001) (Table 1).

Table 1. Comparison between PedsQL domains of functioning before and after receiving EVOO

Score Item	Before	After
School	8.33 ± 5.45	89.79 ± 6.83 **
Emotional	10.00 ± 4.89	83.12 ± 13.97 **
Social	7.08 ± 5.50	84.17 ± 9.74 **
Physical	7.16 ± 3.96	96.48 ± 10.80 **

Data are expressed as mean ± SD (n = 30)

** Significantly different as compared to mean value in the group before EVOO administration using a paired t test was used for normally distributed quantitative variables, whereas the nonparametric Wilcoxon signed-rank test was employed for non-normally distributed quantitative variables (*p* value: <0.001)

Discussion

Colchicine resistance is characterized by a higher frequency or increased severity of attacks or elevated levels of

acute-phase proteins such as CRP and/or SAA (greater than 1.5 times the upper limit between attacks) [33]. Clinically, colchicine resistance is defined as at least one attack per month for six months at the maximal tolerable dose of colchicine in totally compliant individuals [40, 41].

In the present study, FMF patient-reported manifestations were considered attack only if they met the specific criteria identifying an attack and were confirmed by a study team member. In summary, an attack was defined as having the following characteristics: a fever equal to or greater than 38 °C, lasting from 6 h up to 7 days, and along with painful symptoms in the abdomen with signs consistent with peritonitis, chest symptoms consistent with pleuritis, joints symptoms consistent with monoarthritic involvement of large lower extremity joints, or skin symptoms. For evaluation of improvement in those patients, we used a modified FMF50 score. According to this scoring system, the fulfillment of five out of six criteria was considered an improvement [42]. This score required improvement by≥50 in the following: attack frequency, attack duration, global patient assessment, global physician assessment, frequency of attacks with arthritis, and levels of acute-phase reactants or the normalization of these markers. In our study, quality-of-life values (substituting patient global assessment in the original score). The measurements taken at the beginning of the study were compared to those obtained at the end to assess changes according to these criteria.

There is abundant evidence encouraging the significant role of EVOO in safeguarding against amyloidosis, a condition that can result in renal failure among patients with FMF. This protective effect is attributed to EVOO's capability to reduce the levels of SAA. Marina Aparicio et al. conducted a study demonstrating that a diet abundant in extra virgin olive oil can alleviate kidney injury in a pristane-induced model of systemic lupus erythematosus model [43]. Our own results align with these previous findings, as we observed a significant drop in SAA levels after three months of EVOO treatment.

Research has demonstrated that the underlying cause of FMF, an autoinflammatory illness, is mutations in the genes that produce pyrin [12]. This autoinflammation is mediated by IL-1β. Many studies have revealed that pyrin forms an inflammasome, which is a complex formed by the oligomerization of a nucleotide-binding domain-like receptor (NLR) in response to various pathogenic or sterile danger signals. This inflammasome facilitates the maturation of IL-1β by activating caspase-1 and triggers the pro-inflammatory cytokines release, including IL-1β [13, 44]. Another study carried out by Omenetti et al. also showed that those with FMF have increased NLRP3-dependent IL-1β release [45, 46]. It was discovered that OC inhibits both canonical and non-canonical inflammasome signaling pathways. Therefore, EVOO with oleocanthal properties may be a viable natural remedy for immune-inflammatory disorders in the future [47, 48]. In the current study, after three months of daily EVOO consumption, a significant reduction in the number of FMF attacks was observed. The levels of NLRP3 showed a significant reduction. Additionally, the mean caspase-1, IL-6, IL-1β, and TNF-α levels also showed marked reduction and according to much scientific evidence this improvement may be due to the oleocanthal content of EVOO.

Several studies, both clinical and experimental, revealed novel, relevant pharmacological properties of OC in a range of inflammatory disorders. Mice fed an oleocanthal-rich diet in an animal model of collagen-induced arthritis demonstrated significantly lower levels of matrix metalloproteinase-3, IL-17, TNF-α, IL-1β, IFN-γ, and IL-6 than mice fed on diet lacking in oleocanthal [49]. The observation by Rosillo et al. [50] of a significant reduction in IL-1β-induced TNF-α and IL-6 release in human synovial SW982 cells after exposure to a polyphenolic extract primarily composed of oleocanthal and oleacein from EVOO lends credence to these results. These findings have been confirmed also by Scotece et al., who found that OC has an inhibitory effect on particular cellular pathways engaged during inflammation in human osteoarthritis. As a result, genes linked to inflammation, such as COX-2, MIP-1α, TNF-α, IL-6, IL-8, and lipocalin-2, were expressed less frequently. The study also showed that OC could stop the action of an inflammatory protein called macrophage inflammatory protein-1 alpha [48].

These results were consistent with earlier studies [51] that showed OC can suppress the upregulation of pro-inflammatory signaling molecules mediated by lipopolysaccharides, such as IL-6, IL-1β, TNF-α, macrophage inflammatory protein-1α, and granulocyte macrophage-colony stimulating factor (GM-CSF).

Furthermore, previous study suggested that phenolic components in EVOO have an anti-inflammatory and

immunomodulatory role in systemic lupus erythematosus patients and may therefore be taken into consideration as a dietary component in the management of systemic lupus erythematosus [52]. Another study found that EVOO experienced synergistic analgesic, antipyretic, and anti-inflammatory properties when combined with ibuprofen in various albino mouse experimental models [53].

The current study findings indicate a significant improvement in the symptoms of abdominal aseptic peritonitis, which could be attributed to the capacity of oleocanthal present in EVOO to modulate peritoneal macrophages activation. This finding was supported by Montoya et al., who noticed that OC was able to attenuate macrophage activation induced by lipopolysaccharide via regulation of inflammasome: nuclear factor erythroid 2-related factor 2, and mitogen-activated protein-kinase signaling pathways.[51].

Furthermore, our findings also indicate a significant improvement in the school performance of the patients under study after three months of EVOO administration. This aligns with the research undertaken by Al Rihani et al., who demonstrated that EVOO rich in oleocanthal can restore the function of the blood–brain barrier and reduce Alzheimer's-associated pathology by inhibiting NLRP3 inflammasome, thereby reducing neuroinflammation [54].

The benefits of EVOO and its phenolic components are currently well understood. These benefits include their biological characteristics and antioxidant potential in thwarting immune-mediated inflammatory reactions. These include inflammatory bowel disease, cancer, diabetes, obesity, rheumatoid arthritis, atherosclerosis, and neurodegenerative disorders. The growing body of research conducted on this subject provides strong evidence, suggesting that olive polyphenols have the potential to be effective in addressing chronic inflammatory conditions. Furthermore, their potential clinical applications make them promising candidates in the fight against such inflammatory states.

Conclusion

Our study revealed that combining extra virgin olive oil, which is abundant in polyphenols, with the maximum tolerated dose of colchicine effectively reduced both the intensity and frequency of FMF attacks. Additionally, this treatment approach showed promising results in improving the overall quality of life for the patient. These findings provide hope for individuals with FMF, as it offers the potential for a better quality of life with reduced complications from the disease itself and the use of various biological therapies typically employed in FMF cases resistant to conventional treatments.

Limitations

It is a relatively short duration study, and it did not involve random assignment of participants to different groups (as it was pre- and post-study design). Furthermore, because all patients were recruited from a single hospital's Pediatric Rheumatology Outpatient Clinic, the findings of our investigation require confirmation in large multicenter prospective randomized future trials lasting considerably longer.

Pharmaceutical significance of Schiff bases: an overview

Mushtaq, Irfan1 ; Ahmad, Maqbool1; Saleem, Muhammad1; Ahmed, Adnan21 Ghazi University, Department of Chemistry, Dera Ghazi Khan, Pakistan (GRID:grid.448869.f) (ISNI:0000 0004 6362 6107)2 Gomal University, Institute of Chemical Sciences, Dera Ismail Khan, Pakistan (GRID:grid.411749.e) (ISNI:0000 0001 0221 6962)

ABSTRACT (ENGLISH)

Schiff bases are a diverse group of organic compounds with great pharmaceutical importance due to the presence of carbon–nitrogen double bonds (–C=N–). These compounds are synthesized by the condensation reaction between a primary amine and an aldehyde or ketone in a suitable solvent such as methanol. These compounds have shown antibacterial, antifungal, antiviral, anti-inflammatory, and antioxidant activities, which have garnered the attention of organic chemists in synthesizing these compounds. Recent advances have been summarized in this review paper mainly including compounds with potential antibacterial, antifungal, and antiviral activities. Synthetic schemes are included to provide a better understanding of the Schiff base synthesis mechanism. This review paper will provide a way forward for the pharmaceutical chemist to synthesize new compounds with potential biological activities.

FULL TEXT

Background

Hugo Schiff initially described in 1864, the synthesis of Schiff bases by a condensation reaction between a primary amine and multiple carbonyl compounds [1–6]. These Schiff bases are mostly referred to as the azomethine group represented in organic chemistry as $RHC=N–R^1$ [7, 8]. The corresponding alkyl, aryl, or heterocyclic groups can be the R or R^1 in Schiff bases. The Schiff bases are mostly referred to as the imines or the azomethine groups in synthetic chemistry [9, 10]. The presence of lone pairs is attributed to its sp^2 hybridization as the compound is highly reactive due to carbon and nitrogen atoms. Due to the presence of strong properties like adaptability, simplicity, and functionality, these compounds are of high importance [11, 12]. The significance is of high importance in biological assays that the Schiff bases can form diverse functional groups. An advanced approach to the existing nature of Schiff bases can be helpful nature to tackling the biological gaps and increasing the efficacy of Schiff base drugs [13–17] (Fig. 1).

Fig. 1 [Images not available. See PDF.]

General structure of Schiff bases

The discovery of Schiff bases dates back to the nineteenth century during which a chemist named “Hugo Schiff” first documented a reaction showing condensation between amines and carbonyl functional groups [13, 18–21]. In contemporary times, this domain of scientific inquiry about Schiff base coordination chemistry has seen significant growth and expansion [22, 23]. The significance of Schiff base complexes in the fields of material science, biomedical applications, bioinorganic chemistry, encapsulation processes, supramolecular chemistry, catalysis, and separation, and the generation of molecules with exceptional characteristics and structures has been widely acknowledged and extensively examined in the existing literature [24–27]. The literature has documented the use of Schiff bases derived from salicylaldehydes as agents for regulating plant development, as well as exhibiting antibacterial or antimycotic properties [28–30]. Schiff bases have been shown to possess analytical uses as well. The significance of these bases helps explain the difficult mechanisms inside biological systems and gives proper meaning to the imine group activity. These also provide broad-spectrum activity against several species, including *Candida*, *Plasmopora viticola*, *Trichophyton gypsum*, *Staphylococcus aureus*, *Erysiphe graminis*, *Mycobacterium*, *Albicans*, *Bacillus polymyxa*, and *Escherichia coli* [31–34].

Furthermore, the Schiff bases are significant in metal complexes due to their unique ability to form a structure holding transition central metals with the reactants of the condensation reaction as illustrated in the literature for metals like Hg(II), Gd(III), Cu(II), Co(II), Ni(II), Zn(II), Y(III), Al(III), Pb(II), and Ag(II) [35–44]. Extensive research has been conducted on Schiff bases due to their significant catalytic characteristics. These compounds exhibit catalytic properties when used in the process of hydrogenating olefins. Biomimetic catalytic processes are applicable in several contexts. One intriguing use of Schiff bases is in their utilization as a very efficient corrosion inhibitor, owing to their inherent capability to autonomously generate a monolayer on the targeted surface for protection. Numerous

commercial inhibitors often include aldehydes or amines; nevertheless, it is hypothesized that the enhanced efficacy seen in some instances is attributed to the presence of Schiff bases, likely owing to the presence of the C=N link [45–48]. Chemisorption is the primary mode of combination and the combinatorial mechanism of metals with inhibitors. The inhibitor molecule needs to possess active sites that are capable of establishing chemical connections with the metal surface via the process of electron transfer. In instances of this kind, the metal functions as an electrophile, while the inhibitor assumes the role of a Lewis base. The protective chemical has nucleophilic centers, namely oxygen and nitrogen atoms, that possess unshared electron pairs that are easily accessible for electron sharing. In conjunction with the atoms of the benzene rings, these entities provide several absorption sites for the inhibitor, facilitating the establishment of a stable monolayer [49–51]. The biological features of Schiff bases, including their antibacterial and antifungal activity, have been documented in the literature. Metal complexes have garnered significant attention in the scientific community due to their extensive investigation and exploration, primarily owing to their potential use in anticancer and herbicidal contexts. These organisms function as exemplars for species that have significant biological importance [52–58].

Main text

Pharmaceutical significance of Schiff bases

Antibacterial

Antimicrobials are well recognized as a very effective therapeutic approach in the field of medicine [59]. However, the efficacy of antimicrobials is significantly hindered by the emergence of antibiotic-resistant bacteria. The formation of Schiff bases of amino acids was achieved by the condensation reaction between isatin and several amino acids, including phenylalanine, leucine, cysteine, alanine, valine, and glycine. These amino acids exhibited notable antibacterial efficacy [60, 61]. Schiff bases derived from cellulose are produced by the condensation reaction between p-aminophenol and aldehyde moieties and have shown antibacterial efficacy against, *Staphylococcus aureus*, *Escherichia coli*, and *Enterococcus faecalis* [62].

A new collection of aromatic Schiff bases was prepared using a reflux (condensation) reaction between 5-aminopyrazoles and aromatic aldehydes [63]. The synthesis process yielded large quantities of the desired compounds. These Schiff bases were then assessed for their antibacterial efficacy through in vitro experiments against “multi-drug resistant bacteria (MDRB).” In normal circumstances, the majority of the compounds of Schiff bases exhibited superior biological efficacy. Furthermore, the molecular docking investigation revealed that kinase inhibition had a beneficial impact on the activity of dihydrofolate reductase enzymes and *Staphylococcus aureus* DNA gyrase. In addition, the data for drug-likeness indicated that these compounds under investigation satisfy the criteria outlined by Lipinski's rule and exhibit favorable biological drug scores for various activities [64]. The first findings about the Schiff base's effectiveness in combating MDRB have significant potential as a framework for the identification of novel medicines by derivatization or modification (Scheme 1).

Scheme 1 [Images not available. See PDF.]

Synthesis of Schiff Bases **7–18** [63]

The reaction included the utilization of heteroaromatic aldehydes, which were separately reacted with aminoanthracene and aminopyrene. As a result, new Schiff base derivatives 19a–19f and 20a–20f were produced with high yields [65]. The novel synthesized compounds were subjected to several tests to evaluate their reducing power, metal chelating, DNA binding abilities, antibacterial, and free radical scavenging [66]. The radical scavenging activity of the series of compounds was much superior to that of the 19 series compounds. The compound 19c exhibited the greatest metal chelating activity. In three antioxidant test methods, the standards demonstrated greater antioxidant activity compared to the DMSO solution of chemicals. Furthermore, it was shown that both compounds exhibited potential bacterial resistance activity against the employed microorganisms. Additionally, both compounds had a strong affinity for binding to CT-DNA. The findings of this research suggest that the recently examined compounds possess the ability to attach to DNA, making them promising candidates for cancer therapy. However, it is recommended that their structural composition be further modified in further investigations [67, 68] (Scheme 2).

Scheme 2 [Images not available. See PDF.]

Synthesis of anthracene- and pyrene-based Schiff base derivatives [65]

A total of twelve Schiff bases (21a–27a, 21b–25b) were synthesized by the reaction of isatin and 5-bromoisatin with various anilines as shown in Scheme 3. The synthesis process used green chemistry principles, specifically using microwave (MW) and ultrasonic (US) assistance. The antimicrobial efficacy of each chemical was assessed against a total of nine bacterial strains, including both standard and clinical isolates, using the Agar-well diffusion technique. The minimum inhibitory concentration against *Pseudomonas aeruginosa* for 21a and 21b was found to be 78 µg/mL, which is the lowest value obtained. The identification of all synthesized substances was accomplished by the use of multiple characterization techniques including ultra-violet spectroscopy, proton nuclear magnetic resonance, infrared spectroscopy, caron-13 nuclear magnetic resonance, and microanalysis. The antibacterial activity for newly synthesized Schiff bases was rationalized by using the “Molecular Electrostatic Potential Surface (MEPS) analysis” and “Quantitative Structure–Activity Relationship (QSAR).” The findings of the QSAR analysis, which included density functional theory (DFT)-based, steric, and hydrophobic descriptors, indicate that compounds exhibiting higher hydrophobicity and lower dipole moment have antibacterial properties against “*Klebsiella pneumoniae* ATCC700603” [69].

Scheme 3 [Images not available. See PDF.]

Synthetic route of Schiff bases of isatin [69]

According to the processes shown in Scheme 4, chlorobenzene aldehydes were reacted with amino derivatives like L-cysteine by condensing the reactants in a solvent methanol to produce Schiff base **28**, and methoxybenzene aldehydes were reacted with the amino mercapto acids by condensing in a solvent methanol to produce Schiff base **29**. The yields for compounds 1 and 2 were outstanding (77% and 85%, respectively) [70]. TLC was used to evaluate the reaction's progression and the purity of the synthesized compounds. The stationary phase used was of silica gel and the mobile phase was of methanol which ascended higher in the chromatogram. FT-IR, 13C, and 1H, NMR spectroscopy were used to characterize the synthesized compounds 28 and 29. With compound **28** having more antibacterial activity than compound **29**, the newly synthesized Schiff bases demonstrated action against the aforementioned microbes. The Schiff base 1 is a little reactive and more stable in a biological environment according to the estimated global chemical reactivity indices. However, further research will be needed in the future to fully understand the mechanism of these chemicals' antibacterial effects [71].

Scheme 4 [Images not available. See PDF.]

Synthesis of Schiff compounds [70]

Schiff base compounds have broad use across several domains, including organic, inorganic, analytical, and biological disciplines. In the contemporary period, pharmacology applications have exceptional potential and are extensively used within the pharmaceutical sector. A recent study based on the antibacterial activity of Schiff bases was carried out by reacting the compounds in a way to produce two main compounds named DmChDp (2,2′-(5,5-dimethylcyclohexane-1,3-diylidene)bis(azan-1-yl-1-ylidene)diphenol) and the DmChDa (N,N′-(5,5-dimethylcyclohexane-1,3-diylidene)dianiline). These newly synthesized Schiff bases have gained a lot of attention due to their diverse and significant antibiological activities against the strains of *Staphylococcus aureus*. The ligand interactions were also studied to understand the pro-drug-like features that aided in the efficacy of the final products. The characterization techniques included the docking process and the analysis using traditional spectroscopic techniques. The biological activities were evaluated against the six given proteins derived from *S. aureus*. The newly formed Schiff bases showed a great inhibitory effect for bacteria and helped in increasing the efficiency of drugs [17] (Scheme 5).

Scheme 5 [Images not available. See PDF.]

Structure of 30) DmChDp 31) DmChDa Schiff bases [17]

In brief, a series of new lanthanide complexes were synthesized by the use of Schiff base ligands, together with a “benzimidazole moiety.” These complexes were thoroughly characterized by utilizing several analytical methodologies, ensuring their unambiguous identification and understanding. Initial experiments for the compounds were performed to assess various pharmacological uses of the substances under investigation. These assessments were undertaken using a range of bioassays, including tests for antiproliferative activity, antiparasitic activity, and antibacterial activity. The findings indicate that the biological activities of the compounds are influenced by structural modifications. Specifically, ligands L1 and L2, along with their metal complexes, demonstrated minimum inhibitory concentration (MIC) values in comparison with ligands L3 and L4 and their respective complexes. This disparity in MIC values may be attributed to substitutions on the “aminophenol ring.” In a similar vein, it was shown that the compounds had an impact on the fluidity of the cell membrane by modifying the hydrophobic region inside the lipid bilayer. This observation suggests a possible correlation between such alterations and the potential therapeutic uses of these compounds. The aforementioned result has the potential to serve as a valuable point of reference in future endeavors aimed at the advancement of novel pharmacological medicines. Ongoing investigations in the laboratory are now exploring the impact of the alterations on the molecular architecture. This research aimed to provide deeper insights into the mechanism of action associated with these particular molecules [72] (Scheme 6).

Scheme 6 [Images not available. See PDF.]

Synthesis of Lanthanide complex Schiff bases [72]

Antifungal

The recent work included the chemical modification using diabetic insulin structure by the Schiff bases introduction onto the main chain of the reactant. Approximately six different derivatives of the insulin were produced by a simple method, and structures were characterized using FT-IR, proton NMR, and carbon-13 NMR spectroscopic techniques [73]. The structures exhibited variations in the quantity and positional substitution benzene ring using the phenoxide ions or phenolic groups. Following this, further research was conducted to investigate their biological properties, specifically focusing on their antioxidant and antifungal actions. The assessment of antioxidant activity included the determination of scavenging capacities toward superoxide radicals, hydroxyl radicals, and DPPH radicals in addition to antioxidant activities. These activities were of inulin which has shown a considerable enhancement in comparison with that of inulin. In addition, the in vitro evaluation of antifungal activity against three types of plant pathogenic fungus was conducted using the mycelium growth rate technique [15, 74]. The antifungal activity of the inulin derivatives was found to be much higher when compared to that of pure inulin. The biological activity of the inulin derivatives was influenced by many parameters, such as the degree of substitution (DS), as well as the quantity and location of phenolic hydroxyl groups. The products elucidated in this manuscript show significant promise as biomaterials characterized by favorable bioactivity and biocompatibility. Further investigation of the structure–activity link is warranted in future research endeavors [75, 76] (Scheme 7).

Scheme 7 [Images not available. See PDF.]

Synthesis of Schiff bases [73]

The synthesis of Schiff base derivatives of sulfa drugs involved the condensation of commercially available sulfa drugs, namely sulfamethoxazole, sulfamethazine, and Sulfamethoxypyridazine, with suitable “substituted aromatic aldehydes.” A variety of solvents with different levels of polarity were used to optimize the reaction conditions. Ultimately, a solvent combination consisting of ethanol and a small amount of acetic acid was determined to be the most suitable for the condensation processes, as shown in Scheme 8. In all instances, a stoichiometric amount of “sulfonamides and substituted aromatic aldehydes” was used, resulting in reaction yields ranging from 35 to 92%. The purification of the compounds was conducted using either recrystallization or liquid column chromatography before their characterization. It was ensured that all compounds had a minimum purity of 95% before they were deemed suitable for microbiological examination [77].

Scheme 8 [Images not available. See PDF.]

Reaction condition for the synthesis of Schiff base derivatives (**32a-32h**) of aminobenzenesulfonamied [77]
The present work effectively synthesized a range of chitosan derivatives containing active halogenated aromatic imines by the formation of Schiff bases, resulting in high degrees of substitution. The structural characterization of the sample was conducted via the use of elemental analysis, solid-state 13C nuclear magnetic resonance (NMR) spectroscopy, and Fourier transforms infrared (FT-IR) spectroscopy. Additionally, an examination was conducted to assess the antifungal efficacy against three prevalent plant pathogenic fungi, namely *Botrytis cinerea*, *Fusarium oxysporum* f. sp. *cucumerinum*, and *Fusarium oxysporum* f. sp. *niveum*, by in vitro hyphal measurements. The findings of the study indicate that the antifungal activity of double Schiff bases of chitosan derivatives was much higher than that of chitosan, particularly at a concentration of 1.0 mg/mL. The chitosan derivatives with dual Schiff bases, including halogenated benzene moieties, exhibited inhibitory indices of 95% at a concentration of 1.0 mg/mL against *Botrytis cinerea*. This high inhibitory activity may be attributed to the higher electron-withdrawing nature of the halogen substituents. The increased degree of substitution was shown to have a good impact on enhancing the antifungal activity. This work presents a pragmatic approach for the synthesis of novel double Schiff bases of chitosan derivatives including halogeno-benzenes, with the potential for further development as potent antifungal drugs [78] (Scheme 9).

Synthesis pathway for double Schiff bases of Chitosan [78]
Antiviral
In this study, a series of novel Schiff base ligands were synthesized by reacting 5-amino-4-phenyl-4H-1,2,4-triazole-3-thiol **33** with various substituted benzaldehydes (**34a-34d**). Additionally, metal complexes of these ligands with Cu(II), Fe(II), Au(III), and Mn(II) were also prepared. The synthesis of a novel benzothiazole derivative (**37**) was achieved by the reaction between the reactant compound and N-(benzothiazol-2-yl)-2-chloroacetamide through coupling. The spectral qualities of the subject were examined. The anti-HIV-1 and HIV-2 activity of the recently developed and synthesized Schiff base ligands and their corresponding metal complexes were evaluated by the analysis of their ability to suppress “HIV-induced cytopathogenicity in MT-4 cells.” Compounds **37** exhibited significant inhibitory activity in cell culture against HIV1, with EC50 values of 12.2 μg/mL (selectivity index (SI) = 4) and >2.11 μg/mL (SI = >1), respectively. Compound 11 also demonstrated inhibition against HIV-2, with an EC50 value above 10.2 μg/mL and a selectivity index of 9. This finding suggests that compound **37** has promise as a potential candidate for further refinement and enhancement [79] (Scheme 10).
Scheme 10 [Images not available. See PDF.]

Reagents and conditions i) EtOH, reflux, 2h; ii) **36**, K_2CO_3, acetone, 20 °C, then flux [79]
A novel series comprising 3-(benzylideneamino) compounds has been developed. The synthesis of 2-phenylquinazoline-4(3H)-ones included the production of Schiff bases from 3-amino compounds. The reaction of -2-phenyl quinazoline-4(3)H-one with several carbonyl compounds that have been replaced. The chemical structures of the compounds were determined by the use of spectrum analysis. The cytotoxicity and antiviral activity of the tested compounds were assessed against a range of viruses, including influenza B virus, influenza A H3N2 subtype, influenza A H1N1 subtype, vaccinia virus, feline herpes virus, herpes simplex virus-1 TK-KOS ACVr, Punta Toro virus, herpes simplex virus-2 (G), para influenza-3 virus, reovirus-1, Sindbis virus, Coxsackie virus B4, vesicular stomatitis virus, respiratory syncytial virus herpes simplex virus-1 (KOS), and feline coronavirus (FIPV). A compound formed exhibited superior antiviral efficacy against all evaluated viral strains [80] (Scheme 11).
Scheme 11 [Images not available. See PDF.]

Synthetic route for the title compounds [80]

This study presents a unique way to synthesize novel pro-drugs such as abacavir using nitrogen substitution using different ketone and substituted benzaldehyde derivatives. The results of the in vitro experiments demonstrated that compound (3-(2-(4-methylaminobenzylideneamino)-6-(cyclopropylamino)-9H-purin-9-yl)cyclopentyl)methanol (**38c**) exhibited the highest level of effectiveness against HIV, as shown by its EC50 value of 0.05 IM. Furthermore, the compound had an EC50 value above 100 IM, resulting in a selectivity index greater than 2000. Compound **38c** exhibited a much higher potency compared to the original medication, with a 32-fold increase in activity as shown by its EC50 value of 1.6 IM. At a pH of 7.4 and a temperature of 37 °C, the hydrolytic half-life (t1/2) exhibited a range of 120 to 240 min [81] (Scheme 12).

Synthesis of Schiff bases derivatives of Abacavir [81]

Conclusion

The pharmaceutical significance of Schiff bases has gained a lot of attention and this review focuses on giving an insight into the antibacterial, antifungal, and antiviral activities. The Schiff base-derived antibacterial drugs showed significant activities against bacteria by structural modifications while antifungal drugs proved to treat skin diseases mainly. The antiviral Schiff base drugs are currently being used against viral diseases such as influenza, herpes simplex, and HIV. The given literature also explains the mechanism by which the different products are synthesized and their potential activating groups. Furthermore, activities detail for various microorganisms is given which will help chemists to evaluate further compounds. The inhibitory effects of given compounds are also discussed. Overall, this review is a thoughtful and promising contribution to the field of Schiff bases that will bring positive outcomes in the future.

Brentuximab vedotin resistance in classic Hodgkin's lymphoma and its therapeutic strategies: a review

Bera, Dayeeta1 ; Roy, Dattatreya11 St. Xavier's College, Department of Biotechnology, Kolkata, India (GRID:grid.59056.3f) (ISNI:0000 0001 0664 9773)

ABSTRACT (ENGLISH)

Background

Bone marrow cancer has been at the forefront of cancer research. The propensity of cancers to extravasate to the bone makes it a very relevant topic in the topology of this heterogeneous disease. Our narrative review article addresses Brentuximab vedotin (BV) resistance in classic Hodgkin's lymphoma patients and discusses the current trends in the therapeutic process. The data have been collected from the works of well-established researchers, and the scientific evidence was abundantly supplemented with clinical and pre-clinical trial data. Although the findings cited are the latest, this review might not be very accurate for every population as the data from which this was derived have a population bias in several instances. The analysis has mostly been qualitative and interpretive, and quantitative evidence has only been used to explain the clinical trial results. We have divided our paper into the mode of action of BV, its probable and proven causes of resistance, and the therapeutic strategies employed to reverse them to ensure a systemic flow of information throughout the text.

Main body

Brentuximab vedotin is an antibody–drug conjugate with antineoplastic activity, used to target a novel immunophenotype tumor necrosis factor CD30. This factor is specific to the tumor-causing Reed-Sternberg cells in the inflammatory infiltrate. Though the drug had shown promise initially, the cancer was quick to develop resistance against the drug. We have analyzed and represented abundant statistical evidence to back this claim. The paper further discusses the role of the CD30 receptor, MDR1 gene, valine–citrulline linker, and tumor microenvironment in drug resistance. Lastly, we have discussed the possible therapeutics that can be used to overcome this resistance, discussing the well-established and trial-stage approaches taken in the endeavor.

Conclusion

The treatment is much better after the pursuit of reversing the drug resistance phenomenon. However, no therapeutic approach has been entirely successful in restricting the neoplastic property of cancer cells once and for all. This paper describes why that is so and how the heterogeneity of the disease complicates troubleshooting. We have tried to approach such problems through this specific example.

FULL TEXT

Background

Natural selection turns moot when normal human cells in vivo are brought into question. Though free-living unicellular organisms such as bacteria survive based on reproductive fitness, multicellular organisms thrive on collaboration. Somatic cells have a limit to the number of generations they can produce, thus capping their reproductive fitness, and will perish to keep the germ progeny alive and active. If in such a setting, a cell assumes a mutation that renders it superior reproductive fitness, it can soon choose to compete, rather than collaborate, thus developing cancer [1]. Extensive research has been performed which has backed seemingly random observations of metastatic behavior (for instance, prostate cancer often spreads to bones) [2]. The bone is a nutritionally enriched organ having an intricate vascular network and different types of cells. When the tumor affects the stem cells of the bone marrow, different forms of blood cancers develop [3].

Bone marrow cancer can broadly be classified under the following categories: myeloma, leukemia, lymphoma, myeloproliferative disorders, and myelodysplasia [4, 5].

Hodgkin's and non-Hodgkin's are both lymphomas but there are several differences between the two. Hodgkin's lymphoma is localized in a single group of axial lymph nodes and is spread contiguously by the lymph. Though the incidence rate might appear nominal at 3 per 1,00,000 person-years, it is important to note that about 50% of patients are young, within the age bracket of 15–35 years. The disease follows a bimodal age distribution with a second incidence peak in late adulthood (above 55) [6]. Why this is so has not yet been studied in-depth.

The following treatments are available for classic Hodgkin's lymphoma:

•High-dose chemotherapy and radiotherapy cause complete remission of the disease.

•Brentuximab vedotin drug treatment, often supplemented with allo-SCT (allogeneic stem cell treatment) or not.

•Programmed cell death-1 checkpoint inhibitor [7].

On the contrary, non-Hodgkin's lymphoma is localized in multiple peripheral lymph nodes because it spreads through the more extensive blood vessels. Because of this, the homing of the infection often occurs at non-contiguous lymph nodes and thus the disease requires a considerable time before the inflammation is externally perceivable. Diagnosis is thus relatively poor.

Histopathological studies have shown the presence of a special class of cells called the Reed-Sternberg cells which have a very strong correlation with the occurrence of Hodgkin's lymphoma. These cells are transformed B cells from the pre-apoptotic germinal center (GC) (in lymphoid organs) which have undergone extensive genetic reprogramming leading to epigenetic changes that have suppressed the expression of a large fraction (almost all) of the B-cell receptors (BCRs) [8].

Alongside suppressing the native receptor production, the neoplastic Hodgkin's Reed-Sternberg (HRS) cells have a profuse expression of a type I membrane protein, CD30, which is a member of the tumor necrosis factor (TNF) receptor superfamily. This rare expression profile of CD30 makes it a good immunophenotypic disease marker for Hodgkin's lymphoma. Also, HRS cells constitute a mere 1–2% of the inflammatory cell population and thus CD30 is a highly exclusive target for exterminating the tumor cells. Research has also proposed CD30 involvement in the genesis and proliferation of the HRS cells [9]. This makes CD30 a good target for antibody-directed therapies [10]. Though risk remains of cross-cellular CD30 targeting, the population of CD30 is so minimal in normal immune cells that this risk is often ignored [7].

Brentuximab Vedotin as shown in Fig. 1 is an antibody–drug conjugate (ADC). The ADC is synthesized by the chimeric mouse-human IgG1 anti-CD30 monoclonal antibody (SGN—30) conjugated to monomethyl auristatin E (MMAE) via a dipeptide linker, and it is used in the treatment of Hodgkin's lymphoma [10–12].

Fig. 1 [Images not available. See PDF.]

Chemical structure of Brentuximab vedotin showing the mAb (cAC10), dipeptide linker, spacer &drug (MMAE). The mAb is used to target the CD30 expressed as the unique immunophenotype on the HRS cells of the BV infiltrate. The dipeptide linker is cathepsin specific, though specificity to a large number of cathepsins can increase cytotoxicity by promoting non-specific payload release. Scientists are on the lookout for cathepsin B-specific linkers such that the linker is cleaved only in the cathepsin B-producing tumor cells. The spacer is usually a para-amino benzyl carbamate spacer, which helps maintain stability in the bloodstream and undergoes self-immolated disassembly to release the MMAE

Phase I studies showed a significant result with a positive response in patients with relapsed or refractory (R/R) Hodgkin lymphoma upon administration of BV. Phase II trials showed a complete response (CR) rate of 34% and an overall response rate (ORR) of 75% in CD30-positive lymphomas [13]. This outcome resulted in the FDA approving the usage of BV to treat patients with Hodgkin's after the failure of autologous hematopoietic cell transplantation [14]. BV was then started being used as part of initial therapy along with chemotherapy for advanced-stage Hodgkin lymphoma [15].

But soon resistance against the administered drug started registering. Several pharmacokinetic and pharmacodynamic challenges contributed to the gradual resistance to ADCs, due to failure in either antibody, linker, payload, or the poor ADMET properties of the drug [16, 17].

As mentioned above, in the phase II trials, BV demonstrated a CR rate of 34% and an ORR of 75% but patients with Partial Response PR had a very short remission time of medians of 3.5 months [13], therefore patients without a CR will gradually develop a progressive disease even with a continuous BV. Considering BV is the only therapeutic drug prescribed by the FDA in the last 20 years [14], understanding the mechanism of BV resistance and potential solutions are of great importance.

Main text

Brentuximab vedotin: mode of action

Brentuximab vedotin (BV) (ADCETRIS®; Aptuit [Glasgow] Ltd., Glasgow, United Kingdom) is composed of the chimeric monoclonal IgG1 antibody (cAC10, SGN-30) (derived from mouse xenograft model) that is specific to human CD30. It is conjugated to monomethyl auristatin E (MMAE), which is the payload. The payload is linked to the main body of BV by a protease-cleavable peptide linker containing a valine–citrulline combination [18]. MMAE is a synthetic antineoplastic agent and a very potent anti-mitotic drug (because of tubulin-disrupting properties) against Hodgkin's lymphoma [19]. Each of the antibodies is linked to an average of 4 MMAE groups [18].

As seen in Fig. 2 [20], the ADC is endocytosed upon binding to the extracellular CD30 antigen on the tumor cells. Inside the cells, the proteolytic lysosomal enzymes cleave the dipeptide linker thereby releasing the MMAE drug, which then goes and binds to tubulin leading to the collapse of the microtubular network. As a result, the G2/M-phase cell cycle gets arrested and apoptosis occurs (Francisco et al. [10]). The valine–citrulline peptide linker is highly stable in plasma, which results in comparatively low in vivo toxicity of the drugs when compared to other linkers [21]. BV also works by mAb-dependent cellular phagocytosis, affecting cell signaling in $CD30^+$ cells, or sometimes even due to free MMAE leaking out of the tumor cells and killing neighboring $CD30^+$ cells [18, 20, 22].

Fig. 2 [Images not available. See PDF.]

Mechanism pathway of BV, displaying its internalization into the cell, and subsequently disrupting the microtubular network. This figure shows how BV is internalized into the cell. The drug, through its CD30-specific mAb, binds to

CD30 outside the cell, on the cell surface. It is then internalized by endocytosis. Next, the endosome reacts with lysosomes, leading to the release of lysosomal proteases—the cathepsins in the endosome. Cathepsin-specific cleavage of the dipeptide linker occurs, leading to MMAE release. The MMAE exits the endosome and reaches the nucleus, where it binds to microtubules and triggers its anti-mitotic activity

Brentuximab vedotin: efficacy demonstration studies

In 102 Hodgkin lymphoma patients who had relapsed following high-dose chemotherapy and autologous hematopoietic stem cell transplantation, intravenous BV had been linked with an overall ORR (primary endpoint) of 75%. In 94% of patients with cHL, tumor reductions were seen, and the majority of these tumors shrank by almost >65%. The corresponding predicted 12-month survival rates were 89% [23]. The median duration of response for patients in CR was 20.5 months, and the median progression-free survival time was 5.6 months for all patients. After a median observation period of over 1.5 years, 31 individuals were still alive and had no signs of worsening disease that had been medically verified [13]. These trials showed that BV was generally well tolerated [23].

BV demonstrated cell death induction in CD30-positive cells with IC_{50} <10 ng/ml, but showed around 300-fold inactivity on CD30-negative cells, in patients with Hodgkin's lymphoma [10].

In a study conducted by Chen R., two subsets included a group of six patients who received consolidative allo-SCT (allogeneic stem cell transplantation) and another of 28 patients who did not [24]. This study analyzes overall survival (OS) and progression-free survival (PFS) based on the Kaplan–Meier methodology. The survival rates help analyze the efficacy of the allo-SCT treatment [24]. From the study, it is seen that stem cell transplantation often prolongs life or at least delays relapse as compared to only BV treatment [25].

CD30 characterization

The CD30 receptor was first identified from a monoclonal antibody (mAb) derived from an HL cell line [26]. Structural analysis has shown that the protein has intracellular, extracellular, and transmembrane domains [27], and sequence similarity has found CD30 to be similar to other TNF (Tumor necrosis factor) receptors in its extracellular sites, thus raising questions regarding the exclusivity of the target of BV. BV might also be useful in treating non-hematopoietic cancers, such as germ cell tumors (testicular embryonal carcinomas) [28].

These are the normal immune functions of the CD30 found as of now:

- Expressed on the surface of CD4+ and CD8+ T lymphocytes which are activated because of an infection and show a propensity to secrete Th2 cytokines (Il-4, Il-5) predominantly, although Th0 and Th1 cytokine production has also been reported [29].

- Negative selection of partially mature T lymphocytes having double positive CD4+CD8+ antigens is thought to be guided by a transient expression of CD30 in a relatively smaller population of thymic cells that can eliminate T cells with high affinity toward self-peptides via apoptosis, thus preventing potential autoimmune disorders [30, 31].

When analyzing CD30 as a potential cause for BV resistance in cHL patients, it is important to note that several researchers have found CD30 to be an active perpetrator of lymphomagenesis. It is established that CD30 is not downregulated upon and after BV treatment [32]. This rules out the possibility of the lack of a target for BV as a potential cause of drug resistance. However, the involvement of CD30 in continued lymphomagenesis as a potential cause of relapse in BV-treated patients is a glaring possibility. Downstream activation of nuclear factor kappa B (NFkB) and mitogen-activated protein kinase (or extracellular signal-related kinase) pathways both ultimately lead to the activation of anti-apoptotic and pro-proliferative genes. Contrasting views on the role of CD30 in the normal immune system have led to poor functional characterization [33]. The downstream effects of CD30 stimulation might be exploited when searching for a potential reversal of BV resistance.

Brentuximab vedotin resistance: potential causes

Surface antigen level downregulation

BV utilizes a mAb against the antigen CD30 on the cell surface of tumor cells as a potential drug target. It is thus possible that the downregulation of CD30 levels in the tumor cells causes BV resistance.

Chen et al. [32] conducted MTS assays to determine the IC50 (Half-maximal inhibitory concentration) of parental cell lines of L428 (HL). The BV-resistant cell models were selected using persistent exposure to sub-IC50 concentrations of BV and cell numbers in culture were kept on track for 3 months. However, the team was unable to obtain resistant L428 cells through constant exposure to the drug. Then a supra-IC50 concentration of BV exposure was applied and cell numbers were tracked and assessed twice a week until cessation of cell proliferation was seen. In the end, it was seen that BV-resistant cell lines were able to grow at supra-IC50 parental line BV concentrations. This was confirmed by cell proliferation assays. At the same concentrations, the parental cell lines quickly died. However, there was absolutely no significant decrease in the percentage of CD30 + cells [32].

In another research conducted by Nathwani et al. [34], two patients, a 27-year-old woman (with relapsed cHL in IVA stage following prior 6 cycles of ABVD, 2 cycles of ICE, and a cycle of ACT) and a 19-year-old man (with relapsed cHL in IIIA stage following ABVD, ICE and additional treatments including rituximab, gemcitabine, vinorelbine, liposomal doxorubicin, MOPP, and palliative radiation), were enrolled in a study to find out more about the role that CD30 plays in BV resistance. In both cases, the patients achieved a significant reduction in tumor sizes following the BV treatment through 8 and 10 cycles, respectively. Here too, a persistent level of CD30 throughout the treatment demonstrated that a reduction in levels of CD30 does not appear to be a potential cause of BV resistance [34].

Drug transporter protein overexpression

The same study conducted by Chen et al. [32] with L428-R (resistant) and L428-P (parental) cells showed a decrease in the amount of intracellular MMAE in L428-R as compared to L428-P cells. The R cells accumulated 6.7-fold (± 3.4-fold) more MMAE compared to the L428-P cells within 48 h when the cells were incubated with 20 μg/ml of BV [32]. To confirm this, they performed an additional test with rhodamine-123 dye for two days (Rhodamine is a substrate for the transporter responsible for MMAE efflux), and L428-R cells showed tenfold lesser fluorescence than L428-P cells. Subsequent qRT-PCR was done to see mRNA levels for *MRP1*, *MDR1,* and *MRP3*, in sets of resistant and parental cell lines [32]. Results showed increased MDR1 levels (ATP-dependent translocase ABCB1) and protein levels of P-glycoprotein (who preferentially exports hydrophobic cargo like MMAE out of cells) in L428-R cells relative to L428-P cells, though *MRP1* or *MRP3* mRNA levels in both cells lines were same [32].

In another study conducted by Chen et al. [11] they used another BV-resistant HL cell model KMH2-R. They again showed that CD30 expression was unchanged in KMH2-R compared with KMH2-P. And gradually re-confirmed the overexpression of the gene *MDR1* by qPCR in KMH2 cells, where *MDR1* presence was threefold higher in KMH2-R cells compared with KMH2-P cells [11]. *MDR1* RNA expression was threefold greater in KMH2-R cells and sevenfold greater in L428-R cells compared to respective KMH2-P and L428-P cells [11]. This displayed how drug transporters can play such a crucial role in BV drug resistance in HL.

Defective linker-payload processing

There are two types of linkers, cleavable and non-cleavable. An appropriate linker is not only required to prevent degradation during systemic circulation, but also to facilitate the quick and efficient release of the drug inside the tumor cells [35]. Non-cleavable linkers release their conjugated drug only after antibody degradation. For example, for Kadcyla which has a non-cleavable thioether linker, lysosomal membrane proteins are required to first transport the drug catabolite out of the lysosomal compartment and then exert a therapeutic effect [36]. Barok et al. [37] established that non-cleavable linkers are more susceptible to ADC resistance in tumor cells because any faulty

linker degradation will not lead to functional drug release.

BV is composed of protease-cleavable valine–citrulline peptide, where the MMAE does not depend on the degradation of the antibody backbone. Thus, it leads to much faster payload release after ADC internalization compared to a non-cleavable linker [38]. However, a faulty linker cleaving or non-cleaving can lead to an ineffective payload discharge. As per a study conducted by Caculitan et al. [39], valine–citrulline (Val-Cit) linker showed broad-spectrum specificity to different types of cathepsins, including cathepsin B, cathepsin L, cathepsin K, etc. [39]. Since only cathepsin B is postulated to be highly expressed in HL cells, and normal cells have other kinds of cathepsins, this phenomenon could be very deleterious as it would induce toxic side effects on other normal cells [40].

A defective linker thereby affects the cytotoxic drug delivery in many ways from the drug not reaching the target, to off-target toxicity and the drug not being able to dissociate from the mAb and the linker, thereby overall promoting resistance.

Tumor microenvironment

In cHL tumor, the entire cellular infiltrate contains only infrequent neoplastic HRS cells (about 1%) and is surrounded mostly by a characteristic tumor microenvironment (TME) composed of several benign immune and extracellular matrix stromal cells, including different types of T and B cells, eosinophils, fibroblasts, macrophages (M1 and M2). By contrast, NLPHL (nodular lymphocyte-predominant HL) differs from cHL1 based on specific histopathological characteristics [41].

Extensive crosstalk mediated by a large network of cytokines and chemokines between tumor cells and immune cells, acting in an autocrine and paracrine manner, suggesting the existence of an entire pro-malignant cancerous ecosystem present around the tumor cells has been established [41]. As Fig. 3 shows, the CD30 ligand (CD30L), as well as neutrophils and eosinophils are commonly mixed with HRS cells [42].

Fig. 3 [Images not available. See PDF.]

Different interactions of cell surface receptors of HRS cells with the tumor microenvironment describe the way the HRS cells influence the microenvironment. Such influence is the driving cause behind sustained tumor growth and unchecked proliferation. In the figure, we can see the CD30 binding eosinophils and mast cells and also interacting with mast cell-produced interleukins

TME-mediated development of drug resistance occurs by multiple mechanisms quite different from one another [43–45]:

- Metabolic reprogramming, leading to altered drug delivery and various tumor proliferation strategies.
- ECM remodeling through changes in the matrix-forming heterogeneous class of stromal cells.
- Development of cancer stem cell phenotype (CSC) through expression of various immunophenotypic markers such as CD44, CD24, and CD133 and the development of the conserved Nodge and Hedgehog pathways involved in cellular differentiation.
- Angiogenesis plays a major role by determining the level of development of the surrounding vasculature which provides the tumor with oxygen, nutrients, etc., and removal of metabolic wastes.
- Immune suppression mechanisms.
- Exosome-mediated trapping of therapeutic antibodies.

Therapeutic strategies to overcome BV resistance

Usage of different linker-payload combinations

MMAE is uncharged, and hence non-polar. This often leads to the death of cells near cancerous tumor cells known as the “bystander effect”. As seen in Fig. 4 MMAE internalization leads to the destruction of cancer cells and when these cells lyse, they release the MMAE [46]. Because of its hydrophobicity, it can easily pass through the phospholipid bilayer of the surrounding cells, causing anti-mitotic effects in them [46]. While it can have a positive effect if the surrounding cells are cancerous too, on the flip side, the cells develop BV resistance through MDR1 upregulation very quickly. To overcome this resistance, often the MMAE is replaced by a charged payload/linker combination, which is impermeable to the nearby cells upon lysis of the initially targeted cell. This keeps the bystander effect in check, helping in minimizing resistance [46].

Fig. 4 [Images not available. See PDF.]

Schematic of the bystander effect shown by non-polar conjugates showing cytoplasmic leakage shows the cytotoxicity difference between a polar and a non-polar payload because of the permeability exhibited by the non-polar payload in crossing the cell membrane into the nearby cell causing non-specific toxicity. This phenomenon can be positive if the nearby cell is toxic too but that is seldom the case and this kind of effect mostly kills healthy cells

A linker that used a cyclobutane-1,1-dicarboxamide (cBu) structure was designed by Wei et al. which was specific to cathepsin B cleavage. This was proven by intracellular cleavage studies in which a cathepsin B inhibitor stopped drug release from cBu-Cit-containing linkers by over 75%, while a cathepsin K inhibitor did not have an appreciable effect [40].

Peptide linkers have been seen to be easily optimizable by minimal structural changes, including the types and stereochemistry of the amino acids. For instance, valine–alanine (Val-Ala) has better hydrophilicity and stability than Val-Cit [47].

Ward and his coworkers [48] from Texas University have developed an innovative approach to solving drug resistance. They developed such a targeting moiety of the ADC (antibody–drug conjugate) such that its binding affinity was two orders lower in the endolysosomal lumen (pH < 6.5; $[Ca^{2+}] \sim 2$ μM) than it was in the extracellular space (pH > 6.8; $[Ca^{2+}] \sim 2$ mM) [48]. Since the drug is more easily accessible to its intracellular substrate because of faster dissociation from the antibody target, it gives a twofold advantage: recycling of the target to the cell surface to sequester more ADC, and faster downstream signaling from the drug binding to its substrate, which in the case of the anti-tubulin activity of MMAE is cessation of cell proliferation. This diminishes the cytosolic payload of the drug [48].

“Component switch” mechanism

The “component switch” mechanism is difficult to implement because the prognosis will change radically based on the stage of cancer and/or the treatment [46]. Age, ethnicity, and other variable factors will also bear a sensitive relationship to the treatment because targeting multiple pathways or events in an already heterogeneous disease can trigger severe physiological imbalances, resistant phenotypes, and immune weakening events. Think about the different variables involved with the single treatment pathway of ADC delivery: antibody target identification, internalization, payload release, binding of MMAE to tubulin, and the fate of tubulin after cell lysis—problems at a single step can jeopardize the entire treatment [46].

There are many problems with medical and healthcare procedures too. Analysis of resistant mechanisms is limited by the want of systematic and routine pre-and post-treatment biopsies and the problem of setting up standardized clinical assays for quantifying protein levels of clinical biomarkers [46].

Combination of ADCs with immune checkpoint blockade

Immune suppression of cancer is bypassed by the resuscitation of effector T cells which helps in infection response and memory. Antibodies designed to inhibit immune checkpoints help in this. Immune checkpoint blockade has proven promise in many long-lasting cures [46].

The use of such antibodies however has disadvantages. In tumors that have not developed any anti-tumor T cell response, usually comprised of “immune desert” or “immune excluded” types (the former means that the immune system is not recognizing the tumor as an infection, resulting in no T cell production against it, whereas the latter means that T cells are formed against the tumor and are present in the extracellular stromal matrix but are unable to penetrate the core tumor mass), the ICI (immune checkpoint inhibitor) antibodies do not work [49].

Anti-tumor immunity is conferred by ADCs and chemotherapeutics through the following mechanisms:

- release of tumor antigens from dying cells allows these antigens to be taken up by the dendritic cells, macrophages, or B cells, which phagocytose the antigens and present them to the T cells via the MHCs (major histocompatibility complexes) for immune activation [46].

- Maturation and activation of the antigen-presenting dendritic cells are largely influenced by the free payload that comes conjugated with the ADC. If the payload is PAMPs (pattern-associated molecular patterns) and DAMPs (damage-associated molecular patterns) (like Toll receptors), it can directly be presented by the APCs (antigen-presenting cells, here dendritic cells) for immune activation. Free payload can also lead to co-stimulatory molecule release (like CD40, and CD80) or cytokine release [46].

- Triggering cell death, often with the aid of anti-mitotic factors [46].

Combining ADCs with ICI antibody treatment can help immunologically “cold” tumors to get converted to tumors with an active T cell pool by the methods described above. Since T cell activation leads to an overall increase in adaptive immune response, a global mechanism to eliminate the tumors is undertaken without the dependency on surface antigen gene regulation [46].

Ongoing clinical trials involving BV and ICI are given below [46]:

- BV and Nivolumab block PD1

- BV and Pembrolizumab block PD1 too

- BV and Nivolumab +/− Ipilimumab blocks PD1 and CTLA-4

Overcoming MDR1-mediated resistance by using a modified linker

MDR1 transporters use maytansinoids as substrates to be transported across the cell membrane against their gradients. DM1 (Mertansine) is a thiol-containing maytansinoid that is actively pumped out by overexpressed MDR1 receptors as a form of response to DM1 treatment in HER-2-positive breast cancer. Kovtun and colleagues designed an ADC in which the DM1 was linked to an antibody using a hydrophilic linker, PEG4Mal, which was a replacement for the initial SMCC linker. This resulted in the release of lysine-PEG4Mal-DM1 instead of lysine-MCC-DM1 upon cathepsin cleavage. MDR1 does not recognize lysine-PEG4Mal-DM1 as a substrate for transmembrane transport, thus solving the problem of efflux of the payload drug. This method prevented MDR1-mediated resistance in both in vivo xenografts and in vitro cells expressing MDR1 [37]. This can be extended to cHL treatment by BV administration by modifying the dipeptide linker.

Using PD1 inhibitors

Cancer often leads to immunosuppression by inactivating the activated B and T cells. PD1 discovery, which was awarded the Nobel in 2018, led to the dawn of a new direction in cancer therapy. PD1 acts as a negative regulator on T cells. PD1 inhibitors such as pembrolizumab and nivolumab have led to promising clinical results because of the reactivation of immunosuppressed T cells [42]. This has led to the abatement of refractory cancers such as the HL249, 250 cell lines. PD1 inhibitors are now often administered with ADC, as forms of combination therapy. Though some have shown severe autoimmune complications, most patients have been able to accept the treatment, some even being fully cured. Preliminary results of patients diagnosed with advanced-stage Hodgkin's lymphoma administered with a combination therapy of nivolumab and AVD have shown good results [42].

Brentuximab vedotin plus Ibrutinib

BTK (Bruton's tyrosine kinase), an important oncogenic non-receptor tyrosine kinase is active in various subtypes of non-Hodgkin lymphoma and is also expressed in malignant Reed-Sternberg cells. Ibrutinib (Ibr) is a Bruton's tyrosine kinase (BTK) inhibitor which can also use a Th1-based response to inhibit IL-2-inducible kinase (ITK). This can promote immunogenic cell death in combination with BV [50].

According to the research conducted in a phase II trial of Ibr plus BV in patients with r/r HL, 39 patients were enrolled; 67% were male and the median age was 33. Of 36 evaluable patients, the CR rate was 33%, ORR 64%, and the median DOR (Diagnostic Odds Ratio) was 25.5 months (range) [50].

Results showed that Ibr imparted additional toxicity in comparison to BV monotherapy, and even showed no signs of increased efficacy in patients treated with both BV and Ibr, thus ruling Ibr out as a potential treatment [50].

MDR1 inhibition with CsA and VrP

Effects of CsA (cyclosporine) and VrP (vorinostat, a histone deacetylase inhibitor) were studied on the IC_{50} (measures potency of inhibiting tumor growth) of BV in L428-R (missense mutation involving resistant colon cancer cell) and KMH2-R cells [11]. Neither of the drugs had any effect on the viability of the parental and BV-resistant types of the two cell lines mentioned above in the absence of BV. PgP protein expression and *MDR1* mRNA expression were also unchanged on CsA treatment [11]. It was then seen that competitive MDR1 inhibition increased intracellular MMAE levels and resensitized the two-BV-resistant cHL cell lines. It was also seen that overexpressing exogenous MDR1 in the L428-P led to BV resistance, which was nullified on treatment with CsA [11]. These results conclusively support the hypothesis that resistance to BV in Hodgkin's lymphoma is brought about because of the cytosolic loss of MMAE by the ABC drug transporter MDR1/PgP, whose overexpression is triggered by rising MMAE levels [11].

It was previously reported that the addition of VrP led to a 3.9-fold reduction in BV IC_{50} [32] into L428-R cells and a sixfold reduction in that of KMH2 $IC_{50.}$ Compared to this, this reduction was 10,000-fold for L428-R cells and 600-fold in KMH2-R cells [11].

CRISPR-Cas9 system to reverse drug resistance targeting MDR1

It was reported that the expression of P-glycoprotein, which helps the ATP-mediated transfer of anti-mitotic drug against its gradient with the help of the transmembrane MDR1 protein, could be efficiently blocked using the CRISPR-Cas9 system. Inhibiting ABCB1 (another name for P-glycoprotein) in osteosarcoma MDR cell lines (U-2OSR2 and KHOSR2) helped in combating MDR against doxorubicin [51].

CRISPR stands for Clustered Regularly Interspaced Short Palindromic Repeats and it uses Cas9, which can form a complex with single guide RNA (which shows Cas9 its point of activity on the DNA). The sgRNA-Cas9 complex then cleaves the DNA 3–4 base pairs upstream of a protospacer adjacent motif (PAM). Cas9 then helps generate DSBs (double-strand breaks) [52], which when repaired by NHEJ (non-homologous end joining) generates small insertions or deletions at the point of Cas9 activity. This is because NHEJ is very erroneous. These point mutations can

inactivate genes or genomic elements [52].

Similar CRISPR-based editing can be used for classic Hodgkin's lymphoma to target a lot of proteins: ABCB1 can be targeted to prevent efflux pump overexpression, so cytosolic MMAE levels are maintained. ADAM10 and ADAM17 inhibitors can help keep the cell surface concentration of CD30 nearly constant so that BV gets a docking site and no drug loss happens over the lack of a target molecule [53].

Nanoparticle-based MMAE targeting

MMAE is an anti-tubulin agent and can be detrimental to the normal cells of the body. Though BV is quite a specific drug because of its target being the distinct cancer immunophenotype CD30, cross-reactivities because of partial similarity with other F_{ab} segments (hypervariable regions can be assumed to be unique, but similarities in the variable region are possible) of other CD markers is not only possible but also expected [53]. Also, activated B and T cells often express CD30 as a normal phenotype (as previously discussed), so BV can often be led astray. This raises a two-fold possibility:

- Effective drug delivery to the Reed-Sternberg cells decreases.
- Normal cells are prevented from proliferating (mitosis prevented). This decreases the population of the already strained normal cells of the body, thus helping tumor proliferation (The citrulline-valine linker of BV is specific for a lot of cathepsins, including the ones with abundant expression in normal cells) [53].

Another factor causes reduced drug delivery. CD30 is often cleaved in active Hodgkin's lymphoma patients, which leads to a high concentration of sCD30 (soluble CD30) in the plasma. This ectodomain cleavage is caused by members of the ADAM group of proteins (ADAM 10 and ADAM 17), appropriately called sheddases [53].

Nanoparticles containing FRRG (Phenylalanine- Arginine- Arginine- Glycine) conjugated with MMAE (MMAE conjugated to C-terminus of FRRG) can be obtained by EDC-NHS coupling at 37 °C for 24 h. The self-assembled nanoparticle stabilized with the intermolecular hydrophobic interactions and needed no further carrier materials. These nanoparticles (prodrugs) showed vigorous uptake in in vitro breast cancer cells (4T1) [54]. FRRG has proven to be the minimal chain of peptides required to selectively trigger cathepsin B without requiring additional lipids or polymers for nanoparticle assembly [54].

Such nanoparticles can be used as a potential replacement for BV because of the specificity of its cleavable peptide linker and its independence of CD30 presence on the cell surface. The FRRG peptide is a much more specific linker than the citrulline-valine linker in BV. FRRG is specific to cathepsin B, the cathepsin with the most overexpression in tumor cells. Normal cells will not have high enough levels of cathepsin B to trigger the release of MMAE from the prodrug and hence the anti-mitotic action of MMAE will not be active in normal cells, minimizing collateral damage. Cleavage of CD30 ectodomains will also not cause inefficacy in drug delivery [55].

Epigenetic modifications to modulate resistance

Epigenetic modifications often lead the cancer cells to survive and proliferate in the face of subsequent rounds of chemotherapy and since epigenetic changes are defined by their transience, changes call for a lesser strain on the cellular machinery than a genetic change would. Nucleic acid methylation has been the best-characterized epigenetic process contributing to chemoresistance [56]. Methylation rates were studied in FL (Follicular lymphoma) and DLBCL (diffuse large cell B-lymphoma) and compared to that of normal B cells [56]. It was seen that increased dissimilarity in methylation patterns led to faster death of the cells, a fact held even between FL grades. Abnormal methylation patterns had a propensity to be targeted toward promoters of key regulatory factors such as *MYC, BCL6,* and *EZH2.* Upon investigating for similar methylation in DLBCL patients who showed different fates to treatment (durable vs. relapsed) [57], enriched promoter sites with differently hypermethylated regions were found.

For instance, *CTCF*, a transfactor involved with DNA methylation (through interactions with histone acetylases and deacetylases) was differentially hypermethylated at its promoter.

Chemoresistance is much attributed to epigenetic modifications since DNA methylation status can affect a broad range of housekeeping cellular activities like cell cycle, autophagy, protein degradation, immune response, apoptosis, and DNA damage. It also affects signaling pathways involving small molecular targets. For instance, Bruton's tyrosine kinase (BTK), which is used as an immuno-target to curtail mantle-cell lymphoma has undergone epigenetic modification to gain resistance to the inhibitor (of BTK) ibrutinib, which was a general treatment for the disease [58]. Among the major drugs involved with epigenetic changes, post-translational modifications (PTM) in many are assumed to be the major cause of activating chemo-resistant pathways. Among these, an important one is the impaired p53 activity, in which p53 acetylation activates the tumor suppressor and protects it from degradation. To induce the acetylation back, often class III HDAC inhibitors are used. Scientists are also looking at ways in which the epigenetic regulation of the tumor microenvironment immune surveillance cells can help in circumventing chemoresistance. To exemplify this, it has been seen that programmed cell death-1 (PD1) and programmed death ligand 1 (PD-L1) are involved in chemoresistance, both of which are under tight epigenetic control [59, 60]. Epigenetic modulating drugs could be supplemented with essential tumor shrinkage agents with the aim of rewiring pathways causing drug resistance, especially tightening checkpoint inhibitors. Toxicity problems limit the use of epigenetic drugs to minute concentrations. If proper precision medicine data can be obtained to classify patterns of epigenetic derangements, specific epigenetic drugs can be coupled with chemotherapy and immunotherapy to overcome drug resistance.

Conclusions

This narrative review discusses the various ways in which drug resistance can occur in cHL, analyses the existing methods to reverse it, and proposes new ones.

HRS cells are responsible for tumor proliferation in cHL. CD30 is backed by statistical evidence to be proven as the predominant cause of tumor spread and many subsets of patients were shown to have grown resistant against the ADC that was employed to tackle cHL. The potential causes of resistance were hypothesized, some of which were incorrect. For instance, it was seen that BV had an antibody derived from a mouse xenograft which was specific to the CD30 marker on the HRS cells. BV treatment might have led to the downregulation of CD30, thus robbing BV of docking sites to gain entry into the cell. However, clinical data reveals no such happening. This effect was later explained by the action of ADAM proteins, which led to the discovery of the shedding of ectodomains of CD30 in advanced cHL patients. That shedding caused the loss of docking sites and non-specific docking with the sCD30, both aiding in improper drug delivery.

Another hypothesis, the overexpression of MDR1 which pumped out the active payload of BV, and MMAE out of the cells was proved to be correct. Numerous alterations in the ADC were done to prevent the efflux (such as modifying the payload so that it was no more a substrate for MDR1). Changing MMAE to a charged substrate has often been thought to limit the bystander effect. The linker is often changed to ensure its stability under the treatment of non-tumor-specific cathepsins. This prevents collateral damage and reduces tumor proliferation by not killing normal cells and freeing up space and nutrients for the tumor. The antibody part is also engineered to make it more specific to CD30, as CD30 belongs to the class of TNF receptors, which have quite similar ectodomains, which can result in cross-reactivity. Immune checkpoint blockades such as PD1 inhibitors are thought to be more effective than ADCs because this leads to the global activation of the immune response of the body to attack the tumor. This review has therefore been successful in identifying the causes of BV resistance but the remedies for such resistance are under debate.

The use of CRISPR is being hypothesized to mutate MDR1-producing genes so that cytosolic loss of MMAE decreases or ADAM-producing genes to preserve BV docking sites. Nanobiotechnology has made nanoparticles very important drug delivery molecules. FRAG-MMAE-containing nanoparticles are employed to deliver the MMAE, instead of the use of an antibody interaction. This increases efficacy by removing the loss of drug due to lack of docking and also limits bystander effect because of the specificity of FRAG to cleavage only by cathepsin B (the one specific to cHL tumor). Finally, epigenetic modifications are being studied, employing the component switch strategy on various levels. These treatment options are relatively new and many of these are still under thorough investigative research or clinical trial phases. However, BV remains the most promising drug in public use until better solutions are discovered.

Further research should focus on a systems biology approach to investigate the individual causes of resistance, so we have an idea of the effect of each of the causes in the broader in vivo context.

Nanotechnology-based strategies overcoming the challenges of retinoblastoma: a comprehensive overview and future perspectives

Hatem, Shymaa1 ; Mohammed, Donia1; Ezzat, Nermeen11 Future University in Egypt, Department of Pharmaceutics and Pharmaceutical Technology, Faculty of Pharmacy, Cairo, Egypt (GRID:grid.440865.b) (ISNI:0000 0004 0377 3762)

ABSTRACT (ENGLISH)

Background

Retinoblastoma (RB) is a rare type of pediatric ocular cancer with difficulty in treatment and detection owing to alterations in tumor suppressor genes and the lack of focused, efficient, and cost-effective treatments.

Main body of the abstract

The current review presents different approaches adopted for the treatment of RB. Recently, nanodrug delivery-based systems have shown significant reported advancements in RB treatment owing to their effectiveness in delivering their cargo to the site of tumor growth, where they may induce programmed tumor cell death. Among various nanoparticulate systems employed in RB treatment are organic nanoparticles, lipid-based nanocarriers, polymeric nanoparticles, inorganic (metallic) nanocarriers (cerium oxide, iron oxide, gold and silver), and surface-tailored multifunctionalized nanocarriers.

Short conclusion

The current review article aims at demonstrating the superiority of nanotechnology-based formulations to traditional therapies for treatment of RB in order to enhance the bioavailability and targeting of drugs to posterior eye segment specifically, thus improving patient compliance and adherence to treatment by minimizing the number of dosing intervals and hence the likelihood of side effects.

FULL TEXT

Background

Anatomy of the eye

Briefly, the eye is composed of two segments: anterior and posterior segments. The anterior segment comprises (a) Iris which controls the amount of light entering the eye. In front of the lens, the pigmented region of the eye is visible [1], (b) Eye pupil which is the opening in the center of the iris via which light enters the eye lens. The iris controls the pupil's dilation and constriction [2], (c) Cornea, the transparent round anterior segment of the eyeball refracting incoming light onto the lens, which then directs the light to the retina. The cornea lacks blood vessels and has a high threshold for pain [3], and (d) Lens, a translucent structure behind the pupil. It is contained in a thin, transparent capsule and aids in the refraction and concentration of incoming light on the retina [4]. The posterior segment comprises (a) Choroid which separates the sclera and the retina. Additionally, it has a pigment that absorbs excess light to prevent blurred vision [5], (b) Ciliary body which connects the choroid to the iris [6], (c) Retina, a light-sensitive layer lining the interior of the eye, which is composed of rod and cone cells that are sensitive to light [7–9], (g) Optic nerve includes all visual information which is transmitted to the brain [10, 11] and (h) Sclera, the white portion of the eye, representing the protective outer layer of the eye formed by the cornea [12].

Etiology of RB

RB (Fig. 1) is a rare and aggressive, can be hereditary ophthalmological pediatric cancer [13]. Its incidence worldwide is 1/16000–1/18000 live births [14], which translates to around 8000–9000 new cases on annual basis, or 3–4% of all malignancies in pediatrics [15]. It is widespread among children under the age of five, with a prevalence of 1 in 15,000 [16, 17].

Fig. 1 [Images not available. See PDF.]

Comparison between **a** healthy eye and **b** retinoblastoma eye [15]

The prognosis for this condition is poor in around 80% of patients in low- and middle-income countries [18], due to poor health regimens and a lack of early detection; however, the survival rate is close to 100% in high-income countries [19]. Mutations in chromosome 13q14.2 result in the manifestation of RB in the first years of life [20]. The tumor suppressor gene RB1, located on chromosome 13q14.2 with aberrant phenotypic expression, is used to genetically characterize RB [21]. RB only occurs when both copies of the RB1 gene are abnormal functioning or absent [22].

The "two hit" hypothesis postulates that mutations at the germinal stage, which impact all retinal cells, resulting in cell cycle abnormalities and erroneous entrance into S phase of the cell cycle, may be the reason of RB [23]. RB may be hereditary or develop spontaneously. Bilateral RB (inherited RB) is caused by two mutations that occur before fertilization, causing malignancy to manifest at a younger age and often proceeds to bilateral RB [24].

In the spontaneous type of RB (unilateral RB), somatic mutations predominate, and both mutations develop in a single retinal cell following fertilization. This type of cancer usually occurs in the later years, and is not usually transmitted to the off springs [25].

The growth of RB tumors, developing from immature retinal cells, depends on the existence of different types of vasculatures. The tumor spreads as seeds (white mass) toward the vitreous and/or sub-retinal area. Although the seeds are avascular, the primary tumor is vascularized [22].

The retina's inner layer is made up of neurons that are sensitive to light [26]. These cells are linked to the brain through the optic nerve. Without prompt treatment, devastating consequences may occur, including loss of vision, secondary non-ocular cancers, and even death. In severe cases, changes in iris color and eye enlargement caused by high intraocular pressure may occur. The eye's unique anatomical and physiological structures offer an extensive barrier to drugs' delivery to diseased regions of the eye [27].

The blood retinal barrier (BRB), involved in the maintenance of ocular homeostasis, is another barrier to the transport of drug molecules into the eye [28]. The main parts of the BRB that allow solutes to cross from the blood to the retina comprise retinal pigment, retinal capillaries, sclera, and choroid. Retina is a part of the CNS, like the brain. As a result, tight junctions maintain retina's normal function in addition to the crucial oxygen consumption rate and

glycolysis [29–31].

Diagnosis and prognosis

Symptoms of RB include leukocoria (white pupil), strabismus (misaligned eyes) and reflection in the eye of the child. Changes in the iris color and larger eyes owing to increased intraocular pressure are common in advanced stages [32]. Detection, early medical intervention, involving a multidisciplinary team of radiologists, oncologists, geneticists, ophthalmologists, and suitable radiation, chemotherapy, and surgical treatments are necessary for the long-term improvement of patient life [33].

The diagnosis may usually be made using indirect ophthalmoscopy and pharmacologically dilated pupils. Ocular ultrasonography (β-scan) may be utilized to identify RB calcifications; however, MRI is required to assess trilateral RB and optic nerve invasion. Computed tomography should not be used on patients with RB1 mutations as radiation causes secondary malignancies [34, 35].

Alternatively, biopsies might provide crucial details on the histological type of ocular malignancy; however, sampling errors may lead to false negative results [36]. The development of ocular molecular imaging, which permits the early diagnosis of this eye disorder before the formation of any morphological abnormalities, is urgently needed despite the availability of numerous ophthalmic imaging techniques [37]. Fluorescein angiography, needle biopsy, ultrasonography, MRI, and CT are often used by physicians to identify RB based on the presence of retinal tumors [14].

Different treatments are used depending on how the tumor is progressing. However, in more severe cases of the disease, the whole globe and its intraocular contents must be surgically removed (enucleation), while in other cases; conventional treatments are employed [38].

For attaining best therapeutic efficacy and prognostication, RB must be classified. The original categorization was proposed by Reese–Ellsworth in 1963 [39]. Thereafter, in 2005, Murphree's International (IIRC) categorization [40], divides this ocular tumor into five groups (from A to E, with E being the most severe) [41]. Finally, this categorization was somewhat amended by the Children's Oncology Group (COG) [42].

The need for primary enucleation or conservative treatment may rely on the clinical status of the patient. All patients who have unilateral or bilateral RB of groups A, B, C, and D are eligible for specific therapy, however individuals who have bilateral RB of group E are only eligible for conservative treatment [43]. A direct biopsy cannot be used to diagnose RB in order to stop the development of metastases and the spread of disease outside the eye [35].

Main text

Different modalities for treatment of RB

To treat RB, anticancer drugs have been injected via the intravitreal, subconjunctival, topical, systemic or subtenon routes. Although these delivery systems are successful in managing the eye's anterior area, they have been ineffectual in treating the disorders of the eye's posterior segment where RB originates [44].

Different therapeutic procedures may be employed **(**Fig. 2**)**, depending on the stage of the disease. Systemic chemotherapy is frequently used in conjunction with local treatments (for example, cryotherapy, photocoagulation, brachytherapy, laser, radiotherapy, hormonal, and thermotherapy). In severe cases, surgery is frequently required to remove the whole globe and its intraocular components (enucleation) [45].

Fig. 2 [Images not available. See PDF.]

Different modalities used to treat RB and their drawbacks

The absence of a relationship between the outcomes of in-vivo research and in-vitro test findings is one of the obstacles to the development of cancer treatments.

Conventional treatment of RB

For the treatment of RB, several approaches have been presented. In the past, RB treatment was based on the administration of aggressive focused treatments in addition to systemic chemotherapy and beam radiation (EBRT) [46, 47]. The use of EBRT in particular has been reduced lately due to a number of adverse side effects that occurred including ototoxicity, leukemia, and future primary neoplasms. EBRT was widely utilized up until the

beginning of the twenty-first century [48, 49].

For these reasons, selective ocular delivery systems capable of augmenting the drug's effectiveness while decreasing the likelihood of side effects have been developed over the last decade. RB treatment is now tailored to the tumor's site (intraocular and/or extraocular disorders) and is meant to preserve vision. Moreover, patients with intraocular diseases, especially those related to bilateral ocular disorders, may have a high incidence of ocular protection when applying conservative tumor reduction using intravitreous chemotherapy (IVi) or ophthalmic artery chemosurgery (OAC) combined with extensive local treatment. Nowadays, radiation therapy is only used in cases of extraocular or intraocular disease progression [50, 51].

The conservative treatment is often associated with intense and early focused treatments, using conventional chemotherapeutic agents (i.e., Etoposide, Carboplatin, Palbociclib, Cisplatin, Cyclophosphamide, Doxorubicin, Melphalan, Vincristine, and Topotecan) at different durations and doses depending on the intraocular stage [22].

A physiological barrier, blood retinal barrier (BRB), regulates the flow of proteins, ions, and water inside and outside the retina [52]. The use of conventional anticancer drugs is accompanied by a number of adverse effects such as sores in the mouth and on other mucous membranes, hair loss, bone marrow toxicity, cardiac anomalies, and severe nausea and vomiting, besides, their efficacy is hampered by their inability to penetrate the BRB. Intra-arterial chemotherapy has often been employed to manage this problem [4, 53]. The ophthalmic artery and the femoral artery are both inserted with a micro-catheter as part of this method, and chemotherapeutic agents are then infused in a pulsatile manner [54].

Complications accompanying conventional treatment modalities include ophthalmic artery blockage, partial choroidal ischemia, branch retinal artery obstruction, visual neuropathy, ophthalmic artery spasm with reperfusion, vitreous hemorrhage, and in certain circumstances, patient death [55–57].

Drug discovery for RB treatment

Despite advances in treatment of RB, this disease may still be challenging to treat in certain refractory cases. As a result, researchers are now working to identify novel drugs that can cure both RB and intraocular malignancies utilizing two essential methods [58]:

1. Large-scale chemical high-throughput screening (HTS) employing cells.

2. Repurposing of approved drugs for other types of cancers.

Pharmacokinetic features (such as solubility, metabolism, and the capacity to cross the BRB) are regarded as crucial for the targeting of drug molecules and the design of drug delivery systems. With a focus on evaluating drugs on primary cell lines generated from cerebrospinal and intraocular fluids in which RB metastases, HTS has been used. Additionally, animal models with tumors xeno-grafted from intraocular or metastatic RB may be helpful for developing an effective treatment for humans [59].

Nutraceutical agents

In recent years, various naturally occurring agents have been demonstrated for RB treatment in addition to conventional anticancer drugs such as catechol derivatives (as curcumin), sterol derivatives (as ursolic and oleanolic acid), and naphthoquinones (as β-lapachone) [60]. Among these nutraceuticals is ARQ-501 (β-lapachone), an ortho naphthoquinone derivative, isolated from a tree whose extract has been used in medicine for generations, has been utilized for treatment of ocular tumors [61]. Although its exact mechanism of action is still unknown, several studies have shown its efficacy to block topoisomerase enzymes, resulting in DNA damage, cell cycling arrest, or even cell death. According to the latest studies, it may be advantageous in treating a variety of disorders, including cancer [62]. β-lapachone is now being assessed in fourteen clinical trials, primarily for solid tumors (such as pancreatic cancer, adenocarcinoma, and head and neck neoplasms), and for lymphoma [63].

Moreover, Celastrol, a Chinese herbal drug, showed its effectiveness against several tumor cell lines for treatment of

RB. A previous study reported that effectiveness of Celastrol in promoting dose-dependent apoptosis in SO-Rb50 human RB cells [64].

Routes of drugs' administration to posterior eye segment

The efficacy and safety of the drug are highly influenced by the route of administration. Modifying the administration route may boost and extend the therapeutic results. Delivery systems must be tailored to each administration route since each has its own pros and cons to transport drugs effectively and correctly [65, 66]. Different routes and modes of drugs' administration to posterior area of the eyes are discussed thoroughly in Table 1.

Table 1. Routes of drug delivery to the posterior segment of the eye

Delivery route		Advantages	Disadvantages	Present FDA and research approved examples	Ref.
Systemic	Oral	Simplicity of use	Systemic adverse effects		[8]
IV	Low cost Good Patient compliance Minimal systemic adverse effects	Low ocular bioavailability (1-2%)	Intravenous administration of PLA-PEG chains with cell-penetrating peptide nanoparticles enhanced light-triggered local delivery of drug to the infected choroid * Intravenous nanoparticles loaded with doxorubicin dramatically reduced the size of neovascular lesions *	[12]	Topical
Ointment	Low cost	Therapeutic doses can't be delivered to the retina owing to the existence of dynamic and static barriers	A dexamethasone-eluting contact lens achieved sustained therapeutic levels of dexamethasone to the retina 200-fold greater than hourly administered dexamethasone drops *	[127]	Eyedrops

Simplicity of use	Low therapeutic efficacy with amount less than 5% of the drugs diffusing through the eye following administration	An *in situ* thermosensitive hydrogel decreased laser-induced choroidal neovascularization in the posterior segment of the eyes of rats and pigs*	[100]	Gels	Low systemic side effects

Nanotechnology-based approaches for treatment of RB

Ocular cancer treatment has employed topical, systemic, intravitreal, and sub-conjunctival administration techniques. These delivery systems are beneficial for the anterior segments of the eye; however, they have not shown significance in treating disorders (such as RB) at the posterior segments of the eye [44, 67].

Nanodrug delivery systems (Fig. 3) can provide sustained drug release to maintain therapeutically effective concentrations over time, efficient drug targeting and augmentation of pharmacokinetics, pharmacodynamics, toxic, and immunogenic features, thus ensuring increased efficacy for treatment of ocular disorders [68, 69].

Fig. 3 [Images not available. See PDF.]

A schematic diagram showing nanotechnology-based drug delivery systems for the treatment of ocular disorders

[70]

The beneficial properties of nanoparticles (NPs), or particles with sizes between 1 and 1000 nm, have led to their widespread use in medicine. Since NPs are so tiny, they can penetrate cells, having a high surface area-to-volume ratio that amplifies all surface phenomena, thus causing little harm to cell membranes and surrounding cells [71]. Increasing penetration into the retinal pigment endothelium layer, that limits the transport of drugs into the tumor site, is a significant criterion for RB's nanodrug delivery systems. Nanodrug delivery improves the efficiency of cytotoxic anti-cancer drugs by decreasing their toxicity and non-specific interactions and increasing the solubility of weakly water-soluble therapeutic molecules [72]. As indicated in Table 2, many nanoparticulate systems have been utilized for the treatment of RB such as organic, inorganic, multifunctionalized nanocarriers and others. A summary of nanotechnology-based systems used for the management of RB is discussed in the upcoming lines.

Table 2. Summary of the nanocarriers employed in the treatment of RB

Nanodelivery system	Studies	Ref
Organic nanoparticles	Mudigunda et al. reported the effectiveness of hybrid PLGA/PCL NPs loading Palbociclib as well as a photothermal dye on Y79 RB cells with higher drug bioavailability in these cells compared to drug control	[78]

Sims et al. demonstrated the effectiveness of intra-arterial surface-tailored PLGA-NPs carrying melphalan for RB management paving the way for *in-vivo* application	[79]	Silva et al. demonstrated that PLGA-ursolic acid/oleanolic acid nanoparticles showed strong cytotoxic activity against RB cell line
[80]	Narayana et al. documented the efficacy of clinical-grade carboplatin and etoposide-loaded lactoferrin nanoparticles on RB y79 in terms of increasing drug retention, uptake and cytotoxicity compared to their standard drugs	[81]

Ahmed et al. demonstrated the potential of carboplatin loaded lactoferrin nanoparticles with high anti-proliferative activity into the RB cells compared to the drug alone	[82]	Lipid nanoparticles (LNPs)

Xu et al. reported the efficacy of switchable LNPs for the co-delivery of miR-181 and melphalan with good efficacy against RB	[83]	N'Diaye et al. demonstrated the efficaciousness of LNPs incorporating beta-lapachone and temoporfin against RBY79 cells, in which they could be supplied in a

		single intravitreal injection for treatment of RB

[84]	Solid lipid nanoparticles (SLNs)	Ahmad et al. showed the effectiveness of injectable etoposide SLNs for achieving safe and targeted drug against RB

[87]	Nanostructured lipid carriers (NLCs)	Almedia et al. reported the effectiveness of an eyedrop containing ibuprofen dispersion encompassing a combination of NLCs and a thermo-responsive polymer

		with considerable cytotoxicity, improved bioavailability, and therapeutic effectiveness, besides sustained-release drug profiles

[89]	Doxorubicin (DOX)-loaded poly-B-hydroxybutyrate microspheres	Hu et al. showed the functionality of these microspheres to extend DOX release to the posterior eyes' segment

[96]	Carboplatin hyper-branched PAMAM dendritic nanoparticles	Kang et al. proved the potential of carboplatin loaded on dendrimer type PAMAM to increase carboplatin's bioavailability which inhibited toxicity and tumor mass

		in RB compared to free carboplatin
[97]	Makky et al. proved an enhanced targeting and reduced toxicity outcomes when loading concanavalin in dendritic nanoparticles for treatment of intraocular tumors and RB	[98]
Polymeric nanoparticles	Arshad et al. proved that the successfulness of chitosan nanoparticles for delivering DOX to the Y79 RB cell line with increased folate receptor concentration	[100]

Delrish et al. demonstrated the augmented efficacy of thiolated chitosan nanoparticles comprising topotecan relative to free topotecan in Y79 RB cells	[101]	Delrish et al. demonstrated increased ocular bioavailability of thiolated chitosan carboxymethyl dextran nanoparticles in retinoblastoma induced rat eyes

[102]	Godse et al. revealed that galactose conjugated chitosan nanoparticles loaded with etoposide exhibited greater cytotoxicity and resulted in higher apoptosis in RB Y-79 cells relative to pure etoposide	[103]

Mohseni et al. demonstrated that lauric acid-grafted chitosan-alginate nanoparticles incorporating melphalan enhanced its penetrability to the vitreous cavity with augmented efficacy, delineating their potential for RB treatment	[104]	Boddu et al. reported that a micellar system comprising DOX exhibited a two-week continuous release of the drug and a four fold increase in cell absorption over

		the free drug
[105]	Das and Sahoo emphasized that folate-tagged PLGA nanoparticles containing curcumin and nutlin-3a were able to reverse multidrug resistance (MDR) pathways and increase cancer cell apoptosis, expanding therapeutic efficacy for RB treatment	[106]
Rebibo et al. revealed the superior efficacy of tacrolimus-loaded PLGA nanocapsules for RB treatment in augmenting drug's retention and enhancing penetration to posterior eye compartments	[107]	Silver NPs (AgNPs)

Remya et al. reported the cytotoxic efficiency of AgNPs derived from natural sources of brown seaweed Turbinaria ornata against RB cells	[110]	Rajanahalli et al. revealed that AgNPs resulted in cell cycle arrest in G1, and S phases mediated by repression of RB protein phosphorylation using stem mouse embry

		onic stem cells

Organic NPs

Organic nanoparticles are assemblages of organic molecules with an almost infinite number of distinct configurations. They are frequently produced by non-covalent intermolecular interactions, rendering them more malleable in nature and providing a route for elimination from the body. Owing to their flexibility, these nanoparticles can alter shape or conformation when exposed to external stimuli [73]. In RB treatment, the most common type of organic NPs are lipid-based nanoparticles (LNPs), lactoferrin nanoparticles and polymer-based (e.g., poly-caprolactone (PCL), chitosan (CH), polylactic-*co*-glycolic acid (PLGA), and polymethylmethacrylate (PMMA) NPs), showing biocompatibility, high bioavailability in RB cells, with no discernible toxicity besides excellent photothermal and photoacoustic imaging characteristics. Their photothermal properties allow them to absorb light energy and transform it into heat, raising the temperature of the surroundings and causing the death of ocular cancer cells. They can also enable the selective targeting of tumor cells, minimizing the damage to adjacent healthy tissues. The photothermal effect, in addition to destroying cancer cells, can generate acoustic waves that can be detected and turned into imaging signals, a process known as photoacoustic imaging. The method not only gives an additional imaging technique for RB diagnosis, but it also allows for the identification of various biologically relevant signals in a tumor microenvironment, such as reactive oxygen species (ROS), acidic pH, and certain enzymes [74].

A recent study by Mudigunda et al. [75] demonstrated the effectiveness of hybrid PLGA/PCL NPs encapsulating Palbociclib (PCB), as anticancer agent, together with a photothermal dye on Y79 RB cells with higher drug bioavailability in these cells compared to drug control. Furthermore, Sims et al. [76] demonstrated the effectiveness of surface-tailored PLGA-NPs carrying melphalan for intra-arterial treatment of RB, paving the way for *in-vivo* application. Additionally, Silva et al. [77] investigated PLGA nanoparticles sequestering ursolic acid (UA) and oleanolic acid (OA) as a single-dose combination therapy for the management of RB. PLGA-OA/UA nanoparticles showed potent cytotoxic potential against the Y-79 cell line delineating these NPs as a promising approach for treating RB. Moreover, another study documented the efficacy of clinical-grade carboplatin and etoposide-loaded lactoferrin nanoparticles on RB y79 in terms of increasing drug retention, uptake and cytotoxicity compared to their standard drugs [78]. Furthermore, Ahmed et al. [79] demonstrated the potential of carboplatin loaded lactoferrin nanoparticles to enhance ocular drug's retention and intracellular uptake and accordingly, resulting in high anti-proliferative activity into the RB cells compared to the drug alone.

Lipid NPs (LNPs)

Lipid nanoparticles have shown to be promising ocular drug delivery systems since they comprise natural excipients and can incorporate lipophilic drugs, in addition to their distinctive characteristics such as good biocompatibility, safety, and adhesion, which allow for increased bioavailability, compliance, and prolonged drug release. LNPs are useful nanotechnology-based systems used in drug delivery to manage different types of ocular disorders including RB. LNPs gained more attention in the treatment of infectious diseases and cancers, besides the absorption of heavy metals [72].

A previous study reported the effectiveness of switchable LNPs for the co-delivery of melphalan and miR-181 with good efficacy against RB [80]. Furthermore, N'Diaye et al. [81] created LNPs composed of a poly(D, L)-lactide (PDLLA) nanoparticle grafted with a phospholipid (1-palmitoyl-2-oleoyl-sn-glycero3-phosphocholine/1,2-dioleoyl-trimethylammonium propane) bilayer incorporating beta-lapachone as an anticancer agent and photosensitizer, temoporfin, for combined photodynamic and chemotherapy therapy against RB Y79 cells. The investigated system was shown to be efficacious in both chemotherapy and photodynamic treatment and could be supplied in a single intravitreal injection for treatment of RB.

Solid lipid NPs (SLNs)

SLNs represent lipid-based nanocarriers that combine the advantages of emulsions, liposomes, and polymeric particles. To create SLNs, solid lipid matrixes that combine crystalline, highly structured lipid droplets containing bioactive agents, are employed. It is possible to regulate the entrapment of bioactive compounds by changing the SLN lipid matrix's physical state. SLNs provide targeted ocular drug delivery, regulated drug release, and drug stability [82, 83]. A previous study conducted by Ahmad et al. [84] reported the effectiveness of SLNs for the targeted and safe etoposide's injection against RB.

Nanostructured lipid carriers (NLCs)

NLCs are the second generation of SLNs, designed by substituting liquid lipids for the fractional solid lipid components of SLNs, causing an expanded drug corporation space. NLCs are superior to traditional carriers for ocular drug delivery in a number of ways, including improved solubility, the ability to increase storage stability, enhanced bioavailability and permeability, longer half-life, fewer side effects, and tissue-specific delivery [13]. Table 3 provides a comparison between the pros and cons of NLCs and SLNs for ocular drug delivery [85].

Table 3. Advantages of NLCs compared to SLNs limitations regarding ocular drug delivery

Advantages of NLCs	Disadvantages of SLNs
Superior encapsulation efficiency Excellent ocular permeability Proper pharmacokinetic characteristics Extended and controlled drug release Maintaining adequate drugs' concentrations within the aqueous humor, vitreous humor, and retina -Increasing pre-corneal drug retention Increasing drugs' corneal permeation Increasing ocular bioavailability and distribution Positively-charged NLCs have shown to promote a prolonged ocular residence time, circumventing ocular toxicity owing to their close contact with negatively charged mucus membrane Superior biocompatibility and stability	Initial burst release of SLNs Low drug loading efficiency SLNs for ocular drug delivery have not recently assessed through extensive clinical trials, and most investigations have only undergone *in-vitro* evaluations Retinal cell toxicity of SLNs has not been thoroughly studied till current date

Almedia et al. [86] designed an eye drop dispersion of ibuprofen that comprised a combination of NLCs and a thermo-responsive polymer possessing muco-mimetic properties. The cytotoxicity of the formed dispersion was then tested on Y-70 human RB cells, and considerable cytotoxic potential was found. The cytotoxicity of NLCs was then tested using the Alamar Blue reduction assay, which revealed that they were harmless. Later, the results showed that ibuprofen exhibited enhanced bioavailability and therapeutic effectiveness, together with sustained-release drug profiles when loaded in these nanoparticles.

Nanovesicular delivery systems

Nanovesicles comprise an aqueous core enclosed by a lipidic bilayer membrane. Many pharmaceutical enterprises, including those in cancer therapy, employ these systems to encapsulate therapeutic compounds [87].

Liposomes

One of the most popular vesicular systems employed for the management of posterior eye segment disorders is liposomes. Amphipathic phospholipid-based vesicular structures known as liposomes may encapsulate both hydrophobic and hydrophilic molecules [88].

Despite their vulnerability to surface alterations, liposomes have been frequently employed to carry chemotherapeutic agents. Till the current date, no studies have been performed using liposomal systems for the management of RB. However, other studies reported the efficiency of liposomes for the delivery of fluorescein isothiocyanate (FITC) tagged polystyrene or fluorescent probes coumarin-6 to the retina owing to liposomal small particle size, facilitating its permeation across the BRB [89].

Polymeric nanoparticles (PNPs)

Polymeric nanoparticles are particles ranging in size from 1 to 1000 nm that can be laden with biologically active substances which are surface adsorbed onto or entrapped within the polymeric core. They comprise various kinds of polymers, used to produce nanocapsules or nanosphere (Fig. 4). Nanocapsules are reservoir-type systems where

the drug is encapsulated inside a cavity surrounded by a distinct polymeric membrane, whereas nanospheres are matrix-type systems where the drug is uniformly distributed throughout the polymer matrix [90]. The ability to protect drugs and other molecules exhibiting biological activity from the external environment and that to improve their therapeutic index and bioavailability are all advantages of employing PNPs as drug delivery systems [80]. In comparison with other types of nanoparticles, PNPs have received more attention for the management of RB [91].
Fig. 4 [Images not available. See PDF.]

Representation of polymeric-drug delivery systems; nanocapsules and nanospheres

Doxorubicin (DOX)-loaded poly-B-hydroxybutyrate microspheres

Microspheres are monolithic particles with a biodegradable polymer matrix that can be porous or solid. Owing to their pore interconnectivity, low mass density, and large surface area, they are of biotechnological interest where they can provide good particle size control. Polymeric microspheres produced from natural and synthetic polymers may be suitable as monolith templates. They provide a vital role as scaffolds for targeted distribution of bioactive chemicals in a controlled way to improve ocular drug delivery [92]. Regarding RB, DOX-loaded poly-B-hydroxybutyrate microspheres showed extended DOX diffusion to the posterior segment of the eyes, enhancing the drug's penetration into retinal tissues as compared to DOX suspension drops [93].

Carboplatin hyper-branched PAMAM dendritic nanoparticles

Hyper-branched poly(amidoamine) (PAMAM) dendrimers are a novel three-dimensional architecture with nanoscale size and cationic surface charge that could be used as siRNA condensing agents in addition to sturdy nanovectors for targeted ocular drug delivery [71]. Kang et al. [94] proved that carboplatin loaded on dendrimer type PAMAM resulted in an increase in carboplatin's bioavailability which lessened tumor mass in RB. Carboplatin-loaded dendrimers were retained in the tumor vasculature for a longer duration of time and penetrated the sclera until reaching the contralateral eye via the local vasculature, resulting in a prolonged therapeutic effect compared to free carboplatin. Meanwhile, Makky et al. [95] proved an enhanced targeting and reduced toxicity outcomes when loading concanavalin on porphyrin glycodendrimers used in photodynamic therapy for the management of intraocular cancers and RB.

Chitosan nanoparticles

Chitosan is a natural biodegradable polymer that has been extensively researched due to its significant mucoadhesive properties. The ionic interactions provided by chitosan's positively charged nature with the anionic ocular mucosa improve the drug's mucoadhesion, permeability, and retention time on the ocular surface. Consequently, chitosan-based nanoparticulate systems can reduce the number of ocular injections needed while increasing long-term patient compliance [96]. In a previous study, chitosan nanoparticles were fabricated with the goal of delivering DOX to the Y79 RB cell line with increased folate receptor concentration, in which they proved their superior cytotoxicity compared with their unmodified counterparts [97]. Another study demonstrated the augmented efficacy of thiolated chitosan nanoparticles comprising topotecan relative to free topotecan in Y79 RB cells [98]. Moreover, Delrish et al. [99] demonstrated increased ocular bioavailability of thiolated chitosan carboxymethyl dextran nanoparticles in retinoblastoma induced rat eyes. Additionally, Godse et al. [100] revealed that galactose conjugated chitosan nanoparticles loaded with etoposide exhibited greater cytotoxicity and resulted in higher apoptosis in RB Y-79 cells relative to pure etoposide. Furthermore, a previously performed *in-vivo* study showed that lauric acid-grafted chitosan-alginate nanoparticles incorporating melphalan enhanced its penetrability to the vitreous cavity with augmented efficacy, delineating their potential for RB treatment [101].
Another study reported the formulation of a micellar system based on the hydrophilic poly(ethylene glycol) (PEG)

and the biodegradable polymer PLGA comprising DOX, in which folic acid was added to the outer surface of PLGA-PEG-PLGA micelles in order to target the highly expressed folate receptor in Y79 RB cells. This delivery system showed a two-week prolonged release of DOX and a four-fold increase in cell absorption relative to the free drug [102]. A recent study reported the design of curcumin and nutlin-3a loaded folate-tagged PLGA nanoparticles to antagonize multidrug resistance (MDR) pathways and augment tumor cell death. The combined action of curcumin and nutlin-3a expanded therapeutic efficacy for RB treatment [103]. Also, Rebibo et al. [104] fabricated stable and non-irritant PLGA nanocapsules loaded with tacrolimus (TAC) for RB treatment. These nanocapsules showed superior enhancement in augmenting drug retention and diffusion to posterior eye compartments.

Inorganic NPs

Inorganic nanoparticles, comprising non-carbon-based molecules, have attracted significant attention in ocular drug delivery owing to their capacity to be altered in size, form, and crystallinity, besides their large surface area, high density of surface ligand attachment, and simplicity of functionalization. They are divided into metallic and non-metallic NPs [59]. Mesoporous silica, iron oxide, silver, gold, and cerium oxide NPs are the most common types of these nanoparticles used for the delivery of anticancer drugs in treatment of RB disease [7].

Metallic NPs

Metallic nanoparticles are flexible single-element nanomaterials. Some of the most common nanoparticles include Au, Ag, Pt, Cu, Pd, Re, Zn, Ru, Co, Cd, Al, Ni, and Fe nanoparticles. Owing to their flexibility, they can alter composition, shape, size, assembly, structure, and optical properties [72]. They've received much more attention due to their advanced characteristics, such as high surface energy, optical properties, quantum confinement and plasmon excitation, rendering them potential for ocular drug delivery [7].

Silver NPs (AgNPs)

Silver nanoparticles have been widely used in ocular administration of drugs owing to their distinct physical and chemical properties, large surface area-to-volume ratio, biocompatibility, and low production cost, which render them suitable candidates as drug delivery carriers [105]. Silver NPs were employed in RB treatment owing to their affordability, stability, environmentally friendly manufacturing process, and optical properties. Advanced plasma mass spectroscopic techniques, X-ray diffraction (XRD), high-resolution transmission electron microscopy (HR-TEM), Fourier transform infrared spectrum (FTIR), and UV–visible spectroscopy were employed to investigate the synthesized AgNPs [106]. A previous study reported the cytotoxic efficiency of AgNPs derived from natural sources of brown seaweed Turbinaria ornata against RB cells [107]. Meanwhile, another study reported that AgNPs resulted in cell cycle arrest in G1, and S phases mediated by repression of RB protein phosphorylation using stem mouse embryonic stem cells (mESCs) [108].

Gold NPs (AuNPs)

Gold is a noble metal noted for its peculiar optical characteristics, caused by the well-known phenomena of localized surface plasmon resonance. This effect is greatly affected by its shape and is the primary cause for its capability to penetrate biological tissues [85]. The effectiveness of AuNPs as therapeutic agents has been studied in RB treatment on the account of their large surface areas, which allow the adsorption of various functional agents [86]. Accordingly, gold NPs have been studied as drug carriers in RB owing to their ability to [109]:

1. Enhance permeability and retention (EPR) of drugs into the tumor's leaky neovessels, promoting their passive targeting capacity to the tumor site.

2. Sustain drugs' release in response to internal or external triggering factors.

3. Alter the surface with targeting ligands enhancing tumor-selective accumulation as compared to free drugs.

4. Increase the solubility and stability of the drug while also providing a high drug loading capacity by the virtue of their large surface area.

Wang et al. [110] proposed using mesoporous gold nanocages (AuNCs) linked with iron oxide (Fe_3O_4) nanoparticles loaded with muramyl dipeptide (MDP), an immunomodulator and perfluoropentane (PFP), a diagnostic imaging for RB diagnostic imaging and treatment. The cytotoxicity of AuNCs-Fe3O4/MDP/PFP in retinal pigment epithelium ARPE-19 cells and RB Y79 cells was verified, indicating that the delivery system was physiologically safe *in-vitro* and *in-vivo*, accelerating its implementation clinically.

Iron oxide NPs

Iron oxide NPs are magnetic nanoparticles composed of magnetic elements such as iron, cobalt, chromium, and manganese [103]. Since their reactive surface can be modified with biocompatible coatings or bioactive chemicals, they can form a robust drug delivery system that increases their selectivity toward biological targets while avoiding interaction with healthy cells [104]. Iron-containing magnetic nanoparticles combined with heat were employed for the treatment of RB. Hyperthermia is a powerful cancer treatment method because tumor cells are more heat sensitive compared to healthy cells. The temperature may be raised using a variety of techniques, such as microwaves, radio frequency, and focused ultrasound. Iron nanoparticles have been employed as nanoheaters that can target tumor cells without harming healthy tissues [111].

Demirci et al. [111] evaluated magnetic hyperthermia in the Y79 RB cell line utilizing dextran-coated iron nanoparticles. The results indicated that following 24 h of magnetic hyperthermia therapy, apoptosis in 46% to 73% of Y79 RB cells was denoted, suggesting the functionality of magnetic hyperthermia employing dextran-coated iron nanoparticles as an effective therapeutic approach for RB.

Mesoporous silica NPs (MSNPs)

Mesoporous silica nanoparticles are among the most extensively researched inorganic nanoparticles in ocular drug delivery. MSNPs are biodegradable nanomaterials that have the potential to break down into silica or silicic acid. Owing to their known biocompatible nature, they represent one of the most propitious substrates for biological applications including drug administration [7]. It has been determined that MSNPs may increase the solubility and bioavailability of lipophilic molecules due to the subsequent merits [112, 113]:

1. MSNPs' surface is hydrophilic, which improves their wettability. Additionally, the hollowness, surface chemistry, and pore size of microspheres may change the rate of drugs release from them.

2. Enhancement of the amount of entrapped drugs owing to MSNPs’ lack of crystallinity.

3. Large surface area and high dispersibility.

It was reported that functionalized mesoporous nanoparticles loaded with camptothecin (CPT), an anti-cancer agent, as well as one or two photon excitation photosensitizers for photodynamic therapy (OPE-PDT and TPE-PDT) showed their effectiveness using Y79 cells in treating RB [114]. Furthermore, Qu et al. [115] demonstrated that carboplatin (CRB) loaded MSNPs increased cancer cell death in RB cells relative to free CRB. Additionally, Gary-Bobo et al. [116] developed a one-photon excitation photodynamic therapy agent (OPEPDT) employing CPT, mannose, or galactose in MSNPs to target Y-79 RB cells which showed a propitious therapeutic synergy for destroying RB cells. Meanwhile, Warther et al. [117] reported the efficacy of mannose-functionalized MSNPs for targeting and imaging RB cells. MSNPs were almost always located in lysosomes, suggesting that they invade cells

via an endocytic pathway.

Cerium oxide NPs (CeONPs)

Cerium represents the first element in the lanthanide group and appears in both the CeO_2 and $Ce2O_3$ oxidation states. Cerium oxide nanoparticles have cerium (III) and cerium (IV) on their surface, and the pharmacological activity of these nanoparticles depends on their capacity for oxygen absorption and release [118].

Cerium oxide NPs (CeONPs), which have anti-inflammatory and antioxidant characteristics, have attracted a lot of attention in nanotechnology [119]. CeONPs are a viable alternative therapy for a range of acute and chronic disorders since ROS-induced oxidative stress is linked to several disorders [120]. In a previous study, CeONPs showed inhibition in the apoptotic signaling pathway of RB Y78 cell lines, increasing genes expression accompanied by neuroprotection, and decreasing the ROS [119]. Furthermore, Gao et al. [121] reported a novel nanocarrier composed of glycolic chitosan-coated cerium nanoparticles (GCCNP) as a pH-sensitive controlled drug delivery system that can deliver doxorubicin (DOX) for pH-sensitive and tumor-targeted combination therapy. This study reported a synergistic approach for improving the therapeutic potential and lowering the adverse effects of DOX with significant reduction of tumor growth, in addition to improving the *in-vivo* biocompatibility of the proposed NPs with healthy retinal cells. Additionally, Kartha et al. [122] demonstrated the efficacy of cerium-doped titanium dioxide nanoparticles (Ce-doped TiO_2) for their anticancer effects against Y79 RB tumor cells compared to TiO_2 nanoparticles. Both nanoparticles were incubated in Y79 RB cancer cells and then treated with UV irradiation for various time periods varying from one to six hours. Ce-doped TiO_2 showed augmented anticancer cytotoxicity compared to TiO_2 nanoparticles owing to the ability of cerium element to retain the integrity of DNA, generally lost in cancerous cells, by acting on the intimate pathways governing the survival of cancerous cells.

Multifunctionalized nanocarriers

Multifunctional NPs are advanced nanoparticulate systems which can deliver one or more therapeutic compounds, enabling biomolecular targeting through one or more conjugated antibodies or other ligands, and magnifying imaging signals by encapsulating contrast agents [65, 123].

Surface-modified melphalan NPs for the intravitreal chemotherapy of RB

Compared to unmodified NPs, surface-modified melphalan NPs exploited superior effectiveness against RB cells, in which they demonstrated higher efficacy compared to other NPs [124]. Future studies are required to demonstrate the capacity of these nanoparticles to enhance drug's transport to the vitreous humor, where it is expected that surface modification will have a bigger influence on efficacy.

Galactose-functionalized nanocarriers

The sugar entities ligand-based mechanistic technique for attaining enhanced and customized RB treatment is in great demand. RB cells express considerably more sugar moieties in the form of lectins than healthy cells. Hence, targeting overexpressed lectins is an effective way for achieving successful results [125].

Human RB cells express sugar receptors (lectins) with a preference for galactose and mannose residues, according to a prior work by Godse et al. [125]. Sugar is therefore a desirable ligand that can be used to target and improve the endocytosis of drugs-loaded NPs. Additionally, unlike folic acid, sugars do not have photosensitivity or stability concerns. The authors observed that etoposide loaded PLGA nanoparticles coated with chitosan and galactose for treatment of RB slowed the drug release rate and helped in the active targeting of RB cells. Also, cytotoxicity and apoptosis experiments demonstrated that these NPs had improved the drug’s cellular internalization, promoting superior anti-cancer activity.

Hyaluronic acid (HA)-functionalized nanocarriers

HA is an FDA-approved marine polymer possessing exceptional biodegradability, flexibility, mobility and shielding, in

addition to an anticancer action on the HA receptor, the CD44 receptor. A previous study reported that the formulation of electrostatically coated nanoparticles incorporating nonverbal polymeric gene DNA complexed with HA provided increased intravitreal drug delivery in RB cells [126].

Folic acid (FA)-functionalized nanocarriers

Coupling nanocarriers with a targeting moiety can be more successful compared to systemic chemotherapy in the targeted eradication of tumor cells [103] Targeted molecules allow spatial delivery of antitumor agents [98]. Folate receptors are highly expressed in RB cells, so exploiting them in RB treatment to selectively uptake NPs and only kill cancer cells will be very effective [127]. In a study reported by Mitra et al. [128], CNPs and DOX conjugated with folic acid proved their efficacy for targeting RB cells.

Conclusions and future prospects

Retinoblastoma is a type of challenging pediatric ocular cancer that is difficult to treat by the conventional approaches owing to drug expulsion and non-targeted delivery, resulting in therapeutic inefficiency. Nanoparticles-mediated antitumor drug delivery proved to increase therapeutic potential, lower toxicity, customize site-specific delivery and ligand binding that may transport drug through several routes of administration, hence causing cost-effectiveness and cytotoxicity management of RB. These delivery systems have shown their effectiveness to lower the barriers to treating RB and prevent the loss of normal cells. Emerging advances in multifunctionalization and biocompatible ligands in anticancer therapy and diagnosis are ushering in a new era of surpassing conventional barriers by strategically enhancing RB treatment and diagnosis. With the revolutionary breakthrough of nanomedicine in cancer diagnosis, experimental research is designed to establish cell/tissue-specific nanosystems to suit the demanding criteria of intraocular chemotherapy and diagnostics. The last frontier in this study is employing "intelligent nanosystems with several functions" (i.e., systems capable of reaching the challenging anatomical eye components affected by RB). However, further pre-clinical research is required before evaluating the method in clinical trials to determine its benefit-to-risk ratio.

Quisqualis indica Linn.: HRLCMS/MS profiling and anti-asthma activity of leaf extracts

Nemade, Charulata T.1 ; Aher, Anilkumar N.21 SNJB's SSDJ College of Pharmacy, Chandwad, Nashik, India2 MVP's College of Pharmacy, Nashik, India

ABSTRACT (ENGLISH)

Background

Asthma is a chronic inflammatory disorder of the airways, involving various cells and cellular elements precisely eosinophils, mast cells, neutrophils, T lymphocytes, epithelial cells, and macrophages. Worldwide, about 300 million people are affected by asthma, and is expected that 100 million people may get affected, in 2025. *Quisqualis indica* is commonly planted as an ornamental plant in India; and has medicinal uses. Therefore, the petroleum ether (60–80 °C) LPE and methanolic extract LME of the *Quisqualis indica* leaves were analyzed for anti-asthmatic activity by mast cell degranulation and Milk induced eosinophilia and leukocytosis in mice.

Results

It was found that *Quisqualis indica* leaf extracts exhibited protection against the degranulation of mast cells and a reduction in the difference count of leucocytes and eosinophils. LPE and LME (400 mg/kg) have shown 33% and 63% of mast cell protection. LME has shown the most significant mast cell stabilizing action comparable with the standard drug. The extracts decreased the difference count of leucocytes and eosinophils. LME (400 mg/kg) has shown a difference in eosinophil count and a decrease in leukocyte count most comparable with the standard Dexamethasone. Methanolic extract analyzed for phytochemicals by High Resolution Liquid Chromatography Mass Spectroscopy /Mass Spectroscopy method showed the presence of various Phyto-compounds.

Conclusion

From the analysis of methanolic leaf extract of *Quisualis indica* revealed the presence of phytocompounds such as Apigenin7-glucoside, Gallic acid, Quercetin, Quercitrin, Kaempferol, etc. The significant decrease in eosinophil and leukocyte count in animals might be due to the higher content of Tannin and flavonoids. A reduction in leukocyte and

eosinophil is regulated by type 1 hypersensitivity and adaptogenic factors hence *Quisqualis indica* is effectively helpful in allergy conditions like asthma.

FULL TEXT

Background

Asthma is a chronic inflammatory disorder of the airways, involving various cells and cellular elements, precisely eosinophils, mast cells, neutrophils, T lymphocytes, epithelial cells, and macrophages. Asthma is characterized by hindrance of airflow due to inflammation, bronchospasm, and increased airway secretions. [1] About 300 million people worldwide suffer from asthma, and by 2025, it's predicted that 100 million more will likely develop the condition. The prevalence, severity, and mortality of asthma are greatly affected by geographical variation. Asthma incidence is greater in high revenue countries, and maximum death caused by asthma happens in low middle revenue countries [2].

The multifaceted condition known as asthma is brought on by complex relationships between the environment and heredity. The pathophysiology of this condition includes intermittent airflow restriction, bronchial hyperresponsiveness (BHR), inflammation of the airways and bronchial remodeling. Depending on the severity of the condition, bronchodilators and anti-inflammatory medications can be used to treat asthma. Then, additional treatments are still required to better control asthma, and herbal remedies may be a viable substitute for current synthetic medications [3]. Additionally, plant polyphenols are potent components of natural foods and herbal medicine that have anti-inflammatory, antioxidant, and anti-allergic properties. Previous studies have demonstrated the anti-inflammatory effects of resveratrol, genistin, luteolin, and quercetin, as well as their multiple targets, multiple links, and comprehensive coordination [4].

The plant *Quisqualis indica* Linn.*(Combretaceae)* is an evergreen plant planted in homes and gardens of countries like India, China, Australia, the Amazonian region in Peru, and Pakistan. It is a large sub-woody climber shrub with 3–8 m long branches. Leaves are simple, oppositely having an oblong-elliptic to elliptic shape. It bears the inflorescence with white to pink-colored flowers. Flowers appear in constant succession in sagging clusters with a sweet scent [5, 6].

The leaves of *Quisqualis indica* were used to isolate four crystalline components, which were later identified as nicotinic acid and methylbetaine (trigonelline), L -proline, L -asparagines and potassium quisqualate [7]. Triterpenoids, flavonoids and tannins were isolated from the petroleum ether and methanolic extract of leaf and flower, respectively [8]. Ethno-pharmacologically, the flowers, fruit, seeds, leaves, stem and roots of the plant are used. Leaves are used to relieve pain caused by fever. Leaves decoction is given for flatulent distension and pain in the abdomen. Leaf juice is used to heal boils and ulcers [9]. Fruits and seeds are used in folk medicine as anthelmintic, anti-emetic, and anti-diarrhoea [10].

Different parts of plant have been studied for various pharmacological actions such as anti-microbial [11], anthelmintic [12], anti-pyretic [13], anti-inflammatory [14], anti-oxidants [15], insecticidal [16], immunomodulatory [17], anti-diarrheal [18], etc. due to the existence of various phytoconstituents. The stem bark and flowers were evaluated for the total tannin content and anti-oxidant activity [19]. Roots are used to treat rheumatism, cough and hiccup by Philippines [3, 20, 21]. As the whole plant is used as cough cure [10]; in the current work, we have looked into the phytoconstituents and anti-asthma activity of the *Quisqualis indica* leaves. The leaf petroleum ether extract (LPE) and leaf methanolic extract (LME) of *Quisqualis indica* were screened for phytochemicals by High Resolution Liquid Chromatography Mass Spectroscopy /Mass Spectroscopy (HRLCMS/MS) and anti-asthma activity. In the case of *Quisqualis indica* extract, which is high in flavonoids and phenolic compounds, reduces inflammation [14] and act as an immunomodulatory. [17]

Methods

Collection and preparation of plant material

The fresh leaves of *Quisqualis indica* Linn. plant were collected from the residential region in the Indian state of Maharashtra near Nashik. The plant was verified by the India Botanical Survey, which included Pune and

Maharashtra [22, 23]. The allotted authentication No. was BSI/WRC/IDEN.CER/2016/403 (A). The pulverized and sieved dried leaf powder was processed. The petroleum ether (60–80 °C) and methanol solvents were used to extract the phytochemicals such as steroids, flavonoids, tannins; alkaloids, etc. The petroleum ether (60–80 °C) and methanol solvents were used in a continuous hot percolation process (Soxhlet extraction) to extract the coarse powder successively for 48 h. A rotating vacuum evaporator (Evator) was used to concentrate the liquid extracts to produce a semisolid extract [24, 25].

Animals

The healthy adult Wistar albino mice (20–25 g) of either sex were housed in polypropylene cages, under 12 h light: 12 h dark cycle and temperature 22±2 °C and humidity 55±5% maintained in the animal house. The animals had free access to food and water. All the animals were deprived of food but not of water 4 h before the experiment [26]. The Institutional Animal Ethical Committee of the institute (Registration No. 121/1999/CPCSEA) has approved all the protocols of the study (Registration No. IAEC/Jan 2020/09).

Acute oral toxicity study

The acute oral toxicity study OECD guideline (2001) [26, 27] was followed to carry out acute toxicity study for the extracts of *Quisqualis indica* plant.

Mast cell degranulation

There were six groups of mice in total, with six mice in each group. A three-day treatment for drugs program has been followed properly. Group I Control groupwas given the treatment with 1% tween 80 solutions (5 ml/kg, i.p.); Group II received standard drug Sodium chromoglycate (50 mg/kg, i.p) and all test groups Group III to Group VI received LPE and LME at doses of 200 and 400 mg/kg. On the fourth day, 10 mL/kg of 0.9% saline solution was gently massaged into the peritoneal cavity of each mouse before being injected. Five minutes later, the peritoneal fluid was collected. The peritoneal fluid was then put into a test tube containing 7–10 mL of RPMI-1640 buffer medium (pH 7.2–7.3), which is made up of L-glutamine and 25 mM HEPES buffer but not sodium bicarbonate. At 400–500 rpm, this solution was then centrifuged. Centrifugation was used to rinse the mast cells pellets twice with RPMI-1640 buffer media, and the supernatant was rejected. Egg albumin was used to challenge the cell suspension produced from both the treated and control groups of mice, which was then incubated at 37 °C for 10 min.After being stained with 1% toluidine blue, the cells were examined under a microscope. Mast cells that had degranulated were seen as rupture cells rather than whole. In total of 100 cells from various visual regions were counted, and the percentage of protection against degranulation was calculated [28, 29].%Protectionmastcell=[1-(T/C)]x100where, T-No. of degranulated cells of test

C-No. of degranulated cells of control

Milk induced eosinophilia and leukocytosis

There were six groups of mice, six animals in every group. Blood samples (0.5 ml) were collected from the retro-orbital plexus. Group I Control group received vehicle, tween 80 (1%) solution (5 ml/kg, i.p.); Group II received Standard drug Dexamethasone (50 mg/kg, i.p) and test groups Group III to Group VI received LPE and LME at doses 200 and 400 mg/kg. Amul's Fresh milk was procured from the local market. All animals were treated with an injection of freshly cooked and chilled milk (4 mL/kg, s.c.) for 30 min following treatments. Total leukocyte and eosinophil count were carried out in each group before drug administration and 24 h after the milk injection. Difference in total leucocytes count before and after 24 h of drug administration was calculated [30, 31].

Statistical analysis

All the results of various studies were expressed as mean±Standard Error of Mean. Data was analyzed using a one-way ANOVA, which was followed by Dunnet's Multiple Comparison Test. $P<0.05$ was considered statistically significant. The graphs were calculated with the GraphPad Prism 5.

HRLCMS/MS profiling

The phytochemicals of the bioactive extract (LME) were analysed by HRLCMS/MS method. High-resolution liquid chromatography combined with the Q-Exactive Plus Mass Spectrometer TOF/Q-TOF mass spectrometer with ion source dual AJS electrospray ionization (ESI) was used [32]. The plant extract (50 mg) was dissolved in 1 mL of

water: acetonitrile (1:1) solvent mixture, ultrasonically processed for 10 min, and then centrifuged at 10,000 rpm for 10 min. The ZORBX Eclipse Plus C18, narrow bore 2.1 150 mm with 5 microns, was used for the LC/ESI-QTOF-MS/MS analysis. An amount of 5µL was delivered in both positive as well as negative mode. The Mass Spectra scan range was in 120 to 1200, with 1.00 scans rate spectra/second and 1.00 as MS/MS scan rate spectra/second. The gradient elution procedure was done by changing the proportion of water and acetonitrile from 95 to 5% within 30 min, with flow rate of 0.3 mL/min as a constant flow rate. Then, this section was linked to the TOF/Q-TOF Mass Spectrometer for MS/MS fragmentation spectra. Phytochemicals were recognized by comparing their m/z and MS/MS transitions with those documented in reference databases. Further, the molecular formula, retention time, and adduct formula were detected.

Results

Acute oral toxicity study

Oral administration of plant extracts shows no significant body weight variation, neither any sign of toxicity nor mortality of mice at the dose of 2000 mg/kg, body weight.

Mast cell degranulation

In the pathogenesis of allergic asthma, mast cells also play a crucial role. Inhaled antigens enter the lower respiratory tract and produce localised mast cell degranulation and inflammation that trigger an inflammatory response in the airways. These circumstances cause edema, fluid build up, and increased vascular permeability, which can block the airways. Asthma-related airway obstruction can result from bronchial constriction, which can happen as a result of smooth muscle contraction [33]. Novel medications or treatments that help lessen asthma symptoms by lowering the production of these inflammatory mediators can be found by researching the inhibition of mast cell degranulation. In the present study, the effect of LPE and LME at doses of 200 and 400 mg/kg, body weight was examined on mast cell degranulation. The control group showed (83.4 ± 0.34) degranulation of mast cells while groups pre-treated with extracts and disodium chromoglycate significantly protect degranulation of mast cells. [34, 35] LME at dose (400 mg/kg) showed (31.6 ± 3.67) and disodium chromoglycate (26.86 ± 2.34) protection against degranulation as shown in Figs. 1 and 2.

Milk induced eosinophilia and leukocytosis

Airway hyperresponsiveness (AHR), reversible airflow restriction, and airway inflammation are all symptoms of bronchial asthma, a chronic condition. Eosinophilic asthma and non-eosinophilic asthma are two types of asthma's pathophysiological mechanisms. According to recent studies, eosinophils are crucial to the emergence of asthma exacerbations. Immune-modulatory reactions brought on by a high blood eosinophil count include airway inflammation, hyperresponsiveness, epithelial lining damage, and increased mucus secretion, Eosinophilic inflammation affects nearly fifty percent of asthma sufferers. Studies have proven that eosinophilia has been associated with higher disease severity, exacerbation frequency, and symptom burden, as well as decreased lung functions [36]. Therefore, eosinophilic inflammation must be suppressed and eosinophilic and non-eosinophilic asthma must be distinguished in order to treat or avoid asthma aggravation [37]. The maximum increase in difference of eosinophil (578.00 ± 11.10) and leucocytes (11,266.16 ± 149.63) counts was found in the control group which has been treated with milk (4 mL/kg, s.c.) before 24 h *Quisqualis indica* extracts at doses of 200 and 400 mg/kg significantly inhibited milk-induced eosinophilia and leucocytosis in a manner dependent on dose. Like Dexamethasone [38], the LME (400 mg/kg) exhibits substantial inhibition as shown Figs. 3 and 4.

Discussion

A persistent inflammatory illness of the airways is allergic asthma. Leukocyte infiltration into the lung and airway is the primary characteristic of asthma [39]. In the current study, mice with milk-induced eosinophilia and leukocytosis were used to test the anti-asthmatic activity of LPE and LME at doses of 200 and 400 mg/kg. According to reports, giving milk subcutaneously causes a noticeable rise in the number of leukocytes and eosinophils 24 h later. Inflammatory mediators such as cytokines, histamine, and major basic proteins are released by leucocytes during asthmatic inflammation, promoting the continued inflammation. A peripheral eosinophil count that has abnormally increased to over 4% of the total leukocyte count is referred to as eosinophilia. The eosinophil count rises in asthmatic patients [40, 41].

While mice treated with various doses of plant extracts show a decrease in the difference in leukocyte and eosinophil counts, mice treated with 1% Tween-80 in the control group exhibit an increase in these two cell types. *Quisqualis indica* leaf extracts may be helpful in allergy conditions because adaptogenic and type I hypersensitivity mediate the decrease in leucocytes and eosinophils.

Mast cells degranulate in response to immunological stimuli where antigen antibody responses are prevalent. In a dose-dependent way, *Quisqualis indica* leaf extracts at doses of 200 and 400 mg/kg effectively prevent egg albumin-induced mast cell degranulation. At 400 mg/kg, LPE and LME protect mast cells similarly to disodium chromoglycate. This demonstrates the effectiveness of *Quisqualis indica* leaf extracts in type I hypersensitivity reactions and in mast cell stabilization. The anaphylactic allergic reaction, which can be triggered by a variety of triggers, is a potentially fatal reaction that releases mediators like histamine and pro-inflammatory cytokines.

The methanolic extract was subjected to a phytochemical analysis using the HRLCMS/MS technique, which revealed the presence of a number of phytocompounds including apigenin 7-glucoside, 3-Oxo-12, 18-ursadien-28-oic acid, 1-O-Caffeoyl-(b-D-glucose 6-O-sulfate), gallic acid, kurigalin, punicacortein B, etc. Gallic acid has shown a good amount of abundance in LME extract and acts by inhibiting mast cell activation, preventing the release of histamine, and the production of pro-inflammatory cytokines [42]. The highly galloylated compounds inhibits secretion of pro-inflammatory cytokines (TNF-α, IL-1β, IL-6) in a concentration-dependent manner, acting on the transcriptional activity of NF-κB [43]. According to the pharmacological effects of flavonoids like kaempferol, quercetin, and rutin, they may be able to treat allergic inflammatory disorders by inhibiting mast cell activation [44]. Apigenin has been found to be effective in allergic asthma through the decreased activation of epithelial cells, T cells, and eosinophils [45]. As per HRLCMS data of LME extract the flavonoids like kaempferol, quercetin, apigenin, and luteolin and few types of tannin like gallic acid and punicacortein B are present in a notable amount. As a result, *Quisqualis indica*'s leaf methanolic extract has shown significant mast cell degranulation and Milk-induced eosinophilia and leukocytosis action. Hence, *Quisqualis indica* leaves may be helpful in allergic conditions like asthma.

Conclusion

The plant extract is found to comprise phytochemicals such as apigenin 7-glucoside, 3-Oxo-12, 18-ursadien-28-oic acid, 1-O-Caffeoyl-(b-D-glucose 6-O-sulfate), gallic acid, kurigalin, punicacortein B, apigenin, kaempferol, quercetin, rutin, nicotinic acid methylbetaine (trigonelline), L-proline, L-asparagine, potassium quisqualate, etc. Thus, this plant is a plentiful source of phytochemicals with therapeutic value, and the findings of this study offer some scientific support for the use of the plant in traditional medicine for anthelmintic, anti-emetic, analgesic, antiulcer, and anti-diarrheal purposes. The results of the current investigation showed that milk-induced leucocytosis and eosinophilia reduced significantly by *Quisqualis indica* leaf extracts at 400 mg/kg dose. In anaphylactic reactions, extracts

suppress the release of histamine and stabilize antigen-induced mast cells. They also have anti-allergic properties. As a result of its anti-allergic and mast cell-stabilizing properties, which might be due to the presence of flavonoids, tannins, and triterpenoids, *Quisqualis indica* leaf extracts are beneficial in treating asthma.

Acknowledgements

We gratefully acknowledge the management and Principal of Maratha Vidya Prasark's College of Pharmacy, Nashik, and SNJB's SSDJ College of Pharmacy for offering the facilities that are required and also to IIT Pawai for providing the facility of HRLCMS/MS of plant extract. Authors are thankful to the C.V. Jadhav, Botanical Survey of India, Pune for the plant authentication.

Author contributions

CTN carried out the sample collection, conceptualisation, extraction and anti-asthma activity, HRLCMS/MS analysis, results interpretation and write-up. The other author read and approved the final manuscript.

Seaweeds as a potential resource in diabetes management: a review

Vidyashree, J. S.1; Shetti, Priya P.2 ; Ghagane, Shridhar C.21 Jawaharlal Nehru Medical College, Dr. Prabhakar Kore Basic Science Research Centre, Department of Biotechnology, Belagavi, India (GRID:grid.414956.b) (ISNI:0000 0004 1765 8386)2 KLE Academy of Higher Education and Research, Dr. Prabhakar Kore Basic Science Research Centre, Belagavi, India (GRID:grid.414956.b)

ABSTRACT (ENGLISH)

Background

Seaweeds are the marine macroalgae predominantly found in the coastal regions. These species have unique chemical profiles which makes them stand different from terrestrial plants. They are found to be rich in secondary metabolites which have potential in treating various unhealthy conditions. Diabetes is a chronic condition where an individual suffers from high or low sugar levels in the blood.

Main text

This review article aims to review such seaweed species that are potent in treating and managing diabetes. It has become one of the rapidly growing diseases in the world with a high occurrence rate. This paper details the mechanism of glucose regulation in the human body. Seventy percent of the total earth’s surface is accomplished by marine ecosystem. It offers home for about 25,000 species. Among them, many possess health benefits hence these are utilized directly as food or in the form of medicine.

Conclusion

In this article, various such seaweed species which have antidiabetic property has been discussed. Including edible seaweeds in daily diet have numerous healing properties. Inhibition of alpha amylase and alpha glycosidase enzyme has been associated with lowering the postprandial glucose level. This review article attempts in exploring how seaweeds and managing diabetes are interrelated.

FULL TEXT

Background

Diabetes mellitus, commonly referred to as diabetes, is categorized as a group of metabolic diseases that arise when either the pancreas is unable to produce sufficient insulin to support the body's normal blood sugar mechanism or when the body is unable to efficiently utilize the insulin that is already produced. Pancreas has two main functions, out of which one is endocrine function that regulates blood sugar. β-islets of Langerhans cells in the pancreas produce insulin, a peptide hormone whose purpose is to maintain a normal blood glucose level. It is achieved by regulating carbohydrate, lipid, and protein metabolism, facilitating cellular glucose uptake. Insulin is encoded by INS gene. Hyperglycemia refers to elevated levels of glucose in the blood. This condition is commonly associated with diabetes, a chronic disease that affects the body's ability to regulate blood sugar. The lack of insulin's action on the target tissue or its secretion in pancreatic cells is the primary reason for increased glucose

±levels in blood [1]. One more condition is low blood sugar called hypoglycemia. Diabetes comprises of two major types, Type 1, in which the pancreas produces little or no insulin over time, is a chronic condition. Type 2 diabetes is characterized by elevated blood glucose levels because of either absolute or relative insulin deficiency. The decrease in beta-cell mass or impairment in beta-cell function is the cause of this drop-in insulin levels or insufficient insulin secretion [2]. About 90% of cases of diabetes are type 2 [3]. It is primarily the result of an unhealthy lifestyle, excess weight, and lack of physical activity. Initially, only adults were more prone to type 2 diabetes, now it is affecting among children as well.

Incidence and mortality rate

Diabetes has had the fastest incidence rate over a decade. Its prevalence has increased from 108 million in 1980 to 422 million in 2014. In 2015, the count rose to 451 million among the individuals aged between 18–99 [4]. In 2017, type 1 diabetes affected 9 million people; the majority of the cases were reported from high-income countries. By 2021, only children and adolescents (ages 0 to 19) will make up more than 1.2 million. Neither its cause nor the means to prevent is known. Polyuria, that is excessive urination, polydipsia (increased thirst), persistent hunger (polyphagia), weight loss, blurry vision, and fatigue are some of the symptoms in this instance.

Diabetes as a global health issue

According to the recent publication by IDF diabetes organization published in 2021, worldwide, approximately 537 million adults suffer from diabetes, and the number is expected to rise to 643 million by 2030 and 783 million by 2045. China currently has the highest number of adults aged 20 to 79 with diabetes, followed by India and Pakistan. Every 3 in 4 adults are living with diabetes now. About 240 million adults with diabetes are undiagnosed and has resulted in 6.7 million fatalities. Twenty-one million pregnant women are at risk of getting affected by diabetes during their pregnancy [4]. It is medically termed as gestational diabetes. They have the risk of developing type 2 diabetes later at any point of time of life. T2DM affects 541 million adults at an increased risk. The reason it is being categorized as global health issue is due its increased risk of effecting other parts of the organ system. Increase in blood sugar levels might risk the patient in leading way to other diseases, such as glaucoma, cataract, blindness, chronic kidney disease, neuropathy, hypertension, and other heart diseases.

Prevalence

Global diabetes prevalence is estimated to be 9.3% in 2019, or 463 million people. By 2030, it will rise to 10.2% (578 million) and by 2045, to 10.9% (700 million). Urban areas have a commonness rate of 10.8%, while rural areas have a commonness rate of 7.2%. In low-income nations, the prevalence rate is 4%, while it is 10.4% in high-income nations [5]. Half of the population—one in two, or 50.1%—is unaware that they have diabetes. In 2019, the global prevalence of impaired glucose tolerance is estimated to be 7.5 percent (340 million), rising to 8.6 percent (548 million) in 2030 and 2045 [5]. Obesity especially central obesity and increased visceral fat due to insufficient physical activity along with the consumption of high calorie diet, high sugar-based diets are the contributing factors.

Treatment

Till today, there is no exact medication or complete cure discovered for diabetes. Diabetes can be treated by monitoring the sugar levels, switching to healthy lifestyle, practising physical activities that could be yoga, cycling, running any activity of people’s choice. Most of the treatment for type 1 diabetes involves injecting exogenous insulin and by oral medications to sustain normal healthy life [6]. Regular screening from physicians in case of any complications is mandatory requirement. Modifications in lifestyle will be a selfcare treatment which includes proper and healthy diabetic diet, exercising regularly, weight management, nutritional counselling, keeping count on carbohydrate intake. For type 2 diabetes, metformin is typically prescribed [7]. It actions primarily by making the liver produce less glucose and enhancing the body’s sensitive to insulin, allowing it to use insulin way more effectively.

Management

Most people manage their diabetes themselves. No matter how advanced the treatment technology is, the outcome will be poor if the patient is unwilling or unable to manage it on a daily basis [8]. Management of diabetes includes following a proper healthy diet, physical exercise, and keeping their daily sugar and carb intake in control. Regular physician visits and check-ups also help. Now, technology has evolved so much, and we have many diabetes

testing kits through which we can monitor blood glucose level just in fraction of time at home. The American Dietetic Association introduced medical nutrition therapy (MNT) in 1994 to better explain the nutrition therapy process for diabetic patients. This program explains how to use specific nutrition services to treat a condition, injury, or illness. MNT for diabetes consists of a four-step procedure that, when followed correctly, can help reduce the risk of developing diabetes. They are.

i. Assessing the patient's diabetes self-management abilities and nutrition knowledge.

ii. These are designed and tailored for each person, identifying, and negotiating nutritional goals.

iii. Nutritional intervention that combines the patient's needs with a flexible approach to meal planning and education materials so that the patient can put the plan into action.

iv. Keeping tabs on all the activities and evaluating the outcomes.

These are essential for patients to acquire and maintain the knowledge, skills, mindset, behaviour, and commitment necessary to successfully face daily diabetes self-management challenges [9].

Indulging oneself in physical activity is another one such process which is known to have numerous health benefits, both general and specific to diabetes [10]. Practising yoga is found to be an effective way in managing diabetes. Lifestyle related modifications, ditching sedimentary living style and participating in any active form can make an individual lessen the risk of developing diabetes. People with obesity are much prone to diabetes. Weight management is an added advantage. Despite significant advances in diagnosis and treatment, the persistence of inadequate metabolic control continues. Patients fail to manage diabetes on their own and even clinicians' ineffective approaches to intervention which may contribute to poor glycaemia control [11].

Glucose enters our body through food. Absorption of this food, the breakdown of glycogen and gluconeogenesis are the three main ways where body cells meet the glucose. Glucose is stored in the form of glycogen in liver and the biochemical pathway of generating glucose from non-carbohydrate substrate in the body is called gluconeogenesis. Insulin plays a significant role in balancing glucose levels in body [12]. The pictorial representation of mechanism of glucose regulation in humans is explained in Fig. 1.

Fig. 1 [Images not available. See PDF.]

Mechanism of glucose regulation

Main text

Seaweeds

Seaweeds are naturally occurring marine macroalgal species which are found in marine environment. These are adapted to salt conditions provided by seas and oceans. During monsoons, these seaweeds are carried to the seashore along with the waves due to the increase intensity of waves. They are usually found attached to the rocky substrate or any other solid surface along the seaside [13]. They are macroscopic, multicellular, and completely different form of higher plants. Seaweeds do not possess true or definite roots, stem, or leaves [14]. Seaweeds are highly pigmented, based on their pigmentation, they are put into three main algal classification, Rhodophytes (red algae), Phaeophytes (brown algae), and Chlorophytes (green algae).

Brown algae constitute of 16 orders with approximately 285 genera and 1800 species. They are the largest and fastest growing of all the seaweeds. They exhibit a rich composition of pigments of different biosynthetic origins. Chlorophyll *a* and *c,* carotenes particularly α-carotene and β-carotene and xanthophylls. They also exhibit fucoxanthin, violaxanthin and diatoxanthin. Red seaweed is second largest phyla of algae containing over seven thousand species currently recognized. Chlorophyll *a,* phycocyanin, phycoerythrin and phycobilin are the pigments that give red colour to these species. Chloroplasts in green algae contain chlorophyll a and b, which gives them their bright green colour. They are also rich in carotene (red orange) and xanthophylls (yellow) in their stacked thylakoids (Fig. 2).

Marine macroalgae are the promising source for bioactive secondary metabolites which has vast application in drug developments, pharmaceutics and other biotechnological applications [15]. There is an increasing demand for macroalgae and macroalgae derived food. Bioactive compounds are the chemical constituents that are present in the species which has an influence on a living organism, tissue or a cell. They have the capability of regulating or deregulating on specific disease or damage caused to the cell when used in correct manner. They are often referred to as secondary metabolites [16]. This property of theirs is demonstrated by conducting basic research which could be in-vivo (inside the organism's body) or in-vitro (in controlled environment outside the organism's body). Seaweed species are found to have potential phytochemical constituents which are capable of being antioxidant, anti-inflammatory, anticancer, antidiabetic agents. Hence, they play a key role in pharmaceutical industry. These are also used in cosmetics.

Seaweeds and diabetes

Much research works on seaweeds have found out the presence of phytochemical constituents that are responsible in treating and managing diabetes. Including edible seaweeds in daily diet and its regular consumption is associated with the reducing the risk of developing diabetes. A variety of polyphenolic compounds have been isolated from seaweed which are well known for their target against diabetes [17]. According to the studies, some of the seaweeds may be able to prevent enzymes from hydrolyzing carbohydrates in-vitro and lowering effect of blood glucose was noticed in-vivo after the consumption of meal [18]. Bioactive compounds derived from seaweed play a significant role in glucose-induced oxidative stress and the reserve of starch-digestive enzymes [19]. In diabetic patients, the levels of antioxidant parameters tend to decrease, so in this such case, many studies have proven that phytochemicals that can exert antioxidant and free radical scavenging activities can improve the body's sensitivity to insulin.

Phaeophytes

Phaeophytes possess number of active constituents like phlorotannins which is a unique secondary metabolite, that has got specified biological activities [20]. Studies on brown seaweeds have suggested that these species influence in glycemic management and could be benefit patients with type 2 diabetes. Fucales, dictyotales and laminariales are the majorly used orders of phaeophyceae that are extensively used for the extraction of secondary metabolites [21]. Species belonging to fucaceae are great with phytochemicals that have great interest from industrial point of view. Phlorotannins, a class of marine-only polyphenols, have received a lot of attention in recent years due to their enormous potential for therapeutic use [22]. Brown algal species contain significant number of phenolic compounds, a polysaccharide which has got extensive high biological activities. These phytochemicals are found to be more effective as antioxidants when compared to green and red algal species [23].

Phlorotannins are class of phenolic secondary metabolites which has a wide range of biological treatments. Research on this has proven phlorotannins to have antidiabetic, antioxidant, cancer, inflammation, adipogenesis, and numerous other biomedical uses [24]. They are synthesized by polyketide pathway (acetate-malonate pathway) produced by the polymerization of phloroglucinols [25]. These can be later extracted from various extraction methods such as chromatography [26]. α-amylase and α-glucosidase are the two digestive enzymes that are responsible for digestion of carbohydrates and increase the postprandial glucose level in diabetic patients. By inhibiting the enzymatic action of these two enzymes, postprandial hyperglycemia, and the risk of developing diabetes can be reduced.

Brown seaweeds are also rich in fucosterol and its derivatives [27]. This compound was first isolated from *Cystoseia foeniculaceae* and *Dictyota ciliolate* by RP-HPLC method. A fraction of the compound was analysed by NMR technique [28]. Polyphenols found in some species of brown algae support the algae's structural development and protect them from biotic and abiotic stress conditions [29, 30]. It has been reported that marine brown algal species with sulphated polysaccharides possess useful therapeutic properties. Fucoidan has antioxidant and antidiabetic potential. Fucoxanthin is an accessory pigment of some of the algal species. *Fucus*, *Dictyota* and *Laminaria* are rich in carotenoids and even used for extracting it from them. This active constituent has proved to exhibit antioxidant,

anticancer and antidiabetic activities [31].

Red seaweeds

Red seaweeds are major source of vitamins, minerals, calcium and magnesium. They are widely consumed as food in many continents. Bromophenols from red algae have been reported for antidiabetic activities. They are the source of dietary fibres promoting health benefits like lowering bad cholesterol and regulate blood sugar levels. Rhodophytes are rich in sulphated polysaccharides [32]. These SPs were associated in combating different oxidative stress induced diseases [33]. Experiments on red and green seaweeds have proven that they possess inhibiting properties of α-glucosidase enzyme [34]. *Rhodomela confervoides* (Fig. 3a), *Symphyocladia latiuscula* (Fig. 3b) and *Polysiphonia urceolata* (Fig. 3c) consists of bromophenols, 2-piperidione, benzene acetamide, n-hexadecanoic acid and polysaccharide derivatives that were found to exhibit hypoglycaemic potential by inhibiting α-glucosidase [34]. Red seaweeds are beautiful home for hydrocolloids specially, agar and carrageenans. Hydrocollloids are extracted from them and are widely used in diverse medicinal and food industries [35]. Polysaccharides have significant antidiabetic effects in multiple ways, most notably by preventing gastric emptying, inhibiting the activities of amylase and glucosidase, increasing insulin secretion, and improving insulin function [36]. As a result, polysaccharides derived from algae may be effective treatments for diabetes and its complications.

Green seaweeds

Green seaweeds belong to the genus Ulva, they have been reported to possess hypoglycemic activity. Due to their high soluble fibre content, they are used for various food dishes in Asian countries. The aqueous extract of green seaweeds *Ulva lactuca* (Fig. 4a) (Inhibition-α-amylase: 83.4%; α-glucosidase: 61.81%) and *Ulva reticulate* (Fig. 4b) (Inhibition-α-amylase: 89.1%; α-glucosidase: 76.02%)were effective against the enzymes α-amylase and α-glucosidase at a concentration of 100 g/ml after an 8-h extraction period at 37 °C in a water bath, allowing the phytochemicals and colloids to be released into the extract more slowly. Similarly, the crude extract of *Ulva ohnoi* (Fig. 4c) exhibited α-amylase inhibition by 41.7% and complete α-glucosidase inhibition at 10 mg/mL [15, 37, 38].

Reducing postprandial hyperglycemia is one of the healing methods in diabetes management. This can be achieved by reducing carbohydrate hydrolyzing enzymes in the digestive tract suspending glucose absorption. The breakdown of carbohydrates is mostly done by α-amylase and α-glucosidase. Delay in the release of glucose from dietary multiple carbohydrates sources results in the decreased postprandial plasma glucose and hyperglycaemia level [39]. By simultaneously absorbing glucose from the intestine and breaking down starch with pancreatic α-amylase, α-glucosidase and -amylase react to digest in the human body. By hydrolyzing inner 1,4-glycosidic linkages, pancreatic amylase determines the degree of starch digestion and produces linear and branched malto-oligosaccharides. These are then acted upon by α-glucosidase enzymes, which play a crucial role in the conversion of carbohydrates into glucose and may initiate postprandial hyperglycaemia [40].

Alpha-glucosidase is responsible for the ultimate step of hydrolysis of starch or disaccharides into simple glucose units, while alpha-amylase is involved in the digestion of long-chain carbohydrates. As a result, inhibitors of these enzymes delay the absorption of glucose, lowering the blood glucose level after eating [41]. A protease enzyme called dipeptide peptidase-IV participates in the breakdown of incretins, which are a group of metabolic hormones that cause the ß cells of the Langerhans islet to release insulin. Incretins are delivered after supplement admission, and they postponed gastric discharging and decline glucagon emission notwithstanding feeling of insulin discharge [42].

Alpha-amylase participates in the digestion of long-chain carbohydrates, while alpha-glucosidase is responsible for the final step in the hydrolysis of starch or disaccharides into simple glucose units. Therefore, inhibitors of these

enzymes delay the absorption of glucose, resulting in a drop in blood glucose levels following a meal [1]. Incretins, a class of metabolic hormones that trigger insulin release from the ß cells of the Langerhans islet, are broken down by a protease enzyme called dipeptide peptidase-IV. After taking a supplement, incretins are given. Despite the sensation of insulin being released, they delay gastric emptying and reduce glucagon release [43].

Marine macroalgae are found to have bioactive compounds which have DPPH-IV inhibiting potential. Dipeptidyl peptidase IV is also referred to as adenosine deaminase complexing protein 2 which is an enzyme present in human body [44]. It is a protein encoded by DPP-IV gene. This enzyme destroys incretin. Incretins are the group of hormones that stimulates a decrease in blood glucose levels [45]. Its main physiological role in human body is to regulate the amount of insulin that is secreted after the consumption of food. DPPH-IV inhibitors block the action of this enzyme, which destroys this hormone incretin. This hormone is responsible to produce insulin only when there is a need of it. Therefore, reducing the amount of glucose being produced by liver [46] (Table 1).

Table 1. Different seaweed species with their antidiabetic potential

Seaweed	Class	Bioactive compound used	Nature of study	Refs.
Sargassum kjellmanianum	Brown	Polysaccharide-alginate	In-vivo In-vitro	[42]
Ecklonia cava	Brown	Phlorotannin-Dieckol	In-vivo	[1]
Cystoseira compressa	Brown	phlorotannin	In-vivo	[43]
Laurencia dendroidea	Red	Bromophenols	α-glucosidase α-amylase	[44]
Sargassum confusum	Brown	oligosaccharides	In-vivo	[45]
Sargassum horneri	Brown	fucoidan	In-vivo	[46]
Macrocystis pyrifera	Brown	polysaccharide	In-vivo	[47]
Pelvetia siliquosa	Brown	Fucosterol	–	[48]
Grateloupia elliptica	Red	2,4,6-Tribromo phenol	α-Glucosidase inhibition	[49]
Polysiphonia morrowii	Red	3-Bromo-4,5-dihydroxy benzyl alcohol	α-Glucosidase inhibition	[50]

Gelidium amansii	Red	β-D-galactopyranose and 1,4-linked 3,6-anhydro-α-L-galactopyranose units	In-vivo	[51]
Gracilaria opuntia	Red	sulphated galactopyran	α-amylase and α-glucosidase inhibition	[32]
Hypnea spinella	Red	sulfated polysaccharide	In-vivo	[36]
Enteromorpha prolifera	Green	–	Inhibition of the JNK1/2 insulin pathway in liver of mice	[52]
Chaetomorpha aerea,	Green	–	Inhibition against alpha-amylase	[45]
Chlorodesmis	Green	z,z-6,2 8-heptatriactontadien-2-one	α-amylase inhibition	[45]

Seaweeds in food and nutrition

Seaweeds which are fit for human consumption are put under edible seaweed lists which are widely been consumed by Asian countries. Chinese consume seaweeds as traditional medicine. Koreans use seaweeds as a key ingredient in their soups. Women consume seaweed soup after childbirth which is known to boost their immunity and strengthen them along with infant's health. When consumed in the appropriate amounts, edible seaweeds are known to offer a rich and long-lasting source of macronutrients and micronutrients for human consumption [47]. *Porphyra tenera* and *Palmaria palmata* are the red seaweeds which contain elevated levels of proteins that is 47.5 and 30%, respectively [48]. Nori or purple laver, the edible seaweeds belonging to *Porphyra* species, a blackish-purple seaweed that enhances the flavour of sushi, which is a Japanese ethnic food usually wrapped with rice. It is mostly grown in China, Japan, and the Republic of Korea [49]. Nori is the most widely produced product from marine culture in Japan. Some of the edible seaweeds with their regional names are mentioned in Table 2.

Table 2. Edible seaweeds consumed in different part of the world with their regional names

Seaweed	Image	Common name
Ascophyllum nodosum		Egg wrack
Laminaria digitate		Kombu or konbu
Laminaria saccharina		Sweet kombu
Himanthalia elongate		Sea spaghetti
Undaria pinnatifida		Wakame

Porphyra umbilicalis *Porphyra vietnamensis*		Nori
Palmaria palmata		Dulse or Dillisk
Chondrus crispus		Irish moss
Ulva lactuca		Sea lettuce

In the recent article, possibilities of using seaweed capsules which function as a needle-free life for diabetic patients was published on The Economic Times, Tokyo. It further stated that researchers have created a novel capsule using seaweed extract to preserve insulin-producing pancreatic cells, giving diabetics hope for an injection-free treatment. Insulin injections are administered daily to patients with type 1 diabetes [50]. Pancreatic islet transplantation is a successful treatment that can eventually reduce or eliminate insulin dependence completely. Cryopreservation is the general method of preserving and transporting the cells [51]. This process also comes with a disadvantage of sharp ice crystals that can break and pierce into cell membrane and compromise with cell viability.

Although seaweeds being highly nutritious and carry benefits when consumed in proper manner, they are attached with some minor limitations. Marine species though available in huge mass, they are time and temperature restricted. Distinct species need different environmental condition for their active and optimum growth [52]. Their unavailability throughout the year becomes a limitation. As these are marine species, they need intense cleaning and specific storage conditions. Seaweeds possess elevated levels of iodine which when consumed might lead to high levels of iodine in some people which might lead conditions like hyperthyroidism.

Conclusion

Seaweeds offer 60% of marine species in the world. They have unique chemical profile which makes them withstand high salinity conditions. They are usually categorized as unwanted plants in the coastal regions. But these plants are macroalgae which possess various health benefits for humans when consumed as part of their daily diet. Seaweeds have all the potential to the overcome the diseases, such as diabetes, cancer, inflammation. They are distinct from terrestrial species due to the presence of distinct bioactive compounds in them. Diabetes is a disease where a person’s body either does not produce enough insulin required for normal metabolism or body’s inability to accept the insulin. The cause for the diabetes is numerous. As it is one of the lifestyle related disorder, making changes in the living style and switching to a healthy and organized lifestyle can help overcome it. Seaweeds serve enough macronutrients and micronutrients and other essential dietary fibres which when consumed in daily diet can reduce the risk of developing such lifestyle related disorders like diabetes, cancer, etc. Hence, studying these seaweeds species is equally important. In this review article, various research papers on treating diabetes with different seaweed species were studied. Alpha amylase and alpha glucosidase are two digestive enzymes which are responsible for digestion of sugars in the gut itself in postprandial cases. Many of the seaweeds have the potential to inhibit these enzymes which helps in curing diabetes. These studies revealed that, the seaweeds can be used as food, has significant role in medicine, pharmaceuticals, beauty and other industries. So, this study concludes that, such healthy species should be identified and can be used in treating diabetes. This article lays background to the seaweed research area giving an overview for the research scholars sharing equal interest in the area.

ABSTRACT (ENGLISH)

Background

Babassu (*Orbignya phalerata* Mart.) is a palm tree well distributed in Latin America, whose fruit has a mesocarp and kernel used for human feeding, and empirically related to the treatment of gastritis, vaginitis, and wound healing.

Main body of the abstract

The activities attributed to babassu can guide new research on health applications and, for this reason, this study aimed to report in vitro and in vivo biological activities of *O. phalerata* constituents through a systematic review. Searches terms were applied in five world databases and the data from the publications were collected according to PICOS criteria, including the fruit component, concentration/dose, time of exposure, and comparative groups. All outcomes were reported and the most relevant outcomes were described by a narrative synthesis and a risk of bias assessment. A total of 28 in vitro ($n=15$) and in vivo ($n=11$) studies were included, and two showed both experimental designs. The studies were heterogeneous, with the predominance of metabolic analysis, wound and peptic ulcer healing, besides in vivo toxicity, among others. For in vitro analysis, antioxidant tests, cell viability and antimicrobial activity predominated. All in vivo ones used rodents. Meanwhile, tumor and non-tumor cell lines, bacteria strains, *Leishmania amazonensis*, *Artemia salina*, and antioxidant reactions were considered for in vitro protocols.

Short conclusion

The most frequent applications included mesocarp and kernel in a wide range of extracts, emulsions, and concentrations. Their low in vitro lethality and cytotoxicity, and no acute toxicity in vivo open possibilities for the development of long-term toxicity assays with repeated doses in rodents and interventions in clinical trials.

Graphic abstract

FULL TEXT

Background

Orbignya phalerata Mart. (syn. *Attalea speciosa*), belonging to the Arecaceae family, is a palm tree well distributed in different biomes in Latin America, such as Amazon rainforest, Atlantic forest, and especially in Cerrado and Caatinga, and popularly known as Babassu, uauaçu, and catolé [1]. The genus *Orbignya* has more than 20 species, but the binomial nomenclature *Orbignya phalerata* Mart. was adopted by this review because it is the most used and recent in the bibliography consulted (Fig. 1). Its fruit is generally completely used, but only its mesocarp and kernel are edible. The studies related to babassu describe about the mesocarp and/or the kernel, mainly. The first is used in cosmetics industry [2] and the mesocarp flour has been empirically consumed for the treatment of gastritis, vaginitis, and topically as wound healing [3].

Plant species are continuously studied about their potential developing new drugs and products based on

the diverse biological activities and pharmaceutical properties, mainly influenced by primary and secondary plant metabolites. Primary constituents, such as fatty acids, carbohydrates, and amino acids, are crucial macromolecules aiding plant survival and structural development. Meanwhile, secondary metabolites, derived from primary metabolism, play key roles in physiological processes and act as a defense mechanism against biological or chemical agents, such as polyphenols, which are one of the most common types of bioactive compounds, including the flavonoids catechin, epicatechin, proanthocyanidin, and others, all capable of scavenging or neutralizing reactive or radical species [4], which explains, at least in part, their antioxidant, anti-inflammatory, and antimicrobial properties, to name a few [5].

Among the edible parts of babassu, the kernel stands out for its elevated concentrations of fatty acids, primarily lauric acid (12:0; 46.89%), myristic acid (C14:0; 16.95%), and oleic acid (C18:1; 13.54%) [6–8]. Conversely, the mesocarp flour is a source of energy (1375 kJ/100 g), complex carbohydrates (79.19%), potassium (3.62%), magnesium (0.39%), phosphorus (0.35%), and a small content of protein (1.41%) [9].

In human metabolism, while carbohydrates are an energy source, flavonoids act as scavenger molecules. Simultaneously, fatty acids not only contribute to caloric supply but also play specific roles such as bactericidal [10]. Regarding the total phenolic compounds in the mesocarp (558.87 mg/100 g), the most important among them are the flavonoids extracted by organic solvents [9] (Table 1).

Table 1. Flavonoids from mesocarp extracted by organic solvents

Extract	Flavonoid	Content	References
Hydroethanolic	Catechin	8.02—8.22[a]	[62]
Epicatechin	14.17—15.26[a]	Aqueous	Catechin
0.28[b]; 0.88 µg/g[c]	[63]	Epicatechin	na[b]; 29.61 µg/g[c]
Ethyl acetate	Epicatechin	18.4[a]	[35]
Dimer	17.7[a]	Trimer	23.8[a]
Tetramer	18.0[a]	Hydroethanolic	Proanthocyanidin
421.7 mg CE/g	[35]	Ethyl acetate	Proanthocyanidin

Preclinical trials have elucidated the biological effects of babassu crude components and its extracts. However, there is no evidence of compiled findings in a systematic review. Therefore, this study reported in vivo and in vitro biological activities of *O. phalerata* constituents in order to contribute to the development of original studies and applications for health care and research.

Main text

Methods

This systematic review was conducted according to PRISMA guidelines [11] (Preferred Reporting Items for Systematic Reviews and Meta-Analyzes) and registered in PROSPERO [12] (International Prospective Register of Systematic Reviews, registration n° CRD 42022302309).

Publications eligibility was established based on the guiding question “Do different parts of babassu contain compounds capable of exerting biological effects in vivo and/or in vitro?” and PICOS criteria [P: Population; I: Intervention; C: Comparator; O: Outcome; S: Study] (Table 2). Only original articles from indexed journals were eligible, with no limitation of period or language. All publications from gray literature or not fully published articles were excluded.

Table 2. Eligibility criteria according to PICOS

	In vivo	In vitro
P	Experimental strains of any sex, age, and weight	Tumor and non-tumor cell lines and/or microorganism strains, and/or chemical assays
I	Oral or gavage offering of crude or processed babassu components or isolated extracted compounds	Assays with crude or processed babassu components or isolated extracted compounds
C	Positive, negative, and/or parallel control	Positive, negative, and/or parallel control
O	Favorable or unfavorable biological effects, local or systemic, acute or chronic	Favorable or unfavorable biological effects for/against pathogenic or non-pathogenic microorganisms, cell lines, or chemical reactions
S	In vivo experimental studies	In vitro experimental studies

For animal model studies, topical, intraperitoneal, parenteral, or rectal interventions were excluded. To be considered, both in vivo and in vitro designs should clearly describe the type of substance, concentration, and intervention period, at least for the main outcome.

Data sources, searches and studies selection

Explorations in the LILACS [13], SciELO [14], Science Direct [15], Web of Science [16], and PubMed [17] databases were performed by search terms registered in MeSH, combined by AND and OR Boolean operators (Table 3) during April 1st to April 7th, 2022 and again on March 24th, 2022 to update indexes. The searches were exported to Rayyan for prior systematization and metrics [18].

Table 3. Search terms and Boolean operators

Search term 1		Search term 2
Orbignya phalerata OR *Attalea speciosa*	AND	*Polyphenols* OR *Phytochemicals*

Initially, the studies were screened using the title and abstract (by ND and IOC), independently. Those considered eligible were read in full (ND, IOC) and references were kept for possible inclusion if they met the criteria. Disagreements were solved by consensus and, when necessary, a third researcher (JMCS) was consulted.

Data extraction and description of results

Data extraction included authors, publication year, title, locality, and study design. For in vivo publications, characteristics of the population were collected and for in vitro assays, cell lines, strain, and/or chemical reactions

were described. Interventions included fruit part and its product, concentration, time of exposure, and comparative groups. Favorable or unfavorable outcomes were reported, as well as the most relevant assessment instruments and results. The compiled data were organized into tables, facilitating a comprehensive narrative synthesis and outcomes comparison, when applicable. Values were expressed as mean and standard deviation, when available, and compared with control and/or parallel groups. Results were considered significant when $p<0.05$.

Risk of bias assessment

The risk of bias assessment for in vivo experiments was carried out independently by ND and IOC using the SYRCLE Risk of Bias Tool and the individual results were compared between ten domains distributed in six biases (selection, performance, detection, attrition, reporting, and other bias). Each domain was defined as “yes” (low risk of bias), “no” (high risk of bias), or “unclear” (uncertain risk) [19].

For in vitro analysis, the tool developed by the World Cancer Research Fund/University of Bristol was used with adaptations [20]. Each of the six questions was answered with “yes” (low risk of bias), “no” (high risk of bias), “not clear” if details were not recorded properly, or “not applicable”. Risk of bias analysis was recorded individually by study and by domain. Inter-rater reliability was determined by Cohen’s kappa coefficient [21].

Results

Search results and study characteristics

Figure 2 highlights the study selection process. Initially, 424 publications were identified, of which 146 were duplicated ones and removed automatically. A total of 278 articles were eligible by the title and abstract, but only 23 were selected for full-text review and 15 of them met the inclusion criteria. On the other hand, 13 articles not included by unidentifiable reasons in the initial search were included.

Fig. 2 [Images not available. See PDF.]

Screening flow diagram based on The PRISMA 2020 Statement [11]

According to the included reports, 39.3% ($n=11$) refer exclusively to in vivo (Table 4) and 53.6% ($n=15$) to in vitro assays (Table 5). Moreover, two articles showed both experimental designs and, for this reason, were described in both tables [22, 23]. Regardless of the taxonomy mentioned in the publications (*Orbignya phalerata*, *O. martiana*, *O. speciosa*, or *Attalea speciosa*), only the articles of Gaitan et al. [22] and Hovorková et al. [8] are not from Brazil, suggesting great interest about the plant and fruits in the Brazilian scenario. In preclinical interventions with animals, metabolic analysis and toxicity predominated (Fig. 3A), while in vitro assays highlight antioxidant tests (Fig. 3B).

Table 4. Baseline characteristics, intervention, methods, and main results of in vivo studies

References	Sex; strain; age; weight; n/group	Intervention/methods	*O. phalerata* component; dose/volume; time of exposure	Main results
Azevedo et al. [41]	Male (C57BL/6); 8–12 w.o.; 20–25 g; $n=20$	Antithrombotic effect: carrageenan-induced thrombosis, evaluation of necrosis frequency and extension; Onco BCG injection for NO induction in peritoneal cells; platelets, PT, and aPTT analysis	Mesocarp aqueous solution; 500 mg/kg/day; 240 days	↓ induced thrombosis; ↑ PT, and aPTT, no changes in platelets number; ↑ NO production by peritoneal macrophages previously activated by Onco BCG

Barbosa et al. [26]	Male (*Mesocricetus auratus*); 7–10 w.o.; 122–146 g; *n* = 39	Macromolecular permeability and leukocyte adhesion in cheek pouch after ischemia induction. After reperfusion, histamine topical application. Less than 10 leaks/site accepted; IL-1, IL-6, and TNF-α analysis	Crude kernel oil; 0.02 ml, 0.06 ml, 0.18 ml twice/day; 14 days	↓ ischemia-induced leaks during reperfusion in higher doses; ↑ leaks in lowest dose; less pronounced microvascular permeability after histamine in higher doses; ↓ leukocyte adhesion in lowest dose; no significant changes in TNF-α, IL-1, and IL-6
Barroqueiro et al. [27]	Male/female (C3H/HePas); 8–12 w.o.; 25 g; *n* = 40	Acute toxicity: weight, macroscopic, and histological analysis of heart, liver, spleen, kidney, and brain; glucose, urea, creatinine, ALP, TC, TG analysis	MEE; 1000 mg, 3000 mg, 5000 mg/kg; single dose	No deaths after 14 days; no significant increase in body weight; no cutaneous, neurological or behavioral changes, glucose, TC, or creatinine; ↑ ALP in 3000 and 5000 mg/kg groups; ↑ urea in all groups; ↑ TG in 1000 mg/kg
Gaitan et al. [22]	Female (Sprague–Dawley); 7 w.o.; weight (NA); *n* = 25	Antithyroid effect: 14 mcg/day of iodine-rich diet; MAE and KPPS acute intake. After 1 h, i.p. Bq $Na^{125}I$; ^{125}I uptake and organification analysis by MIT + DIT coupling in thyroid tissue	MAE (16 g) and KPPS (2 g); single dose	Distinct antithyroid effects for MAE and KPPS; ↓ iodine uptake in 16 g MAE group; ↑ inorganic iodine % in MAE and KPPS; ↓ iodine % as MIT + DIT; ↑ ratio ^{125}I/MIT + DIT in MAE and KPPS

Maia and Rao [24]	Male/female (Wistar); age (NA); 180–220 g; *n*= 107. Male and female (Swiss); age (NA); 25–30 g; *n*=88	Anti-inflammatory effect: carrageenan-induced inflammation in paw and edema analysis; subcutaneous cotton pellet implant-induced granuloma, pellet removal and weighing; formaldehyde-induced arthritis in paw and edema analysis; carrageenan-induced inflammatory exudate by leukocyte migration. Ulcerogenesis: gastric lesion assessment. Coagulation: bleeding time after opening the abdomen, micropuncture in a mesenteric vein, and time of hemostasis; Antipyretic: *S. cerevisiae*-induced pyrexia; Analgesia: hot-plate positive response; writhing induced by acetic acid; acute toxicity after 72 h	Mesocarp chloroformic extract; 125 mg/kg, 250 mg/kg (carrageenan, hot-plate, writhing) in a single dose; 250 mg/kg (granuloma) for 7 days; (arthritis) for 10 days; (ulcer) for 21 days; (pyrexia) in a single dose; up to 4 g/kg (toxicity); dose (NA) (exudate) 3 times/24 h; dose (NA) (bleeding) for 3 days	↓ dose-dependent acute inflammatory edema after carrageenan induction; ↓ granuloma; ↓ edema in arthritis on 7th and 8th days; absence of peptic ulcer; no influence on leukocyte migration, no effects on bleeding time and pyrexia control; no significant effect on hot-plate response; ↓ writhing; no overt acute toxicity
Pinheiro et al. [39]	Male (BALB/c, DBA/2, CBA, C3H/HePas, C57BL/6); 8–12 w.o.; 20–30 g; *n*=10	Glycolipid profile: TC and urea analysis. Immunotoxicity: medullary and splenic cell analysis	MAE; 50 mg/kg/day; 30 days	↓ splenic cells in C3H/HePas and BALB/c; no changes in medullary cells; ↑ TC in CBA and ↓ in C3H/HePas; ↓ U in all strains, except in C57BL/6

Scheibe et al. [43]	Male (Wistar); age (NA); 271.3 g (average); *n*=54	Wound healing: laparotomy with cecum exteriorization. Monitoring and euthanasia on 7th, 14th, and 21st day; macroscopic wound evaluation (infection, dehiscence, haematoma,and fistulae); abdominal cavity evaluation (collection, infection, fistulae, and adherence); terminal ileum air insufflation test; vascular congestion analysis, edema, presence of mono and polymorphonuclear leukocytes, angiogenesis, fibrosis, and collagen deposition	MAE; 50 mg/kg/day; 7, 14, 21 days	Adequate healing in all animals; no evidence of infection, dehiscence, haematoma, abscess; widespread adhesion, without adhering to the abdominal wall (grade III) in 1 rat on 7th day, grade II adherence on the 21st day in 100% of the animals; ↓ burst pressure over time after insufflation test; ↓ polymorphonuclear leukocytes, congestion, angiogenesis, fibroblast proliferation, and collagen deposition on the 14th day
Silva et al. [23]	Male (Swiss); 8 w.o.; 25–30 g; *n*=28	Locomotor activity: total crossings in activity cage. Motor coordination: remaining time on rotarod test (180 s at 9 RPM)	MAE; 1, 2, 3 g/kg; single dose	No significant changes in the number of crossings or in remaining time on the rotarod test

Silva et al. [44]	Male (Wistar); 7–8.5 w.o.; 275.6 g (average); *n*=54	Colonic healing: cecorrhaphy by laparotomy an exteriorization of the colon. Euthanasia on 7th, 14th, and 21st days. Animal weighing, wound analysis (infection, dehiscence, haematoma, and fistulae); abdominal cavity analysis (collection, infection, fistulae, and adhesion); terminal ileum air insufflation test; analysis of congestion, edema, presence of mono and polymorphonuclear leukocytes, angiogenesis, and fibrosis	MAE; 50 mg/kg; single dose	No dehiscence, fistulae or other complications; ↑ grade II adherence on 21st day; moderate/severe mononuclear leukocytes, congestion, and angiogenesis on the 7th day; ↓ congestion and angiogenesis on 14th day
Silva et al. [25]	Non-obese diabetic male mice (strain NA); 12 w.o.; 29–33 g; *n*=25	Onset of diabetes: individual average of extract, water, and food intake for 6 days; weighing, blood glucose analysis on 0, 30th, 90th, and 120th day; anti-insulin IgM antibodies, and total antibodies (IgG, IgM) with anti-immunoglobulin antibodies	MAE; average 66 mg/day; 120 days	Daily average intake of MAE 3.3±0.9 ml; ↑ weight from 20 to 50th day and ↓ after 50th; ↓ glucose on 30th day; ↓ IgM; no significant changes in anti-insulin IgM and IgG
Silva and Parente [40]	Male (BALB/c); age (NA); 15–20 g; *n*=15	AIE and IME: Evans blue and i.p. acetic acid-induced vascular permeability. Leak analysis in the peritoneal cavity; phagocytic activity by colloidal carbon injection. Blood sample dissolved in Na_2CO_3 and absorbance determination at 660 nm	Mesocarp isolated α-glucan; 100 mg/Kg (AIE) single dose; 50 mg/kg/day (IME) for 5 days	↓ vascular permeability; ↑ phagocytic activity

Soares et al. [6]	Male (Swiss); 8.5 w.o.; 35–40 g; *n*=32	Lipid profile and IME: pre and post-euthanasia weighing; macroscopic and histological analysis of heart, liver, kidneys, spleen, gastrocnemius muscle, and retroperitoneal fat. AST, ALT, TC, LDL, HDL, TG, glucose, urea, creatinine, IL-6, and TNF-α analysis; immunophenotyping of splenic cells; RT: stair climbing with load adjustment in daily sessions, 5 days a week for 8 weeks	MAE; 5 mg/kg/day; 5 days/week for 8 weeks	MAE: ↓ total weight; ↓ fat tissue; ↓ TG; ↓ TC; ↑ AST; ↑ medullary cells; ↑ B lymphocytes; ↓ activated macrophages; ↓ IL-6; ↑ TNF-α MAE/RT: ↓ total weight; ↑ kidneys weight but no histological changes; ↓ fat tissue; ↓ TG; ↓ TC; ↑ AST/ALT; ↓ splenic or medullary cells; ↓ activated Th; ↑ activated B lymphocytes; ↑ macrophages; ↓ activated macrophages; ↓ IL-6; ↑ TNF-α
Torres et al. [42]	Male (Wistar); 6 w.o.; 180–240 g; *n*=40	Prevention and treatment of peptic ulcer: macroscopic analysis (ulceration, mucosal hyperemia, loss of fold, and/or bleeding; histopathological analysis (inflammation, necrosis, fibroblasts, fibrosis, reepithelialization, neocapillar generation)	MAE; 2 g/kg/day; 3 days	Prophylaxis: ↓ peptic ulcer, mucosal hyperemia, loss of fold, and bleeding; treatment: ↓ necrosis, fibrosis, reepithelialization, and neocapillar generation; marked inflammation and mucosal ulceration

↑ increase; ↓ decrease; *AIE* anti-inflammatory effect, *ALP* alkaline phosphatase, *ALT* alanine aminotransferase, *aPTT* activated partial thromboplastin time, *AST* aspartate aminotransferase, *BCG* bacillus Calmette–Guérin, *DIT* diiodotyrosine, *HDL* high-density lipoprotein, *IgG* immunoglobulin G, *IgM* immunoglobulin M, *IL* interleukin, *IME* immunomodulatory effects, *i.p.* intraperitoneal, *KPPS* kernel pressed paste with skin, *LDL* low-density lipoprotein, *MAE* mesocarp aqueous extract, *MAE/RT* mesocarp aqueous extract combined with resistance training, *MIT* monoiodotyrosine, *NA* data not available, *NO* nitric oxide, *PT* prothrombin time, *RPM* rotations per minute, *TC* total cholesterol, *TG* triglycerides, *Th* T helper lymphocytes, *TNF-α* tumoral necrosis factor, *w.o.* weeks old

Table 5. Baseline characteristics, intervention, methods, and main results of studies

References	Species/cell lines/strains/reactions	Intervention/methods	*O. phalerata* component; concentration	Main results

Barroqueiro et al. [46]	*E. coli* (ATCC 25922), *P. aeruginosa* (ATCC 27853), *E. faecalis* (ATCC 29212), *S. aureus* (ATCC 25923), *S. aureus* (MRSA)	AMA: disk diffusion method by analyzing zones of inhibition; MIC: growth absence or presence after inoculation in tubes	MEE; 500 and 250 mg/mL (disk diffusion); 500 to 0.9 mg/mL (MIC)	Disk diffusion: inhibition >7 mm on *S. aureus*, MRSA, and *E. faecalis*; no inhibition on *E. coli* and *P. aeruginosa*. Complete inhibition on *S. aureus*, MRSA, and *E. faecalis* by the highest concentration. MIC: 7.8 mg/mL (*E. faecalis*)
Bezerra et al. [38]	Promastigote forms of *L. amazonensis*	Leishmanicidal activity: promastigotes incubated during 24 h with extract. Count of living protozoa after 24 h by flagellar motility. CL_{50}	MAE; serial concentrations 500 to 31.25 µg/mL	CL_{50} >500 µg/mL. Deaths about 20% in all concentrations
Caetano et al. [37]	*S. aureus* (ATCC6538, ATCC9144), *S. aureus* MRSA (2 nosocomial strains), *S. aureus* MSSA (3 nosocomial strains)	AMA: disk diffusion method by analyzing zones of inhibition	Mesocarp hydroalcoholic extract; 30 mg/mL	Growth inhibition on all strains (14 to 18 mm zones)
Ferreira et al. [45]	AMA: *S. epidermidis* (ATCC12228), *S. aureus* (ATCC25923), *E. coli* (ATTC11229), *P. aeruginosa* (ATTC27853); $DPPH^{\bullet}$; *A. salina*	AMA disk diffusion method by analyzing zones of inhibition; AA: $DPPH^{\bullet}$ scavenging. EC_{50}; Lethality: *A. salina* assay for 24 h. CL_{50}	Kernel oil; 10 mg/mL (AMA); 300, 250, 200, 150, and 100 mg/mL ($DPPH^{\bullet}$); 50 to 0.05 mg/mL (lethality)	AMA: no inhibition; $DPPH^{\bullet}$: EC_{50} 70.57 mg/mL; CL_{50} >1000 µg/mL
Gaitan et al. [22]	Porcine thyroid slices; TPO	Antithyroid effect: thyroid hormone synthesis assessed by measuring total accumulated iodine and iodine organification in MIT + DIT, and $T_3 + T_4$; TPO: spectrophotometry by oxidation of I^- to I^{3-}. Inhibition of TPO-catalyzed iodination, compared to PTU concentration. I_{50}	MAE, MME, kernel skin, KPPS, kernel oil; cellular assays: 1×10^5 µg/5 mL (MAE, skin); 5×10^4 µg/5 mL (KPPS, oil); TPO: 100 to 200 µg/mL	Cellular: antithyroid effect in all extracts by ↑ ^{125}I/MIT + DIT ratio, ↓ % ^{125}I demonstrated as $T_3 + T_4$ (NA). Kernel oil 1/5 from KPPS I/MIT + DIT ratio (I/MIT + DIT = 15). Higher ratio for mesocarp; TPO: ↑ inhibition % by MME and kernel skin

Hovorková et al. [8]	*E. cecorum* (CCM3659, CCM4285), *C. perfringens* (CIP105178, CNCTC5454, UGent 56), *Listeria monocytogenes* (ATCC7644), *S. aureus* (ATCC25923), *Bifidobacterium animalis* (CCM4988, MA5), *Bifidobacterium longum* (TP1, CCM4990), *Lactobacillus fermentum* (CCM91), *Lactobacillus acidophilus* (CCM4833)	AMA: previous kernel oil hydrolysis with porcine pancreatic lipase. Inoculation of each strain with emulsion. Growth assessment by the culture turbidity read at 405 nm. MIC_{80}	Kernel hydrolyzed lipid emulsion; 4.5 mg/mL	MIC_{80}: 0.56 mg/mL on *C. perfringens,* 1.13 mg/mL on *S. aureus*, and 2.25 mg/mL on *E. cecorum.* No effect on pathogenic strains before hydrolysis or on commensal strains
Nobre et al. [30]	TBARS, deoxyribose degradation, $DPPH^{\bullet}$, iron chelation, FRAP	AA: TBARS: phospholipids diluted in the extract with or without iron to induce peroxidation and absorbance with MDA; Deoxyribose degradation: induction of sugar decomposition by Fe/ H_2O_2 added to the extract to produce MDA; $DPPH^{\bullet}$: scavenging, read at 518 nm; Iron chelation: chelation potential by extract (plus Fe^{2+}, Tris–HCl, and phenanthroline), absorbance read at 510 nm; FRAP: ability to reduce the equivalent of 1 mM $FeSO_4 \cdot 7H_2O$. IC_{50}, EC_{50}, EC	Kernel methanolic extract; 1000 to 100 µg/mL (TBARS, deoxyribose, $DPPH^{\bullet}$, iron chelation); 50 to 5 µg/mL (FRAP)	No TBARS inhibition; deoxyribose IC_{50} >1000 µg/mL; $DPPH^{\bullet}$ EC_{50} 3517.01 ± 77.07 µg/mL; iron chelation: <20%, IC_{50} >1000 µg/mL; FRAP EC: 1560.2 ± 18.30 µmol.L^{-1}/g
Nobre et al. [10]	*S. aureus* (ATCC12692), *P. aeruginosa* (ATCC15442), *E. coli* (ATCC25922), *E. coli* (Ec27), *S. aureus* (Sa358)	Antibacterial activity: growth evidence after inoculating extract with resazurin solution into tubes. MIC	Fixed kernel oil: 512 to 8 µg/mL	Higher inhibition on *E. coli* 27 (MIC 23 µg/mL); ↓ MIC in the association between oil and amicacin on *S. aureus* 358 and *P. aeruginosa*, as well as neomycin on *S. aureus* 358, *P. aeruginosa*, and *E. coli* 27 (NA)

Pessoa et al. [31]	Enteropathogenic *E. coli*, mononuclear phagocytes	Cellular viability: slides fixed by acridine orange method; viability index by counting dead and alive cells in a total of 100. Functional activity by phagocytic index: number of cells that ingested at least 3 bacteria in a pool of 100 cells. Bactericidal index: dead/alive bacteria ratio by acridine orange	Kernel microemulsion and oil; 20 μL	↑ viability index and ↑ phagocytic index by microemulsion; ↑ bactericidal index by oil
Rennó et al. [28]	Leukaemic cell lines (HL-60, K562), K562-Lucena 1 MDR counterpart, lymphocytes, mouse fibroblast cell line (3T3-L1), human breast cancer cell line (MCF-7)	Cellular viability: erythroleukemic cells evaluated by permeability to trypan blue up to 24 h. Inhibition of cell proliferation calculated by comparing treated/untreated cells. Morphology: non-viable stained cells were separated in retained shape and lysed; lymphocytes evaluated with trypan blue after 24 h; MCF-7 and 3T3-L1 trypsinized and evaluated with trypan blue. Metabolism: 6-phosphofructo-1-kinase activity to convert into fructose-1,6-bisphosphate in HL-60. ID_{50}	Mesocarp with epicarp ethanolic extract; 2000, 1500, 1200, 600, 300, and 150 μg/mL	ID_{50} more effective on HL-60; moderate sensitivity on K562, K562-Lucena 1, and MCF-7; Resistance on 3T3-L1 and lymphocytes; morphological changes by 1200 μg/mL on HL-60; ↑ 6-phosphofructo-1-kinase on HL-60

Santos et al. [33]	Mouse fibroblasts (L929) and peritoneal macrophages	Cellular viability: MTT assay up to 72 h; absorbance read at 560 nm; macrophages stimulated by LPS from *E. coli* for 1 h and treated with kernel oil. NO and cytokines measured after 24 h; Scratch assay: fibroblasts migration in monolayers, production of 1.2001.500 μm width wounded area. Cellular migration measured each 6 h	Kernel oil; 100 to 1.56 μg/mL	No toxicity up to 100 μg/mL; cell proliferation with MTT metabolism ↑ above 25 μg/mL on L929; dose-related ↓ NO; ↑ IFN-γ, IL-6, and ↑TNF-α by 3.12 μg/mL; ↑ fibroblasts migration in scratch assay by 6.25 and 12.5 μg/mL
Santos et al. [32]	$DPPH^{\bullet}$, mouse fibroblasts (NIH/3T3, ATCCR, CRL-1658)	AA: $DPPH^{\bullet}$ scavenging, read by electron spin resonance; EC_{50}; Cellular viability: MTT assay with nanoemulsion up to 72 h, IC_{50}	Kernel oil, lipidic nanoemulsion; 4.0; 24.9; 49.9; 74.8, and 99.8 mM ($DPPH^{\bullet}$); 2500 to 39.06 $\mu g.mL^{-1}$ of nanoemulsion (MTT)	$DPPH^{\bullet}$ EC_{50}: nanoemulsion: 0.4329 mg mL^{-1}; oil: 0.5488 mg mL^{-1}; cytotoxicity by nanoemulsion ≥ 78.12 $\mu g.mL^{-1}$
Silva et al. [34]	$DPPH^{\bullet}$, *S. cerevisiae* (BY4741)	AA: $DPPH^{\bullet}$ scavenging, read at 518 nm; $IC_{50.}$ *S. cerevisiae*: incubation of 0.1 mg mL^{-1} cells with 3 mM TBH and 5 mg ml^{-1} extracts; microorganism viability assessed after 72 h	Endocarp, flowers, and leaves ethanolic extract; 1.0 mg ml^{-1}	$DPPH^{\bullet}$ IC_{50}: 4104.3 ± 6.7 $\mu g.ml^{-1}$ (endocarp); 427.4 ± 1.8 $\mu g.ml^{-1}$ (flowers), and 895.9 ± 2.3 $\mu g.ml^{-1}$ (leaves); no yeast survival

Silva et al. [23]	NO, TBARS, deoxyribose degradation	AA: nitrite measured by Griess reaction after NO generated in sodium nitroprusside decomposition. Absorbance read at 540 nm. TBARS: phospholipids diluted in the extract with AAPH as peroxidation inducing agent, absorbance read at 532 nm; $OH^{\bullet}$ production by MDA synthesis, a product of deoxyribose degradation induced by Fe/H_2O_2 added to the extract, absorbance read at 532 nm	MAE; 1000, 100, 10, and 1 μg/mL	No effect on NO and $OH^{\bullet}$ removal or over lipid peroxidation
Silva et al. [35]	$DPPH^{\bullet}$, $ABTS^{\bullet+}$, FRAP, tyrosinase	AA: $DPPH^{\bullet}$ scavenging, absorbance read at 517 nm; $ABTS^{\bullet+}$ scavenging absorbance read at 734 nm; FRAP: analysis of ability to reduce Fe^{3+} into Fe^{2+} with, read at 593 nm; Tyrosinase inhibition: L-tyrosine for monophenolase reaction and 3,4-dihydroxyphenylalanine for diphenolase reaction. Absorbance read at 492 nm	Mesocarp hydroalcoholic extract and fractions (hexane, chloroform, ethyl acetate, hydroalcoholic); 100 to 5 μg/mL ($DPPH^{\bullet}$), 6 to 1 μg/mL ($ABTS^{\bullet+}$), 100 to 1 μg/mL (FRAP), 200 to 50 μg/mL (tyrosinase)	↑ AA by ethyl acetate fraction in $DPPH^{\bullet}$ IC_{50}: 3.38 ± 0.05 μg/mL, $ABTS^{\bullet+}$ IC_{50}: 2.04 ± 0.03 μg/mL and FRAP: 15.41 ± 0.18 mmol Fe^{2+}/g; IC_{50} for tyrosinase: 48.43 ± 29.51 μg/mL (monophenolase) and 132.63 ± 5.71 (diphenolase)
Silva et al. [29]	Promastigote forms of *L. amazonensis* (IFLA/BR/67/PH8)	Leishmanicidal activity: promastigotes incubated with the isolated extract and mesocarp-loaded microparticles. Protozoa counting after 48 h by flagellar motility. CL_{50}	MAE; 500 to 62.5 μg/mL and mesocarp-loaded microparticles; 100 to 3.125 μg/mL	Lethality: pentamidine >microparticles>extract in solution. CL_{50} microparticles: 12 pg/mL

Souza et al. [36]	Benign prostate hyperplasic cells	Cellular viability: MTT assay, absorbance read at 570 nm up to 72 h; cytotoxicity by LDH release: damage estimated after from 4 up to 48 h, absorbance read at 490 nm; Immunohistochemistry: cultures treated for 24 h, PCNA immunostained; Apoptosis: TUNEL test by blocking endogenous peroxidase. DNA fragmentation assessment; Histomorphometry: nuclei counting with PCNA or TUNEL stained, distribution and intensity of staining assessment inside the glandular epithelium or stroma; Morphology: indirect assessment using phalloidin after 4, 6 and 12 h	Kernel crude oil, oily extract, nanocomposite with lipophilic extract; 300 to 100 µg/mL (MTT), 300 µg/mL (LDH, Immunohistochemistry, histomorphometry, apoptosis)	Viability: ↑ dose-related inhibition by nanocomposite; time-dependent disorganization of the actin cytoskeleton; ↑ time-dependent LDH release; immunohistochemistry: preserved glandular architecture; ↓ cell proliferation in 24 h; diffuse apoptosis and ↑ in apoptotic index after 24 h

↑ increase; ↓ decrease; *AA* antioxidant activity, *AMA* antimicrobial activity, *AAPH* 2,2′-azobis(2-methylpropionamidine) dihydrochloride, *ABTS*$^{\bullet+}$ 2,2′-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid), CL_{50} lethal concentration, *DIT* diiodotyrosine, *DPPH*$^{\bullet}$ 2,2-diphenyl-2-picryl-hydrazine, *EC* equivalent concentration, EC_{50} effective concentration, *FRAP* ferric-reducing antioxidant power, I_{50}/IC_{50} inhibitory concentration, *IFN-γ* interferon-γ, *IL-6* interleukin-6, *KPPS* kernel pressed paste with skin, *LDH* lactate dehydrogenase, *LPS* lipopolysaccharide, *MAE* mesocarp aqueous extract, *MDA* malondialdehyde, *MEE* mesocarp ethanolic extract, *MDR* multidrug resistant, MIC/MIC_{80} minimum inhibitory concentration, *MIT* monoiodotyrosine, *MME* mesocarp methanolic extract, *MRSA* methicillin-resistant *Staphylococcus aureus*, *MSSA* methicillin-sensitive *Staphylococcus aureus*, *MTT* (3-[4,5-dimethylthiazol-2y]-2,5-diphenyltertrazolium bromide), *NA* data not available, *NO* nitric oxide; $O_2^{\bullet}$ superoxide anion, $OH^{\bullet}$ hydroxyl radical, *PCNA* proliferation cell nuclear antigen, *PTU* propyl-2-thiouracil, *TBARS* thiobarbituric acid reactive substances, *TBHtert*-butylhydroperoxide, T_3 triiodothyronine, T_4 thyroxine, *TNF-α* tumor necrosis factor-α, *TPO* thyroperoxidase

Assessed outcomes from in vivo (**A**) and in vitro (**B**). Some publications have more than one outcome

Risk of bias assessment

Individual and for each domain in vivo

SYRCLE RoB Tool identified 130 entries distributed in ten domains for each one of the 13 studies (Table 6). It was found uncertain risk or inappropriate records in 80 entries (81.54%), low risk was present in 45 (34.61%) and high risk in five studies (3.85%). The average agreement by Cohen's kappa was 0.53 (68%), classified as intermediate to good [21].

Table 6. In vivo individual risk of bias

Domains: D1—sequence generation; D2—baseline characteristics; D3—allocation concealment; D4—random housing; D5—blinding (performance bias); D6—random outcome assessment; D7—blinding (detection bias); D8—incomplete outcome data; D9—selective outcome reporting; D10—other sources of bias. Total: 130 (100%); (+) Yes: 45 (34.61%); (−) No: 5 (3.85%); (?) Unclear: 80 (61.54%) [19]

Uncertain risk prevailed for the domains related to sequence generation, allocation concealment, random housing, and random outcome assessment (Fig. 4). There was no record of uncertain risk related to selective outcome reporting. In the domain related to other sources of bias, only one entry was registered due to the lack of clearness if the same animals or distinct animals were submitted to the different tests and if there was no contamination by the induction of some substance used in control groups [24].

Fig. 4 [Images not available. See PDF.]

In vivo risk of bias assessment by domain. (legend) Domains: D1—sequence generation; D2—baseline characteristics; D3—allocation concealment; D4—random housing; D5—blinding (performance bias); D6—random outcome assessment; D7—blinding (detection bias); D8—incomplete outcome data; D9—selective outcome reporting; D10—other sources of bias. Yes: low risk; No: high risk; Unclear: uncertain risk [19]

The analysis of the effective risk of bias revealed a higher frequency of low risk in baseline characteristics (92.3% of entries for the domain), selective outcome reporting, and other sources of bias (84.61% for both). Low risk was evidenced due to the appropriate description regarding the specificities of the animals. As well as for high risk of bias, specific analysis indicates that the circumstances in the intervention route were not similar in all groups [23], and there was animal loss with unknown reason, groups equalization, and randomization of the final sample [25]. Besides that, some primary outcomes were not showed [26, 27].

Individual and for each domain in vitro

The analysis of 17 studies checked 102 entries divided into six questions (Table 7). There was a predominance of low risk of bias by adequate methods reporting (65.69%), high risk in eight (7.84%), and uncertain risk in seven studies (6.86%). The average agreement by Cohen's kappa was 0.39 (51.96%), classified as low [21].

Table 7. In vitro individual risk of bias

Questions: Q1—cells/strains from validated repository or appropriately verified; Q2—technical repeats and controls inclusion; Q3—use of different cell lines/strains/reactions; Q4—comparable conditions between groups/assays; Q5—selective outcome reporting; Q6—comparison of different cell lines/strains/substances. Total: 102 (100%); (+) Yes: 67 (65.69%); (−) No: 8 (7.84%); (?) Unclear: 7 (6.86%); (∅) Not applicable: 20 (19.61%). Questions adapted from Lewis et al. [20]

The most detailed and complete descriptions were seen in antimicrobial evaluation of hydrolyzed kernel lipid emulsion in strains of pathogenic and commensal microorganisms [8], kernel oil in pathogenic strains [10], and mesocarp with epicarp methanolic extract in viability, changes in morphology, and metabolism in different cell lines [28].

The high risk of bias was highlighted by the use of a single organism and the mean values of primary outcomes have not been presented [29]. Nine studies (47.05%) demonstrated the non-application of two questions, most frequently for the impossibility of comparing cell lines/strains or culture conditions between groups, as they were assays with a single microorganism, strain or distinct chemical reactions (Q4, Q6) [23, 29–36].

When analyzing the methodological quality by domain (Fig. 5), the selective result was avoided in 94.11% of the studies and the low risk of bias was in 76.47%, regarding the validation of cells and strains repository and the use of a control group (Q1, Q2). Less frequently, there were some doubts about the cell line origin (Q1, 5.88%) and technical repeats (Q2, 17.65%) [22, 29, 30, 37].

Fig. 5 [Images not available. See PDF.]

In vitro risk of bias assessment by domain. (legend) Q1—cells/strains from a validated repository or appropriately

verified; Q2—technical repeats and controls inclusion; Q3—use of different cell lines/strains/reactions; Q4—comparable conditions between groups/assays; Q5—selective outcome reporting; Q6—comparison of different cell lines/strains/substances. Yes: low risk; Não: high risk; Unclear: uncertain risk. Questions adapted from Lewis et al. [20]

The most frequent classification for 'high risk' was based on the use of a single cell line/strain in 41.17% of the investigations [22, 29, 31–33, 38] and, less frequently, for the reason of the impossibility in comparing reactions due to different outcomes [23], and again, due to selective report when the result was presented by a single sample [29].

In vivo interventions and main results

Animals' interventions and related results are described in Table 4. The antithyroid effect was evaluated by offering acutely mesocarp aqueous extract (MAE) and kernel pressed paste with skin (KPPS) after a previous iodine-rich diet. This effect was observed by thyroid uptake reduction of ^{125}I and by the ratio between ^{125}I and monoiodotyrosine (MIT) coupled to diiodotyrosine (DIT). As a result, ^{125}I uptake was suppressed by MAE, but not significantly by KPPS. However, the ratio $^{125}I/MIT+DIT$ was high for both MAE and KPPS, suggesting a thionamide-like antithyroid effect [22].

Concerning the effect on lipid metabolism, urea and the development of type 1 diabetes, three studies offering MAE evaluated the intake of 50 mg/kg for 30 days in five mouse strains and found a significant increase in total cholesterol (TC) levels only in CBA strain (27 vs. 9 mg/dL) and a decrease only in C3H/HePas (18 vs. 47 mg/dL). There was a significant decrease in urea levels, except for C57BL/6 (49 vs. 67 mg/dL). Despite the glycolipid profile outcome mentioned, levels of lipoproteins, triglycerides (TG) or glucose were not demonstrated [39]. Another intervention offered a dose ten times lower than the previous study for 40 non-consecutive days, associated or not with resistance training (RT). They verified weight of loss after an 8-week supplementation period and, associated with RT, after 4 weeks. In addition, animals supplemented combined or not with RT had retroperitoneal fat reduction up to 73%, a decrease in TC levels (MAE: 79 mg/dL; MAE/RT: 70 vs. 97 mg/dL) and TG (MAE: 90 mg/dL; MAE/RT: 82 mg/dL vs. 166 mg/dL). There was a reduction in glucose only in RT animals (131 vs. 145 mg/dL). Animals trained without supplementation showed greater Delta force, suggesting a possible ergolytic effect of the substance [6].

On the other hand, Silva et al. [25] observed weight gain with intake of 3.3 mL/day of a suspension of MAE 20 mg/mL. In this study, the animals were not subjected to any type of physical labor and weight gain occurred between the 20th and 50th days, but with an abrupt drop afterwards. There was blood glucose fluctuation with lower levels on the 30th day and returning to baseline on the 60th. They did not observe significant changes in immunoglobulin IgG levels, possibly due to the low effect of MAE on T lymphocyte activation and cytokine production.

Acute toxicity effects were observed with high doses of mesocarp extracts and measured by organ relative weight and histological and biochemical analysis. No deaths were registered after a single dose up to 5000 mg/kg of mesocarp ethanolic extract (MEE) [27], as well as significant physical and or behavioral changes were not found. The same investigation also evidenced a reduction in urea levels at 5000 mg/kg (26 vs. 40 mg/dL) and increased TG at 1000 mg/kg (104 vs. 54 mg/dL) in a dose-dependent way. Alkaline phosphatase (ALP) increased after 3000 and 5000 mg/kg intake (23 and 21 U/L, respectively, vs. 6 U/L). No toxic effects were observed with gradual doses up to 4000 mg/kg [24]. MAE, mainly associated with RT, increased both aspartate (AST) and alanine aminotransferase (ALT) [6]. Alterations in locomotor activity and motor coordination can also be a sign of toxicity. Thus, a single dose of up to 3 g/kg of MAE did not affect these outcomes [23].

Low toxicity was observed since no changes in the number of medullary cells and a decrease of splenic cells only in BALB/c and C3H/HePas (both 3×10^7 vs. 5×10^7) was noted. Weight loss in organs was reported for HePas after 30 days exposure at 50 mg/kg of MAE [39]. On the other hand, MAE 5 mg/kg was able to increase the number of medullary cells in the absence of RT in Swiss mice (30×10^6 vs. 13×10^6), but in the scenario of splenocyte levels' preservation (41×10^6). When associated with RT, splenic cells were reduced (30×10^6) [6].

After different doses and periods, Maia and Rao [24] evaluated the effect of mesocarp chloroform extract intake on the inflammatory process. Analyzing the carrageenan-induced inflammation in edema paw, it decreased up to 32%

with progressive doses. The edema reduction caused by formaldehyde-induced arthritis was also observed on the 7th and 8th days of treatment. In this same study, seven-day intake at 250 mg/kg inhibited subcutaneous granuloma, measured by the weight of the cotton pellet introduced (112 vs. 192 mg) and it reduce leukocyte migration (24.19 vs. 23.62 cells/mm^3) and inflammatory exudate after a subcutaneous sponge implant impregnated with carrageenan.

In a stage before exudate induction, Silva and Parente [40] verified a significant inhibition in vascular permeability progression following a single dose of an isolated polysaccharide from mesocarp composed of alpha-(1 → 4) linked D-glucopyranose residues. Meanwhile, Barbosa et al. [26] observed the same effect in microvessels after volumes greater than 0.06 mL of the crude kernel oil twice a day. This study also reported attenuation in leukocyte adhesion with intake of 0.02 mL.

When analyzing proinflammatory cytokines, MAE intervention decreased interleukin-6 (IL-6) and increased tumoral necrosis factor-alpha (TNF-α) levels [6]. However, kernel oil was not able to cause significant changes in IL-1, IL-6, and TNF-α [26].

Leukocyte-specific activity is closely related to inflammatory stages. In this regard, five days of α-glucan from mesocarp increased zymosan-like phagocytic activity induced by colloidal carbon [40]. However, MAE associated with RT increased total splenic macrophages, but reduced activated macrophages, without changes in monocytes [6]. There was an activated T helper decrease and an increase of B cells, suggesting an immunomodulatory effect well [6].

Other outcomes, similar or antagonistic, were also evaluated. Although the antithrombotic effect of the aqueous mesocarp suspension was indicated by the prothrombin time increase (11.2 vs. 10 s) and activated partial thromboplastin time (33.6 vs. 29.5 s) [41], on the other hand, the chloroform extract of mesocarp given for three days did not extend the hemostasis time (98.0 vs. 90.3 min) [23].

Regarding peptic ulcer induction, prevention, or treatment, Maia and Rao induced ulceration with phenylbutazone and observed an average score of 1.03 for the lesion in five of six animals treated with phenylbutazone, on a 0–4 scale [24]. In opposition, animals treated with mesocarp chloroformic extract for 21 days did not exhibit lesions. In a different study, the prophylactic and therapeutic effect of MAE was compared to omeprazole, before or after ethanol-induced ulcers. In the preventive treatment, the effect was similar to omeprazole in the absence of lesions (60% of the animals), but superior to the drug in the absence of hyperemia, bleeding, and preservation of folds (100% vs. 60% on all outcomes). Despite the accentuated related-inflammatory lesions, such damage reached only the mucosa in MAE-treated animals, while there was deeper damage up to the submucosa in those ones receiving vehicle. Moreover, microscopic analysis showed MAE prevented necrosis in 80% of animals [42].

Scheibe et al. [43] evaluated 21-day MAE intake for healing. After this period, the animals underwent laparotomy with cecum exteriorization. Significantly, they identified a grade II adhesion (two adhesions between organs or between an organ and abdominal wall) in 100% of the animals on the 21st postoperative day compared to the negative control. Morphological evaluations did not identify polymorphonuclear leukocytes (vs. moderate presence), and mild congestion and angiogenesis (vs. severe) and moderate fibroblasts (vs. severe) were detected in MAE-exposed animals. Collagen production was also more intense than in the control group. Silva et al. [44] used the same procedures, but offered a MAE single dose. They found similar results, except for collagen production.

Finally, antipyretic and analgesic properties of mesocarp chloroform extract were analyzed [24]. After pyrexia induced by *Saccharomyces cerevisiae*, no time-related decrease in body temperature was observed (1 h: 39.18 vs. 39.18 °C; 2 h: 39.1 vs. 39.3 °C; 3 h: 39.18 vs. 39.31 °C). The analgesic effect was compared to morphine after exposure to a hot-plate at 55 °C. After 30 min of 250 mg/kg intake, the extract was not able to promote analgesia. Reaction time was similar to negative control and shorter than morphine (extract: 3.5 s; control: 2.83 s; morphine: 14.0 s). In contrast, the same dose was able to reduce acetic acid-induced writhing around 62% [24].

In vitro assays and main results

In vitro studies are useful for preliminary testing of substances in a controlled environment. The studies included are described in Table 5. Six studies evaluating antimicrobial and phagocytic activities on pathogenic or commensal

strains [8, 10, 27, 31, 37, 45] and two investigations against protozoa [29, 38] were identified. Cellular assays were carried out with tumor or non-tumor cell lines to study viability or cytotoxicity, morphological or metabolic changes [22, 28, 31–33, 36]. Lethality assays were carried out in microcrustaceans (*Artemia salina* Leach.) [45].

Assays using chemical reactions or yeasts can also be developed to measure preliminary effective concentrations (EC_{50}) for achieving half desirable effects. This review included six studies which evaluated the antioxidant activity of babassu [23, 30, 32, 34, 35, 45].

The most common component of *O. phalerata* was the kernel (52.9% of the studies) [8, 10, 22, 30–33, 36, 45]. MAE and mesocarp alcoholic extracts were tested in 47% and one publication associated mesocarp with epicarp [22, 23, 28, 29, 35, 37, 38, 46]. Only Silva et al. [34] used endocarp, flowers, and leaf extracts. The concentrations ranged a lot from 500 mg/mL of MEE [46] to assess the antimicrobial effect to 1 µg/mL of MAE for the antioxidant activity [23].

The disk diffusion assay was used to evaluate the effect of mesocarp on pathogenic bacteria strains. At 250 and 500 mg/mL, MEE promoted concentration-dependent inhibition zones on *Staphylococcus aureus* (18.5 mm), methicillin-resistant *S. aureus* (17.4 mm), and *Enterococcus faecalis* (14.4 mm). The most relevant minimum inhibitory concentration was observed for *E. faecalis*, while 500 mg/mL inhibited the growth of them completely. In contrast, there was no inhibition of *Escherichia coli* and *Pseudomonas aeruginosa* [46]. Similar levels of inhibition on methicillin-resistant or sensitive *S. aureus* were observed with lower concentrations of the hydroalcoholic extract [37].

Kernel oil also did not demonstrate efficacy on Gram-positive and negative strains [45], but after hydrolysis, it inhibited 80% of *Clostridium perfringens*, *S. aureus,* and *Enterococcus cecorum* [8]. Furthermore, the fixed oil increased the effectiveness of antibiotics over *S. aureus*, *P. aeruginosa,* and *E. coli* [10].

After evaluating mononuclear phagocyte activity and bactericidal potential, Pessoa et al. [31] found a higher rate of phagocytosis by lipid microemulsion (69.1 vs. 47%), and the bactericidal activity was higher by isolated oil (47.9%). When testing the leishmanicidal effect of MAE, it was observed a low activity when compared to Glucantime® (LC_{50} >500 vs. 440.3 µg/mL) [38]. On the other hand, microparticles loaded with the same extract demonstrated upper effectivess, but lower than pentamidine (IC_{50} 12 vs. 0.8 pg/mL) [29].

In a study developed by Rennó et al. [28] using the trypan blue method, leukemic promyelocytes (HL-60) were more sensitive to the crude ethanolic extract from mesocarp combined with epicarp when compared to negative control (ID_{50} 9.3 vs. 125 µg/mL), whose activity was time dependent (150 µg/mL: 8.6 h; 2 mg/mL: 0.4 h). The concentration of 1.2 mg/mL promoted changes in HL-60 morphology, with decrease in size and cytoplasmic/nuclear condensation. Interestingly, there was an increase in levels of 6-phosphofructo-1-kinase (PFK) enzyme at 300 µg/mL were tested, 6.6 times greater than the negative control. In this study, non-tumor cells showed greater resistance, such as L929 (127 vs. 88.7 µg/mL) and human lymphocytes (141.2 vs. 84.4 µg/mL). It is important to highlight that both erythroleukaemic sensitive to chemotherapy line and its multidrug-resistant counterpart were equally affected.

Regarding cytotoxicity, Santos et al. [32] tested a lipid nanoemulsion from kernel oil droplets in L929 cells and it was found a time and concentration-dependent IC_{50} after 24 h of exposure (396.1 µg mL^{-1}), 48 h (363.3 µg mL^{-1}) and 72 h (333.1 µg mL^{-1}). Santos et al. did not find kernel oil toxic effects on L929 after MTT (3–4,5-dimethyl-thiazol-2-yl-2,5-diphenyltetrazolium bromide) assay. Conversely, the same effect was not verified on peritoneal macrophages. Furthermore, they reported an increased migration of L929 cells in the scratch assay, concentration-dependent nitric oxide attenuation (0.31 to 0.29 vs. 1.15 µM), and higher levels of INF-γ (interferon-γ) production with 6.25 µg/mL of the nanoemulsion (2214.2 vs. 980.4 pg/mL), TNF-α (107.7 vs. <0.9 pg/mL) and IL-6 with 3.12 µg/mL (1286.1 vs. 584.4 pg/mL) by macrophages, suggesting a modulation of inflammatory response in wound healing situations.

Concerning phagocyte viability, a higher viability index similar to culture medium was found for lipid microemulsion when compared to isolated oil (98 vs. 94.3%) [31]. Another study using benign prostatic hyperplasic cells observed viability inhibition up to 75% after 24–72 h of exposure to a 300 µg/mL of nanocomposite with lipophilic extract. Even after the addition of fetal bovine serum, the inhibition was sustained. There was also induction of disorganization (disassembly) or disruption in the structure of actin microfilaments in a time-progressive manner, and a progressive lactate dehydrogenase (LDH) release. For this enzyme, there was a release of up to 75% after 48 h.

Immunoreactivity for proliferation cell nuclear antigen (PCNA) was also tested and proved to be 50% lower when compared to the negative control in association of apoptosis induction [36]. The single report about multicellular organisms observed no toxicity on *A. salina* (LC_{50}>1000 μg/mL) after testing concentrations up to 50 mg/mL of kernel oil [45].

The antithyroid effect in porcine thyroid slices was tested by Gaitan et al. [22] with different babassu components. The study verified that, although ^{125}I absorption by thyroid tissue was similar between the substances, the extracts showed a higher incorporation of ^{125}I/MIT + DIT, mostly after MME (mesocarp methanolic extract) exposure indicating iodine organification inhibition. Concerning thyroperoxidase activity, the MME and kernel peel evidenced an EC_{50} of 140 and 160 μg/mL, respectively, for thyroperoxidase-catalyzed iodination. Tyrosinase inhibition was also tested and a higher IC_{50} was found for the mesocarp ethyl acetate in comparison with extract or hydroalcoholic fraction for both monophenolase and diphenolase activity [35].

The antioxidant potentiality of babassu is detailed in Table 5. EC_{50} required for $DPPH^{\bullet}$ (2,2-diphenyl-1-picryl-hydrazyl) scavenging was described for kernel oil [37, 45] and for a nanoemulsion [32]. Nobre et al. [30] did not find thiobarbituric acid reactive substances (TBARS) inhibition and evidenced a low effect on deoxyribose degradation, $DPPH^{\bullet}$, and iron chelation by kernel methanolic extract. In this study, the expected effect occurred only for FRAP (ferric-reducing antioxidant power), but required higher concentrations than quercetin (1560 vs. 155.2 μmol $L^{-1}Fe^{2+}$). Likewise, no antioxidant effect of MAE up to 1000 μg/mL was detected. Endocarp, flower, and leaf alcoholic extracts also did not demonstrate antioxidant potential based on reaction with $DPPH^{\bullet}$. Furthermore, there was no yeast survival when the same extracts were associated with tert-butylhydroperoxide [23]. A positive result was verified only by Silva et al. [35] for mesocarp ethyl acetate fraction on $DPPH^{\bullet}$ (IC_{50} of 3.38 μg/mL), $ABTS^{\bullet+}$ (2,2′-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) scavenging (2.04 μg/mL), and FRAP (15.41 mmol Fe^{2+}).

Discussion

In vivo studies

The fruit of babassu has shown favorable biological activities. However, the absence of results or undesirable outcomes were also observed, such as the antithyroid effects.

In animal models, the sex, age, weight, and metabolic condition are essential to optimize the relevance of the results [47]. Despite the analysis of beneficial effects, the in vivo trials seem to be useful for acute, subacute, or chronic toxicity tests, since even natural substances cannot be considered completely safe. Notably, widely studied nutrients also exhibit upper limits and restrictions [48]. In this context, investigations subjected animals to varied experimental conditions, including a single dose [23, 27], short or moderate durations throughout their lifetime [6, 39], or progressive dose regiments [24], but not always waiting for long latency periods [23], which limits the outcomes.

One of the alterations found that could indicate possible toxicity suggests that even after 14 days of latency, ALP increase was not followed by changes in liver and kidney functions. The hypothesis suggests that young animals are susceptible to alterations in this enzyme according to their diet [27]. In turn, increasing levels in aminotransferases should be evidence of oxidative stress due to lipid peroxidation, notably when there is a greater oxygen demand, as the rodents submitted to RT [6]. In terms of immunotoxicity, the decrease of splenic cells and spleen weight were both selective. The authors suggest sparse effects due to the divergence of results in strains with distinct haplotypes [39]. In short, despite the cited changes, all publications suggest low toxicity of the kernel and the mesocarp, not only with a single dose intervention up to 5 g/kg [23, 24, 27], but also with low doses up to 40 days [6, 39].

Results on metabolic effects show discrepant changes in serum TG. This marker increase could suggest an increment in lipogenesis due to the high carbohydrate content in the mesocarp (79.2%) [6], but it did not worse with doses above 1000 g/kg [27]. The presence of fibers in the mesocarp (17.9%) could also be associated with TC and LDL (low-density lipoprotein) decrease by reducing lipids absorption when they interact with lipase and/or colipase and limit the enzymatic activity [6, 49].

The reason for urea level reduction lies in the fact that foods with a high carbohydrate content, mostly resistant types, are not absorbed and remain available for gut microbiota fermentation. In this condition, endogenous proteins and plasma nitrogen would be recruited to ensure microorganism growth, reducing plasma urea levels, especially

when dietary protein intake is deficient [50].

Investigations have also displayed weight gain and glycemic fluctuation after intervention with MAE, which would contraindicate mesocarp intake, mainly for type II diabetes patients, in which weight loss is the most common aim, or when the risk of developing diabetes is increased [25]. However, the glycemic load of foods with a high content of digestible carbohydrates can be attenuated in association with proteins, lipids, and dietary fiber, constituting an essential strategy for maintaining adequate glycemic levels [51]. In opposition, the absence of weight gain and retroperitoneal adiposity reduction was demonstrated by Soares et al. [6] after MAE intake associated or not with RT, indicating a possible adjuvant effect of mesocarp in fat loss and weight control.

The anti-inflammatory activity of mesocarp chloroform extract suggests its application in subacute situations due to the inhibition of granuloma, a proliferative phase of inflammation. However, as the chloroform extract had no effect on pyrexia or leukocyte migration, arachidonate metabolism is not possibly involved in the mechanism [24].

Despite the high content of saturated fatty acids in crude kernel oil, the hypothesis is that vascular permeability decrease and leukocyte adhesion observed by Barbosa et al. [26] may have attributed to the anti-inflammatory action of oleic acid and the antioxidant effect of α-tocopherol.

Other positive effects on inflammation processes demonstrated by α-glucan propose that the residual chains of $1 \rightarrow 3$ bonds not hydrolyzed by amylase may be long enough to contribute to phagocytic amplification and vascular protection [40].

In vitro studies

The selective antibacterial effect of MEE, mainly on *E. faecalis* and *S. aureus*, has likely clinical effects because these strains are associated with nosocomial infections and usually resistant to antibiotics. Its mechanism of action probably involves the generation of complexes between phenolic acids, proteins, and polysaccharides capable of breaking cell wall and inhibiting microorganisms' enzymes [37, 46]. In turn, the synergistic effect between mesocarp and antibiotics may occur by different pathways, including changes in drug receptors [10, 52]. The microparticle encapsulation system can delay compound cytoplasm release, which improves the effect [29]. Applications with crude kernel oil on gram-positive or negative strains were not effective [45]. After its hydrolysis, it showed a selective effect against pathogenic bacteria, but not commensal strains [8]. This effectiveness is related to the free lauric acid, which can cross cell membranes, acidify the intracellular medium, and block bacterial growth, besides the oxidative effect after phagocyte activation [31, 53].

The results observed against tumor cells only demonstrated relative selectivity of mesocarp with epicarp ethanolic extract, including over chemoresistant cell lines, a phenomenon that represents the main failure of antineoplastic treatments. However, the absence of PFK inhibition on HL-60 suggests that the remaining tumor cells may have increased metabolic activity in face of extract toxicity [28, 36].

Fibroblasts have been employed because they are abundant cells in the human body and one of the first to come into contact with substances during absorptive processes. Thus, nanoemulsions based on kernel oil extracts showing low toxic effects against fibroblasts in vitro can predict in vivo studies, as well as the low toxicity against *A. salina* by a wide number of plant species [32, 45, 54].

Experimental evidence demonstrated the antithyroid effect of mesocarp flours, imputing its intake for the persistence of endemic goiter in Maranhão (Brazil) in the mid-1990s [22]. Nonetheless, since the sodium chloride iodination strategy was implemented in the 1950s, the prevalence of iodine deficiency disorders in Brazil has reduced from 20.7% in 1955 to 1.4% in 2000 [55].

The inhibition of tyrosinase activity promoted by the mesocarp ethyl acetate fraction was justified by the high concentration of proanthocyanidins (453.7 mg CE/g) in the inhibitory steps of monophenolase and diphenolase activity [35]. This enzymatic inhibition is one of the key mechanisms for alterations in melanogenesis, responsible for some characteristics of malignant melanoma [56]. The mechanism of this phytochemical consists of blocking L-tyrosine oxidation, depressing L-dopa oxidation products, and preventing pigment synthesis [57].

Given the importance of controlling oxidative stress and its pathological consequences, some tests identified the antioxidant potential of babassu to neutralize free radicals and prevent lipid peroxidation. After finding a total

phenolic content of 288 mg/g in kernel oil, the antioxidant activity did not overcome the ascorbic acid, there may not be a direct correlation between high levels of phytochemicals and better effects though [45]. It is also suggested that specific flavonoids may act in the intermediate process of lipid peroxidation, but they do not neutralize specific radicals [30]. Some concerns about the interference of kernel oil pigments in antioxidant assays have some grade of plausibility, such as DPPH$^{\bullet}$, because they can affect the optical density, which can lead to misinterpretations [58]. Therefore, the use of electronic spin resonance may be useful to bypass this interference [32].

The low affinity between MAE and lipids in TBARS can be answered by the lack of interaction with specific lipids, or hydrophilic portions of amphipathic lipids, as they are more sensitive to radical activity [23], even using polar solvents which can extract flavonoids that provide hydroxyl radicals to neutralize reactive species. However, different solvents can optimize the extraction of polyphenols [59, 60]. With the use of ethyl acetate to prepare samples from mesocarp, it was possible to identify monomers and tetramers of catechins. While the monomer is capable of reacting with a single free radical, its polymer can neutralize three radicals simultaneously [61]. On the other hand, the lack of effect by the endocarp, leaf, and flower ethanolic extracts on radicals and protection against tert-butylhydroperoxide, can be explained by low flavonoid content [34].

Conclusion

This review highlights the prevalent use of mesocarp and kernel in alcoholic extracts and emulsions, emphasizing their low lethality and weak cytotoxicity in vitro, along with the absence of acute toxicity in vivo. This opens perspectives for advancing to in vivo toxicity assays with repeated doses. The empirical intake of both mesocarp flour and kernel oil provides a basis for considering an extension to clinical trials to comprehensively understand the potential applications and effects of these substances.

Screening and characterization of bioactive compounds from two epiphytic microlichen and evaluation of their in vitro antioxidant activity

Pradhan, Shubham1 ; Dash, Satyabrata1 ; Sahoo, Bijayananda1 ; Parida, Sabyasachy1 ; Rath, Biswajit1 1 Maharaja Sriram Chandra Bhanja Deo University, Department of Biotechnology, Baripada, India (GRID:grid.444567.0) (ISNI:0000 0004 1801 0450)

ABSTRACT (ENGLISH)

Background

Lichens in symbiosis produce a wide range of primary and secondary fine compounds in extreme environmental conditions that have a broad range of biological properties as well as antioxidant potential and can be used in future pharmaceuticals as a natural source of antioxidant molecules.

Results

The two microlichen species collected are identified based on morphological and molecular techniques; further studies are carried out by analyzing phytochemicals (FTIR, GC MS), and antioxidant assays are evaluated. The non-enzymatic antioxidant activity is evaluated by DPPH and FRAP assays. The methanol extract of both lichens showed virtuous DPPH scavenge with IC50 of *P. nitida* (125.76 ± 0.023 µg/ml) and *G. scripta* IC50 (176.90 ± 0.058 µg/ml). FRAP activity was prominent in the methalonic extract. The enzymatic antioxidant activity is observed by SOD and catalase activity. The cytosolic (Cu–Zn-SOD and Fe-SOD) and mitochondrial SOD (Mn-SOD) are

detected in lichens, though *P. nitida* shows mitochondrial Mn-SOD and cytosolic Cu–Zn-SOD and Fe-SOD, whereas *G. scripta* has a single cytosolic Cu–Zn-SOD; however, two isoforms of catalase were reported. GC–MS analysis screened bioactive metabolites such as phenols, Quinons, heterocyclic compounds, benzofurans, fatty acids, pyrans, carboxylic acid, aliphatic aldehydes, organic alcohol, fluorinated aliphatic substances, ketones, terpenes and fatty alcohols in *P. nitida*, whereas, in *G. scripta* screened fatty acids, alcohols, hydrocarbons, carbonyl compounds, polyols, terpenes, glycosides, phenols, and sugar alcohols detected in the chromatogram peak. FTIR analysis revealed functional groups like Alcohols, Amines, Amides, Alkanes, Aldehydes, Carboxylic acid, Alkynes, Esters, Ketones, Anhydrides, Acid chlorides, Alkenes, Aromatic compounds, Nitro compounds, Alkyl and Aryl Halides in both lichens.

Conclusions

The results obtained in the present study proved that *P. nitida* and *G. scripta* have promising antioxidant activity owing to the presence of polyphenols and terpenes, as evidenced by DPPH and FRAP assay along with enzymatic analysis (SOD and CAT). Thus both the lichens may be used as natural sources of new bioactive molecules having pharmaceutical interest.

FULL TEXT

Background

Lichens are poikilohydric symbiotic organisms with non-flowering living structure composed of an alga (phycobiont) and a fungus (mycobiont). They live in their natural habitats and can subsist in extreme environments. The water content of lichen thallus broadly depends upon environmental conditions. They have the potential to sustain long durations in a dry ecological condition with high adaptability to slower metabolic activity but can rapidly revive normal physiological activity upon rehydration [1].

Metabolic activities like respiration and photosynthesis are sensible for the generation of ROS (reactive oxygen species) causing damage to cell, thereby enhancing a number of degenerative diseases such as premature aging, inflammation, atherosclerosis, deoxygenation of ischemic tissues and cancer [2]. Free radicals attack unsaturated fatty acids, including PUFAs (polyunsaturated fatty acids), in plasma membranes, resulting in lipid peroxidation, decreased membrane fluidity and dissolution of membrane-associated proteins. Oxidative stress is influenced by environmental factors and aging, but some oxidative diseases and stresses can be treated with antioxidant agents. Antioxidants prevent oxidative chain reactions by eliminating free radical intermediates, which prevent cellular components from getting oxidized [3]. The carcinogenetic effect of synthetic antioxidants implicates the growing interest in natural antioxidants for human sustainability [4]. These are enhanced or triggered stress, such as dietary restriction, xenobiotic exposure, desiccation and/or rehydration. To overcome the latent damaging effects of reactive oxygen species (ROS) and maintain their limited consistency, cells have adopted protection mechanisms, including non-enzymatic antioxidants such as ascorbate, *α*-tocopherols, *β*-carotene and other minerals, and antioxidant enzymes such as superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidases (GTX), as well as low molecular weight antioxidants such as glutathione reductase (GRX) and glucose 6-phosphate dehydrogenase (G6PD) [5].

Graphis scripta and *Pyrenula nitida* are two epiphytic crustose lichens predominantly distributed to different phorophytes on the MSCBU campus. The lichenized thallus of both species consists of Ascomycetes fungus with associated *Trentepohlia* alga. This was associated with a burst of cellular ROS generation by both the mycobiont and the photobiont, as well as nitric oxide production that we only found in the fungus. These actions resulted in a transitory decrease in water-soluble low molecular weight antioxidant capacity but did not induce significant membrane damage. Imbibition of some lichens after desiccation stimulated extracellular antioxidant production [6]. Some recent evidence regarding the antioxidant response of lichens to rehydration reveals that this increases with thallus pre-treatment prior to testing species, drying and rehydration procedures, and experimental time periods [7, 8]

Several lichens have reported numbers of unique secondary metabolites such as terpenes, usnic acid, pulvinic acids, chromones, depsons, depsidones and xanthone derivatives that have been broadly labeled in the regulation

of lichen growth as well as protection along with series of biological activities [9] and the synthesis of these compounds increases their antioxidant capacities [10]. Recently, lichens have emerged as a valuable source of antioxidants, with implications for the development of pharmaceuticals and cosmetics [11]. Furthermore, this study was carried out to screen and identify the major bioactive constituents of both the lichens, *P. nitida* and *G. scripta*, and to evaluate in vitro, the enzymatic and non-enzymatic antioxidant activity by using different solvent extracts. This is the first report from this region on the isolation and characterization of compounds from both the lichen species having their antioxidant activity.

Methods

Sampling and study area

MSCBU campus positioned at 21.9303° N 86.7636° E, Odisha, India (Fig. 1). Seasonal field visits (Spring, Rainy and Winter) and collection (Dates: 07/03/2021, 22/08/2021 and 21/01/2022) of lichens were performed regularly, and all collected lichens were sampled by random sampling technique. Collected lichens are wrapped in white paper bags with zippers, with its microhabitat data (latitude, longitude, temperature and humidity) of each bisect.

Fig. 1 [Images not available. See PDF.]

Study area: MSCBU campus, shadow area showing coverage and distribution of lichens

Diversity index of collected samples

This study explored a number of epiphytic lichen species under 12 genera in 8 families from the MSCBU campus, which is situated near the Similipal Biosphere Reserve (SBR). The preceding study was carried out by studying the epiphytic lichen species on twenty dominant trees/phorophytes. The lichen family Graphidaceae has the maximum distribution and is represented by SWI (Shannon-Weiner Index) as $H=2.053$, with a SIV (species index value) of 206.72, and both the lichen species with SIV as in *Pyrenula nitida*- OQ146904 (55.96) and *Graphis scripta*- OP861477 (63.46) were distributed within vegetation.

Morphological identification of lichens

Morphological identification was done using a stereo-zoom microscope (Stemi-305, 40 × magnifications) and scanning electron microscope (Model-S3400N, magnification 10X to 300,000 X Max) observation. Morphological identifying characteristics are studied using the lichen identifying key book [12].

Molecular identification

DNA isolation from lichens

For the isolation of DNA from Lichen thallus, 10 mg of scraped lichen thallus was used and put into a micro-vial, deepen in liquid nitrogen with three or four 2.5-mm sterile glass beads for 30 s and disrupted with a Mini-Beadbeater-24. The sample was stirred vertically with 300 µL KCl extraction buffer, 300 µL chloroform and kept reversed. The sample mixture was centrifuged at 12,000 rpm for 1 min. The supernatant was transferred to a microcentrifuge vial with the addition of 180 µL of chilled isopropanol and centrifuge at 12,000 rpm for 1 min; the supernatant was descanted. The remaining pellet was poured out with 300 µL chilled ethanol (70%). The pellet was dried at 55 °C in oven, then 100 µL of TE buffer was added, and purified DNA was stored at 4 °C [13].

PCR and sequencing

A partial sequence of DNA for analysis (28s, and 18s rDNA) was isolated from the upper cortex of both lichens. Amplification of rDNA performed using PCR primers for the 28s larger sub-unit of *P. nitida* strain PNSB04 used forward primer used was PN1- 5′-aacaggggggtgagatgtcaga-3′ (25 nm STD, GC: 54.5%, Tm: 60 °C, ΔG: − 41.7 kcal/mol), and reverse primer PN2-5′-ctagtacgatacattcaaatgt-3′ (25 nm STD, GC: 31.8%, Tm: 47.8 °C, ΔG: - 34.33 kcal/mol) for *G. scripta strain* SPB25 rDNA, Forward primer-GS1: 5′-ttgtaatttggagaaggtgttt-3′ (25 nm STD, GC: 31.8%, Tm: 50.4 ΔG: − 38.42 kcal/mol), and reverse primer-GS2: 5′-catcctagcttttgcgcggacc-3′ was used, following the protocol of White et al. [14]. PCR products were visualized on a 1.5% agarose gel analysis for 25 min with content 120 V, to authenticate the presence of amplicons size, then exonuclease-I and recombinant shrimp alkaline phosphatase used for molecular purification and sequenced bidirectionally by genetic analyzer (ABI 3730). Proofreads (forward and reverse) were assembled in MEGA and Sequencher v. 5, with GenBank submission having

accession number for *G. scripta* (OP861477) and *P. nitida* (OQ146904).

Antioxidant activity of Lichens

Preparation of the lichen extracts for non-enzymatic antioxidant activity

Collected lichen samples were dried in a hot air oven and then crushed to a fine powder, and 10 g of dry powder was poured into a Borosil Soxhlet at 45–50 °C for 24 h using methanol, acetone, benzene and diethyl ether. After 6–8 cycles, the solutions are collected and further evaporated in oven at 42–45 °C. After evaporation, the dry extract of each solvent was taken for further analysis.

DPPH radicals scavenging assay

DPPH (1,1-diphenyl-2-picryl-hydrazil) is a complex radical mixture used in an H^+ Ion transformed-based scavenging non-enzymatic antioxidant assay [15]. An earlier prepared 1 ml DPPH solution (0.1 mM) was added to 3 ml of different progressive concentrations (100, 250, 500, 750 and 1000 µg/ml) of lichen extract and instantly incubated in dark conditions for 30 min at room temperature. After incubation, the absorbance was taken at 517 nm using a Janway-119 spectrophotometer. The radical scavenging activity (RSA) was measured in percentage (%) by using the formula Activity (%) = [(control Absorbance (A_0)—sample Absorbance (A_1))/control Absorbance (A_0)] × 100, where A_0 is the absorbance of the − ve control, and A_1 is the absorbance of the sample added reaction mixture or standards, i.e., butylated hydroxytoluene. Based on the percentage of radical scavenging activity, the IC-50 value was calculated according to the increase in percentage of radical scavenging. For comparative analysis, the natural antioxidant Ascorbate was used as a + ve control against the sample.

Ferric-reducing assay

ET (electron transfer)-based antioxidant assay determined the ferric ion-reducing activity of both lichens by the method of Oyaizu [16]. The concentrations of a standard range of lichen extracts (100–1000 µg/ml) were mixed with 2.5 ml of PO_4 buffer of pH 6.6 (0.2 M) with 1% potassium ferricyanide and incubated for 25 min at 50 °C and subsequently mixed with 10% trichloroacetic acid, followed by centrifugation at 3000 rpm for 20 min. The collected supernatant was vigorously mixed with 2.5 ml of distilled water while simultaneously adding 0.5 ml of 0.1% $FeCl_3$, and absorbance was measured at 700 nm. For the comparative observation, BHT (butylated hydroxytoluene) was taken as the positive control.

Determination of antioxidant enzymatic assay

Preparation of cellular extract

For analysis of superoxide dismutase and catalase activity, 0.5 g of lichen extract was prepared by using ethylene diamine-tetra acetate (50 mM), sodium phosphate buffer of pH 7.4 (50 mM), polyvinyl pyrrolidone 10% (*w*/*v*) and phenyl methyl sulfonyl fluoride (2 mM) in a frozen condition with a pestle in the dark. The well-gelatinous ground material was centrifuged at 14,000 rpm at 4 °C for 20 min in a collapsing centrifuge. After centrifugation, the supernatant was evaluated for SOD and CAT activities.

Superoxide dismutase (SOD) activity

The activity and quantity measures of SOD were evaluated by the standard procedure of Das et al. [17]. This activity measured the superoxide-driven nitrite formation inhibition from hydroxylamine hydrochloride. The reaction cocktail was prepared in dark conditions by adding 1.11 ml of phosphate buffer of 50 mM (pH 7.8), 0.075 ml of 10 mM hydroxylamine hydrochloride, 0.04 ml of 1% Triton X-100 (*v*/*v*), 0.075 ml of L-methionine (20 mM), 0.1 ml of 50 mM EDTA and 80 µl of 50 mM, riboflavin to the mixture. After preparation of the reaction mixture, 10 min of light exposure is required to produce the appearance of white fluorescence and absorbance measured at 543 nm with the addition of Griess reagent. A single unit of enzyme activity represented the amount of SOD, which prevented 50% of nitrite formation. The enzymatic activity was measured using the formula V_0/V_{-1}, where V_0 (control absorbance) and V (sample absorbance). The activity and total enzyme were expressed in units nkat (nanokatal per liter)/mg or U (Unit per liter)/ml.

Catalase (CAT) activities

The catalase activity of two tested lichens is evaluated by the method of Aebi [18]. The preparative chemical mixture for catalase analysis contained 2 ml of 0.1, potassium phosphate buffer (pH 6.8), an enzyme extract of 500 µL and H

$_2O_2$ of 500 µL that reached a final volume of 3 ml. The catalase activity was measured over a 3-min time interval at 240 nm against the blank by the rate of H_2O_2 consumption.

Native-PAGE analysis for SOD and CAT enzyme

For the analysis and estimation of total SOD and catalase, native-PAGE analysis was performed. The SOD and catalase staining was performed by Beauchamp and Fridovich [19]. Enzymatic analysis through native-PAGE is done by early preparation of 10% resolving and 5% stacking gels and then loaded the sample solution at 4 °C with a constant current of 40 V for 12 h. For gel support, 10% glycerol was added [20]. The gel was stained in dark for 30 min by using solutions (i.e., 50 mM sodium phosphate buffer of pH 7.8), tetramethylethylenediamine (28 mM), riboflavin (0.003 mM), NBT(0.25 mM) and EDTA (0.1 mM), and the gel after 30 min of light exposure, resulting in the visible protein bands. Similarly, the catalase staining was done in a dark condition. The gel was washed with water (ddH_2O) and stained with 0.003% H_2O_2 for 10 min. Thereafter, a mixture of 2% potassium ferric cyanide, 2% ferric chloride and 1% HCl was added for the catalase isoforms to appear dark green in the background of the gel. The activity and total enzyme were expressed in units nkat (nanokatal per liter)/mg or U (Unit per liter)/ml.

Fourier transform infrared spectroscopy (FTIR)

In FTIR analysis, the IR spectra are equipped with a Thermo Nicolet iS10 FTIR spectrometer (Thermo Scientific, USA) with the Smart iTR attenuated total refraction (ATR) accessory. Soxhlated dry lichen extract is placed on a horizontal ATR crystal of the spectrometer under constant pressure. The sample is 32 scans across the range of (v4000 to 400 cm^{-1}) with a resolution of 4.0 cm^{-1}, an absolute threshold of 96.395 and a sensitivity of 50. For analysis of spectral data, essential FTIR and prism software (version 8.0.1) was used, and all sample analysis was carried out in triplicate.

Gas chromatography–mass spectrometry analysis (GC–MS)

For GC–MS analysis, methanol is used as a reliable solvent for extraction. GC–MS analyses were performed on an Agilent Capillary-column 60.0 m × 250 µm × 25 µm. Injection in autosampler was used 1.5 µl of the sample split to 10:1. Oven: Initial temp 60 °C, ramp (temperature regulation) 7 C/min to 200 °C, (hold for 3 min), ramp 10 °C /min to 300 °C (hold 5 min), inject autosampler = 280 °C, Volume = 1.5 µl, split = 10:1, Helium as carrier gas, Solvent delay = 7.00 min, Transfer temp = 160 °C, Source temp = 150 °C, scan = 50 to 600 Da and column 60.0 m × 250 µm. The GC peak regions were used to calculate the percentage of extract composition. PubChem and the NIST Chemistry web-book used for analysis.

Determination of total phenolic

The estimation of total phenols includes total aromatic and polyphenols and is expressed against the gallic acid standard calibration curve as GAE mg/g of total DE (dry extract). The Folin–Ciocalteu reagent method is used for estimating total phenol [21]. Lichen extract of 100 µl was taken and mixed with 2 ml of 2% sodium carbonate, and in a 10-min interval, 500 µl of Folin's reagent was added and incubated for 20 min. Absorbance was measured by Jenway-119 spectrometer at 650 nm.

Estimation of total flavonoid

Total flavonoid estimation of both lichen species was carried out by method of Zhishen et al. [22] and expressed as quercetin equivalent, i.e., µg QE/g dry extract. One milliliter of Lichen extract was mixed with 10% of aluminum chloride (300 µl), 500 µl of sodium nitrite and 1 ml of 1 M hydroxide, and final volume was made up to 5 ml with dd H_2O. After a period of incubation absorbance was measured at 510 nm.

Estimation of total tannin

The total tannin content of two lichens was estimated, expressed as tannic acid equivalent (TAE/mg/g DE) of dry extract and calibrated in a tannic acid calibration curve using the method of Oyaizu [16]. The lichen extract of 200 µg/ml was taken and added to 7 ml of distilled water, followed by 0.5 ml of Folin phenol reagent and 1 ml of a 35% sodium carbonate solution and volume adjusted with added dd H_2O and up to 10 ml. The mixture was shaken and incubated for 30 min, and absorbance was taken at 725 nm.

Estimation of total terpene

The quantitative estimation of total terpene in both lichens was carried out by the standard procedure of Ghorai et al.

[23], and total terpene was plotted against the linalool equivalent (a monoterpene) calibration curve and expressed as LE mg/g DW. Lichen extract of 1 ml was mixed with conc. 1 ml, conc. H_2SO_4 and 1 ml chloroform and then shaken gently, to take absorbance at 538 nm.

Results

Thallus morphology and identification

Pyrenula nitida PNSB04

Substrate: Mostly on bark, but also on non-calcareous rock, the genus is in its current delimitation characterized by the combination of clypeate ascomata and brown, distoseptate ascospores (brown, ellipsoid to fusiform) and simple paraphyses. Thallus: crustose, submerged but sometimes exposed, areolate, possibly with pseudocyphellae or crystal pockets, ascomata (perithecial) are black masses that are habitually grouped in pseudostromata. Ascomatal wall: black, generally continuous under the hamathecium and frequently partially buried in the thallus with true exciple (brown to pale brown, entire or not developed below the perithecial cavity, colorless or orange) (Fig. 2A, 3A).

Fig. 2 [Images not available. See PDF.]

Fig. 3 [Images not available. See PDF.]

A Scanning electron microscope (Model-S3400N) observation showing: A colonies of perithecium in upper surface of thallus, B–D bunch of ascomata (perithecium), E two perithecium with ostiolar canal opening, F individual perithecia with ascospore and ostiole canal opening of *P. nitida*. **B** Scanning electron microscope (Model-S3400N) observation showing: A and B branching Apothecia on thallus surface with dark gray to whitish pruina margin with black and thin exciple, C–Edistally carbonized excipular lips (base and entire), F individual apothecia with carbonized excipular lips and epihymenium of *G. scripta*

Graphis scripta SPB25

Substrate: Found on the smooth bark of deciduous trees in humid and submontane zones. Thallus: crustose surface with a continuous to somewhat rugose surface: dull, cream-colored, white, pale gray or grayish green apothecia. Apothecia: oblong, flexuous and branching, 1–3 × 0.2–0.4 mm. Disc: narrow to broad and open, dark gray to brown with whitish pruina margin: strongly developed, covering the lateral half of the ascocarps excipular lips. Excipular lips: black, whole and occasionally thin Exciple: poorly formed and not carbonized at the base, and carbonized distally, entire excipular lips, the basal slice of which is typically less developed and less carbonized epihymenium. Epihymenium: brown, with distinctive brown or yellowish-brown tips ascospores (Fig. 2B, 3B).

Molecular identification

Evolutionary relationships of taxa

The evolutionary history analysis of both lichens using the Minimum Evolution method [24]. The bootstrap consensus tree inferred from 600 replicates that represent the evolutionary history of the taxa by analyzed Cluster-W preliminarily. Branches with lesser then 50% bootstrap are collapsed. The percentage of replicate trees in which the associated taxa clustered together in the bootstrap test of 600 replicates are shown next to the branches [25]. The evolutionary distances were measured by Maximum Composite Likelihood method and the molecular evolutionary tree (MET) tree was searched using the CNI (Close-Neighbor-Interchange) algorithm at a search level of 1. [26, 27] Here, the neighbor-joining algorithm was also used to generate the phyla analysis [28]. This analysis involved 30 closer neighbors with high accuracy of nucleotide similarity. There were a total of 928 positions *for P. nitida* PNSB04and 472 positions for *G. scripta* SPB25 in the final dataset (Fig. 4 (A&B)). Evolutionary analyses were conducted in MEGA11 software [29].

Fig. 4 [Images not available. See PDF.]

A Phylogenetic analysis of *P. nitida* by using Minimum Evolution method of MEGA 11 software. **B** Phylogenetic analysis of *G. scripta* by using Minimum Evolution method of MEGA 11 software

Phylogenetic relationship of taxa

Data validation

All nucleotide is NCBI (National Centre for Biotechnology Information)/BLAST (http://www.ncbi.nlm.nih.gov/ Basic Local Alignment Search Tool) analysis and submitted to GenBank with accession number, *G. scripta* (OP861477) and *P. nitida* (OQ146904). Proofreads were edited and assembled in MEGA (Molecular Evolutionary Genetics Analysis-Version 11) and Sequencher v. 5.

Non-enzymatic antioxidant activity

DPPH scavenging activity

DPPH scavenging activities were analyzed in both lichens by using different solvent extractions such as acetone, methanol, diethyl ether and benzene in a particular concentration range (100, 250, 500, 750 and 1000 µg/ml). Both species highlighted significant radical scavenging in the methanol extracts i.e., *P. nitida* (83.09 ± 0.89%) (Fig. 5A) and *G. scripta* (80.65 ± 0.96%) (Fig. 5B). The acetone and diethyl ether extracts of both the lichens show moderate radical scavenging activity, whereas the benzene extracts have minimal scavenging activity. However, the methanolic extract of *P. nitida* showed comparatively higher scavenging activity with half the minimal concentration, IC-50 (165.76 ± 0.003 µg/ml) followed by *G. scripta* IC-50 (176.90 ± 0.025 µg/ml) in the final data set.

Fig. 5 [Images not available. See PDF.]

A DPPH radical scavenging activity of *Pyrenula nitida* was carried out by taking 100–1000 µg/ml concentration of lichen extract in X-axis and scavenging activity (% of inhibition) in Y-axis, butylated hydroxy toluene (BHT) represented as standard. **B** DPPH radical scavenging activity of *Graphis scripta* was carried out by taking 100–1000 µg/ml concentration of lichen extract in X-axis and scavenging activity (% of inhibition) in Y-axis, butylated hydroxy toluene (BHT) represented as standard

Ferric-reducing activity

The ferric-reducing activity of both the lichens was analyzed using four organic solvents such as acetone, methanol, diethyl ether and benzene. The reducing activity was significant in methanolic extract of test lichen species followed by acetone, diethyl ether and benzene. However, the methanol extract of *P. nitida* and *G. scripta* exhibits comparatively maximal ferric ion reducing activity (0.35 ± 0.051 and 0.33 ± 0.036 nm) (Fig. 6A and B) in the final data set against standard butylated hydroxytoluene (BHT).

Fig. 6 [Images not available. See PDF.]

A Ferric-reducing antioxidant power assay of *P. nitida* was carried out taking 100–1000 µg/ml concentration of lichen extract in X-axis and reducing activity (absorbance at 700 nm) in Y-axis. The experiment was carried out in triplicate, while the error bars indicate standard deviation among the replicates. **B** Ferric-reducing antioxidant power assay of *G. scripta* was carried out taking 100–1000 µg/ml concentration of lichen extract in X-axis and reducing activity (absorbance at 700 nm) in Y-axis. The experiment was carried out in triplicate, while the error bars indicate standard deviation among the replicates

Enzymatic antioxidant activities (SOD and CAT)

The cellular extracts of two microlichens were evaluated for SOD and CAT activity. The better SOD and CAT activities were obtained in *P. nitida* (34 U/ml or 566. 667 nkat/mg and 3.120 U/ml or 52 nkat/mg), compared to *G. scripta* (27 U/ml or 450 nkat/mg and 2.280 U/ml or 38 nkat/mg). Further, in 2D native-PAGE analysis, *P. nitida* showed two significant isoforms of SOD, such as mitochondrial Mn-SOD and cytosolic Cu–Zn- Fe-SOD, whereas *G. scripta* had purely a single cytosolic Cu–Zn-SOD. On the contrary, both lichens from the same habitat contained two isoforms of CAT in native gel analysis (Fig. 7 i, ii).

Fig. 7 [Images not available. See PDF.]

i and **ii** Native-PAGE analysis of SOD and catalase enzyme in two lichens, arrow indicates SOD and catalase isoforms. A- *P. nitida* and B- *G. scripta*

Quantitative estimation of total phenol, flavonoid, tannin and terpene

Quantitative phytochemical estimation of lichens was carried out by estimating major phytochemicals, i.e., phenols, flavonoids, tannins and terpenes. Maximum phytochemical content was recorded in methanol extract of both the lichens i.e., *Pyrenula nitida* and *Graphis scripta* (Table 1).

Table 1. Quantitative phytochemical estimation of *P. nitida* and *G. scripta*

Solvents	*Pyrenula nitida*				*Graphis scripta*			
Phenolic (mg/g) GAE	Flavonoid (mg/g) QE	Tannin (mg/g) TAE	Terpenoid (mg/g) LE	Phenolics (mg/g) GAE	Flavonoid (mg/g) QE	Tannin (mg/g) TAE	Terpenoid (mg/g) LE	Acetone
0.378 ± 0.013	0.031 ± 0.007	0.21 ± 0.0012	0.16 ± 0.041	0.297 ± 0.033	0.029 ± 0.01	0.184 ± 0.002	0.180 ± 0.0018	Methanol

For FTIR analysis for *G. scripta* (L2), Here, IR spectrum showing bands with following frequencies (cm^{-1}) (Fig. 8B), vAlkynes (≡C–H stretch), Alcohols (O–H stretch), Amines (N–H stretch), Amides (N–H stretch), Alkanes, Aldehyde (C–H stretch) and Carboxylic acid (O–H stretch) (3320–2920 cm^{-1}), vAlkanes, Aldehydes (C–H stretch), and Carboxylic acid (O–H stretch) (2920–2847 cm^{-1}), vAlkynes (C≡C stretch) (2178–2059 cm^{-1}), vAlkenes, Aromatic compounds (C=C stretch), Amides (C=O stretch), Alkyl &Aryl Halides (C–F stretch), and Nitro compounds (NO2 stretch) (1647–1048 cm^{-1}), vAlkyl and Aryls (C–F stretch), Alkenes (=C-H bend) and Aromatic compounds (C-H bend) (1048–568 cm^{-1}).

GC–MS analysis

Gas chromatography–mass spectrometry screened for lichens and some compounds are analyzed through gas chromatography and other known and unknown class of compounds are analyzed throughout mass spectrometry (Fig. 9A–D). Compounds classes like phenols, Quinons, benzofurans, heterocyclic compounds, pyrans, hydrocarbons, carboxylic acid, aliphatic aldehydes, alkanes and fatty acids characterized through gas chromatography, while mass spectrometry detected some classes of compounds like phenolics, organic alcohol, fatty acids, fluorinated aliphatics, ketones, terpenes and fatty alcohols in *P. nitida* (Table 2). However, in *G. scripta*, GC detected fatty acids, alcohols, hydrocarbons, carbonyl compounds and fatty alcohols, and MS detected terpenes, glycosides, phenols and sugar alcohols in highlighted pick areas of chromatogram (Table 3).

Statistical analysis

Statistical analyses were performed with the EXCEL, IBM-SPSS and GraphPad Prism software version 8.0.1. Data were presented as mean ± standard deviation (SD) of three replicates. The *P*-values less than 0.05 were considered significant.

Discussion

In the current study, both the tested lichens have marked antioxidant properties; through the intensity of antioxidant activity in *in-vitro* oxidative systems depends upon the solvents used for extraction. The variations in the antioxidant potential of solvents could be related to their ability to extract bioactive molecules [30], whereas the aqueous extracts had the least amount of antioxidant activity because lichen metabolites are partially soluble or insoluble in aquas [31]. Thus, organic solvents were used which withstand significant extraction of bioactive metabolites. Several findings proved that environmental factors such as air pollution, desiccation, high temperatures, rehydration and high light have a great influence on the antioxidant activity of lichens, affecting the increasing as well as decreasing and synthesis of antioxidants [32, 33]. Formerly, it was concluded that natural compounds, including tocopherols, phenolics, flavonoids, terpenes and carotenoids, have strong antioxidant activity. Due to their ability to scavenge free radicals such as singlet oxygen, superoxide and hydroxyl radicals, phenolic ingredients such as flavonoids, tannins and lichen phenolics such as depsides, depsidones, diphenyl ethers, polycyclic and monocyclic aromatic classes are classified as high-level antioxidants [34].

The present study was aimed at exploring the antioxidant potential, screening and characterization of the total phytochemicals of *Graphis scripta* and *Pyrenula nitida*. For this purpose, enzymatic (SOD and catalase) and non-

enzymatic antioxidant activities (DPPH and FRAP), reducing power, and total phenolic, flavonoid, tannin and terpene content of the extracts of both lichens were determined, in vitro. Tatipamula and Kukavica [35] examined *D. consimilis* with acetone (DA) and methanol (DM) extracts against DPPH assays. From their findings acetone extract of *D. consimilis* showed better IC50 values of 80.90 ± 6.42 mg/mL against DPPH compared to DM with 95.04 ± 6.36 mg/mL. As indicated in our findings, relatively maximal radical scavenging was measured in the methanol extract of *P. nitida* at 83.99% of RSA with an IC-50 62.90 ± 0.003 mg/ml and it was also rich in terms of total phytochemicals. From our previous findings indicated methanol extracts of *D. applanata* and *P. andium* have strong DPPH scavenging activity with IC50 i.e., 471.16 ± 0.85 µg/ml and 534.77 ± 0.75 µg/ml with acetone extract showing comparatively lower scavenging in both species [36]. Thus, present findings are in agreement with the experimental results of previous workers Manojlović et al.; Hawrył et al. [37, 38].

According to some researchers, complex ion-reducing power is usually a better indicator of the antioxidant capacity of extracts and purified compounds. Thus, the extracts, which had metal ion-reducing power, were considered a potential antioxidant source [15]. While Gordan [39] established antioxidant effect of reaction chain termination of the free radicals by the donation of electrons, the reduction of ferrous ion (Fe-3) to ferric ion (Fe-2) is measured qualitatively by the density of visibility (green–blue outline of solution) that measured by spectroscopically (absorbance at 700 nm). The reducing power of the methanol extract of *Cetraria islandica* may also indicate its potential antioxidant activity [40]. However, the reducing power of the methanol extract of *P. nitida* was higher as compared to other solvents (0.33 ± 0.054 nm). Earlier study reported methalonic extracts of *P. nitida* had strong ferric-reducing activity compared to *G. scripta*, which related to [36]. The reducing features are mainly linked to the presence of ionic reduction reactions. The outcomes provided here suggest that the extract's high ferric-reducing power activity is related to the presence of polyphenols (phenol and its derivatives), which may operate similarly to reductions in that they react with free radicals to convert them into stable products and terminate free radical chain reactions [41]. SOD and catalase estimation by native-PAGE analysis of *Pyrenula nitida* and *Graphis scripta* was used for the first time to perform qualitative enzymatic antioxidant analysis.

Multiple studies have found a link between lichen antioxidative activity and the quantity of phenolic compounds content [42]. Kosanić and Ranković [43] estimated the total phenolic and flavonoid constituents in *C. furcata* and *U. polyphylla* and *H. physodes* at 52.76 µg/ml of pyrocatechol equivalents (PE); however, higher phenolic contents were also found in methanol extracts of *C. furcata* and *U. polyphylla* with 52.67 and 52.65 µg/ml PE. But in the present study of total phenol estimated against gallic acid equivalent (GAE mg/g) using acetone, methanol, diethyl ether and benzene extract, maximal phenol content was reported in methalonic extracts of both lichens, *P. nitida* (0.511 ± 0.07 mg/g GAE) and *G. scripta* (0.682 ± 0.008 mg/g GAE), whereas benzene extract showed relatively lower content in both lichen species. Total flavonoid content was found in the acetone and methanol extracts of *U. polyphylla* (30.31 µg/ml of Rutin equivalents (RE) for acetone and 47.24 µg/ml for methanol extracts). Good flavonoid content was also found in the acetone and methanol extracts of the lichen *H. physodes* (30.09 µg/ml of RE for acetone and 32 µg/ml of RE for methanol extracts) as reported by [44]. The methalonic extract of both lichens reported a higher content of flavonoid *P. nitida* (0.049 ± 0.002 mg/g QE) and *G. scripta* (0.041 ± 0.03 mg/g QE), among other solvents. However, the quantification of total tannin against tannic acid equivalent (TAE mg/g) and total terpene against linalool equivalent (LE mg/g) was carried out for the first time and the relatively higher content of tannin and terpene recorded was methanolic extract of both lichens, i.e., *P. nitida* (0.47 ± 0.03 mg/g TAE and 0.252 ± 0.012 mg/ml LE) and *G. scripta* (0.32 ± 0.007 mg/g TAE and 0.192 ± 0.006 mg/ml LE); these estimations support the previous findings that methanol extract of *Trypethellium virens* SPTV02 and *Phaeographis dendritica* SPB041 quantified relatively maximum and acetone and diethyl ether contains moderate and benzene extract quantify lowest in all tested lichens [45].

Conclusions

In vitro antioxidant and phytochemical screening of both lichens showed high bioactive potential. GC–MS and FTIR analysis confirm the presence of active metabolites, including primary and secondary metabolites such as phenols, quinons, benzofurans, carboxylic acid, alkanes, aliphatic aldehydes, organic alcohol, fluorinated aliphatic

compounds, ketones, terpenes, and fatty alcohols, fatty acids, alcohols, hydrocarbons, fatty alcohols, terpenes, glycosides and sugar alcohols. As a result, this investigation deals with the use of lichen extracts as natural antioxidants. These lichens appear to be promising and alternate supply of synthetic antioxidant chemicals as well as a momentous source of polyphenols. Upcoming research should essence on isolating different bioactive phenolic compounds at the next step to assess their natural qualities in vitro and in vivo having a wider application in pharmaceuticals and cosmeceuticals.

ABSTRACT (ENGLISH)

Background

Pharmacists have an important role in preventing prescribing errors and providing appropriate information. They can detect potential drug–drug interactions (DDIs), which are associated with a more extended hospital stay and higher medical costs that lead to substantial financial burdens on healthcare systems. This study aimed to evaluate and assess the knowledge of community and hospital pharmacists toward drug–drug interaction and their attitude and motivation to find DDI information, in addition to identifying the pharmacist factors affecting this knowledge. A cross-sectional multicenter study was conducted using a self-administered questionnaire. Nineteen drug pairs, that are common in clinical practice, were evaluated. This study aimed to evaluate and assess the knowledge of community and hospital pharmacists toward drug–drug interaction and their attitude and motivation to find DDI information, in addition to identifying the pharmacist factors affecting this knowledge.

Results

A total of 4363 pharmacists (2260 community pharmacists and 2103 hospital pharmacists) have completed the survey. The participants' knowledge of DDIs was 58.25%, and there was no significant difference in pharmacist knowledge between community and hospital pharmacists ($p=0.834$). The highest correct answer was for sildenafil and isosorbide mononitrate pair 78.8%. The most used source of information was the internet or mobile applications, 47.1%. Participants who always considered PDDIs while prescribing detected more drug interactions than those who did not ($p=0.001$).

Conclusion

According to the findings of this study, community and hospital pharmacists had comparable knowledge of DDIs. However, before dispensing uncommon prescriptions, they should consult evidence-based drug information resources and DDI software to identify potential drug interactions.

FULL TEXT

Background

Drug–drug interactions (DDIs) can be defined as a clinical response to drug administration of a combination of two or more drugs that is different from the expected effects of the individual drugs when given alone [1]. DDIs are one of the medication errors that threaten patient safety as a result of pharmacodynamic or pharmacokinetic interaction between the administered drugs, which can lead to failure of treatment strategy or adverse effects or specific toxicity [2, 3]. The consequences of DDIs vary from minor to severe impacts that can be lethal to patients [4, 5]. The recrudescence of DDIs was found to be about 15–45% of hospitalized patients, with many studies linking DDIs with the increase in the length of hospital stay and healthcare costs [6, 7].

Chronic disease prevalence, polypharmacy, elderly, and cancer patients are all associated with an increased incidence of drug interactions [8–11]. The management of DDIs is a complex process that requires understanding the risk rating of DDIs mechanism, severity, and reliability and includes risk–benefit assessment [12, 13]

Computerized provider order entry (CPOE) combined with clinical decision support systems (CDSS) are being widely implemented to prevent adverse drug events (ADEs). Still, the effectiveness of these systems remains unclear and does not appear to avoid clinical ADEs reliably. In Egypt, most works identifying potential DDI depend on pharmacists' knowledge or the usage of online applications for drug–drug interactions. Methods for decreasing the possibility of drug interactions include the improvement of the knowledge of healthcare providers, developing systems for checking DDIs, and improvement of patient education regarding drug use [14].

Pharmacists play essential roles in preventing prescribing errors, providing appropriate information, and detecting potential DDIs. For example, community pharmacists can detect and prevent DDI in their pharmacies by detecting potential interactions and giving advice to patients [15]; in addition, published studies have reported that the rates of potential DDIs in hospitalized patients vary from 2.2% to 30%, so the high knowledge of DDIs among hospital pharmacists is essential in the reduction of DDIs complications that are associated with longer hospital stay [16]. In addition, exposure to potential DDIs can result in unnecessary healthcare costs; for example, a study revealed that the costs due to preventable ADRs in the USA and European countries range from €2,851 to €9,015 [17], and these medical costs represent a financial burden on healthcare systems [18, 19].

Despite drug information resources and online websites that are used to identify potential DDIs, the occurrence of possible DDIs is still high, which is usually due to different causes such as availability of pharmacist time, trustiness of patient to pharmacist, and cooperation between patient and pharmacist [20]. The studies of DDIs and their consequences in Egyptian community pharmacies [21] and hospitals [22, 23] are limited, and these interactions may be associated with severe adverse events. Pharmacists in community settings or hospitals play essential roles in DDI detection; however, their knowledge and attitude toward drug interactions do not appear to be studied sufficiently [24]. Most published studies evaluated the knowledge among prescribers [25].Our study aimed to evaluate and assess the knowledge of community and hospital pharmacists toward drug–drug interaction and their attitude and motivation to find DDI information, in addition to identifying the pharmacist factors affecting this knowledge.

Methods

Study design

This cross-sectional multicenter study was conducted using a self-administered questionnaire distributed with pharmacy students' aid between February 1, 2021, and June 30, 2021. Pharmacists working in a private or chain community pharmacy and Ministry of Health or university or private hospital pharmacy were included in the study; those in other sectors, such as industry and academia, were excluded.

Survey questionnaire and data collection

The DDI questionnaire was designed and developed from previous studies that assessed the knowledge of healthcare professionals about DDIs [5, 26, 27]. The structured questionnaire consisted of two sections. The first one was demographic data of the participant pharmacists, including pharmacists' educational level, age, gender, setting, and experience years. The second one contains 19 pairs of common drug interactions in clinical practice [24]. Pharmacists' knowledge was assessed as “No interaction, Contraindication, May be used together with monitoring, and Not sure.”

After finishing the questionnaire, participants were supplied with the correct answers to raise their awareness and knowledge about these potential drug–drug interactions. Participants were informed that their responses and the information was kept securely.

Outcome measures

The primary objectives were to assess the knowledge of community and hospital pharmacists toward potential drug–drug interactions (PDDIs) that reflect the quality of health systems in pharmacies, while the secondary outcomes were to determine the predictor factors impacting pharmacist knowledge of drug interactions.

Sample size calculations

According to Egyptian pharmacists' syndicate records, there are approximately 216,072 registered pharmacists in Egypt, with a confidence level of 97% and a margin of error of 5%. If 50% of the pharmacists would have good knowledge, the minimum acceptable sample size is 470 participants.

Statistical analysis

The data were analyzed using SPSS software version 24 for Analysis. For descriptive Analysis, results were presented as frequencies and percentages. Mann–Whitney test was used for independent nonparametric data. A linear regression model was used to determine the potential predictors of (potential drug–drug interactions) PDDIs knowledge, including participant's age, education, settings, years of practice, and attitude toward PDDIs. For all tests, $p<0.05$ was considered statistically significant.

Results

Characteristics of the participants

A total of 4363 pharmacists (2260 community pharmacists and 2103 hospital pharmacists) have completed the survey. As shown in Table 1, the majority (58.4%) aged from 20 to 29 years old. Most (61.1%) had bachelor's degrees, and 69.1% of the participants were from urban regions. About 79.6% of the participants had practiced up to 10 years. There is no significant difference in age and years of practice between community and hospital pharmacists as shown in Table 2.

Knowledge of pharmacists of DDIs

The participant's knowledge of DDIs was 58.25% (average of correct answers about DDIs). Table 3 summarizes participants' responses to the DDI questions, presenting the frequencies (percentages) of respondent answers for each of the 19 drug pairs. The lowest correct answer was between alprazolam and itraconazole ($n=778$, 17.8%). In contrast, most participants answered the remaining 18 drug pairs questions correctly, and the most correct answer was for sildenafil and isosorbide mononitrate pair ($n=3438$, 78.8%).

Table 3. Frequencies and percentages of participants' response to potential DDIs

Drug–drug interaction pairs	No interaction	Used with monitoring	Contraindication	Not sure
n (%)	*n* (%)	*n* (%)	*n* (%)	Acetaminophen/codeine and amoxicillin
3395 (77.8)	580 (13.3)	167 (3.8)	22 1 (5.1)	Warfarin and sulfamethoxazole/trimethoprim
403 (9.2)	**2432 (55.7)**	1241 (28.4)	287 (66)	Warfarin and digoxin

The boldness indicates the correct ones

As shown in Table 4, the highest frequency of correct answers among the community pharmacists was 17 questions, and 0.8% of the community pharmacists answered all the questions incorrectly. However, the highest frequency of correct answers among the hospital pharmacists was 13 questions, and 0.9% answered all 19 questions incorrectly. None of the pharmacists knew all the 19 questions correctly in both groups. The mean rank of the sum of correct answers for the community and hospital pharmacists was 2178.14 and 2186.14, respectively, with a *p* value of 0.834 (the difference in knowledge between community pharmacists and hospital pharmacists was nonsignificant).

Table 4. Frequencies and percentages of the community pharmacists and hospital pharmacists correct answers

Number of correct answers	Frequency (%) (community pharmacist)	Frequency (%) (hospital pharmacy)
0	18 (0.8)	19 (0.9
1	25 (1.1)	13 (0.6)
2	54 (2.4)	36 (1.7)
3	79 (3.5)	57 (2.7)
4	84 (3.7)	85 (4)
5	102 (4.5)	108 (5.1)
6	139 (6.2)	123 (5.8)

17	221 (9.8)	153 (7.3)
18	5 (2)	4 (2)
19	0 (0)	0 (0)
Total	2260 (100)	2103 (100)

Source of potential DDI information

The sources of DDI information are shown in Fig. 1. The internet or mobile applications were the most used source of information ($n=2057$, 47.1%). The least commonly used sources were knowledge bases in Arabic and package inserts (2.2% and 1.2%, respectively).

Fig. 1 [Images not available. See PDF.]

Source of PDDIs information

Attitude toward potential DDIs

As shown in Fig. 2, about 86.98% of the participants consider DDIs when prescribing, with 48.38% agreeing with the statements and 38.60% strongly agreeing, respectively, and only about 1.5% do not consider it when prescribing. More than 88% of participants said that DDI information is essential for their practice. In addition, more than 85% always check DDI when unsure about it, and about 80% are willing to learn about it.

Fig. 2 [Images not available. See PDF.]

Participants attitude toward PDDIs

Predictors of PDDIs knowledge

As shown in Table 5, the linear regression model indicates that significant predictors of a higher number of recognized drug pairs were age, education, and attitude toward PDDIs. Participants who always considered PDDIs while prescribing detected more drug interactions than those who did not ($p=0.001$). In addition, those who did not check PDDIs when not sure about it had lower scores for PDDIs than those who did ($p<0.001$).

Table 5. Predictors of the knowledge level of the study participants for PDDIs

Character	Unstandardized β coefficient	*p* value
Constant	6.252	<0.001
Age	0.297	0.034*
Geographic region	0.145	0.308
Education	−0.121	0.004*
Setting	−0.146	0.28
Years of practice	0.052	0.618
Attitude I always consider PDDIs while prescribing	0.351	0.001*
I think PDDIs information is important for my practice	0.145	0.204
I always check PDDIs when I am not sure about it	0.379	<0.001*
I am willingness to learn more about PDDIs	0.09	0.356

Linear regression test was used

*For this test, $p<0.05$ was considered statistically significant

Discussion

The recognition of interacting drugs is critical for any healthcare providers, including pharmacists, to decrease the DDIs and, consequently, reduce the drug-related morbidity and mortality that may occur as a result of these interactions [5, 28]. Although thousands of articles on drug interactions have been published and numerous computerized screening systems have been developed, patients continue to suffer from adverse drug interactions. It was found that about twenty percent of the adverse drug effects in the developed countries, which are responsible for more than 700,000 deaths, are due to drug–drug interactions [14]. Possible methods for reducing the risk of drug interactions include improving healthcare providers' knowledge, improving computerized screening systems, providing information on patient risk factors, increasing pharmacogenetic information, more attention to drug administration risk factors, and improving patient education on drug interactions.

In this survey, we assessed the ability of pharmacists to recognize clinically significant drug combinations. It was found that among DDI information sources, internet or mobile applications and medical textbooks were the most used sources of information. The majority of the participants (47.1%) tended to receive information regarding DDIs from electronic sources, which is consistent with a previous study conducted in Iran [29]. The possible explanation for this finding may be the high percentages of young participants in the present study, and people in this age group are usually interested in technology and use it in many fields. A small percentage of the participants in our survey (1.2%) reported that they use package inserts, which is a risk factor for incorrect use of drugs [30].

Our study showed no significant differences in the proportion of community pharmacists and hospital pharmacists who correctly answered the same number of questions about DDIs. The level of the participants' knowledge of DDIs was 58.25% (average of correct answers about DDIs), and this finding is comparable to another study (53.3%) [31]. However, our results are not consistent with another study [24] that revealed a level of knowledge among

pharmacists of about 37.3%, but the later study included 26 drug pairs; however, our study included 19 pairs, and these differences in drug pairs may be the cause of the differences in the level of the participant's knowledge on DDIs.

Among the drug pairs selected to assess DDIs knowledge, sildenafil, and isosorbide mononitrate were the most highly recognized drug pairs (78.8%), which is consistent with another study [32]. The lowest recognized pairs were alprazolam and itraconazole (17.8%), which are contraindicated with each other. In accordance with another study [5], even if one justified that the drug combinations classified as contraindicated could be used with close monitoring and considered both choices to be correct, up to 65% of the participants remained unsure if there was a potential interaction or not. In our study, we tried to investigate the predictors of DDI knowledge of participants, including age, education, setting, years of practice, and the participants' attitudes toward DDIs. It was found that a significant correlation exists between participants' age and their knowledge level in DDIs. The older participants answered more DDI questions than younger ones, which is consistent with another study that used identical drug pairs as our study [33]. Another study, in contrast to ours, found no connection between age and DDI knowledge level [34], but this may be explained as the later study involved participants of relatively the same age.

Another predictor of DDI knowledge is the education level, which was found to have a significant correlation with the level of knowledge of DDIs. Unexpectedly, participants with bachelor's and postgraduate certificate holders recognized a higher number of interactions than did those with Ph.D. and board-certified pharmacists, and this finding was in accordance with a study carried out in Khartoum state and showed that pharmacists with bachelor's recognized higher number of DDIs than those with master [31]. The results of our study were in contrary to a previous study [33] that reported that participants' education level did not affect the knowledge level of DDIs. These findings could be due to several factors, including the fact that Ph.D. holders are not recent graduates and may not have as good recall of DDIs, as well as the fact that the majority of pharmacists have bachelor's or postgraduate diploma degrees rather than PhDs and board certifications.

Interestingly, the number of years of experience of the participants was not a significant predictor of DDI knowledge level, and this is consistent with other studies that used different drug pairs for DDI knowledge assessment [5, 31].

Regarding attitudes toward DDIs and their relation to the level of DDI knowledge, it was found that participants who always consider DDIs while prescribing and checking about DDIs when not sure about them recognized a more significant number of DDIs than those who did not, and these results are consistent with previous study conducted in China [33]. This indicates the strong association between the participants' tendency to check references and their knowledge of PDDIs, as proved by the correct recognition of the drug pair interactions.

Astonishingly, this study revealed no significant association between setting (whether community or hospital pharmacists) and the level of their knowledge of DDIs.

The findings of the present study have several implications for practice. This article highlights an important issue that requires urgent attention in Egypt which is the improvement of drug–drug interaction knowledge among community and hospital pharmacists. It is crucial for improving patient safety and healthcare outcomes in the country to ensure the rational and optimal use of drugs. By raising awareness of this issue and identifying potential solutions, this study makes an important contribution to the field of healthcare in Egypt and beyond. Our study has identified some recommendations to improve the knowledge and practice of hospital and community pharmacists regarding DDIs. Based on the study's findings, it is recommended that continuing education and training programs should be developed for hospital and community pharmacists in Egypt to improve their knowledge of DDIs. The Egyptian Ministry of Health should develop guidelines and protocols for the management of DDIs in hospitals and community pharmacies to ensure consistency in practice. Additionally, these pharmacies should have access to electronic databases that provide up-to-date information on DDIs to support their practice. This study highlights the need for ongoing education and training programs, updated guidelines, and increased resources to support pharmacists in their efforts to provide safe and effective care to patients. Finally, future studies should be conducted to assess the impact of education and training programs on hospital and pharmacists' knowledge and practice regarding DDIs.

The limitation of our study is that the 19-drug pairs might not be adequate to reflect the extent of knowledge

applicable to the vast number of PDDIs. In addition, the study's sample size may limit the generalizability of the findings. The sample size is small or not representative of the entire population of hospital and community pharmacists in Egypt, so, the results may not accurately reflect the overall knowledge level of pharmacists in the country. Additionally, the study's reliance on self-reported data from pharmacists introduces the possibility of response bias. Participants may overestimate their knowledge to present themselves in a more favorable light or may underreport their knowledge about DDIs due to various reasons, such as social desirability bias. Furthermore, the study focuses solely on assessing the pharmacists' knowledge without considering other factors that may influence their ability to apply that knowledge in practice, such as time constraints, workload, or access to resources. In addition, future studies of larger sample sizes of pharmacists and more drug pairs are required to face the challenges and limitations of this study taking into consideration other factors such as time constraints, workload, or access to resources that may affect their ability to apply that knowledge in practice,

Conclusion

According to our study findings, community and hospital pharmacists had comparable knowledge of DDIs. Pharmacists should improve their knowledge of drug–drug interactions (DDIs) to ensure patient safety. Also, they should consult evidence-based drug information resources and DDI software to identify potential drug interactions before dispensing prescriptions. Developing a system for checking DDIs is necessary.

Acknowledgements

With much respect and appreciation, we wish to thank all faculty of pharmacy October 6 University level 4 students for their participation in questionnaire distribution among hospital and community pharmacists.

Author contributions

Study conception and design were done by EAW, MA, and AE. Data analysis and interpretation were performed by AEAW, AE, YSAD, and EMS. EAW, AEAW, MA, AE, and EMS helped in drafting, revision of the paper, and final approval of the published version.

Funding

This research received no specific Grant from any funding agency in the public, commercial, or not-for-profit sectors.

Availability of data and materials

The datasets generated and analyzed during the current study are available from the corresponding author on a reasonable request.

Declarations

Ethics approval and consent to participate

All procedures performed in the study involving human participants were in accordance with the ethical standards of Faculty of pharmacy October 6 University ethics committee and with the 1964 Declaration of Helsinki and its later amendments. The study was received approval from the Ethics Committee and institutional review boards of October 6 University (Approval Number: PR-Ph-2112005). Pharmacist's participation in this survey was voluntary. Informed consent was obtained from all participants. They were asked before questionnaire if they participate in this study, and they able to refuse take part in the research or exit the survey at any time without penalty. Pharmacists were only required to complete the questionnaire once. Participants informed that their personal details were not linked to their responses and the information were kept securely.

Consent for publication

Not applicable.

ABSTRACT (ENGLISH)

Background

Carivalan® dosage form containing carvedilol and ivabradine is widely indicated for patients with stable angina. Three precise, eco-friendly and reproducible spectrophotometric techniques were created for resolving the researched drugs in their mixtures using zero and/or ratio spectra. Technique I is a factorized dual wavelength coupled with spectrum subtraction (FDW-SS), technique II is a ratio difference, and technique III is a constant center coupled with spectrum subtraction (CC-SS). Moreover, CAR and IVA were simultaneously determined in the existence of their oxidative degradation products exploiting the newly developed induced tripartite amplitude difference coupled with ratio subtraction (ITAD-RS) technique.

Results

The calibration curves for CAR and IVA showed linearity within 3.0–30.0 µg/ml, each. Techniques' precision, accuracy, and linearity ranges were resolved and validated in harmony with ICH guidelines. Additionally, the specificity was examined by examining created combinations of the proposed drugs with LOD of 0.258 and 0.290 for CAR, while for IVA 0.272 and 0.204.

Conclusion

These techniques were used to determine the presence of the provided drugs in Carivalan® tablets. There is statistical comparison between the found results of the offered spectrophotometric techniques and the previously reported ones with no discernible variance in the acquired results.

FULL TEXT

Background

Carvedilol (Fig. 1a) is chemically [1-(9H-carbazol-4-yloxy)-3-[[2-(2methoxyphenoxy) ethyl] amino] propan-2-01]. It is a non-selective beta-blocker which works by reducing heart beats and facilitating smoother blood circulation. Additionally, it widens some blood arteries, acting similarly to an alpha blocker, which in turns helps in lowering the

blood pressure [1, 2].

Fig. 1 [Images not available. See PDF.]

Chemical structures of **a** carvedilol and **b** ivabradine

Ivabradine (Fig. 1b) is chemically (3-[3-[[(7S)-3,4-dimethoxy-7-bicyclo[4.2.0]octa-1,3,5-trienyl]methyl-methylamino]propyl]-7,8-dimethoxy-2,5-dihydro-1H-3-benzazepin-4-one). It is a drug that lowers heart rate by precisely and selectively blocking the cardiac pacemaker current; (I_f) and hence regulates the heart rate via direct sinus node inhibition without affecting myocardial contractility or blood pressure [3, 4].

Carivalan® containing CAR and IVA has received a widespread indication for treating the symptoms of stable angina, where few analytical HPTLC [5] and HPLC [6, 7] techniques for analyzing CAR and IVA have been stated. In the meantime, their simultaneous determination was achieved spectrophotometrically by only one reported research [8], while no spectrophotometric techniques have been previously conveyed for the declared drugs' resolving in the occurrence of their degradation products.

It is well known that the chromatographic analytical technique, which is distinguished by its superior accuracy and reproducibility in the process of samples' separation and analysis in parts per million (PPM) level as well as its speed and automation [9], is one of the most well-liked and frequently used techniques in the field of drug analysis. However, and particularly in light of the current conditions faced by the majority of the world's nations, especially developing nations, many analysts and researchers now turn to the usage of less expensive analytical techniques while keeping accuracy and precision.

The UV spectrophotometric approach is at the forefront of the methodologies that achieve most researchers' objectives because of its ease of use, low implementation cost besides widespread accessibility in laboratories for quality control [10].

This work focuses on the creating and validation of three green UV spectrophotometric techniques for the selective resolution of CAR and IVA in their pure forms and Carivalan® tablets by utilizing zero and/or ratio spectra; FDW-SS, RD [11–13] and CC-SS techniques [13–15]. Furthermore, induced tripartite amplitude difference (ITAD), a newly developed spectrophotometric technique, was able to solve the issue of resolving and analyzing CAR and IVA in their quaternary mixture with their oxidative degradates and succeeded in determining them without even requiring any preliminary separation steps. Green assessment of the offered, official and the reported techniques was achieved by using Analytical Eco-Scale [16], National Environmental Methods Index (NEMI) [17], Green Analytical Procedure Index (GAPI) [18] and Analytical Greenness Metric (AGREE) [19]. The proposed techniques' suitability for the intended usage has been validated in accordance with ICH criteria [20].

Factorized dual wavelength coupled with spectrum subtraction technique (FDW-SS)

This technique depicts coupling between dual wavelength [21–24] and spectrum subtraction [24–26] for analyzing CAR and IVA in their mixture, where one drug X shows a noteworthy absorbance difference at two selected wavelengths which is directly proportional to its concentrations. While the other interfering drug *Y* shows equal absorbance reading with an insignificant absorbance difference at the same selected wavelengths (ΔA=zero), thus its effect is negligible. Recovering the parent D^0 of *X* is accomplished by firstly preparing *X*'s factorized $\triangle A$ spectrum using computer software via dividing (D^0) *X* at any concentration within Beer's law by the ΔA between the chosen wavelengths; X(D◦)ΔA.

Secondly, $\triangle A$ is recorded in the laboratory mixtures between the chosen wavelengths then multiplied by *X*'s factorized $\triangle A$ spectrum.

1

ΔA.X(D◦)ΔA=RecoveredD◦ofX

While D^0 of the interfering drug *Y* is obtained via spectrum subtraction [25–27] technique; $D^0\ (X+Y)-D^0\ (X)$.

Induced tripartite amplitude difference coupled with ratio subtraction technique (ITAD-RS)

An advanced technique that can be used on a ratio spectrum of quaternary mixtures made up of X+Y+Z+WW′ at selected wavelengths at which component X has a ΔP noteworthy value and the amplitude readings of *Y* are not

equal ($\Delta P \neq 0$) at the same chosen wavelengths.

Meanwhile, component *Z* exhibits an equal amplitude value with a zero difference ($\Delta P = 0$); thus, the effect of *Z* is canceled. It is a moderation of both induced dual-amplitude difference [27] and dual-amplitude difference [28] techniques.

The effect of *Y* was canceled via calculating the equality factor [13, 29] of *Y* by getting average Py1/Py2 at the suggested wavelengths (FY). Component *Y* will be canceled by calculating the difference. As a result, *P* (FyPm1–Pm2) is only connected to *X*.

A factorized induced ratio spectrum of X ;X/W′ΔP.Fy is set via division of the ratio spectrum of X by the calculated induced amplitude difference.

For laboratory mixtures, the induced amplitude difference values (ΔP. Fy) at the suggested wavelengths are noted and multiplied by X's factorized induced ratio spectrum to acquire X's ratio spectrum.ΔP.Fy.XW′ΔP.Fy=XW′

Multiplying the recovered ratio spectrum of *X* by the divisor, *W*′, will attain the parent D^0 of X; XW′×W′=X(D0)

Finally, subtracting the regained D^0 of *X* from the quaternary mixture's D^0 spectrum and applying the same previously mentioned steps, the other components in the mixtures will be determined.

Exploiting the factorized induced ratio spectrum and the divisor's spectrum multiplication in this newly developed method allows the mentioned component's determination at its λ_{max} through minimal signal output analysis of data. In addition, random error is highly minimized since the preparation of factorized spectrum is founded on the response only in contrast to normalized spectrum which is based on concentration.

Methods

Instrumentation

Shimadzu double-beam spectrophotometer (UV, Japan), Sonicator (Model 3510, UK), Analytical Balance, Italy, Digital Stirring Hot Plate, China, Pure laboratory flex to obtain distilled water

Silica gel F254 (20 × 20 cm) pre-coated TLC plates (Sigma-Aldrich, Germany). The degradation tracing and plate visualization were carried out using a UV lamp with a wavelength of 254.0 nm.

Reagents and chemicals

Pure samples of CAR and IVA were kindly obtained from Global Napi, 6th of October, Egypt. The pureness was certified to be 99.88 ± 0.95 and 99.60 ± 1.06, respectively, depending on their official [1] and reported [8] techniques. The market-available Carivalan® tablet dosage form, made in France by Les Laboratories Servier Industrie, was purchased. According to the product label, Carivalan ® batch number (29,044) contains 12.5 mg of CAR and 5.0 mg of IVA. 30% H_2O_2 (ADWIC, Egypt).

Standard solutions

To prepare stock solutions of carvedilol and ivabradine (100.0 µg/ml), in volumetric flasks, 100 ml, 10 mg of each of CAR and IVA was dissolved separately in distilled water.

In two rounded flasks, 10 mg of each of CAR and IVA was refluxed with 10 ml of 30% H_2O_2 for 8 h at 80 °C. After refluxing, hydrogen peroxide was evaporated using hot plate at 50 °C, transfer oxidative degraded product to volumetric flask, 100 ml, which is completed with distilled water to prepare standard solutions of 100.0 µg/ml for each.

Laboratory mixtures

Exact amounts of the stated drugs were conveyed into different volumetric flasks, 10 ml, with varied ratios and topped off with distilled water to produce variable sets as follows:

Set A: Binary mixture containing CAR and IVA.

Set B: Quaternary mixture containing CAR and IVA along with their oxidative degradation products.

Procedures

Stress stability studies

Studied drugs' stress studies were conducted as per ICH guidelines [30] by applying different stress acidic, basic, photolytic, thermal and oxidative surroundings. Different molar concentrations of HCl and NaOH were tried out where, in each trial, 10 ml of each of the investigated medications was combined individually with either HCl or

NaOH. Reflux was applied at 100 °C for 3 h.

To conduct oxidative trials, 10 mg of each medication was refluxed individually in 10 ml of 10, 20 and 30% H_2O_2 for 8 h at 80 °C.

Drugs' photostability was tested on their solid powdered form by the exposing them to UV light, 254.0 nm for 10 h.

Finally, drugs' thermal stress testing was performed in glass ampoules by heating them in a thermostatic oven at 10 °C boosts (50–100 °C) for 10 h.

Spectral characteristics

D^0 spectra of each examined drugs were measured at 200.0–400.0 nm.

Construction of calibration graphs

To prepare calibration standards across concentrations of 3.0–30.0 µg/ml for CAR and IVA, from each standard stock solution (100.0 µg/ml), an accurately transferred amounts were conveyed to separate series of volumetric flasks, 10 ml, and finalized with distilled water. The D^0 spectra acquired after scanning solutions between 200.0 and 400.0 nm were recorded. The calibration graph for each suggested technique was performed via the mean of three experiments, as shown below:

Factorized dual wavelength coupled with spectrum subtraction technique (FDW-SS)

The regression equations were created by plotting the stored D^0 maximum absorbance of CAR and IVA at 285.6 and 287.0 nm, respectively, against the associated concentrations. A factorized ∆A spectrum for IVA was constructed using spectrophotometric software by division of D^0 of a certain concentration of IVA by (∆A) at 285.2 nm and 255.0 nm.

Ratio difference technique

The ratio spectra were produced via division of the scanning spectra of the CAR and IVA solutions by the absorption spectra of the IVA (15.0 µg/ml) and CAR (15.0 µg/ml) standard solutions, respectively. CAR's and IVA's concentrations were plotted against their respective amplitude differences at 252.6 and 275.0 nm and 294.0 and 320.0 nm, respectively.

Constant center coupled with spectrum subtraction technique (CC-SS)

The regression equations have been calculated by setting two calibration curves. The first one is between the maximum absorbance of D^0 of CAR and IVA at 285.6 nm and 287.0 nm and their related concentrations, respectively. The second one is between the ΔA at 294.0 nm and 320.0 nm versus amplitudes at 294.0 nm for IVA after generating a ratio spectrum by dividing of the stored absorption spectra of IVA by the absorption spectrum of CAR; 15.0 µg/ml.

Induced tripartite amplitude difference coupled with ratio subtraction technique (ITAD-RS)

The regression equations were computed by plotting the maximum absorbance of the stored D^0 of CAR and IVA at 285.6 nm and 287.0 nm versus their corresponding concentrations, respectively.

The equality factor of IVA ratio spectra was calculated by using amplitude ratios' average at 296.0 nm ($P_{296.0}$) and 242.7 nm ($P_{242.7}$) using CAR's oxidative degradate spectrum as a divisor.

Via dividing the ratio spectrum of a certain concentration of CAR using CAR's oxidative degradate's spectrum as a divisor by ΔP at 242.7 nm and 296.0 nm after multiplying the former by F, ($FP_{242.7}$–$P_{296.0}$), factorized induced ratio spectrum for CAR was created.

Through the division of the ratio spectrum of IVA using CAR's oxidative degradate's spectrum as a divisor by the value of the ∆P at 242.7 nm and 296.0 nm, factorized ratio spectrum for IVA was created.

Laboratory mixtures' analysis

Different mixtures in different sets, set A (binary mixture of CAR and IVA) and set B (quaternary mixture of CAR and IVA with their oxidative degradates), were analyzed by carrying out the following manipulation actions for each method:

Analysis of set A containing CAR and IVA in their binary mixtures

Factorized dual wavelength coupled with spectrum subtraction technique (FDW-SS)

The D^0 of IVA was obtained by noting ΔA at 285.2 nm and 255.0 nm and multiplying by IVA's factorized ΔA

spectrum in the prepared laboratory mixtures of CAR and IVA. CAR's D^0 spectrum was resulted from the subtraction of IVA's D^0 spectrum from the spectra of laboratory mixture.

Ratio difference technique

The D^0 of binary laboratory mixture in set A was divided separately by the absorption spectrum of standard IVA' and CAR' (15.0 µg/ml, each). The amplitudes of the obtained ratio spectra were noted at 252.6 and 275.0 nm for CAR and 294.0 and 320.0 nm for IVA. The concentrations of CAR and IVA were resolved from their related regression equations.

Constant center coupled with spectrum subtraction technique (CC-SS):

Via employing the formerly manipulated ratio spectra in RD method, the following steps were employed: Firstly, IVA's ratio spectrum in each mixture was recorded at 294.0 nm and 320.0 nm using CAR's D^0 as a divisor. Secondly, the postulated amplitude at 294.0 was acquired from the correspondent related regression equation followed by subtracting the postulated amplitude from the recorded one to obtain a constant value; CAR/CAR'. Finally, via multiplying the constant value by the spectra of 15.0 µg/ml standard CAR', the parent D^0 of CAR was obtained in which its concentration might be determined using the matching regression equation built at its maxima. As a result, the D^0 of IVA could be calculated via subtraction of the acquired spectra of CAR from the spectra of its related mixtures' spectra. The concentration of IVA was estimated using the relevant regression equation.

Analysis of set B containing CAR and IVA with their oxidative degradates in their quaternary mixtures

Induced tripartite amplitude difference coupled with ratio subtraction technique (ITAD-RS)

CAR/CAR's degradate ratio spectrum in mixtures of set B was acquired after multiplication of CAR's factorized induced ratio spectrum by ($FP_{242.7}-P_{296.0}$) of each mixture's ratio spectrum. After multiplication of the former ratio spectrum, CAR/CAR's degradate by the D^0 spectrum of the CAR oxidative degradates, CAR's D^0 was calculated. The ratio spectrum comprising, IVA + IVA's degradate + CAR's degradate/CAR's degradate was acquired by subtraction of the obtained ratio spectrum; CAR/CAR's degradate from that of quaternary mixture.

For IVA, its ratio spectrum in the combination can be acquired by multiplication of ΔP at 242.7 nm and 296.0 nm by the formerly set IVA's factorized ratio spectrum. IVA's parent D^0 was acquired after multiplication of the acquired ratio spectrum by the spectrum of the CAR oxidative degradate.

CAR and IVA concentrations were figured using their respective regression equations generated at their maxima.

Application to pharmaceutical formulation

Five Carivalan® tablets were crushed and blended together. Amounts equivalent to 25.0 mg CAR and 10.0 mg IVA were precisely moved to beaker, 100 ml, dissolved in 30 ml distilled water, sonicated and filtered into a volumetric flask, 100 ml, then accomplished with distilled water.

Further dilutions were proceeded to produce concentrations of 10.0 µg/ml for CAR and 4.0 µg/ml for IVA. The proposed techniques were used for the analysis of the examined Carivalan® following the described measures under laboratory-prepared mixtures analysis to compute their concentrations utilizing the related regression equation for each proposed drug.

Results

As a result of the current global conditions that most countries are going through either economically or practically, the main movement has become toward using analytical techniques at the lowest costs and in the easiest and most accurate ways at all once.

This was the main reason behind the resort to the use of spectrophotometric technique in drugs' analysis, as it proved accuracy, reliability and simplicity among the rest of the other analytical techniques as well as its availability in most quality control laboratories.

Unfortunately, the presence of extremely overlapped spectra made several challenges to use direct absorbance measurements in zero-order spectra, which led to numerous obstacles during spectrophotometric analysis, particularly for multicomponent mixtures.

Therefore, the primary objective is to concentrate on creating highly advanced eco-friendly spectrophotometric techniques that enable both the researcher and the analyst to explore complex mixtures and to overcome any

challenges that may arise.

Carvedilol and ivabradine were chosen as a model for demonstrating the successful application of new spectrophotometric techniques for their analysis, either in their binary or in their quaternary mixture with their oxidative degradation products without the need for pre-separation procedures.

Complete CAR's and IVA's oxidative degradation was observed. Quite the reverse, they conveyed relative acidic, basic, photolytic and thermal stability. Samples were frequently taken out to track the drugs' degradation; for the drugs in question, total oxidation was verified by the disappearance of the TLC spot using TLC aluminum plates. CAR and IVA along with their oxidative degradation products were UV scanned and found to be highly overlapped in the UV region 200.0–340.0 nm, Fig. 2. Direct measurement of the studied drugs was not possible. Thus, two sets were constructed, one for determining CAR and IVA in their binary mixture (set A) exploiting zero or ratio spectra through the application of FDW-SS, RD and CC-SS methods [15], while the other set (set B) was created for the proposed drugs' determination in the presence of their oxidative degradates exploiting the innovative induced tripartite amplitude difference together with ratio subtraction (ITAD-RS) spectrophotometric technique.

Fig. 2 [Images not available. See PDF.]

Zero-order spectra of carvedilol, ivabradine and their oxidative degradation products (10.0 µg/ml, each)

Set A: CAR and IVA in their binary mixture:

An overlapped (D^0) spectrum was observed for CAR and IVA. Using suitable recommended techniques, simultaneous determination of the considered drugs was performed.

Factorized dual wavelength coupled with spectrum subtraction technique (FDW-SS)

This suggested technique was used to analyze CAR and IVA in their binary mixture via picking two wavelengths (285.2 nm and 255.0 nm) where the ΔA is proportional to IVA concentration versus a zero ΔA for CAR at the selected wavelengths, as shown in Fig. 3a.

Fig. 3 [Images not available. See PDF.]

Spectral scheme of resolution of 10.0 µg/ml of each CAR (red line) and IVA (black line) using DW-SS in set A

Figure 3b shows how the original (D^0) of IVA was acquired from each combination after noting (ΔA) value at 285.2 nm and 255.0 nm and multiplying this value by IVA's factorized ΔA spectrum.

Subtraction of IVA's (D^0) spectrum from (D^0) spectrum of the mixture yielded CAR's parent (D^0) spectrum, Fig. 3**c**.

Via relieving the recorded absorbance values at the maxima of each of CAR and IVA in their corresponding regression equations, each drug's concentration was calculated, Table 1**.**

*RSD%[a], **RSD%[b]: the intra-day AND inter-day, respectively, (n = 3) relative standard deviation of concentrations (6.0, 20.0, 25.0 µg/ml for CAR and 6.0, 18.0, 25.0 µg/ml for IVA)

Ratio difference technique

The paramount principle of this technique is that D^0 of the mixture is divided by D^0 of the interfering element obtaining a ratio spectrum. At this moment, the studied drug has a marked (ΔP) at two wavelengths opposing a canceled contribution of the interfering component for being a constant all over the curve. Thus, the interfering component's determination is possible.

This proposed technique was utilized to determine CAR and IVA simultaneously in binary set A mixtures. Dividing the mixture's absorption spectra by the absorption spectrum of IVA' (15.0 µg/ml) was performed to achieve a ratio spectrum. CAR in the mixture was determined using the amplitudes at 252.6 and 275.0 nm, Fig. 4.

Fig. 4 [Images not available. See PDF.]

Ratio spectra of 10.0 µg/ml of CAR (red line), IVA (black line) and their binary mixture (red dotted line), separately in distilled water, using spectrum of IVA (15.0 µg/ml) as a devisor showing the two selected wavelengths (252.6 and 275.0 nm)

Similarly, for the estimation of IVA in the prepared mixture utilizing CAR' (15.0 µg/ml) as a divisor, the amplitudes at 294.0 and 320.0 nm were used, Fig. 5.

Fig. 5 [Images not available. See PDF.]

Ratio spectra of 10.0 µg/ml of IVA (black line), CAR (red line) and their binary mixture (black dotted line), separately in distilled water, using spectrum of CAR (15.0 µg/ml) as a devisor showing the two selected wavelengths (294.0 and 320.0 nm)

The estimated ΔP of the ratio spectra at 252.6 and 275.0 nm and 294.0 and 320.0 nm, respectively, was shown to have a linear relationship with the corresponding concentrations of CAR and IVA, respectively, Table 1.

RD is advantageous over FDW method which requires the specific choice of two wavelengths for the studied drug opposing an equal absorbance value for the other interfering component, while in the RD approach, the wavelength selection is considerably more flexible because the interfering element is a straight line for being a constant.

Constant center coupled with spectrum subtraction technique (CC-SS)

This proposed technique is regarded as a complement to the previously applied RD method, where a ratio spectrum for the binary mixture in set A was obtained with a marked amplitude difference at 294.0 and 320.0 for IVA using CAR' as a divisor. Meanwhile, the practical ratio amplitude of each mixture was noted at 294.0 nm {(IVA/CAR') + (CAR/CAR')}. The supposed ratio amplitude value of (IVA/CAR') was obtained by putting the recorded ratio amplitude in the equation expressing the linear relationship between the ΔP at 294.0 and 320.0 nm with the associated ratio amplitudes at 294.0 nm.P1-P2ΔP=0.8801P1-0.0862r=0.9999, where $P1$, $P2$ are the ratio amplitudes of the ratio spectra of different concentrations of IVA (3.0–30.0 µg/ml) by utilizing CAR; 15.0 µg/ml as a divisor at 294.0 and 320.0 nm.

The constant value (C.V.);CAR/CAR' was figured as the deviation among the measured amplitudes of the mixture's ratio spectra at 294.0 nm and the postulated amplitudes obtained from the established regression equation.; [$P_{recorded}$]−[$P_{postulated}$].

The recovered CAR's D^0 in the mixture, Fig. 3c, was obtained by multiplication of the laboratory mixture's obtained constant (CAR/CAR') by the CAR's divisor.

For IVA, its recovered D^0, Fig. 3b, can be calculated by subtraction of the acquired spectra of CAR from the corresponding spectra of their laboratory-generated mixtures.

By substituting the recorded absorbance values at the maxima of each of CAR and IVA in their corresponding regression equations, each drug's concentration was calculated, Table 1

Set B: CAR and IVA in their quaternary mixture with their oxidative degradates:

The determination of CAR and IVA existed with their degradates was not that possible by the commonly used spectrophotometric techniques. Thus, a novel technique, namely, induced tripartite amplitude difference was devised to assign the targeted drugs by overcoming their completely overlapped spectra.

Induced tripartite amplitude difference coupled with ratio subtraction technique (ITAD-RS)

On the ratio spectrum of CAR, two wavelengths, 242.7 nm and 296.0 nm, were chosen using its oxidative degradate as a divisor.

The ratio spectrum of IVA degradate demonstrates equal amplitude values at these specified wavelengths. The ratio spectrum of IVA, on the other hand, revealed un-equalized values. As a result, an equality factor (F) of 2.497 [$P_{296.0}$/$P_{242.7}$] was calculated by obtaining the average of ΔP of diverse concentrations of IVA's ratio spectra using CAR degradate's spectrum as a divisor at (296.0 nm and 242.7 nm). This factor prospered to match the amplitudes of IVA at the proposed wavelengths, Fig. 6a.

Fig. 6 [Images not available. See PDF.]

Spectra scheme of resolution of 10.0 µg/ml of each of CAR (red line), IVA (black line), CAR's degradate (red dotted line) and IVA's degradate (black dotted line) using ITAD-RS in set B

After calculating the ΔP at 242.7 nm and 296.0 nm along with the equality factor for each set B quaternary mixture, multiplication of the previous value with the previously prepared CAR's factorized induced ratio spectrum resulted in an additional spectrum reflecting the CAR/CAR's degradate ratio spectrum in the mixture, Fig. 6b. By multiplication of the generated ratio spectrum by CAR oxidative degradate's D^0 spectrum, CAR's D^0 was successfully obtained, Fig. 6c.

Subtracting the acquired CAR's ratio spectrum from that of the quaternary mixture resulted in a ratio spectrum comprising IVA + IVA's degradate + CAR's degradate/CAR's degradate. The ratio spectrum of IVA/CAR's degradate in the combination was obtained by recording ΔP at 242.7 nm and 296.0 nm and then multiplying by IVA's factorized ratio spectrum, Fig. 6d. The parent D^0 of IVA was revealed afterward by multiplication of the acquired ratio spectrum by the spectrum of CAR oxidative degradate, Figure 6e

CAR and IVA concentrations were obtained using the respective regression equations generated at their maxima, Table 1.

Privileges proposed by the developed methods

From the achieved results, it was found that determination of the cited drugs through grabbing the beneficial impact of using spectral factorization gave the proposed methods, FDW-SS and the newly developed ITAD-RS a huge privilege. This was attributed to the great ability of factorized spectrum to recover the parent profile of each drug and their determination at each corresponding maxima. Additionally, manipulation using factorized spectra allows the resolution of the analytes via minimal arithmetic operation and spectrophotometer software's manipulation steps. Moreover, CC-SS method occupied a high capability in analyzing the cited drugs through obtaining their D^0 spectra in addition to highest accuracy in their quantification at their λ_{max}. Finally, and through using a spectral divisor, RD method was able to cancel the interfering component in the form of constant, which is a straight line across the curve; as a result, there would not be any crucial measurements at any particular wavelength, and the difference

between any two wavelengths will always equal to zero.

Discussion

Method validation

The suggested spectrophotometric techniques were validated in accordance with the ICH guidelines [20]. Accurate linear results were obtained by analyzing 6 concentrations ranging from 3.0 to 30.0 µg/ml of each cited drug conferring to obedience to Beer's law and their concentration in the pharmaceutical dosage form, Table 1. Accuracy of the results was also checked through analyzing different CAR's and IVA's blind samples where their concentrations were obtained from the corresponding regression equations for the percentage recoveries to be calculated, Table 1. Moreover, three concentration levels were prepared and analyzed in triplicates within and between days for each of CAR and IVA to assess the precision of the employed methods obtaining percentage relative standard deviation (RSD %) not exceeding 2%, Table 1.

Table 2 displays the outcomes of laboratory-prepared mixtures: sets A and B having various ratios of the drugs with or without their oxidative degradates, verifying the specificity of the specified techniques when results were within the calibration range and acceptable. The suggested techniques were additionally successful in distinguishing the drugs contained in Carivalan® tablets. The standard addition approach was used to further evaluate the suggested methods' validity, Table 3.

Greenness profile assessment

The goal of the green analytical chemistry is to boost the environmental friendliness without compromising the performance of analytical methods by recommending the reduction of hazardous substances' usage. Applying various assessment techniques to compare the proposed methods' levels of greenness allowed for the method's greenness to be evaluated.

Analytical Eco-Scale [31] is a semi-quantitative approach that operates on the method's penalty points (PP) minus 100. National Environmental Methods Index (NEMI) [32] is a circular NEMI pictogram, consisting of four quadrants coded with green if they meet the requirements. Green Analytical Procedure Index (GAPI) [32] is a color-coding representation. The output representation will provide insight into the method's greenness and the list of chemicals that must be verified in this GAPI in accordance with the National Fire Protection Act (NFPA) by applying the necessary data in the 11 quadrants of the GAPI. Analytical Greenness Metric (AGREE) [32, 33] is a software-based quantitative method. The necessary information was entered into the software to obtain the pictogram.
As a result, greenness assessment of the proposed techniques, official [1], and the reported spectrophotometric technique [8] was performed for obtaining a more fruitful and purposeful comparison. The obtained results showed that the proposed spectrophotometric technique is greener than the official and the reported methods as shown in Table 5. Regarding Analytical Eco-Scale, the developed method shows a 97 green Eco-score in comparison with both official and the reported methods where they possess an Eco-score of 79 and 93 for CAR and IVA, respectively.

Table 5. Greenness assessment of the proposed, official and the reported methods according to Eco-Scale, NEMI, GAPI and AGREE tools

Tool	Proposed	Official [1]	Reported [8]
Analytical Eco-scale			
Water	0	–	–
Acetic acid	–	8	4
Perchloric acid	–	8	–
Energy Consumption	0	0	0
Occupational Hazard	0	0	0
Waste	3	5	3
Total Penalty Point	3	13	7
Eco-score	97	79	93
NEMI			
GAPI Tool			
AGREE Tool			

Additionally, the developed method's greenness assessment profile by applying national environmental method index tool (NEMI) obtained four full green quadrants as the used solvent; water is completely safe regarding persistence, bioaccumulation and corrosiveness, while only 1 and 2 green quadrants for both the official and reported methods of CAR and IVA, respectively, were obtained.

Moreover, method’s complete framework greenness profile was acquired using green analytical procedure index tool (GAPI) where ten green and five yellow zones with a complete absence of any red zones were possessed in comparison with official and reported methods.

Finally, a score value of 0.84 was obtained which is greener than that obtained by official, 0.73, and reported method, 0.76, after applying the analytical greenness metric tool.

Briefly, the usage of distilled water and minimizing instrumental's energy consumption in the proposed methods was reflected by gaining high analytical greenness scores besides having full green NEMI pictogram and a complete absence of any red zones in GAPI pictogram.

Conclusion

UV spectrophotometric techniques have several advantages over other analytical techniques, including their simplicity, low solvent usage and low cost. The suggested spectrophotometric techniques demonstrated great sensitivity and accuracy for determining CAR and IVA in dosage form, laboratory-generated combinations, and in presence of their oxidative degradates with no interference and excellent outcomes. Additionally, the greenness profile was argued green by applying various green assessment tools as analytical eco-scale, national environmental method index, green analytical procedure index and analytical greenness metrics. Therefore, the proposed method is capable of routine analysis of the cited drugs in quality control laboratories.

ABSTRACT (ENGLISH)

Background

Diffuse astrocytoma (a type of glioma) and its prevalence are matters of concern worldwide. Patients with this type of tumour have a poor prognosis because after surgical treatment, radiotherapy and/or chemotherapy, these tumours eventually regrow or progress. To date, there is no effective treatment that can cure affected patients. Quercetin and 3-bromopyruvate are chemical compounds that have been proven to have antitumour effects alone or in combination with other compounds. Nevertheless, combination treatments including these agents are not used for treating diffuse astrocytoma.

Methods

The use of nanoliposomes loaded with quercetin and 3-bromopyruvate as combination therapy was evaluated by treating C6 cells in vitro and in vivo (in Sprague–Dawley rat brain).

Results

The 0.5 mg/mL quercetin + 0.75 mg/mL 3-bromopyruvate combination treatment decreased the expression of the biomarkers Annexin V and Caspase-3 and inhibited tumour growth; this was consistent with the in vivo results that revealed the administration of this treatment resulted in improved animal survival.

Conclusions

The observations in the present study support the further exploration of this combination of active agents in the treatment of high-grade diffuse astrocytoma, especially in cases for which wide resection is possible.

FULL TEXT

Background

The incidence rates of all primary malignant brain tumours range from 6.10 to 8.65 per 100,000 person-years; among these tumours, 80% are diffuse gliomas and 76% are high-grade astrocytomas and glioblastomas [1]. These tumours have become issues of concern worldwide since the population will increase to 2 billion people in the next 30 years [2]. The reason for the appearance of diffuse gliomas is unclear, but the process seems to be multifactorial. Factors that contribute to the development of diffuse gliomas include population ageing, overdiagnosis, ionizing radiation, air pollution, virus infection, etc. [3, 4]. The degree of malignancy depends on location, patient age, growth rate, infiltration of healthy tissues, and the presence of established and specific molecular markers [5]. Nevertheless, in most patients with grades 3 and 4 gliomas, aggressive evolution results in poor prognosis, and risk of mortality increases one year after diagnosis [6, 7]. Despite increasing technological advances to achieve more significant tumour surgical resection, effective treatment is lacking [5, 8, 9]. Consequently, the recurrence of these tumours is frequent [10, 11]. Therefore, searching for new treatments and using more effective drugs to target tumour progression or regrowth is a significant issue in neuro-oncology [12, 13].

In vitro and in vivo studies make it possible to evaluate the efficacy of new cancer treatments. The direct administration of chemical compounds and drugs to C6 cell cultures and the intrathecal or intraperitoneal administration of these agents to tumour cell transplantation rat models are both widely used to study gliomas [14]. These models have histopathological and molecular features that are similar to those of developing adult-type

diffuse gliomas in humans [15]. The pharmaceutical preparations that have been proposed for treating high-grade gliomas include formulations with nanoparticles, particularly formulations with nanoliposomes (liposomes with a radius smaller than 100 nm), which have more attractive characteristics such as enhanced bioavailability of carried substances and increased efficacy due to the active substances and liposome components [16–18].

Moreover, nanoliposome formulations containing quercetin (Quer, a flavonoid with anti-inflammatory, antioxidant, and antineoplastic properties) have been shown to exert an antitumour effect against high-grade glioma [19, 20]. In recent reports, Ersoz et al. found that quercetin-loaded nanoparticles improve cytotoxic effects and antioxidant activity in C6 glioma cells [21]. Wang et al. also showed that PEGylated Quer-containing nanoparticles exert similar effects [22]. Zang et al. reviewed several Quer-containing formulations that are characterized by high encapsulation efficiency, stability, sustained release, prolonged circulation time, improved accumulation at tumour sites, and therapeutic efficiency. In addition, the authors suggested that combining quercetin with specific agents enhances the ability to detect or treat tumours [23].

One active compound that been used to treat glioblastoma is 3-bromopyruvate (3BP), which is a pyruvate-like alkylating compound that inhibits hexokinase II and glyceraldehyde-3-phosphate dehydrogenase [24]. 3BP exerts effects against several tumour cells, and its cytotoxicity is associated with the induction of autophagy; however, at the doses required for 3BP to be effective against glioblastoma cells, 3BP exerts toxic effects against healthy cells, which indicates a need to administer lower doses to limit systemic adverse effects [25]. In this sense, combinations of valproate, antimycin, menadione, and other antineoplastic agents with low doses of 3BP have also been suggested as effective and safe combinations for targeting some neoplastic processes [26, 27].

Hence, in this work, a nanoliposome formulation loaded with Quer and 3BP was evaluated as a combination therapy for treating C6 glioblastoma cells in vitro and in vivo. The current observations support further exploration of this combination of active agents for the treatment of diffuse astrocytoma.

Methods

Cellular culturing and selection of cells

The rat cell-line C6 (ATCC, USA) was cultured in culture recipients of 75 cm^2 with D-MEM FK12 (Dulbecco's Modified Eagle Medium/Nutrient Mixture F-12, ATCC, USA) media, supplemented with 20% horse foetal serum (HSF, ATCC, USA); 10% bovine foetal serum (BFS, ATCC, USA) and 2% antibiotic/antimycotic media (A.A., GIBCO, USA). The culture plates were kept in an incubator (Water Jacketed, Nuaire, USA) at stable condition, 5% CO_2 at 35 °C for growth and propagation.

The sub-cell-cluster (Sub-C6) was obtained with serial dilutions 1:10 from the starting C6-cells. The last dilution was seeded in a 96 wells-plate/100 µL with supplemented D-MEM FK12 (20% HSF, 10% BSF, 10% A.A.). The wells with one cell were selected, then, growth to confluence. After that, sub-clusters were recovered with trypsin (Trypsin-EDTA 0.05%, cat 25,300,054, ThermoFisher) and spread into 6 well-plates and bottles of 75 cm^3. The cluster with highest FOXM1 (K19 clone SC500, SantaCruz biotechnology, USA) and VEGF (C20 clone- SC152, SantaCruz biotechnology, USA) protein expression was selected.

Apoptosis-markers detection

Cells, each for treatment from C6 cluster and sub-clusters, were seeded in 24 well-plates with 5×10^4 cells each well in supplemented D-MEM FK12 (20% HSF, 10% BSF, 10% A.A.) and treated with 5.7 ng, 17.1 ng y 34.2 ng of 3BP (376,817-M, Millipore) and/or 3.8 ng, 11.4 ng and 22.8 ng of Quer (Q4951, Sigma-Aldrich) during 3, 6, 12, 24, 48 and 72 h. Next, cells were washed with PBS and fixed by using paraformaldehyde 2%. Treated cells were incubated with the primary antibody against Annexin V (1:500, Santa Cruz Biotechnology, mouse sc-74438) by 48 h at 4 °C and Caspase 3 (1:500, Santa Cruz Biotechnology, mouse sc-56053), then with the secondary antibody Alexa 546 (anti-mouse 1:1000, cat A-11030, ThermoFisher) during 48 h a 4 °C, finally contrasted with Hoechst 33,342 (cat H3570, Invitrogen) by 20 min.

Samples from cultures were analysed with an inverted confocal microscope (Nikon Ti Eclipse with A1 through the NIS Elements v.4.5.0 software). Three photography were acquired to different fields at 20× in each treatment. The quantification and analysis were determined by a binary mask (black and white) to discard noise or artefacts by

using the Image-Fiji software (London SW7 2AZ, UK). Values considered as Caspase 3 activation and translocation by Annexin V were calculated as mean density by each cell.

Liposomal formulations preparation and characterization

10 mL of each unilamellar liposome preparation was made with a mixture of Quer and 3BP. Three different classes of liposomes were prepared: (1) control liposomes or empty liposomes, (2) low-dose liposomes (0.5 mg/ml Quer + 0.75 mg/mL 3BP) and (3) high-dose liposomes (0.75 mg/mL of Quer + 1.125 mg/mL of 3BP), based on the reverse phase evaporation method [28]. Briefly, for the formation of the lipid bilayer, 10 mg of cholesterol were dissolved in 2–3 mL of chloroform and added, together with 440 µL of phosphatidylcholine, in a conical flask with two necks (one with vacuum connection and the other with ability to place a removable filter) from 13 to 100 mm in diameter, and dried under vacuum so that the lipids remain uniformly distributed at the bottom of the flask.

Simultaneously the active ingredient was dissolved in milli-Q® water. As far as the Quer is concerned, it was dissolved in chloroform and a (1:1) proportional amount of water was added to them. Subsequently, the lipid bilayer was dissolved with 3 mL of diethyl ether and the previously dissolved active ingredient was added to this solution. The flask was then vortexed for 1 min and through immersion in a sonicator for an additional 1 min (5 s pulses). To carry out the control of liposomes, water was added instead of the active principle. Returning the flask to the vortex, a vacuum was applied for approximately 1 min, during which the ether was evaporated [29]. Maintaining erasure, 6 mL of saline solution containing 0.13% spermine was added. At this point, the preparation was evaluated by visualization (a cloudy suspension is considered adequate; the formation of lumps, inadequate). The liposome preparations obtained were filtered by extrusion, with Millipore Swinnex® membranes with 0.22 µm pore diameter (pressure 100–100 psi), to homogenize the size of the vesicles and to preserve them under sterile conditions. This suspension of liposomes was titrated with saline to a volume of 10 mL, pH 7.0.

Morphological characterization was done by means of atomic force microscopy, using a Nanos-Senterra (Bruker Optiks, Ettlingen, Germany) in the non-contact / tapping-mode; analysis was done on a plate with a maximum xy scan range of 40 × 40 µm and a z range of 8 µm. Cantilevers were standard microfabricated (POINTPROBE-PLUS® Silicon-SPM-Sensor, Nanosensors® Wetzlar-Blankenfeld, Germany). The length of the AFM tip was 200 mm, and the resonance frequency was 165 kHz. The average height and roughness of the cell surface were analysed, and images were processed by using SPIP® software (Image Metrology, Hørsholm, Denmark) as previously [30].

Animal model

Animals

Forty-two male *Sprague–Dawley* rats, ageing 10 weeks, and weighting 210–255 g at the start of assays, were used. They were contained in acrylic boxes (50 × 40 × 40 cm), maintained under 12:12 h light/dark cycles, with FormuLab Diet #5008 food and water ad libitum.

This protocol was evaluated by the local committee for research and ethics in health research 3601 (Registering Number: R-2012–3601-106). The surgical procedures were done in the vivarium by using all the aseptic and antiseptic protocols and materials. The project followed the local laws for animal care and the ARRIVE (Animal Research: Reporting of In Vivo Experiments) guidelines (available at https://arriveguidelines.org/arrive-guidelines) for avoiding suffering to involved animals.

Stereotaxic approach was done in anaesthetized animals (90 mg/kg ketamine + 10 mg/kg xylazin). Once the head was fixed, the skull was exposed a trephine was done at anteroposterior 2 mm, lateral 2 mm and deep 2 mm from bregma [31]; at this site, 2.5×10^5 or 1×10^6 cells suspended in D-MEM FK12 medium (ATCC, USA) were injected and the skin was sutured. Then, a 5-day recovery period was permitted, being at the first three days treated with antibiotics (Gentamicin 80 mg + Benzathine penicillin 1,200,000 IU) and analgesic (Tramadol dose, 10 U).

Individual and combined treatments

The animals were divided into four groups (N = 24, n = 6 per group): Control) Treated with empty liposomes; Experimental 1) Treated with liposomes + Quer (1 mg/kg of Quer); Experimental 2) Treated with liposomes + 3BP (1.5 mg/kg of 3BP) and Experimental 3) Treated with liposomes + Quer + 3BP (1 mg/kg of Quer + 1.5 mg/kg of 3BP).

Low and high combined treatments

The animals were divided into three groups (N = 18, n = 6 per group): Control) Treated with saline solution; Experimental 1) Treated with low-dose liposomes (1 mg/kg of Quer + 1.5 mg/kg of 3BP) and Experimental 2) Treated with high-dose liposomes (1.5 mg/kg of Quer + 2.25 mg/kg of 3BP).

Administration of treatments and obtaining samples

The liposomal formulations were administered 3 times, at 72 h intervals, via i.p. being the first administration on the sixth day of the implant. Finally, the animals were sacrificed three weeks after implantation, due to an overdose of pentobarbital (100 mg/kg), to obtain and dissect the brains.

Samples processing

The brains were perfused and fixed in 4% paraformaldehyde for posterior paraffin embedding. After that, 5 µm slices were obtained every 250 microns for tumour identification. Briefly, the slices were mounted on slides covered with poly-L-lysine (10%, P4832, Sigma), the excess paraffin was removed (55ºC, oven), and they were rehydrated (xylol, 100% alcohol, 96% and 70%, and water). Subsequently, the sections were stained with Harris haematoxylin for 5 min, rinsed with water, treated with lithium bicarbonate, and counterstained with eosin. Before mounting the slides with Entellan resin (107,960, Merck-Millipore), they were dehydrated (70%, alcohol, 96% and 100%, and xylol) [32]. The images were photographed with a NI5_Elements D (5.110064 bit, Nikon, Japan) microscope 40 × and the calculation of the tumour areas were calculated with the Image Pro7 (Media Cybernetics, Rockville, MD 20852 USA) software. Tumour volumes were calculated with the formula:vµm3=∑VnVn+113∗250∗(An+An+1+An∗An+1) Subsequently, the values were converted to mm^3 and 75% of the volume of water was added.

Statistic analysis

The differences in the medians of Caspase 3 activation and translocation detected by Annexin V in C6-cells culture by exposure to Quer, 3BP or the combination were analysed using the nonparametric Kruskal–Wallis test. Differences in tumour size were analysed using the Mann–Whitney U nonparametric median comparison statistical test. All performed by using the Prima STAT v 12.0 software, a p-value < 0.05 was considered significant.

Results

Liposomal formulations were obtained as described for similar liposome formulations that contain nanoparticles (with radii ranging from 20 to 200 nm, Fig. 1). The Quer and 3BP encapsulation efficiency was not determined, but it was estimated to be > 90%, as described in multiple previous reports of similar systems [28, 33, 34]. When in solution, the rest of the described compounds were administered as original formulations and were used in our in vivo evaluations.

Effects of Quer and/or 3BP on C6 cell culture

Annexin V detection.

Decreased cell viability in the initial stage of apoptosis induction was reflected by Annexin V-stained Alexa 546-positive cells [35]. The administration of Quer to cell cultures induced significant differences in proportion of apoptotic cells, which differed with both Quer concentration and treatment time (p < 0.0001). The highest proportions of Annexin V-positive cells were observed at 12 and 72 h, and the lowest proportion of Annexin V-positive cells was observed at 6 h after treatment with all Quer concentrations (Fig. 2A).

Fig. 2 [Images not available. See PDF.]

Annexin V (as a marker of initial phase of cellular death involving cell membrane dysfunction) staining of C6-cells treated with Quer and/or 3BP. C6 cells were treated with different concentrations of Quer or 3BP, and then, the mean cell density was measured at 3, 6, 12, 24, 48 and 72 h. **A** Cells treated with 3.8, 11.4 or 22.8 ng Quer. **B** Cells

treated with 5.7, 17.1 and 34.1 ng 3BP. **C** Cells treated with 3.8 ng Quer + 5.7 ng 3BP, 11.4 ng Quer + 17.1 ng 3BP and 22.8 ng Quer + 34.1 ng 3BP. Significant differences were determined by the Kruskal–Wallis test and are indicated by &p<0.01, †p<0.001, #p<0.005 and *p<0.0001

The administration of 3BP to cell cultures induced significant differences in the proportion of Annexin 5-positive cells at all the concentrations that were tested and at all the time points that were studied (p<0.0001). The highest proportion of Annexin V-positive cells was observed at 72 h, and the lowest proportions of Annexin V-positive cells were observed at 3, 6 and 24 h (Fig. 2B).

When both compounds were added to cell cultures, significant differences were observed in the proportions of Annexin V-positive cells at all the concentrations that were tested and at all the time intervals that were studied (p <0.0001), except for 6 and 48 h. The highest proportions of Annexin V-positive cells were observed at 12 and 72 h, and the lowest proportion of Annexin V-positive cells was observed at 6 h (Fig. 2C).

Finally, when individual treatments were compared with the combination treatment, a higher proportion of Annexin V-positive cells was observed in the group that received the combination treatment.

Caspase 3 activation.

The apoptosis execution pathway was studied by measuring Caspase 3 activation in cultured cells as described elsewhere [36]. The administration of Quer to cell cultures induced significant differences in Caspase 3 activation, which differed with both Quer concentration and treatment time (p<0.0001). In fact, the highest degree of Caspase 3 activation was observed at 12 h, followed by 48 and 72 h. In contrast, the lowest degree of Caspase 3 activation was observed at 6 h (Fig. 3A).

Fig. 3 [Images not available. See PDF.]

Caspase 3 (marker of apoptosis pathway) expression in C6-cells treated with Quer and/or 3BP. C6 cells were treated with different concentrations of Quer or 3BP, and then, the mean cell density was measured at 3, 6, 12, 24, 48 and 72 h. **A** Cells treated with 3.8, 11.4 or 22.8 ng Quer. **B** Cells treated with 5.7, 17.1 and 34.1 ng 3BP. **C** Cells treated with 3.8 ng Quer + 5.7 ng 3BP, 11.4 ng Quer + 17.1 ng 3BP and 22.8 ng Quer + 34.1 ng 3BP. Significant differences were determined by the Kruskal–Wallis test and are indicated by an asterisk, *p<0.0001

Additionally, 3BP administration to cell cultures induced significant differences in Caspase 3 activation, which differed with both Quer concentration and treatment time (p <0.0001); these results similar to those after Quer treatment (Fig. 3B).

When both compounds were administered, significant differences were observed in the activation of Caspase 3, which differed with both concentration and treatment time (p<0.0001), except for the 3-h timepoint. In this case, the highest degree of Caspase 3 activation was observed at 3 and 12 h, and the lowest degree of Caspase 3 activation was observed at 6 h and 12 h (Fig. 3C).

Finally, when the effects of the single treatments were compared with those of the combination treatment, the highest degree of Caspase 3 activation was observed after treatment with 3BP.

In vivo effects of liposomal formulations with combined treatment on tumour growth

A subclone of the C6 cell line was used, and the number of implanted cells that allowed the longest model survival was determined; this number of cells was used for subsequent experiments. For this experiment, intracranial tumour growth was measured in rats (n = 20) that received 1×10^5 cells (n = 10) or 2×10^5 (n = 10) cells. A placebo treatment of empty liposomes (n = 5) or saline solution (n = 5) was administered, and the experiment was continued for three weeks. One hundred per cent of the animals in the 1×10^5 cell implant group survived at 21 days; however, only 80% of the animals in the 2×10^5 cell implant group survived at 21 days (data not shown).

Subsequently, the Quer and/or 3BP individual and combination treatments that had been tested in cell cultures and had elicited the best apoptotic pathway response (11.4 ng Quer, 17.1 ng 3BP and 11.4 ng Quer + 17.1 ng 3BP) were administered.

Figure 4 shows representative tumour growth in the section with the largest area that was identified in each case. A tumour region was observed mainly in the control groups, and similar regions were observed in the groups treated

with either Quer or 3BP alone; in contrast, no areas of necrosis and less angiogenesis were observed in the combination treatment group (liposomes with Quer + 3BP), and only the inoculated cells, without obvious tumour formation, was observed.

Fig. 4 [Images not available. See PDF.]

Sections of the brain from rats implanted with 2.5×10^4 C6 cells and treated with liposomes containing Quer or 3BP were stained with H&E. **A** Treated with empty liposomes, **B** treated with liposomes loaded with 0.5 mg/mL Quer, **C** treated with liposomes loaded with 0.75 mg/mL 3BP and **D** treated with liposomes loaded with 0.5 mg/mL Quer + 0.75 mg/mL 3BP. These sections were obtained from rats 3 weeks after C6 cell implantation. The arrows indicate histopathological alterations due to the tumour. Scale bar 100 μm

Consequently, it was decided to test the combination treatment at a higher dose and to increase the cellular inoculum to further test the efficacy of the treatments.

After the administration of low and high doses of the liposomal formulations of the combination treatment, the animals were reactive, and obvious tumour formation was observed. Figure 5 shows representative tumour growth after the administration of low and high concentrations of liposomes. Smaller tumours were observed in the low-dose treatment group, but an apparent reversal of the therapeutic effect was observed in the high-dose treatment group.

Fig. 5 [Images not available. See PDF.]

Comparison of brain sections with free development of implanted C6 cells and brain sections from rats implanted with 1×10^5 C6 cells and treated with liposomes containing Quer or 3BP. Above are the entire brains, below are brain sections. All sections were stained with Haematoxylin &Eosin. **A** Treated with saline solution, **B** treated with liposomes loaded with 0.5 mg/mL Quer + 0.75 mg/mL 3BP and **C** treated with liposomes loaded with 0.75 mg/mL Quer + 1.125 mg/mL 3BP. These sections were obtained from rats 3 weeks after C6 cell implantation. The arrows indicate histopathological alterations due to the tumour. Scale bar 100 μm

Figure 6 shows a plot of the mean tumour volumes in the three groups of liposome-treated animals; there was a significant decrease between the control group and the group treated with low-dose combination treatment of Quer + 3BP ($p<0.05$).

Fig. 6 [Images not available. See PDF.]

Tumour volumes and effect of liposomal formulation treatment. Tumour volume from rats 3 weeks after implantation of 1×10^5 C6-cells treated with **A** empty liposomes, **B** liposomes loaded with 0.5 mg/mL Quer + 0.75 mg/mL 3BP and **C** liposomes loaded with 0.75 mg/mL Quer + 1.125 mg/mL 3BP. Significant differences were determined by the Kruskal–Wallis test and are indicated by #$p<0.05$

Discussion

The increasing incidence of glioblastoma and the regrowth of tumours after gross total resection followed by adjuvant treatment with temozolomide (gold standard in chemotherapy) and radiation therapy require the development of pharmacological tools for glioblastoma treatment [37, 38].

The implantation of glial cells into rat brains has been used to model human glioma for more than four decades; effective models have been used to test different treatments that control the growth and development of these cells [39]. Auer et al. (1981) determined the number of cells necessary to obtain a reliable model by studying an implant concentration gradient; they determined that the implantation of 1×10^4 cells results in a 100% glioma formation rate [40]. In this work, we implanted 2.5 and 10 times more cells than the number originally recommended by Auer et al. because preliminary experiments in our laboratory (not shown) revealed no tumour development after implantation of the original cell number.

The aim of this study was to test a liposomal formulation of Quer and 3BP combination treatment. These two components have been separately tested as neuroprotectors and glioblastoma cell regulators, although not in a combined formulation, and they have been demonstrated to exert effects in animal glioma models [21, 26, 41–44].

Notably, the material in the liposomal formulation used to improve drug availability to neoplastic cells is a third component of this formulation. In this work, the methodology used in the formulation of liposomes assumes a high encapsulation efficiency as has been reported [28]. Originally, the encapsulation efficiency was reported >65%, but currently is near 90% (84.7 ± 5%) [45].

Quercetin is insoluble in water due to its lipophilic property, so it has poor absorption, low bioavailability, and a limited ability to cross the BBB, therefore could not be used for the treatment of gliomas. The use of this liposome formulation increased the solubility of quercetin and guaranteed the probability of acting in the brain as well as limiting peripheral effects and reduction of drug-related toxicity [20, 33, 34, 46, 47]. In fact, several concentrations were evaluated for treating rats acting as a murine model of grade 4 astrocytoma, with the purpose of evaluating the possible therapeutic effects of adjuvant treatment after wide (implantation of 2.5×10^4 cells) or partial resection (implantation of 1.0×10^5 cells).

Anticancer properties of Quer are a consequence of different mechanisms that favour the progression of cancer cells. The antioxidant property is reflected in being an effective reactive oxygen species (ROS) scavenger and inhibiting lipid peroxidation; also, regulating signal transduction pathways, such as NRFB, MAPK and AMPK, as demonstrated by in vitro studies [48–50]. The anti-inflammatory properties are related to the inhibition of pro-inflammatory cytokines (TLR4 pathway) and a decrease in the production of cyclooxygenase (COX) and lipoxygenase (LOX) [51, 52]. Cell cycle progression of different cancer cells is affected by the arrest of the G0/G1 and G2/M phases, because of the inhibition of cyclins, release of p53 and caspase activation [53–55]. The synergistic effect of Quer with different chemotherapeutic agents and with radiotherapy has been reported; these studies are complemented by the cytotoxicity of Quer in glioma cells when the late stage of autophagy is inhibited [56, 57].

The suggested mechanisms of 3BP action include decreasing ATP by disrupting the function of several cysteine-rich proteins [58, 59]. Additionally, 3BP-mediated inhibition of hexokinase II, which is involved in the survival of glioblastoma cells, has been demonstrated, probably providing additional sources of ATP in neoplastic cells [60, 61]. In addition, several reports showed increased intracellular ROS production in diverse malignancies after 3BP exposure as well as the specific pyruvilation of glyceraldehyde 3-phosphate dehydrogenase, which is a major intracellular biochemical mechanism, resulting in the metabolic disruption of cells and inducing apoptosis [62–64]. Thus, considering that tumour growth and progression are favoured by acidic microenvironments and the reactive oxygen and nitrogen species that are produced during anaerobic glycolysis (Warburg effect), in which hexokinase II (HK II) degrades glucose into pyruvate, producing two molecules of ATP and various glycolytic intermediates that are fed into multiple biosynthetic pathways, it is suggested that the combined effect of this formulation is additive, as differences were observed with formulations that included only one of these compounds. 3BP can also act directly because pyruvate is converted into lactate in the cytoplasm by the enzyme lactate dehydrogenase (LDH). In contrast, normal astrocytes use the combination of acute aerobic glycolysis (Crabtree effect) and slow aerobic glycolysis, favouring high glucose contents and ATP generation without affecting the integrity of the mitochondrial membrane and maintaining a balance between glycolysis and respiration [65, 66].

Annexin V, which is specifically related to the processes that are associated with the initial phases of cell death, is considered a marker of membrane dysfunction [35]. Quer administration modulated the changes in the cell cycle that are associated with the initial phase of apoptosis, as shown by the increased proportion of Annexin V-positive cells described in prostate, colorectal and other neoplastic cells [67–69]. 3BP administration also induced high expression of Annexin V or high proportions of Annexin V-positive cancer cells, such as was observed in melanoma and lung neoplastic cells [70, 71].

Complementarily, in this study, caspases (cysteine proteases) are considered key proteins in apoptotic processes, specifically in the execution phase. Caspase 3 expression and activation have been shown to be modulated by Quer administration in different cells [72–74]. Similarly, 3BP induced an increase in the Caspase 3 staining intensity in potentially different types of neoplastic (liver, lung, colorectal) cells, including glioma cells [64, 71, 75].

Regarding the formulation used (simple bilayer liposomes with charges neutralized by spermidine addition), it should

be noted that the main advantages of the use of liposomes is efficient transport to the target site and evasion of natural barriers in the organism; however, other functional properties have been described in the treatment of gliomas; among these the facilitation of drug transport across the blood–brain barrier, the improvement of cellular uptake and the reduction of P-glycoprotein (P-gp) excretion of drugs, reversing of multidrug resistance, regulation of autophagocytosis and induction of apoptosis [34].

Additionally, formulations could include active protein members of the ATP-binding cassette (ABC) transporter superfamily. In the brain, these proteins are found in the blood–brain barrier, the blood-cerebrospinal fluid barrier, and the blood-arachnoid barrier, while in tumour cells, the overexpression of these ABC transporters is associated with drug resistance and regulated by metabolites that are generated during aerobic glycolysis; thus, 3BP could act indirectly by inhibiting the expression of these transporters [76–78]. On the other hand, there are reports that Quer favours the overexpression of P-gp, which is considered a substrate of these transporters [79, 80].

It should be noted that in vitro (Annexin V and Caspase 3 expression) and in vivo (limitation of growth) results are congruent and in line with the involvement of the mechanism(s) of action linked to regulation of death cells, mainly by apoptosis. However, other mechanisms such as metabolism disorders, avoiding of drugs expulsion of neoplastic cells and limitation of vascular development could be key in the observed effect. In this sense, an interesting finding of our in vivo experiments is that the combination treatment strategy seems to inhibit vascular formation. An antiangiogenic effect of Quer (at different doses and in different formulations) has been reported in multiple in vitro and in vivo studies, including those using liposomes as carriers [41, 81–85]. In contrast, scarce data suggest an effect of 3BP on vascularization in tumours; truly, its effects are linked to metabolism disruption, as briefly described above. In this work, the inhibition of neovascularization by the combination treatment could be an effect of both disrupted metabolism (particularly aerobic glycolysis) and direct inhibition of the production and actions of stimulating factors, such as VEGF (Vascular endothelial growth factor) [86, 87]. Further studies are required to support or refute these hypotheses. The determination of efficient doses of each component, the exploration of additional nanoliposome formulations as well as the comparison of effects from diverse administration pathways are desirable for testing this formulation in human cells, since this would increase the potential outcomes of this study and the possible clinical application. Also, an intentioned toxicity evaluation in higher or prolonged administration (studies of posology) compared with those used in this study should be done.

Conclusions

The tested combination liposomal formulation (Quer + 3BP) inhibited the expression of the biomarkers caspase-3 and Annexin V and tumour growth, but in vivo, its administration resulted in higher animal survival and lower volumes of developed tumours than in control groups. These observations support the further exploration of these active agents in the treatment of high-grade diffuse astrocytoma. Specifically, this exploratory study suggests that postsurgical treatment with liposomes loaded with Quer 1 mg/kg + 3BP 1.5 mg/kg allows glioma inhibition in cases where wide resection is possible or slows tumour growth when partial resection is possible. Further studies are required to support these findings.

Acknowledgements

Coordination of Health Research of-IMSS sponsored this study, with the registration number R-2012-3601-106. We thank the staff of the vivarium M. en C. Itzel Isaura Vaca Ibarra, M.V.Z. Julio García Hernández, Nurse Fabiola Ortíz Pérez and Biol. Ricardo Neftali Bravo Rodríguez by their support in the care and surgery of the animals.

Author contributions

The author’s contributions are follows: Conceptualization was done by MASU and IAFR; methodology was done by AVG, VBA, ALON and JMM; formal analysis was done by MASU and IAFR; investigation was done by MASU and IAFR; resources were done by IAFR; writing—original draft preparation was done by MASU and IAFR; supervision was done by IAFR; funding acquisition was done by IAFR. All authors have read and agreed to the published version of the manuscript.

Funding

This research receives a grant from Coordination of Health Research-IMSS funding (number

FIS/IMSS/PROT/G12/1111).

Availability of data and material

The datasets generated during and/or analysed during the current study are available from the corresponding author on reasonable request.

Declarations

Ethics approval and consent to participate

The local ethics committee evaluated this protocol (Registering Number: R-2012-3601-106). The project followed the local laws for animal care NOM-062-ZOO-1999 and the ARRIVE guidelines for avoiding suffering to involved animals.

Consent for publication

Not applicable.

ABSTRACT (ENGLISH)

Background

The evaluation of the correlations between antioxidant and anti-acetylcholinesterase activities of methanol leaf extracts of three Nigerian endemic plants, *Spondias mombin*, *Carica papaya* and *Kalanchoe crenata*, was carried out. Their constituent phytochemicals were identified by HPLC–DAD fingerprinting. The antioxidant activity as typified by 2,2-diphenyl-1-picrylhydrazyl ($DPPH^{\cdot}$), 2,2′-azino-bis-(3-ethylbenthiazoline-6-sulfonic acid ($ABTS^{\cdot+}$) and nitric oxide (NO) scavenging activities were evaluated. The acetylcholinesterase (AChE) inhibitory activity of the extracts was also determined.

Results

The extracts contained appreciable amounts of the flavonoids, quercetin and kaempferol. The extracts of *Spondias mombin*, *Carica papaya* and *Kalanchoe crenata* showed concentration-dependent inhibitory activities against $DPPH^{\cdot}$ and $ABTS^{\cdot+}$ with IC_{50} of 43.29 ± 0.443 μg/mL, 59.27 ± 0.644 μg/mL and 80.20 ± 0.414 μg/mL; 25.43 ± 0.325 (μg/mL), 39.84 ± 0.163 μg/mL and 59.02 ± 0.376 (μg/mL), respectively. The IC_{50} for the NO scavenging activities of the *Spondias mombin*, *Carica papaya* and *Kalanchoe crenata* extracts were 41.99 ± 0.217 μg/mL, 50.44 ± 0.281 μg/mL and 60.12 ± 0.512 μg/mL, respectively. The IC_{50} for the inhibitory effects on AChE was 53.24 ± 0.327 μg/mL, 60.95 ± 0.290 μg/m and 70.5 ± 0.426 μg/mL, respectively. The effectiveness of the plant in all the experimental tests was in the following order: *S. mombin>C. papaya>K. crenata.* The total flavonoid and total phenolic contents have extremely significant positive correlations with the antioxidant activities and AChE inhibitory activity. The correlation coefficients (r^2) of DPPH scavenging activity and NO scavenging activity with the AChE inhibitory activity were 0.8295 μg/mL and 0.7337 μg/mL, respectively (P<0.0001). The molecular docking and pharmacokinetic analyses on some constituent phytochemicals showed that quercetin, kaempferol, ferulic acid, leucocyanidin, gallic acid and isorhamnetin fulfilled the requirements for an anti-Alzheimer drug.

Conclusions

The results suggest that the plant species provide a significant source of secondary metabolites that can act as natural antioxidants and acetylcholinesterase inhibitors, which will be helpful in the treatment of Alzheimer's disease.

FULL TEXT

Background

Discovering improved disease modifying therapies against dementias remains a major challenge. Dementias are characterized by the gradual onset and continuing decline of higher cognitive functioning as exemplified by Alzheimer's disease [1, 25]. Alzheimer's disease (AD) patients present a gradual decrease of acetylcholine levels, which arises from loss of the cholinergic neurons in the hippocampus and cortex of the brain. Other defects that occur include accumulation of decrepit plaques and neurofibrillary tangles [31]. Consequently, inhibition of

acetylcholinesterase, that enhances the build-up of acetylcholine at the synapse, will improve the cholinergic shortage, which is a remedial target for the development of drug for AD ("cholinergic hypothesis"). Galantamine, rivastigmine and donepezil are drugs for AD, all are acetylcholinesterase inhibitors [14].

Synthetic drugs show unwanted serious side effects accompanied by insufficient response rates. They mainly get rid of symptoms of AD rather than curbing the progression of the disease so the problem of how to treat the disease still persists [19]. Therefore, there remains an urgent need for new, safe and effective drugs. This opens an avenue for the exploration of medicinal plants. Medicinal plant products have proved to be favorable sources of acetylcholinesterase inhibitors [48]. AChE inhibition is also considered as a promising remedial strategy for other types of dementia, myasthenia gravis, glaucoma and Parkinson's disease in addition to AD [32].

The formation of reactive oxygen species, which leads to oxidative stress, is another significant neurotoxic pathway in AD. Oxidative stress is produced by the disturbance of equilibrium between free radicals and antioxidants. Damage of biomolecules such as lipids and proteins in relation to increased free radical levels leads to oxidative damage of cells and consequently, to overexpression of oncogenes, formation of mutagens, induction of atherogenic activity, or inflammation [47]. Oxidative stress is suggested to play a crucial role in the pathogenesis of numerous neurodegenerative diseases like AD, myasthenia gravis, glaucoma and Parkinson's disease [50].

As of late, there has been an upsurge of interest in plant-derived antioxidants because of their ability to break the chain reactions of free radicals [56]. Numerous constituents of herbal extracts have inherent antioxidant properties. Along these lines, reestablishing oxidative equilibrium might be one of the fundamental mechanisms by which therapeutic plants can protect against ageing and cognitive decline. The antioxidant activity of plants might be because of the presence of polyphenolic compounds, for example, phenolic acids and flavonoids [17, 39]. Medicinal plants with remarkable antioxidant and AChE inhibitory properties could therefore offer benefits in the therapy of neurodegenerative diseases.

Nigeria, one of the most important countries in West Africa, is richly blessed with an incredible variety of medicinal plants. Notable among them are *Spondias mombin, Carica papaya and Kalanchoe crenata.* The plants are known by various names but among the Yorubas, *Spondias mombin* is known as Iyeye, *Carica papaya* is known as ibepe and *Kalanchoe crenata* is known as Odundun. They are used independently or in combination with other herbs for the management of neurodegenerative diseases in Nigeria [41, 55]. Industrially, *Spondias mombin* fruit is commercialized as frozen pulp in Brazil where it is utilized for the production of juices, popsicles, ice creams, yogurts and jams [6, 58]. By-products of *Carica papaya* such as pectin and papain are used in the food industry [15]. *Kalanchoe* is a popular genus, typically produced for the floriculture industry. The new variety is suitable for both indoor and outdoor ornamental uses [13, 46].

Spondias mombin has antioxidant, antimicrobial, cardioprotective, antiepileptic and antipsychotic properties [2, 4, 5, 9, 42]. On the other hand, *Carica papaya* leaves have anticancer and muscle relaxant activities [11, 51]. *Kalanchoe crenata* leaves have been reported to demonstrate antioxidant and anticonvulsant effects [8, 40]. However, there is a dearth of information in the literature on the acetylcholinesterase inhibitory and anti-Alzheimer's disease activities of these plants, which could shed more light on their therapeutic potentials against neurodegenerative diseases. Therefore, this study evaluated the antioxidant and anticholinesterase properties of methanol extracts of *Spondias mombin*, *Carica papaya* and *Kalanchoe crenata* and ascertained the strength and direction of the correlation between these properties.

Methods

Chemicals

Thiobarbituric acid (TBA), trichloroacetic acid (TCA), Ellman's reagent (DTNB), N-(1-Naphthyl)ethylenediamine dihydrochloride, neocuproine, 2,4,6-Tris(2-pyridyl)-s-triazine (TPTZ), 2,2-diphenyl-1-picryl-hydrazyl (DPPH), acetylthiocholine iodide and quercetin were obtained from Sigma-Aldrich, USA. Methanol was obtained from Merck (Darmstadt, Germany). The remaining chemicals and reagents used for this study were obtained from other standard sources.

Extraction of plant leaves

Spondias mombin, *Carica papaya* and *Kalanchoe crenata* leaves were obtained from farmlands (Latitude 7° 18′ 15.372″ N and longitude 5° 8′ 13.247″ E; Latitude 7° 18′ 37.076″ N and longitude 5° 15′ 28.789″ E; Latitude 7° 16′ 57.698″ N and longitude 5° 13′ 39.065″ E, respectively) in Akure, Southwest Nigeria, in July 2019. Authentication was carried out at The Federal University of Technology, Akure, Nigeria, and voucher specimens were deposited at the University's herbarium. The leaves were air-dried at 25–30 °C for 2 weeks with relative humidity ranging between 56 and 57%. The dried plant materials were pulverized, and 200 g of each powdered sample was extracted by maceration in 800 mL of 80% methanol for 48 h. The mixtures were filtered, using Whatman (No. 1) filter paper, concentrated and lyophilized to obtain the dry extracts of the plants. The percentage yields were *Spondias mombin* 10.5%, *Carica papaya* 8.5% and *Kalanchoe crenata* 7.0%.

Qualitative and quantitative phytochemical screening

Qualitative and quantitative phytochemical screening were carried out to detect and quantify phytochemicals present in the plant extracts.

Qualitative phytochemical

The preliminary phytochemical studies were performed to identify diverse classes of chemical compounds present in the plant extracts using standard procedures. Test for tannins, alkaloids, anthraquinones, saponins [59], test for flavonoids [54] and test for steroids [23] were performed as previously described.

Determination of total phenolic content (TPC)

Deionized water (0.5 mL) and 125 µL of Folin–Coicalteu reagent were added to 125 µL of extract (1 mg/mL), mixed and then allowed to stand for 6 min before 1.25 mL of a 7% (w/v) Na_2CO_3 solution was added. The reaction mixture was then allowed to stand for an additional 90 min before the absorbance was taken at 760 nm. Various concentrations of gallic acid solutions (6.25, 12.5, 25, 50, 75, 100, 200 µg/mL) were prepared and used to create a standard curve. The amount of total phenolics was expressed as gallic acid equivalents (GAE, mg gallic acid/g sample).

Determination of total flavonoid content (TFC)

The total flavonoid content was determined using a colorimetric method described by [16]. Extracts (1.0 mg/mL), 75 µL of 5% (w/v) $NaNO_2$ solution, 0.150 mL of freshly prepared 10% (w/v) $AlCl_3$ and 0.5 mL of 1 M NaOH solution were added. The final volume was then adjusted to 2.5 mL with deionized water. The mixture was allowed to stand for 5 min, and the absorbance was measured at 510 nm. Various concentrations of quercetin solutions (6.25, 12.5, 25, 50, 75, 100, 200 µg/mL) were prepared and used to create the standard curve. The amount of total flavonoids was expressed as quercetin equivalents (QE, mg quercetin/g sample).

Determination of tannin content

Tannin content of extracts was determined by the Folin–Ciocalteu method [28]. Sample (0.1 mL) was added to a 10-mL volumetric flask containing 7.5 mL of distilled water, 0.5 mL of Folin–Ciocalteu phenol reagent, and 1 mL of 35% sodium carbonate solution and diluted to 10 mL with distilled water. The mixture was thoroughly shaken and kept at room temperature for 30 min. A standard curve was prepared with graded concentrations of tannic acid (6.25, 12.5, 25, 50, 75, 100, 200 µg/mL). The absorbance was measured at 700 nm and tannin content was expressed in terms of mg of tannic acid equivalent/ g of dried sample.

HPLC–DAD fingerprinting

High-performance liquid chromatography (HPLC) was used to identify the presence of phytocompounds in methanolic leaf extracts of *Spondias mombin*, *Carica papaya* and *Kalanchoe crenata.* The samples were dissolved in aqueous acetonitrile (10 mg/20 mL) and mixed vigorously for 30 min. After mixing, the aqueous end was run off while the organic solvent end was collected into a 25-mL standard flask. The analysis was performed on a Shimadzu (NexeraMX) HPLC system fitted with uBONDAPAK C18 column (length 100 mm, diameter 4.6 mm, and thickness 7 µm). The mobile phase consisted of a mixture of an aqueous acetonitrile (acetonitrile/water, 80:20). The flow rate of the sample was 2 mL/min. Compounds were detected by a UV detector (Diode Array Detector, DAD) at 254 nm. The retention times of the identified compounds of interest were measured by standard solution at a concentration of 15.69 mg/g. The extract was injected into the high-performance liquid chromatographic machine to obtain a curve

providing peak area and retention time in a chromatogram. The peak area of the sample was compared with that of the standard relative to the concentration of the standard to obtain the concentration of the sample.

Evaluation of antioxidant and radical scavenging potentials

DPPH (1, 1-diphenyl-2-picrylhydrazyl) radical scavenging activity

The ability of the extracts to scavenge DPPH radical was determined according to the method described by [33]. One mL of 0.3 mM DPPH methanol solution was added to individual extracts and quercetin (6.25–200 µg/mL, 2.5 mL) and allowed to react at room temperature for 30 min in the dark. The absorbance of the resulting mixture was measured at 517 nm and converted to percentage antioxidant activity.

Superoxide radical scavenging activity

The superoxide radical scavenging capacity was determined according to the method of [26]. Tris–HCl buffer (50 mM, pH 8.2, 4.5 mL), 25 mM pyrogallol solution (0.4 mL), sample (1 mL) were mixed together and incubated at 25 °C for 5 min. Then, 1 mL of 8 mM HCl solution was dripped into the mixture promptly to terminate the reaction. The absorbance was measured at 420 nm. Quercetin was used as the reference standard. The superoxide radical scavenging capacity was calculated using the formula:Scavenging capacity%=A0-A1A0∗100where A_0 is the absorbance of the control, A_1 is the absorbance of the sample.

Nitric oxide (NO) scavenging activity

NO scavenging activity was determined as previously described [10]. The reaction mixture (3 mL) containing sodium nitroprusside (10 mM) in phosphate-buffered saline and the extract were incubated at 25 °C for 150 min. Then, 0.5 mL of the reaction mixture was removed, and 0.5 mL of Griess reagent was added. The absorbance of the chromophore formed was measured at 546 nm. The results were expressed as percentage radical scavenging activity.

Hydroxyl radical scavenging activity

A mixture containing $FeCl_3$ (10 mM), ascorbic acid (1 mM), H_2O_2 (10 mM), deoxyribose (28 mM), EDTA (1 mM) and different concentrations of test samples in 500 µL phosphate-buffered saline (PBS, 20 mM, pH 7.4) was incubated for 30 min at 37 °C. After adding 1 mL of trichloroacetic acid (10%, w/v) and 1 mL thiobarbituric acid (2.8% w/v; in 25 mM NaOH), the reaction mixture was boiled for 15 min. After cooling, the extent of oxidation was measured at 532 nm and the scavenging activity of test sample was expressed as the percentage inhibition of the deoxyribose degradation to malondialdehyde [22].

2,2′-Azino-bis-(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) radical scavenging activity

The $ABTS^{\cdot+}$ stock solution was prepared by mixing the two stock solutions (7 mM ABTS solution and 2.45 mM $K_2S_2O_8$ solution) in equal quantities and allowing them to react for 16 h at room temperature in the dark. The working solution was then prepared by mixing 5 mL $ABTS^{\cdot+}$ solution with 145 mL of distilled water to obtain an absorbance of 0.076 ± 0.001 units at 734 nm. Extracts (1 mL) at various concentrations (6.25–200 µg/mL) were allowed to react with 1 mL of $ABTS^{+}$ solution, and the absorbance was measured at 734 nm after 30 min using a spectrophotometer [45]. The percentage scavenging activity was calculated using the formula: scavengingActivity%=Ac-AsAc∗100where A_c is the absorbance of control and A_s the absorbance of the extract.

Fe^{2+} chelating ability

The principle of the assay is based on disruption of *O*-phenanthroline-Fe^{2+} complex in the presence of a chelating agent. The Fe^{2+} chelating ability of the extracts was assayed according to a previously described method [36]. $FeSO_4$ (500 µL, 500 µM) and 200 µL of extract were incubated for 5 min at room temperature, and 500 µL of 1,10-phenanthroline (0.5 mM) was added. The absorbance of the orange-colored solution was read at 510 nm with a spectrophotometer. The in vitro Fe^{2+} chelating ability of the sample is calculated using the formula:Chelating ability% =Ac-AsAc∗100where A_c is the absorbance of control and A_s the absorbance of the extract.

Cupric ion-reducing antioxidant capacity (CUPRAC)

Determination of the cupric ion (Cu^{2+})-reducing ability of the individual extracts was based on a previously described method [7]. $CuCl_2$ solution (0.01 M), 1.0 M ammonium acetate buffer solution and 7.5 mM of ethanol neocuproine solution were added to each test tube containing different concentrations of standard antioxidant (Trolox) or extracts.

Finally, the total volume was adjusted to 2 mL with distilled water and incubated for 30 min at room temperature. Absorbance was measured at 450 nm against a reagent blank.

Ferric-reducing antioxidant power (FRAP)

The assay involved the rapid reduction of ferric-tripyridyltriazine (Fe^{3+}-TPTZ) to ferrous-tripyridyltriazine (Fe^{2+}-TPTZ), a blue-colored product by antioxidants present in sample [12]. FRAP reagent comprising 300 mM acetate buffer (pH 3.6), 100 mM TPTZ in 40 mM HCL solution, and 20 mM ferric chloride (10:1:1) was prepared, and 0.2 mL of each sample was mixed with 1.3 mL of the FRAP stock solution. Absorbance was measured at 620 nm, and FRAP value was extrapolated from a standard curve of Fe^{2+} solution.

Lipid peroxidation inhibitory activity

Brains were obtained from albino rats and homogenized in ice-cold Tris–HCl buffer (20 mM, pH 7.4). The resulting homogenate was centrifuged at 3000 rpm for 10 min to obtain the supernatant. Aliquot (0.5 mL) of the supernatant was added to 0.2 mL extracts of various concentrations (6.25–200 µg/mL), and the volume was made up to 1 mL with distilled water. Then, 0.05 mL of 0.07 mM $FeSO_4$ was added, and the mixture was incubated at 37 °C for 30 min and 1.5 mL of acetic acid (pH 3.5, 20%) was added. Thereafter, 1.5 mL of 0.8% (w/v) TBA in sodium dodecyl sulfate 1.1% (w/v) was added. The mixture was heated at 95 °C for 60 min. Then, the samples were cooled and centrifuged at 3000 rpm for 10 min. The intensity of the pink-colored complex was measured at 532 nm and converted to percentage inhibition of lipid peroxidation [49].

Acetylcholinesterase (AChE) inhibitory activity

AChE inhibitory activity was measured by the colorimetric method of [18]. Rats were decapitated; the brains quickly removed and placed on an ice-cold plate. The brain was weighed and homogenized in cold 10 mM Tris–HCl buffer, pH 7.2, containing 160 mM sucrose. The homogenates were centrifuged at 10,000×*g* for 10 min at 4 °C, and the resulting clear supernatants were used as enzyme sources. Briefly, enzyme in 20 mM phosphate buffer (pH 7.4) was incubated in the presence of 10 mM DTNB solution with different concentrations of each extract. The enzyme reaction was initiated by the addition of 75 mM acetylthiocholine iodide after the pre-incubation times of 0, 1, 2 and 3 min. Substrate hydrolysis was monitored by the formation of a yellow anion of 5-thio-2-nitrobenzoic acid at 415 nm. Enzyme activity was estimated through differences in absorbance/min and the percentage inhibition of AChE.

Prediction of pharmacokinetic properties

Pharmacokinetic properties of natural compounds such as MW (molecular weight), LogP, HBD (number of hydrogen bond donors), HBA (number of hydrogen bond acceptors), TPSA (topological polar surface area), nrtB (number of rotatable bonds), nViolation (violations of Lipinski's rule of five) were predicted using SwissDock Online server (http://www.swissadme.ch/) and Molinspiration Online tool (http://www.molinspiration.com/). The percentage of absorption (% ABS) was calculated using the Zhao et al. formula:%ABS=109-0.3345×TPSA

Molecular docking

The molecular docking study of compounds was performed to evaluate the binding interaction mode in the active site of the AChE enzyme (4EY5) that was obtained from the Protein Data Bank. The binding pocket of the receptor was predicted using DogSite platform of the protein-plus webserver (http://proteinsplus.zbh.unihamburg.de). The protein was prepared by removing co-crystallized ligands and additional water molecules using Pymol 2.5.1. The 3D sdf file of the compounds (Quercetin (CID: 5280343), Kaempferol (CID: 5280863), Ferulic acid (CID: 445858), Lycopene (CID: 446925), Leucocyanidin (CID: 3705436), Gallic acid (CID: 370), Isorhamnetin (CID: 5281654) were obtained from PubChem database and OpenBabel 2.4.1 was used to convert to the pdb format. AutoDock Vina version 1.1.2 was used for molecular docking process. Docking analysis was carried out with the grid size set as 60 ×60×60 with 1.0 Angstrom spacing and Centres *x*, *y* and *z* to be −2.857, −40.075 and 30.865, respectively. The exhaustiveness that determines how comprehensive the software search for the best binding mode was set to the default value of 8 Angstrom. Biovia Discovery Studio 2021 was used for visualization and analyzing of the docking results.

Inhibition constant (Ki)

The inhibition constant (Ki) of all the compounds against AChE was calculated from docking energy using the following equation:KinM=exp$\Delta G \times 1000/RT$

where $T = 298.15$ K, $R = 1.987$.

Correlation analyses

The strength and direction of the relationship between the antioxidant properties and AChE inhibitory activities of the extracts were evaluated statistically.

Statistical analyses

All statistical analyses were performed using the GraphPad version 6 software. Results were expressed as mean ± SEM ($n = 3$). One-way analysis of variance was used for data analysis. Significant differences between groups were detected in the analysis of variance using Duncan's multiple range test at $P < 0.05$. Statistical differences between mean values of individual tests were detected using independent-sample t test. The correlation analyses the GraphPad software.

Results

The phytochemical screening of *Spondias mombin, Carica papaya* and *Kalanchoe crenata* leaves methanolic extract showed the presence of alkaloids, flavonoids, and tannins (Table 1).

Table 1. Phytochemicals detected in methanol extracts of the plants

Test	*Spondias mombin*	*Carica papaya*	*Kalanchoe crenata*
Tannins	+	+	+
Alkaloids	+	+	+
Flavonoids	+	+	+
Anthraquinones	+	+	+
Steroids	+	−	+
Saponins	+	−	+

Key: + indicates present; − indicates absent

The total phenolic content (TPC) of the extracts calculated using the gallic acid regression equation of a calibrated linear curve ($y = 0.0117x + 0.1241$; $R^2 = 0.9916$) is shown in Table 2. The highest TPC value was observed in *S. mombin*, followed by *C. papaya*. Total flavonoid content (TFC) of the extracts was calculated from the regression equation of the calibration curve ($Y = 0.0071x - 0.0901$; $R^2 = 0.9903$) and showed a similar trend to that of TPC. *Spondias mombin* has the highest value (43.86 ± 0.905 mg QE/g) and *K. crenata* the lowest (22.89 ± 0.586 mg QE/g) (Table 2). The TTC of *S. mombin*, *C. papaya* and *K. crenata* was 89.52 ± 1.360, 38.21 ± 0.136 and 18.48 ± 0.156 mg TAE/g of plant extract, respectively, as shown in Table 2.

Table 2. Quantitative estimates of constituent phytochemicals in the plant extracts

Test	*Spondias mombin*	*Carica papaya*	*Kalanchoe crenata*
Total phenols (mg GAE/g)	91.30 ± 0.794^{a}	34.15 ± 0.242^{b}	18.60 ± 0.786^{c}

Total flavonoids (mg QE/g)	43.86 ± 0.905[a]	39.97 ± 0.666[b]	22.89 ± 0.586[c]
Total tannins (mg TAE/g)	89.52 ± 1.360[a]	38.21 ± 0.136[b]	18.48 ± 0.156[c]

Data are expressed as mean ± SEM (n = 3).

GAE gallic acid equivalent, *QE* quercetin equivalent, *TAE* tannic acid equivalent. Values with the same superscript letter in a row are not significantly different (P > 0.05)

Spondias mombin leaf extract HPLC–DAD fingerprinting (Additional file 1: Fig. S1) revealed the presence of phenolic acids (chlorogenic acid, ellagic acid and gallic acid), flavonoids (rhamnetin, isorhamnetin, isoquercetin, quercetin, kaempferol, rutin, isoquercitrin and astragalin), terpenoids (humulene, lupeol and cadinene), and other compounds as shown in Table 3. For *C. papaya* leaf extract, the phytochemicals obtained from the analysis of the chromatogram (Additional file 1: Fig. S2) include carotenoids (β-carotene, lycopene), terpenoid (linalool), sterols (papayaglyceride, glucopaeclin and β-sitosterol), flavonoids (quercetin, kaempferol), and alkaloids (carpaine, sinigrin) (Table 3). The analysis of the HPLC chromatogram (Additional file 1: Fig. S3) of the *K. crenata* leaf extract showed the presence of phenolic acids such as caffeic acid, *p*-coumaric acid, *p*-hydroxycinnamic acid, protocatechuic acid and ferlic acid; flavonoids such as luteolin, quercetin, kaempferol, rutin and leucocyanidin (Table 3). The major chemical class identified in *S. mombin*, *C. papaya* and *K. crenata* leaf extracts was flavonoids with quercetin as predominant compound.

Figure 1 shows the antioxidant activity of the extracts. A clear comparison of the performance of the extracts and the reference compounds as revealed by their IC_{50} values (obtained using inverse logarithmic method) in the different tests is depicted in Table 4. The scavenging activities, metal chelating ability, reducing power and inhibition of lipid peroxidation were in a concentration-dependent manner. *Spondias mombin* was the most effective extract followed by *C. papaya* and then *K. crenata*. The CUPRAC assay shows the effectiveness of *S. mombin* (IC_{50} 24.29 ± 0.165 μg/mL) where its value was clearly superior to that of the reference standard, trolox (IC_{50} 34.77 ± 0.242) and other samples.

Values are presented as mean ± SD ($n = 3$). Values having the same superscript letters are not significantly different ($P < 0.001$)

DPPH 1,1-diphenyl-2-picrylhydrazyl, *ABTS* 2,2′-Azinobis-(3-ethylbenzthiazoline-6-sulphonate), *CUPRAC* Cupric ion reducing antioxidant capacity

The order of AChE inhibitory activity of the extracts followed the pattern established in the antioxidant activity assays. The AChE inhibitory activity of *S. mombin* (53.24 ± 0.327) was the highest, while that of *K. crenata* (70.5 ± 0.426) was the least. The AChE inhibitory activities of the extracts were lower than that of the reference standard, quercetin (20.52 ± 0.112) as shown in Fig. 2.

Fig. 2 [Images not available. See PDF.]

Acetylcholinesterase inhibition activity of *Spondias mombin, Carica papaya and Kalanchoe crenata* leaf extracts

Table 5 shows the correlation analyses of the total flavonoid contents, total phenolic contents, antioxidant activities and AChE inhibitory activities of the extracts, which confirmed a positive association between antioxidant activity and AChE inhibitory activity. The r^2 values have been used to show the relationship between the phytochemical constituents, antioxidant activities and AChE inhibitory activities of the extracts of *Spondias mombin, Carica papaya* and *Kalanchoe crenata.* The total flavonoid and total phenolic contents have extremely significant correlations with the antioxidant activities and AChE inhibitory activities. Table 5 shows that DPPH scavenging activity, NO scavenging activity and lipid peroxidation inhibitory activity all have extremely significant positive correlations with AChE inhibitory activity (r^2 = 0.8295, 0.7337, 0.7214, respectively, P<0.0001). Superoxide radical scavenging activity, hydroxyl radical scavenging activity, ABTS radical scavenging activity and iron chelating ability also have above 50% correlation with AChE inhibitory activity.

Table 5. Correlation coefficients of the total flavonoids, total phenolics, total tannins and acetylcholinesterase inhibitory activity with antioxidant activities of *Spondias mombin*, *Carica papaya* and *Kalanchoe crenata*

Antioxidant test	R^2			
AChE	Total flavonoid	Total phenolic	Total tannin	$DPPH^{\cdot}$ scavenging activity
0.8295	0.6457	0.6177	0.6316	Superoxide radical scavenging activity
0.5485	0.3684	0.9046	0.8654	Nitric oxide radical scavenging activity
0.7337	0.5463	0.8705	0.9074	Hydroxyl radical scavenging activity

Correlation is significant at the 0.05 level (one-tailed)

DPPH 1,1-diphenyl-2-picrylhydrazyl, *ABTS* 2,2′-Azinobis-(3-ethylbenzthiazoline-6-sulphonate), *CUPRAC* Cupric ion reducing antioxidant capacity. R^2 coefficient of determination

The results of the predicted pharmacokinetic properties for selected phytochemicals (quercetin, kaempferol, ferulic acid, lycopene, leucocyanidin, gallic acid and isorhamnetin), the TPSA and %ABS are presented in Table 6. According to the Lipinski's rule of five, drug compounds must have molecular weight <500, hydrogen-bond donors <5, hydrogen-bond acceptors <10, partition coefficient (log *P*) value not greater than 5 and not more than one rule can be violated by an orally active drug. Among the selected phytochemicals, only lycopene violated the rule. With the exception of lycopene, ferulic acid has the lowest TPSA (66.76 Å) while the highest TPSA is observed in quercetin (131.36 Å). Quercetin, kaempferol, ferulic acid, lycopene, leucocyanidin, gallic acid and isorhamnetin also show similar pharmacokinetic properties when compared to rivastigmine commonly prescribed for AD patients.

Table 6. Predicted pharmacokinetic properties of selected compounds

Compound	Formular	Molecular weight (g/mol)	Log P	HBA	HBD	TPSA	%ABS	nAtom	nRB	nViolation
Quercetin	$C_{15}H_{10}O_7$	302.24	1.23	7	5	131.36	65.06	22	1	0
Kaempferol	$C_{15}H_{10}O_6$	286.24	1.58	6	4	111.13	71.83	21	1	0
Ferulic acid	$C_{10}H_{10}O_4$	194.18	1.36	4	2	66.76	86.69	14	3	0
Lycopene	$C_{40}H_{56}$	536.89	9.98	0	0	0	109.00	40	16	2
Leucocyanidin	$C_{15}H_{14}O_7$	306.27	0.11	7	6	130.61	65.31	22	1	1

Gallic acid	$C_7H_6O_5$	170.12	0.21	5	4	97.98	76.23	12	1	0
Isorhamnetin	$C_{16}H_{12}O_7$	316.26	1.65	7	4	120.36	68.74	23	2	0
Rivastigmine	$C_{14}H_{22}N_2O_2$	250.34	2.34	3	0	32.78	98.03	18	6	0

Log P Octanol/water partition coefficient, *HBA* hydrogen bond acceptor, *HBD* hydrogen bond donor, *TPSA* topological surface area, *%ABS* % absorption, *nAtom* number of atoms, *Nrb* number of rotatable bonds, *nViolation* number of violation. There was no violation of the Lipinski's rule

DogSite platform of the protein-plus server was used to predict the active site of AD target (4EY5). The predicted druggable pocket of the co-crystallized ligand in 4EY5 are Trp86, Tyr337, Tyr133, Tyr337 and Gly121. These amino acids were selected for the binding of all the selected phytochemicals. Figure 3 and Table 7 show the top docked binding pose of the selected phytochemicals; quercetin (−9.1 kcal/mol), kaempferol (−8.6 kcal/mol), ferulic acid (−7.3 kcal/mol), lycopene (−15.1 kcal/mol), leucocyanidin (−7.8 kcal/mol), gallic acid (−7.2 kcal/mol) and isorhamnetin (−8.2 kcal/mol). Although lycopene showed very good binding affinity, it was not considered for further docking analysis because it does not comply with the Lipinski's rule of five. The binding of rivastigmine to the predicted site on 4EY5 shows a binding affinity of −6.9 kcal/mol (Table 7). This implies that the selected phytochemicals showed high affinity toward 4EY5 as compared to rivastigmine commonly prescribed for AD patients. The 2D interactions by Biovia Discovery Studio 2021 are presented in Fig. 4, and parameters such as hydrogen bond, distance, hydrophobic interactions, *π*-interactions and inhibitory constant are presented in Table 7. The orientation of each of these phytochemicals resembles that of the native ligand. The selected compounds and rivastigmine (Fig. 5) showed similar binding interactions with the amino acids on analysis. The interactions were prominently observed in the region of Tyr337 and Trp86 amino acid residues due to the pronounced existence of the pi-cation interaction at the catalytic anionic site.

Fig. 3 [Images not available. See PDF.]

3D Binding interaction of 4EY5 with **a** Quercetin **b** Kaempferol **c** Ferulic acid **d** Lycopene **e** Leucocyanidin **f** Gallic acid and **g** Isorhamnetin

Table 7. Summary of docking results

Compound	Binding affinity (kcal/mol)	Inhibition constant (Ki) (nM)	No. of H bond formed	No. of hydrogen bond interaction residues	Distance	Hydrophobic interaction	Residues forming π-interactions
Quercetin	−9.7	7.76E−08	2	Gln71, Tyr133	2.36 and 2.76	Ser125, An87, Pro88, Leu130, Tyr337, Gly126, Glu202, Val73, Gly120, Gly121 and Asp74	Trp86, Tyr337 and Asn87

Discussion

Plants as a potential source of drugs for the management of clinical disorders have been extensively studied over the past few years. The limitations and side effects of drugs in current use for the management of AD and other dementias warrant search for more effective therapeutic agents [19]. A gradual decrease of acetylcholine levels, arising from the loss of the cholinergic synapses and reactive oxygen species production, play an important role in the pathogenesis of AD [20]. Therefore, plants and phytochemicals with antioxidant activity and the ability to balance acetylcholine levels will be potentially useful in the management of AD. These considerations necessitated the phytochemical investigation, and evaluation of the antioxidant and anticholinesterase activities of the three medicinal plants popularly used in traditional herbal medicine in Nigeria for the treatment of brain-related disorders. Phytochemicals such as tannins, alkaloids, flavonoids, anthraquinones, steroids and saponins detected in the extracts are bioactive agents. These phytochemicals have demonstrated activities such as inhibition of

neuroinflammation and oxidative stress, maintenance of neurotransmitter balance, antiapoptosis and mitochondrial stabilization in the brain [61].

The analysis of the chromatograms obtained from the three plant validates the presence of various phytocompounds like phenolic acids, flavonoids and terpenoids. Flavonoids were the preponderant phytochemicals in the extracts. Flavonoids, for example, quercetin and kaempferol, are viewed as having powerful cell reinforcement property that are helpful in the avoidance of different oxidative stress-related diseases including neurodegenerative disorders, for example, AD [34].

The presence of polyphenolics (which includes phenolic acids, flavonoids and tannins) in plants has a direct relation with their antioxidant and radical scavenging properties [29]. The antioxidant activity of polyphenols is influenced by the presence of free hydroxyl groups. Several mechanisms have been demonstrated for the antioxidant activity of polyphenols. These include free radical scavenging, inhibition of lipid peroxide formation, metal chelation, and reductive ability. The notable activities of the extracts under consideration in the in vitro tests which covered different mechanisms of antioxidant protection are an allusion to their potential therapeutic efficacy.

The oxidation of pyrogallol forms superoxide anions (a purple solution). It reacts with proton in solution and form hydrogen peroxide. Hydrogen peroxide is an important substrate that produce singlet oxygen and hydroxyl radicals. Superoxide anion is a major reactive oxygen species that leads to the oxidation of cells and tissues [21, 53]. *Spondias mombin*, *C. papaya* and *K. crenata* leaves extracts inhibited pyrogallol autoxidation in a dose-dependent manner, thereby reducing the probability of peroxide formation. Also, a number of physiological processes need nitric oxide during metabolism. Abnormalities in NO production, that is high concentration of NO, has been linked to different diseases [57]. The toxicity of NO increases greatly when it reacts with superoxide radical, forming the highly reactive peroxynitrite anion ($ONOO^-$) [62]. The NO scavenging activity of the extracts buttresses their potential to limit oxidant-mediated damage.

Hydroxyl radical is the leading cause of oxidative biological damage such as protein disulfide bond breakage or denaturation, which results in unfolding and refolding of proteins into abnormal spatial configurations, and it is observed in neurological disorders [44, 52]. The results of the present study showed that *S. mombin*, *C. papaya* and *K. crenata* leaf extracts are effective hydroxyl radical scavengers, indicating that they can prevent or mitigate brain oxidative biological damage.

Lipid peroxidation is a chief feature of many pathologies including AD. Many studies have demonstrated increased lipid peroxidation in brain of patients with AD [38, 43]. Damage to cell membrane generates a number of degraded products which is associated with lipid peroxidation. A major degraded product of lipid peroxidation is malondialdehyde [24]. The significant lipid peroxidation inhibitory activity of *S. mombin*, *C. papaya* and *K. crenata* leaf extracts is a further reflection of their medicinal potential.

A promising management of neurological and neurodegenerative disorders such as AD and senile dementia is linked to acetylcholinesterase enzyme inhibition [19]. The enzyme is important in the breakdown of acetylcholine, and inhibition of the enzyme leads to increase in the concentration of acetylcholine and increase in communication between the brain nerve cells [62]. The anti-acetylcholinesterase activity shown by the extracts in this study suggests that the plants are potential sources of effective compounds that can stimulate an increase in acetylcholine level in AD and other dementias. Plants that possess high phenolic content have also been reported to inhibit AChE activity [3]. Therefore, the inhibitory effect of the extracts on AChE activity may be linked to their phenolic components. The Pearson correlation coefficients of the total phenolic and flavonoid contents, and the antioxidant activities obtained in this study buttresses this point. The Pearson correlation coefficients obtained in the present study also show that the polyphenolic contents and antioxidant activities of the extracts have strong positive correlations with the AChE inhibitory activity.

Alzheimer's disease (AD) is the most prevailing neurodegenerative disease in the ageing population. Two major factors involved in the pathogenesis of AD are oxidative stress and reduction in brain acetylcholine level. *Spondias mombin*, *C. papaya* and *K. crenata* leaf extracts demonstrated positive correlation between their remarkable antioxidant and anticholinesterase inhibitory effects supporting their traditional use in managing brain-related

disorders and indicating their potential usefulness in the treatment of AD. However, further investigations are necessary in in vivo and clinical settings to establish the promising in vitro effects.

Lipinski's rule of five assists in evaluating the pharmacokinetic properties and bioavailability of oral drugs. According to the rule, a violation of more than one rule is an indication of poor bioavailability. The TPSA reflects the phytochemicals' hydrophilicity and is important in protein–ligand interaction. Generally, druggable compounds with TPSA less than 140 Å and the number of rotatable bonds less than 10 have good oral bioavailability [60].

Molecular docking is the process by which 2 molecules fit together in 3-dimensional space; it is a key tool in structural biology and computer-aided drug design [30]. The best pose of each compound is always selected based on their best conformation that allows the lowest free binding energy and analyzed for further interaction of the docked structure [27]. Quercetin, kaempferol, ferulic acid, leucocyanidin, gallic acid and isorhamnetin fit into the active site of 4EY5, and the binding affinity between these phytochemicals and AChE (4EY5) is stabilized by non-covalent bonds, which includes hydrogen bond, hydrophobic bond and pi-interactions. Hydrogen bonds play a crucial role in enzyme catalysis, protein–substrate and protein–inhibitor complexes, and the structural stability of various biological molecules [37]. Pi–pi stacking observed in most of the interactions is formed between the phenyl ring of the phytochemical and the amino acid residues. Pi–pi interactions are a type of non-covalent interaction pivotal to biological events such as protein–ligand recognition by providing a significant amount of binding enthalpy [35]. The results of the molecular docking and pharmacokinetic studies showed that quercetin, kaempferol, ferulic acid, leucocyanidin, gallic acid and isorhamnetin fulfill the requirements for an anti-Alzheimer's disease drug, such as ADMET, non-toxicity, binding affinity, inhibition constants, antioxidant and neuroprotective inhibitory properties and good interaction with Alzheimer's disease-associated target. Thus, these six phytochemicals from *S. mombin*, *C. papaya* and *K. crenata* leaf extracts with antioxidant activity, inhibitory and neuroprotective activities may be considered an anti-Alzheimer's disease drug agents.

Conclusions

This study reveals that *Spondias mombin*, *Carica papaya* and *Kalanchoe crenata* methanol leaf extracts provide a significant source of secondary metabolites that act as natural antioxidants and acetylcholinesterase inhibitors, which will be helpful in the treatment of Alzheimer's disease.

Unlocking the power of precision medicine: exploring the role of biomarkers in cancer management

Gadade, Dipak D.1 ; Jha, Hariom1; Kumar, Chetan1; Khan, Farzan11 Delhi Skill and Entrepreneurship University, Government of NCT Delhi, Department of Pharmacy, DSEU Dwarka Campus (Formerly Integrated Institute of Technology), New Delhi, India

ABSTRACT (ENGLISH)

Background

Personalized or Precision medicine (PM) is a promising approach for the cancer treatment that tailors treatment to a patient's characteristics. Biomarkers are crucial for identifying the patients who are expected to derive greatest advantage from targeted therapy.

Main body

Here, various biomarkers, including genetic, epigenetic, protein, and metabolites, and their clinical significance, are discussed. The review provides insights into the use of biomarkers and their clinical significance in cancer treatment. There are several hurdles in use of PM in oncology, such as the complexity of tumor biology and heterogeneity, limited availability of biomarkers, high cost of targeted therapies, resistance to targeted therapies, and ethical and social issues.

Conclusion

The biomarkers play a crucial diagnostic role in the treatment of cancer. The review also acknowledges the challenges and limitations of personalized medicine which, if resolved, can be helpful in the management of cancer.

FULL TEXT

Background

The old concept “One size fit for all” is now turned into an individualized tailormade approach to personalized or precision medicine (PM). Cancer is a complex and heterogeneous disease that is responsible for a significant proportion of morbidity and mortality worldwide. Despite decades of research, the management of cancer remains a significant challenge due to the diverse biological and genetic characteristics of tumors. Since it is based on the distinct molecular characteristics of each patient's tumor, PM has revolutionized cancer treatment. PM has shown promise in improving treatment outcomes and reducing toxicities associated with traditional chemotherapy. As PM continues to evolve, more effective and targeted therapies will likely emerge in near future, offering hope for patients with previously incurable cancers [1].

National Human Genome Research Institute, U.S. has defined PM as, “an emerging practice of medicine that uses an individual’s genetic profile to guide decisions made regarding the prevention, diagnosis, and treatment of disease.” It is a medical model that considers individual patients characteristics, including genetic, environmental, as well as lifestyle [2]. PM is particularly important because cancer is a complex disease that can vary significantly from individual to individual. What works for one patient may not work for another, and what causes cancer in one person may not be the same as what causes it in another [3]. Figure 1 depicts points which give a brief idea of why PM is important.

Fig. 1 [Images not available. See PDF.]

Characteristics of PM

PM is an approach to medical treatment that considers the individual patients’ medical needs. To examine the distinct genetic and molecular characteristics of each patient's cancer, the method makes use of a variety of technologies and instruments. The PM approach in oncology involves collaborative efforts among healthcare workers including physicians, radiation oncologists, surgeons, nursing staff, pharmacists, etc. This team works together to gather all the necessary information about the patient's cancer and with the use of that information to design a personalized treatment plan [4].

Main text

Definition of biomarkers and their role in oncology

Biomarkers are defined as, “measurable indicators of normal or abnormal biological processes, and they can be

used to diagnose diseases, monitor disease progression, and guide treatment decisions." In oncology, biomarkers can also be used to identify subtypes of cancer that may have different treatment requirements. A well-known example is breast cancer which can be classified into different subtypes based on the presence or absence of certain biomarkers, such as estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2). This information can be used to guide treatment decisions, such as whether to use hormone therapy or chemotherapy [5]. The biomarker test is also referred to as 'liquid biopsy'. Biomarkers are molecules that can be found in blood, tissue, or other bodily fluids that can indicate the presence or severity of a particular disease [6].

Targeted therapy, on the other hand, is a type of cancer treatment that specifically targets cancer cells, while sparing healthy cells. Biomarkers play a critical role in the development of targeted therapies by identifying the specific molecular targets that are involved in cancer growth and progression [7]. The growing interest in the use of biomarkers in PM is revealed in PubMed database Search shown in Fig. 2. Using these tools to identify the specific molecular pathways that are involved in cancer growth and progression, researchers and doctors can develop more effective and targeted treatments for patients with cancer. As we continue to learn more about cancer and its underlying causes, biomarkers and targeted therapy will become even more important in the fight against this devastating disease [8].

Pubmed® Search using MeSH, "Precision medicine and Biomarkers" (till 22 Sept. 2023)

Different types of biomarkers

There are several different types of biomarkers which include genetic biomarkers, epigenetic biomarkers, metabolite biomarkers and protein biomarkers. Once a biomarker has been identified, researchers can use that information to develop therapies that specifically attack the molecular pathways that are involved in cancer growth and progression [9]. Several different types of biomarkers that can be used in medicine, each with its usage and examples shown in Table 1.

Table 1. Biomarkers used in cancer

Type of biomarker	Description	Usage	Examples
Genetic biomarkers	Mutations or other genetic abnormalities specific to certain diseases	Identifying patients who are more likely to respond to targeted therapies for cancer, such as the EGFR (epidermal growth factor receptor) mutation in lung cancer	MutL protein homolog 1 (MLH1), MutS homolog 2/6 (MSH2/6), PMS1 homolog 2 (PMS1/2), Breast cancer type ½ (BRCA1/2), Kirsten rat sarcoma viral oncogene homolo (KRAS), Tumor protein p53 (TP53), etc.
Epigenetic biomarkers	Changes in gene expression associated with disease	Diagnosing and treating cancer, such as the DNA methylation in breast, lung and colon cancer	Histone modification, Non-coding RNAs, Chromatin accessibility, MicroRNA expression
Protein biomarkers	Proteins produced by disease cells that can be detected in the blood or tissue of patients	Monitoring the progression of cancer	C-reactive protein (CRP), Troponin, Cancer antigen 125 (CA-125), HER2, B-type natriuretic peptide (BNP)

Metabolite biomarkers	Produced during metabolism and associated with tumor growth	Used as a biomarker for the diagnosis and monitoring of lung, pancreatic, thyroid, breast and hepatic cancer	Palmitic acid, Cholesterol, Lactate, Creatinine, Triglycerides, Urea, Ketone bodies
Transcriptome biomarkers	Changes in the expression of RNA molecules that are indicative of cancer	Differentiate types of cancers, Identify molecular targets for cancer	Immune-related genes (CD8A, IFNG), Non-coding RNA molecules (microRNAs, long non-coding RNAs-), Splice variants of RNA

Genetic biomarkers

Genetic mutations or other genetic abnormalities that are specific to certain diseases. Genetic biomarkers can serve as a clinical guide for treatment selection customized for the patients. Patients with certain genetic mutations may benefit from targeted therapies that specifically target the molecular pathways that are involved in cancer.

There are several types of genetic biomarkers for cancer, including:

Oncogenes Oncogenes are genes that can cause cancer when they are overactive or mutated and are depicted in Fig. 3. Proto-oncogenes are normal genes that allow cells growth and division or allow them to thrive [10]. However, when a proto-oncogene undergoes a mutation, it can become an oncogene, which is activated when it should not be. Oncogenes are like gas pedals that are stuck down, causing cells to divide uncontrollably, leading to the development of cancer. Different factors such as gene variants, epigenetic changes, chromosome rearrangements, and gene duplication can turn on oncogenes in cells. These factors cause changes in the DNA or RNA sequence, chemical groups attached to genetic material, or extra copies of a gene, leading to the production of too much protein that drives uncontrolled cell growth. Eg. HER2, BRAF, c-KIT, NF1 and KRAS [10].

Fig. 3 [Images not available. See PDF.]

Normal and mutated Oncogenes (Courtesy-National Human Genome Research Institute https://www.genome.gov/)

Tumor suppressor genes Tumor suppressor genes are those genes that normally help to prevent cancer by regulating cell growth and division. The mutated genes lead to cancer as shown in Fig. 4. Tumor suppressor genes act as brake pedals in cells, slowing down cell division to prevent excessive growth. The deactivation of tumor suppressor genes can cause carcinogenesis. While the majority of mutations are acquired, some types of cancer are passed down through families due to abnormalities in tumor suppressor genes. More than 50% of all cancers are caused by mutations in the TP53 gene, which makes the p53 protein. These mutations can occur in many different types of cancer. Other such genes includes TP53, BRCA1, and BRCA2, etc. [11].

Fig. 4 [Images not available. See PDF.]

Normal and mutated tumor suppressor genes (Courtesy-National Human Genome Research Institute https://www.genome.gov/)

DNA repair genes DNA repair genes are involved in repairing DNA damage that can lead to cancer. Mutations in these genes can increase the risk of developing cancer. During cell division, errors may occur while copying the DNA, and DNA repair genes help to identify and repair these mistakes or trigger cell death if they can't be fixed. When DNA repair genes don't function properly, mistakes can accumulate, which may lead to uncontrolled cell growth. Changes in DNA repair genes can be inherited or acquired, just like other types of gene mutations. The BRCA1 and BRCA2 genes are examples of DNA repair genes that, when mutated, increase the risk of certain cancers, especially breast and ovarian cancer. However, mutations in these genes can also occur in tumor cells of individuals who did not inherit them. Eg. MSH2 and MLH1 [10].

Microsatellite instability (MSI) MSI is a biomarker that indicates a defect in a short segment of DNA leading to an

increased risk of cancer development. MSI are prone to errors during DNA replication and repair. MSI is commonly seen in certain types of cancer, such as colorectal, gastric, breast, thyroid, and prostate cancers, cholangiocarcinoma, leukaemia, endometrial carcinoma, pancreatic ductal adenocarcinoma, etc. It can be further classified as MSI-low and MSI-high. However, currently, MSI-low and microsatellite stability are considered the same. Further details are reviewed by Baudrin et al. [12] and Li et al. [13] MSI can be detected using next generation sequencing, immunohistochemistry and single molecule inversion probes having accuracy more than 90%. However, fluorescent multiplex polymerase chain reaction and capillary electrophoresis are referred as gold standard for MSI detection having accuracy 100%. Flurouracil, nivolumab, ipilimumab, pembrolizumab, and bevacizumab are reported to be useful in colorectal cancer with MSI [13].

Epigenetic biomarkers

Epigenetic biomarkers measures variation in disease or drug associated epigenic expressions that can also be used to identify disease. Epigenetic biomarkers are particularly useful in the diagnosis and treatment of cancer. The DNA molecules and the proteins that interact with DNA can undergo chemical modifications that influence the activation and deactivation of genes. These modifications can be passed on from one cell to another during cell division, and they can also be passed from one generation to the next. All epigenetic changes that occur in a genome are referred to as an epigenome [14]. Some epigenic biomarkers are discussed below.

DNA methylation

DNA methylation is a common epigenetic modification that involves the addition of a methyl group to DNA. Methylation of CpG islands, which are often located in the promoter regions of genes, can lead to gene silencing. Aberrant DNA methylation patterns have been observed in many types of cancer, including breast, lung, and colorectal cancer [15].

Histone modifications

Histone proteins, which package DNA in the nucleus, can be modified by the addition or removal of chemical groups. These modifications can alter the accessibility of DNA to the transcriptional machinery and can affect gene expression. For example, acetylation of histones is generally associated with gene activation, while deacetylation is associated with gene silencing. Changes in histone modifications have been observed in many types of cancer, including leukaemia, prostate, liver, and lung cancer [16, 17].

Protein biomarkers

These are other types of biomarkers that can be used in medicine. Protein biomarkers are specific proteins that are produced by disease cells and can be detected in the blood or tissue of patients with the disease. Protein biomarkers are particularly useful in the diagnosis and monitoring of cancer. Certain proteins such as PSA, CA-125, HER2, CEA, etc. may be overexpressed in cancer cells, and monitoring the levels of these proteins in the blood or tissue of patients can help a physician to track the progression of the disease [18].

Metabolite biomarkers

These are small molecules that are produced by cellular metabolism, and they can be detected in biological samples such as blood, urine, or tissue. Metabolite biomarkers could be a useful tool for the diagnosis of lung, pancreatic, thyroid, breast and hepatic cancer, etc. as they offer a non-invasive and cost-effective approach to disease detection. The diagnostic accuracy of metabolite biomarkers could be further improved by combining multiple biomarkers into a single diagnostic test [19].

Nucleotide metabolites

Nucleotide metabolites are involved in DNA synthesis and repair, and their levels can be altered in cancer cells. The increased levels of deoxythymidine monophosphate (dTMP) and decreased levels of inosine monophosphate (IMP) have been observed in breast cancer cells. Antimetabolites targeted toward Thymidylate synthase, Dihydrofolate reductase and Glycinamide ribonucleotide formyl transferase are used in clinical practice [20].

Amino acid metabolites

Amino acid metabolites are involved in protein synthesis and energy production, and their levels can be altered in cancer cells. The increased levels of alanine and decreased levels of glutamate have been observed in lung cancer

cells. Higher levels of Kynurenine are observed in lung and ovary cancer while Hydroxyproline has been related to hepatic cancer [21].

Lipid metabolites

Lipid metabolites are involved in cell membrane structure and function, and their levels can be altered in cancer cells. Increased levels of phosphocholine and decreased levels of phosphatidylcholine have been observed in breast cancer cells. Targeting Stearoyl CoA-desaturase can benefit in gastric cancers and it is also associated with hepatic cell cancer. High levels of phospholipase A2 are associated with colorectal cancer [22].

Carbohydrate metabolites

Carbohydrate metabolites are involved in energy production and cell signaling, and their levels can be altered in cancer cells. The increased levels of lactate and decreased levels of glucose have been observed in many types of cancer cells. Glycoproteins antigens such as CA19-9, CA125, and α-fetoprotein are found to have diagnostic potential in colon carcinoma and ovarian cancer. Iminosugars such as swainsonine, Castano spermine, siastatin B, etc. reported to exhibit antitumor effects [23].

Transcriptome biomarkers

It refers to the group of biomarkers that are identified based on changes in gene expression patterns. Transcriptome biomarkers can be used to understand disease progression, drug efficacy, and patient response to treatment. By analyzing the changes in gene expression between different conditions, researchers can identify specific genes or sets of genes that are upregulated or downregulated [24]. Two types of transcriptome biomarkers are discussed below.

mRNA expression biomarkers

The oncotype DX test measures the expression of twenty genes in breast cancer tissue and is used to envisage the recurrence and the possible benefit of chemotherapeutic treatment. *PAM50* test is used as a tool to check the expression of fifty genes and it serves to classify breast cancer based on prognosis and treatment outcomes. *Mammaprint* is another test that is used to check seventy genes expression in breast cancer tissue and is used to predict the risk of recurrence and the potential benefit of chemotherapy [25].

Decipher gene expression test measures the genetic expression in prostate tumor and serve as tool to identify recurrence and effects of radiation therapy. The test score as shown in Fig. 5 is useful in the prediction of risk of prostate cancer [26].

Fig. 5 [Images not available. See PDF.]

Decipher scores and risk of metastasis and death from prostate cancer

Non-coding RNA biomarkers

Non-coding micro-RNA biomarkers viz*. MiR-21, MiR-155* and long non-coding biomarkers HOTAIR, MALAT1, etc. are known to be upregulated in many types of cancer, including breast, lung, liver, and colorectal cancer. These are used as a tools to determine tumor progression invasion and metastasis [27, 28].

These biomarkers all have unique strengths and limitations, and can be used in different ways to diagnose, monitor, and treat a wide range of diseases. By identifying the specific biomarkers associated with a particular disease, doctors can develop more personalized treatment plans for their patients.

Imaging biomarkers (IB)

IB are integral part of routine cancer management serving as indispensable tool in the standard care of the cancer patients and clinical decision making. The key techniques used as IB are magnetic resonance imaging (MRI), positron emission tomography (PET), computed tomography scan and ultrasound imaging. These techniques provide information about patient health, diagnosis, disease progress and response to the treatment. The quantifiable characteristics including size, shape, density, texture, and functional information of the tumor allows the healthcare providers to tailor the treatment plans [29]. Artificial intelligence can be trained using a prior database of IB to redefine the biomedical imaging as a clinical decision making tool and to improve diagnostic precision [30, 31].

Spotlight on biomarkers in cancer

HER2 in breast cancer

HER2 protein is overexpressed in approximately 20% of breast cancers, and its overexpression is associated with a more aggressive form of the disease. HER2 plays a critical role in breast cancer development and progression. HER2 overexpression can lead to abnormal cell signaling, increased cell proliferation, and decreased apoptosis (programmed cell death). It all contribute to tumor growth and spread. HER2 has also been identified as a target for breast cancer treatment. Drugs that target HER2, such as trastuzumab and pertuzumab, have been shown to be effective in the treatment of HER2-positive breast cancer. Additionally, nelipepimut-S vaccine trastuzumab–emtansine conjugate is also strategically employed in clinical setting against HER2. However, it is worth to noting that trastuzumab–deruxtecan is known to cause hematological effects, hepatic toxicity and gastrointestinal toxicity. In some cases pulmonary toxicity with it caused death [32].

Furthermore, tyrosine kinase (TK) inhibitors designed to inhibit HER2 were also developed. Lapatinib and pyrotinib are reversible while neratinib and tucanib are irreversible TK inhibitors. These drugs can be prescribed for advanced breast cancer [33].

EGFR in non-small cell lung cancer (NSCLC)

EGFR mutations are present in approximately 10–15% of NSCLC cases, with the majority of these mutations being exon 19 deletions or exon 21 L858R substitutions. These mutations lead to the activation of the EGFR pathway, which plays a critical role in the development and progression of NSCLC. Targeted therapies that inhibit EGFR activity, such as gefitinib, erlotinib, and afatinib, have been developed and are effective in treating NSCLC patients with EGFR mutations. However, resistance to these drugs can develop over time, and alternative therapies are needed. Osimertinib is a third-generation EGFR inhibitor that is effective in treating NSCLC patients with EGFR mutations, including those with resistance to first-generation EGFR inhibitors. It may be a more effective than the first-line treatment option for NSCLC patients with EGFR mutations [34].

Raf murine sarcoma viral oncogene homolog B (BRAF) in melanoma

BRAF mutations are present in approximately 50% of melanoma cases and lead to the activation of the Mitogen-activated protein kinase (MAPK) signaling pathway, which plays a critical role in the development and progression of melanoma. BARF mutations can cause unstoppable cell division which may lead to tumor formation. BRAF V600E is a very commonly observed type of mutation where mutations occur in valine (V) and glutamic acid. It is useful as a prognostic marker in the detection of malignancies. BARF mutations are a reason for adenocarcinoma in nonsmoking as well as women population [35]. Its testing is suggested in metastatic colorectal cancer [36].

Targeted therapies that inhibit BRAF activity, such as vemurafenib, dabrafenib, and encorafenib, have been developed and are effective in treating melanoma patients with BRAF mutations. However, resistance to these drugs can develop over time, and alternative therapies are needed. In addition, targeted therapy can also lead to adverse events, such as skin toxicity and the development of secondary malignancies. The development of combination therapies that target multiple pathways, the use of immunotherapy to enhance the immune response to melanoma, and the identification of biomarkers that can predict response to targeted therapy and help guide treatment decisions. The identification of predictive biomarkers, such as baseline lactate dehydrogenase levels, can also help guide treatment decisions and improve patient outcomes [37].

BRCA1/2 mutations

BRCA1/2 are genes that are involved in DNA repair. Mutations in these genes increase the risk of developing breast and ovarian cancer. Testing for BRCA1/2 mutations can help identify individuals who are at high risk of developing these cancers and may benefit from early screening and preventive measures. Breast cancer that is associated with BRCA1/2 mutations may respond better to certain types of chemotherapy, such as platinum-based drugs. Additionally, some targeted therapies, such as poly ADP-ribose polymerase (PARP) inhibitors, have shown promise in treating breast and ovarian cancers that are associated with BRCA1/2 mutations. In cells with BRCA1/2 mutations, PARP inhibitors can lead to the accumulation of DNA damage and ultimately cell death. PARP inhibitors have been approved for the treatment of certain types of ovarian and breast cancers that are associated with BRCA1/2 mutations. PARB inhibitors olaparib, rucaparib, and niraparib are approved for cancer treatment [38, 39].

Clinical significance of biomarker-based PM

Biomarkers are measurable indicators of physiological or pathological processes, and their use in PM allows for tailored treatment strategies based on individual patient characteristics. The clinical significance of PM is summarized in Fig. 6. Biomarker-based PM has significant clinical significance in cancer treatment. Biomarkers help identify patients who are most likely to respond to specific therapies, enabling clinicians to select the most appropriate treatment for an individual patient. Biomarker-based PM can also help reduce the use of ineffective treatments, saving patients from unnecessary toxicity and healthcare costs. Biomarker-based PM can also help reduce the use of ineffective treatments, saving patients from unnecessary toxicity and healthcare costs. For example, testing for KRAS mutations in colorectal cancer can identify patients who will not benefit from anti-EGFR therapy such as cetuximab [40].

Fig. 6 [Images not available. See PDF.]

Clinical significance of biomarkers at different stages of cancer

Screening

Biomarkers can be used in cancer screening to identify individuals who may be at increased risk of developing cancer. The elevated levels of PSA in the blood can be a sign of prostate cancer and may prompt further testing. Other biomarkers, such as carcinoembryonic antigen (CEA), can be used to monitor the response to treatment in patients with certain types of cancer [41]. It is reported that Circulating tumor DNA (ctDNA) such as EGFR, KRAS or BRAF and protein biomarkers like CA125, CEA, etc. in addition to screening may be helpful in monitoring response in lung cancer patients [42].

Differential diagnosis

Liquid biopsy can help distinguish between different types of cancer or between cancer and non-cancerous conditions. Testing for the presence of specific gene mutations, such as EGFR mutations in lung cancer, can help determine the appropriate treatment for the patient. Elevated levels of PSA in the blood can be a sign of prostate cancer, but can also be elevated in non-cancerous conditions such as benign prostatic hyperplasia (BPH) or prostatitis. CA-125 is often used as a biomarker for ovarian cancer, but it can also be elevated in other conditions such as endometriosis or fibroids. CEA can be elevated in a variety of cancers, including colon, lung, and pancreatic cancer, but can also be elevated in non-cancerous conditions. ALK gene rearrangements are commonly found in NSCLC, but can also be present in other types of cancer, such as anaplastic large-cell lymphoma [43, 44].

Cancer classification

Biomarkers can also be used to classify different types of cancer based on their molecular characteristics. Breast cancer can be classified into different subtypes based on the expression of certain genes, such as ER and HER2. This information can be used to guide treatment decisions and predict the response to therapy. BRAF mutations are used to classify melanoma as either BRAF-mutant or BRAF-wildtype. MSI is used to classify colorectal cancer as either MSI-high or MSI-low/microsatellite stable [45].

Prognosis

Biomarkers can provide important information about the likely course of the disease and the patient's chances of survival. Testing for the expression of certain genes, such as the Oncotype DX gene panel in breast cancer, can help predict the likelihood of cancer recurrence and guide treatment decisions. Ki-67 is a protein that is present in rapidly dividing cells and is commonly used as a biomarker of tumor proliferation. High levels of Ki-67 expression and mutations in the p53 gene are associated with poorer outcomes in breast cancer, lung cancer, and other types of cancer [46].

Cancer prediction and treatment stratification

Biomarkers can be used to predict the likelihood of developing cancer or to stratify patients into different treatment groups based on their risk profile. Genetic testing for mutations in the BRCA1/2 genes can help identify individuals who are at increased risk of developing breast and ovarian cancer and may benefit from more frequent screening or prophylactic surgery. BCR-ABL gene fusion is associated with chronic myelogenous leukemia (CML) and can be

targeted with tyrosine kinase inhibitor therapy, which has dramatically improved outcomes for CML patients. PD-L1 testing can help predict which patients are likely to respond to immune checkpoint inhibitor therapy, which targets PD-L1 [47].

Therapy-related risk management

Biomarkers can help identify patients who are at increased risk of developing treatment-related toxicities, allowing for more personalized treatment regimens. Testing for certain genetic variants can help predict the risk of chemotherapy-induced peripheral neuropathy or other adverse effects. CYP2D6 genotype can help identify patients who may be at increased risk of developing toxicities from chemotherapy drugs like tamoxifen, which is used to treat breast cancer [48]. UGT1A1 is a gene that is involved in the metabolism of irinotecan, a chemotherapy drug used to treat several types of cancer and drug toxicity can be assessed [49].

Therapy monitoring

Biomarkers can be used to monitor the response to therapy and guide treatment decisions. Imaging biomarkers such as PET scans or MRIs can be used to assess the response of tumors to treatment, while blood-based biomarkers such as circulating tumor DNA (ctDNA) can provide early indications of treatment efficacy or resistance [50]. An integrated approach using PET/CT and PET/MRI as imaging biomarkers can be useful for the therapy endpoint selection, standard tool as imaging biomarkers reduce diagnostic variability [51].

Post-treatment monitoring

Biomarkers can be used to monitor patients for cancer recurrence or the development of secondary cancers. For example, measuring serum levels of certain proteins, such as CA-125 in ovarian cancer, can help detect cancer recurrence at an early stage and guide further treatment [52]. BNP and N-terminal proBNP is used in the clinical decision making treatment paediatrics with pulmonary hypertension. Quantification of HCV-RNA may serve as guide for monitoring hepatitis-C treatment. Similarly, PSA used for prostate cancer, HIV-RNA for antiretroviral therapy monitoring, prothrombin time is useful in follow-up after warfarin treatment [53]. Mycobacterium tuberculosis specific $CA4^{+}$ T cells can be used for post-treatment monitoring [54].

Challenges and limitations of PM in oncology

PM in oncology involves using a patient's genetic information to determine the most effective treatment for their cancer. While this approach has shown promise, some challenges and limitations need to be addressed. These challenges include data analysis, tumor heterogeneity, and clinical trial design, while limitations include cost, accessibility, ethical concerns, resistance to targeted therapies, etc. are depicted in Fig. 7.

Fig. 7 [Images not available. See PDF.]

Challenges and Limitations in PM in Oncology

The use of biomarker-based PM has the potential to revolutionize healthcare by improving the accuracy of diagnosis, the effectiveness of treatment, and ultimately patient outcomes. However, there are also potential consequences associated with the use of biomarkers in PM.

Complexity of tumor biology and heterogeneity

Tumor biology is a complex and heterogeneous process that involves numerous genetic and epigenetic alterations. Tumors can contain multiple subclones with different genetic mutations or other biomarkers. This means that different parts of the same tumor can have different molecular characteristics [55, 56]. Even tumors of the same type can have different molecular characteristics, making it difficult to identify a single biomarker that can be used to guide treatment decisions for all patients. Tumor heterogeneity has been recognized as a major contributor to the complexity of tumor biology. Tumor heterogeneity can occur both spatially and temporally, resulting in subpopulations of cells with distinct phenotypic and genotypic characteristics. This heterogeneity poses significant challenges to the diagnosis, prognosis, and treatment of cancer. Tumors can evolve, leading to changes in molecular characteristics and the emergence of new subclones. This can make it challenging to determine the most appropriate treatment for a patient based on a single biomarker [57]. Tumors can develop complex signaling pathways that interact with each other, making it difficult to identify a single target for therapy [58]. Not all tumors

have biomarkers that are robust and reliable predictors of response to therapy. Some biomarkers may have limited sensitivity or specificity, leading to false positives or false negatives [59].

Limited availability of biomarkers

The limited availability of biomarkers is a major challenge in the field of PM. Biomarkers are molecular or cellular characteristics that can be used to identify a disease or its progression and can also be used to predict the response to therapy. However, the identification and validation of biomarkers is often a lengthy and expensive process, and many potential biomarkers fail to make it to the clinical setting due to limited availability [60]. The lack of biomarkers also limits the ability to personalized treatment for patients. Without reliable biomarkers, clinicians may have to rely on a trial-and-error approach to treatment, leading to delays in effective therapy and unnecessary side effects from ineffective treatments [61]. To address this issue, researchers are exploring new methods for identifying biomarkers, such as the use of artificial intelligence and machine learning algorithms. These techniques can analyze large amounts of data and identify patterns that may not be apparent to the human eye, leading to the discovery of new biomarkers. Along with the limited availability of biomarkers, limited sensitivity and specificity, the need for specialized tools and techniques, cost and validation of the method parameters may pose the challenges in the clinical use of biomarkers [62].

High cost of targeted therapies

Targeted therapies have revolutionized cancer treatment by selectively targeting cancer cells and minimizing damage to healthy cells. However, these therapies are often associated with high costs, which can limit access for patients. The high cost of targeted therapies is due to a variety of factors, including the development and manufacturing process, the cost of clinical trials, and the exclusivity granted by patents. In addition to limiting patient access, the high cost of targeted therapies also puts a strain on healthcare systems and insurance providers. This can lead to difficult decisions about which treatments to cover and which patients to prioritize for treatment. To address this issue, researchers and policymakers are exploring new approaches to drug pricing and reimbursement, such as value-based pricing and outcome-based contracts [63].

Resistance to targeted therapies

The development of resistance in cancer tissues is a chief issue in the use of targeted cancer therapies. Resistance can arise from a variety of mechanisms, including genetic mutations, activation of alternative signaling pathways, and changes in the tumor microenvironment [64]. Research has shown that the development of resistance to targeted therapies can be delayed or prevented by combining targeted therapies with other treatment modalities, such as chemotherapy or immunotherapy. Additionally, the use of combination therapies that target multiple pathways involved in tumor growth and survival may reduce the likelihood of resistance development. Another approach to overcoming resistance to targeted therapies is the use of PM. By identifying specific molecular alterations in a patient's tumor, clinicians can tailor treatment to target those specific alterations, potentially increasing the effectiveness of therapy and reducing the likelihood of resistance [65].

Ethical and social issues

Biomarkers have revolutionized cancer treatment, allowing for more personalized and effective therapies. However, the development and use of targeted therapies also raise ethical and social issues that need to be addressed. One of the major issues is the high cost of biomarker testing and targeted therapies, which can limit access for patients who cannot afford them. Additionally, the use of targeted therapies can raise questions about the allocation of healthcare resources and the prioritization of certain patients over others in terms of receiving these treatments. Another ethical issue is the potential for targeted therapies to exacerbate existing health disparities, as certain populations may not have access to the same level of care or may not be included in clinical trials. Additionally, there are concerns about the potential for genetic discrimination, as the use of targeted therapies may reveal information about a patient's genetic makeup that could be used against them in areas such as employment or insurance [66].

Risk of misinterpretation

Biomarkers are complex indicators of disease, and their interpretation requires a deep understanding of the

underlying biology and context of the patient. Misinterpretation of biomarker results can lead to inaccurate diagnoses, ineffective treatments, and unnecessary interventions. Biomarkers can give false positive or false negative results due to limited biomarker specificity, tumor heterogenicity or lack of standardization methods. Overreliance on the biomarkers leads missing important clinical information during treatment [67].

Conclusion and future perspectives

Targeted therapies are transforming cancer treatment, but there is more work ahead. PM needs better clinical guidelines, trials and biomarkers to enhance patient outcomes, demanding new practices and tools. Biomarkers improve treatment by matching patients' right therapy, saving costs. PM fight drug resistance through new targets and tailored treatments based on tumor characteristics, boosting outcomes.

In the future, we aim to improve biomarkers, discover new targets and explore therapies to combat resistance in cancer treatment. Challenges include high cost and ethical concerns. We need more sensitive diagnostic tools for limited biomarker quantities in the body fluids. Collaboration among researchers, clinicians, and policymakers is essential. Genomic sequencing enables personalized cancer treatment, and artificial intelligence helps to analyze vast data. Ongoing research is vital to find biomarkers, genetic drivers and affordable targeted treatment for wider patient population.

ABSTRACT (ENGLISH)

Background

Medical fraternity are continuously pitching toward the development of novel mechanisms to combat the menace of cancer and to enhance the efficacy of prevailing molecules. During the drug development phase, majority of new molecular entity pose a threat due to hydrophobic nature, that compromises its bioavailability upon administration. These suboptimal accumulation and low drug loading hampers the clinical translation in cancer therapy.

Main body of abstract

Nanotechnology with valuable advantages create possibilities to accelerate the efficacy of treatment. Compared to matrix-based formulations, drug nanocrystals (NCs) with smaller size, high drug loading, high active targeting, extended circulation, great structural stability, tailored dissolution, and being carrier free have sparked a lot of interest in drug delivery. Many hydrophobic drugs were explored as drug NCs such as—doxorubicin, paclitaxel, campothecin and so on. However, premature leakage and clearance by mononuclear phagocytosis system lead to some great obstacles in the clinical applications of drug NCs.

Conclusion

In the recent years, strategies leading to surface modification are applied to improve uncontrolled drug release and targeting efficiency to tumor cells. The current review sheds light on various properties of drug nanocrystals, brief insights on its fabricating techniques, approaches for tumor targeting with NCs, and their applications in cancer imaging and therapeutics.

FULL TEXT

Background

The field of medicine faces challenges for effectively addressing the complexities of cancer, a multifaceted group of diseases characterized by uncontrolled growth and spread of abnormal cells. Unlike normal cells, which follow a regulated life cycle, cancer cells disrupt this balance and undergo uncontrolled division, leading to the formation of tumor masses[1]. Many factors contribute to development of cancer, like—genetic predisposition, food habits, lifestyle changes, infection caused by harmful microorganisms, and environmental factors [2]. Cancer has become a global burden with approximately 10 million deaths in the year 2022 [3–5]. The conventional therapies include radiation therapy, chemotherapy or combination therapy, while immuno-therapy, gene therapy, cell therapy, photodynamic therapy, and antibody therapy have also gained momentum, however, there effectiveness is still under debate as it lacks site specificity and low build-up inside the tumor cells [6, 7]. As a consequence, cancer treatment has now turned toward tailoring approaches which are patient specific depending on the profiles and characteristic of the disease. In this era, nanotechnology being a blend of technology, biomedicine and biomaterials, has been growing as a plausible approach to overcome the current shortfalls. Of them, NCs have sparked a lot of interest in the field of cancer therapeutics, offering unique advantages over conventional drug delivery systems. These nanoscale particles possess the ability to precisely target tumor tissues, stimulate drug solubility, and enhance therapeutic efficacy, revolutionizing the landscape of cancer treatment. The application of NCs in cancer therapy is driven by their small size, large surface area, and unique physicochemical characteristics. These attributes enable efficient drug loading and controlled release, facilitate targeted drug delivery with minimizing side effects on healthy tissues. They have also shown potential to overcome biological barriers, penetrating deep into tumor tissues by both active and passive pathways, and reaching intracellular targets, thereby maximizing treatment outcomes [8, 9]. In addition to drug delivery, NCs play a pivotal role in cancer imaging techniques. Their unique optical and magnetic properties have transformed cancer imaging, providing high-resolution and sensitive modalities. NCs in the form of semiconductor quantum dots, exhibit size-dependent fluorescence emission and high photo-stability, making them exceptional candidates for precise tumor visualization. Similarly, surface modifications with targeting ligands, NCs can be used as contrast agents for imaging, enabling accurate diagnosis, staging, and real-time monitoring of treatment responses [10, 11]. The integration of NCs with imaging techniques allows for multimodal approaches, facilitating comprehensive cancer diagnosis and personalized treatment regimens. Furthermore, NCs offer a versatile platform for combining different therapeutic agents within a single system, enabling synergistic effects, improved drug ratio, and targeted release. This approach enhances therapeutic efficacy while minimizing systemic toxicity. Further by engineering NCs to respond to external stimuli, controlled drug activation and spatiotemporal release can be achieved, paving the way for treatment tailored to individual patient profiles [12, 13].

Despite their immense potential, the full utilization of NCs in cancer treatment requires addressing challenges associated with formulation stability, scalability, and establishing reliable quality control measures. Thus, the current review comprehensively focuses on unveiling the potential of NCs as targeted delivery for the management of cancer.

Main text

Brief insights on nanocrystals and their fabricating method

NCs are nanometer-sized particles consisting purely of drug substances stabilized using suitable stabilizers [14]. The term "nanocrystals" is specifically used to refer to these crystalline nanoparticles or liquid crystalline nanoparticles. Comparing NCs to other carrier-based nanoparticles (NPs), nanocrystals exhibit a high drug loading which allows for a reduction in dose while still enhancing bioavailability and drug safety. Also, for formulating NCs, there is practically no use of organic solvents, making NCs devoid of residual solvents and solvent associated toxicity concerns. Additionally, improved solubility and dissolution rate will promote the pharmacokinetics and bio-distribution of drugs as suggested by Peltonen et al. [15].

The main excipient in fabricating NCs include a stabilizer. The primary function of a stabilizer is to prevent ostwald

ripening or aggregation of intrinsically diminuted drug nanoparticles and to preserve them in nano-crystalline form [16]. The selection of stabilizer and its concentration form one of the critical process parameter [17]. Now-a-days, researchers have a wide list of stabilizer starting from non-ionic, ionic, amphoteric to polymeric. Polymeric stabilizers have gained an edge over the others due to their enhanced wetting and steric stabilization property. These stabilizers impart stability to NCs via electrostatic repulsion, van der Waals forces, steric stabilization, surface coating, reducing interfacial tension, etc., [18].

Production techniques of NCs are categorized as top-down, bottom-up and combination technologies (details briefed in Table 1), subsequent section describes briefly the different sub-types of these technologies explored by researchers across the globe.

Table 1. Different techniques for formulating nanocrystals, including both top-down and bottom-up approaches, as well as combinational technologies [19–22]

Formulation methodology	Formulation techniques	Mechanism of size reduction
Top-down approach technologies	Media milling	Impact and attrition
High-pressure homogenization	High shear and high pressure	Bottom-up approach technologies
Precipitation or crystallization	Precipitation or controlled crystallization processes	Combinational technologies
Hybrid approaches	High energy driven	Supercritical fluid technology

Top-down techniques diminute the drug substances in micron size state to nanometer size. Different approaches include—media milling, high-pressure homogenization (HPH) (diagrammatically described in Fig. 1), and ultrasonication. Media milling, a mechanical technique used for size reduction, has demonstrated considerable efficiency in the production of NCs. This method employs milling media to fragment drug particles into smaller dimensions, milling agent such as beads/coated balls made of—glass, zirconium oxide, chromium, agate or some special polymers for grinding of drug particles and a stabilizer to ensure the stability of formulation. The main principle of media milling includes impact and attrition [23–26]. HPH is another top-down technique used for NC formulation. It involves subjecting the drug suspension to high pressure (ranging from 100 to 2000 bar)/ultra-sonication, forcing it through a narrow nozzle or valve. During this process, the particles under-go high shear stress resulting in generation of nano-sized crystalline particles [27, 28]. Dissocubes, Nanopure and Nanoedge are few patented technologies based on use of HPH [29]. Another approach, utilizes ultra-sonication as a means to reduce the particle size. Probe sonicator is a tool to transmit high and low power ultrasound cycles through the drug suspension. These cycles create alternative low and high pressure respectively in the suspension, causing formation of bubbles in low pressure cycle, which break during high pressure cycle. These results in cavitation effect causing reduction in particle size [30, 31].

Fig. 1 [Images not available. See PDF.]

Top-down approaches for fabrication of nanocrystals

An alternative strategy for developing NCs is through a "bottom-up" approach, where drug substances are precipitated to form nanoparticles with accurate control on particle growth. The critical aspect with this approach is controlling the size of re-crystallized particles, as uncontrolled growth might result in Oswald ripening. Some of the technologies using these approach include- high gravity controlled precipitation, sono-crystallization, liquid jet

precipitation, rapid expansion of supercritical solution, super critical anti-solvent, multi-inlet vortex mixing, evaporative precipitation into aqueous solution, etc. All these approaches have their own applications, however, major limitation lies in the use of organic solvents [20, 32, 33]. Some of these techniques have been modified by using supercritical fluids instead of organic solvents. Rapid expansion of supercritical solutions (RESS) and supercritical solvent/anti-solvent (SAS) methods of fabricating drug NC are based on the solubility of drugs in supercritical fluids [34, 35]. Hydrosol® and Nanomorph® are the patented technologies to produce drug NCs with size less than 100 nm. An innovative work reported by Han et al., revealed fabrication of paclitaxel nanocrystals (PNC) using a novel approach of evaporation and precipitation technique. The PNC were coated with tannic acid and ferric chloride to enable them for dual therapy—photothermal-chemotherapy. The in-vivo results exhibited mild photothermal activity along with strong tumor inhibition [36]. Through such innovative approach, advancements in the field of cancer treatment are being made, offering the potential for more effective and targeted therapies.

The combination technologies comprise of a two-step process—pre-treatment followed by processing. The pre-process step might be- pre-milling or precipitation, with a high-energy top-down process, such as milling or HPH, while the processing step includes evaporation, lyophilisation, etc. [37]. NANOEDGE®, was developed by Baxter, Inc., USA which involved precipitation of crystals as pre-treatment step and later the processing involved HPH to control the particle size and morphology [38]. More recent advancements have introduced- Nanopure® and SmartCrystal® technology into the market. Later technology integrated high-pressure homogenization with various pre-processes—like H42 (spray-drying pre-process), H69 (precipitation pre-process), H96 (lyophilization pre-process), and CT (media milling pre-process) [39, 40]. Hence, it could be summarized that all the different technologies are efficient enough for fabrication of different and stable NCs.

Role of nanocrystal technology in tumor targeting

Nanotechnology has sparked a lot of possibilities for effective delivery of poorly soluble drugs [41, 42]. They have emerged as a promising tool in the field of cancer therapy, offering unique properties and versatility to revolutionize treatment approaches [8]. One of the key advantage is their ability to serve as carriers for chemotherapy drugs by addressing crucial challenges of poor solubility, limited bioavailability, and systemic toxicity, thereby enhancing drug stability and solubility while enabling their efficient delivery to the tumor site. By modifying the surface of NCs with specific ligands, such as antibodies or peptides, they can be engineered to selectively recognize and bind to cancer cells. These targeted approach facilitates the direct delivery of therapeutic agents to the tumor site while minimizing exposure to healthy tissues [43].

NCs offer opportunities for both passive and active targeting. Passive targeting exploits the enhanced permeability and retention (EPR) effect, leveraging the unique characteristics of tumors to achieve increased drug concentration at the tumor site. This occurs due to the presence of leaky blood vessels and impaired lymphatic drainage in tumor tissues, allowing NCs to passively accumulate. On the other hand, active targeting involves incorporating ligands on the NC surface that can specifically recognize and bind to receptors overexpressed on tumor cells. This active targeting further enhances the accumulation of NCs within the tumor, augmenting treatment effectiveness [15, 44, 45]. The unique features of both pathways have been reflected in Table 2. Furthermore, NCs possess imaging capabilities that enable real-time monitoring of treatment response. Certain types of NCs, like quantum dots, exhibit unique optical properties and emit fluorescent signals when stimulated by light. This characteristic enables non-invasive imaging of tumors, facilitating early detection, precise diagnosis, and evaluation of treatment outcomes [46, 47]. Detailed application of NC-based treatment for targeting different cancers with different delivery mechanism has been discussed in the following sections.

Table 2. Role of nanocrystals in tumor targeting, along with their description, applications, and unique characteristics

Role	Description	Applications

Passive targeting	Facilitated by the enhanced permeability and retention effect	Imaging and Drug delivery
Active targeting	Surface modified with ligands or targeting molecules that specifically recognize biomarkers found in tumors	Targeted delivery to tumor cells that express specific biomarkers Facilitates precise imaging
Antibody-mediated targeting	Conjugation with antibodies that bind to tumor-specific antigens	Precise delivery and accurate imaging with great selectivity
Surface receptor-mediated	NCs are designed to specifically identify and attach to surface receptors on tumor cells	Facilitates precise receptor targeted drug delivery

Passive targeting

Passive targeting is a decisive strategy involving advantage of tumor vasculature hyper-permeability, and the immature lymph drainage system, NCs facilitate the accumulation of cytotoxic agents in tumor masses through EPR effect [48, 49]. This effect is particularly advantageous with nanoparticles having the size range of 20–500 nm. The size of particles has an impact on their interaction with macrophages and uptake by tumor cells [28]. Generally, smaller nanoparticles (20–100 nm) are cleared from the bloodstream at a slower rate (as shown in Fig. 2) [50]. For instance, Zhang et al. developed carrier-free NCs with an average size of 461.6 ± 57.72 nm, which were designed to incorporate indomethacin (IDM) and paclitaxel (PTX) using a one-step method. The concentration of PTX in tumor tissue using IDM/PTX- NCs was 2.21 times higher than that achieved with free PTX, resulting in a higher inhibition rate of 70% compared to 54% for the free PTX group [51]. Similarly, the self-assembled mitoxantrone NCs (MTO NCs) were developed by Mao et al., which showed passive targeting with particle size of 100 nm. The size optimization improved the lymph targeting of MTO NCs while reducing systemic toxicity. Bolaños et al. developed gold NCs coated with albumin, a natural protein that enhances nanoparticle stability and biocompatibility. The albumin coating improved the circulation time of the NCs and facilitated accumulation in tumor tissues. Thus, surface modifications, such as adjusting molecular weight, size, surface hydrophobicity, and surface charge, surface functionalization, etc. play a critical role to enhance circulation bypassing reticuloendothelial system (RES) [52]. Polyethylene glycol (PEG) is the most commonly used biocompatible polymer for surface coating as it extends the circulation time of the NCs in the bloodstream, allowing them to act as depot for the administered drugs until they reach the targeted tumor tissues [53–55]. In a study conducted by Mohammad et al., febuxostat NCs were coated with polylactic-glycolic acid/polyethylene-glycol (PLGA-PEG) using nanoprecipitation method, resulted in potential cytotoxic effect with significant high percentage of apoptotic cells in A549 lung cancer cells, suggesting effectiveness of NCs for targeted delivery [56, 57]. By understanding these studies and harnessing passive targeting strategies with NCs, remarkable advancements can be made in cancer treatment, improving drug delivery, minimizing side effects, and enhancing overall therapeutic efficacy.

Fig. 2 [Images not available. See PDF.]

Active and passive targeting mechanisms

Active targeting

Active tumor-targeted drug delivery is a strategy that involves modifying the surface chemistry of NCs with ligands or molecules such as proteins, nucleic acids, polysaccharides, peptides, and antibodies [58]. In general, two types of targeting are: active targeting to tumor cells and active targeting to the tumor endothelium. Tumor cell targeting involves the recognition and binding of ligands to receptors that are overexpressed on tumor cells, such as

transferrin, folate, epidermal growth factor (EGF), or glycoproteins (as shown in Fig. 2). On the other hand, tumor endothelium targeting aims to target the blood vessels within tumors by recognizing and binding to overexpressed factors like vascular endothelial growth factors (VEGF), αvβ3 integrins, vascular cell adhesion molecule-1 (VCAM-1), or matrix metallo-proteinases (MMP). Different approaches for active targeting include- receptor-mediated targeting, peptide-mediated targeting, antibody-mediated targeting, and aptamer-mediated targeting. Each approach utilizes specific ligands or molecules that facilitate the active recognition and binding of NCs to the desired target, thereby increase drug accumulation while reducing drug distribution in normal tissues, thereby reducing toxicity [59, 60]. In addition, there is a tactic for organelle-specific targeting, such as targeting the cytoplasm, mitochondria, or nucleus. Biomimetic nano-carriers can mimic the surface molecules on cell membranes and exhibit active targeting [61, 62]. A study involved combination of doxorubicin and tumor necrosis factor (TNF) related apoptosis-inducing ligand formulated as NPs and surface coated with P-selectin for targeting overexpressed CD44 over the tumor cells of breast revealed significant reduction in growth of tumor and metastatic nodules [63]. In a study conducted by Danhier et al. [64] authors investigated the active targeting using arginine–glycine–aspartic acid (RGD)-grafted PLGA-NPs loaded with the PTX. This results highlighted the potential of RGD peptides, to enhance drug delivery to tumor endothelium. Similar study was reported by Amreddy et al. [65] on polymeric nanoparticle-mediated gene delivery for lung cancer treatment. These approach illustrated accurate drug bio-distribution, minimizing multiple dose administration, enhancing biological barrier penetration, and improving overall treatment safety. Hence, presenting a new frontier in the fight against cancer, offering hope for more effective and personalized therapy.

Antibody-mediated targeting

Antibody-mediated drug targeting has emerged as a highly promising and precise strategy for delivering therapeutic agents directly to tumor cells. It is based on recognizing and binding to cancer-related antigens (carcinoembryonic antigen, fetoprotein, and human chorionic gonadotropin antigen) [66–68]. Antineoplastic immunoconjugates are created by linking monoclonal antibodies (MoAbs) with anticancer drugs through covalent bonds. To implement this conjugation, an inert spacer molecule, is engaged to facilitate the direct attachment of the drugs and antibodies. Several drugs, such as methotrexate, mitomycin C, 5-fluorouridine, maytansinoids, alkaloids, and daunorubicin, have been successfully conjugated with antibodies [69–71]. Zhi et al. [72] conducted a study harnessing antibody-conjugated NCs for the treatment of breast cancer. They synthesized NCs bounded with a potent anticancer drug and modified its surface with antibodies that specifically recognized human epidermal growth factor receptor 2(HER2) receptors. This resulted in targeted approach with increase in drug accumulation within the cancer cells, and minimizing off-target effects [72]. Antibody–drug conjugates like Mylotarg and Zevalin have gained food and drug administration (FDA) approval for the treatment of acute myelogenous leukemia (AML) and non-Hodgkin's lymphoma (NHL), respectively [73]. Moreover, the other side of antibody-mediated drug targeting presents a challenge of potential cross-reactivity with healthy cells that possess surface proteins similar to those present on cancer cells. Additionally, the restricted penetration of large macromolecular antibody-conjugates into solid tumors can hinder their ability to effectively target cancer cells deep within the tumor mass [74]. In-spite of such limitations, this strategy holds a ray of hope at the end of tunnel in enhancing the therapeutic effects of anticancer drugs and minimizing off-target toxicity, ultimately improving patient outcomes.

Surface receptor-mediated targeting

Scientists have made significant progress in enhancing the accuracy and effectiveness of cancer treatments by taking whip-hand of the specificity and binding ability of surface receptors. They have developed nanoparticles that are seasoned with targeting ligands or peptides that attach to the surfaces of cancer cells and enter them through a process called receptor-mediated endocytosis [75]. In a study focused on treatment of prostate cancer, NCs functionalized with ligands specific to the prostate-specific membrane antigen (PSMA) exhibited aberrant binding affinity at receptor site, facilitating enhanced uptake of therapeutic agents, leading to improved anticancer activity [76]. Integrins, a type of cell surface receptors involved in cell attachment and the surrounding matrix, have been targeted for tumor therapy. Peptides and peptidomimetics that bind to integrin αvβ3, expressed on endothelial cells in tumor blood vessels, have shown propitious results. In a study, carbohydrate-based NCs covalently bound to

DOX have demonstrated tumor-specific drug targeting [77]. Similarly, folate-mediated targeting has also gained engrossement due to the overexpression of folate receptors on cancer cells. FA-modified stearic acid-grafted chitosan micelles and FOL-PEG-DOX conjugates have exhibited enhanced intracellular uptake and potent cytotoxic effects in folate receptor-positive cancer cells [78]. Moreover, by utilizing ligands that recognize and bind to cancer-specific surface receptors, personalized treatment plans can be developed based on the characteristics of patients cancer cells, thus maximizing therapeutic outcomes [79]. Researches on NC-based drug therapy are listed in Table 3.

Table 3. Concise literature on research undertaken with NC-based drug formulations

Drug NCs	Route of administration	Indication	Particle size (nm)/PDI/Zeta potential(mV)	References
Bexarotene	Oral	Breast and prostate cancer	631; 0.33; + 24.6	[81]
5-flurouracil	I.V	Colorectal cancer	69.53 ± 1.14	[82]
Resveratrol	I.P	Ehrlich's ascites tumor	270; 0.31	[83]
Paclitaxel	I.V., I.P., I.T., Oral	All benign tumors	118–397; <0.3; − 20.87 ~ + 52.5	[84–90]
Docetaxel	I.V., intravaginal	Breast-, head and neck-, stomach-, hormone-resistant prostate cancer	70–526; 0.3 <; − 20.8 ~ + 10.4	[91–93]
Cabazitaxel	I.V	Breast cancer	110	[47]
Campothecin	I.V	Breast cancer	80–700; 0.128; − 11.4 ~ − 28.5	[94, 95]
Salinomycin	Oral	Colorectal cancer	210 ± 10	[96]
Amoitone B	I.V	Anti-cancer	256.3; 0.206; − 21.52	[97]
Anlotinib	I.V	Hepatocellular carcinoma	200;/; − 30	[98]
Nintedanib	Oral	Non-small cell lung cancer	325; 0.22; + 32.70	[99]

Curcumin	I.V	Inhibits cell proliferation and migration	158–749; 0.156; − 29.1	[100]
Flubendazole	I.P	Lung cancer	253; 0.358; − 30.45	[101]
Carfilzomib	I.V	Breast cancer	270–328; 0.27; − 13.7	[102]
Partheno lide	I.V	Advanced hepatocellular carcinoma	126–208; 0.230; − 11.18	[103]

Nevertheless, the development of resistance poses a significant limitation to surface receptor-mediated targeted therapies. Over time, cancer cells can develop resistance to targeted treatments. This resistance can diminish the long-term effectiveness necessitating the exploration of combination therapies or alternative treatment approaches to overcome resistance mechanisms [80].

Pharmacokinetics, bio-distribution, and in-vivo fate of nanocrystals

Understanding the pharmacokinetics, biodistribution, and in-vivo fate of drug-NCs is crucial for their buoyant use in cancer therapeutics. In the case of oral ingestion, NCs enter the gastrointestinal tract (GIT) and pass through the intestinal epithelium to enter the bloodstream. Later upon absorption they undergo metabolism via enzymatic degradation and post-absorption metabolism by liver enzymes [104]. On contrary when injected into the bloodstream, NCs can spread around the body, and their distribution is influenced by factors such as particle size, surface characteristics, and targeting strategies. They undergo biotransformation through processes such as immune recognition, enzymatic degradation, or elimination (described in Fig. 3) [105]. Hence, understanding the in-vivo fate of NCs and the quirky challenges posed by the physiological environment is crucial for their successful application in drug delivery [106, 107].

Fig. 3 [Images not available. See PDF.]

Pharmacokinetics and bio-distribution of nanocrystals via different routes of administration

Oral administration

NCs when administered via oral route enter into the GIT. A part of the NCs are absorbed via villi in the intestine, the remaining amount enters the blood stream while some still get excreted via feces. In the intestinal lumen they form complex with the bile acid, which later go across the mucus layer, epithelial layer and finally reach the blood capillary. In the blood stream, enzymes cause metabolism of the NCs in liver and spleen, a part of it is excreted via kidney and a fraction reaches the target site. In a study, PTX-NCs were administered orally to BALB/c tumor-bearing mice with two doses 80 mg/kg and 60 mg/kg. The tumor volume measured after day 6 of the treatment revealed reduction to one third volume when treated with NCs as compared to free PTX [108]. In another study PTX-NCs were coated with *N*-((2-hydroxy-3-trimethylammonium) propyl) chitosan chloride (HTCC) maintaining the average particle size around 130 nm, were observed to be localized in GIT within 3 h of oral administration. Eventually after 24 h, fluorescence signals showed their preferential accumulation in the tumor. The control group treated with taxol, also inhibited the tumor growth, however, the NCs had long residence time in tumor resulting in remarkable inhibition. The medial survival rates were lengthened even after discontinuation of the treatment [8, 109]. Thereby, such studies have unveiled the path traveled by NC after oral administration.

Parenteral administration

Upon i.v. administration the NCs enter the blood stream and bruit around in the body. During this journey they

encounter interactions with different proteins and other elements present in the blood stream. While circulating, they stumble on with the mononuclear phagocytic system (MPS), the larger size NCs are taken up by these MPS present in organs. The smaller size NCs, take a french leave across the MPS and show prolong circulation in the blood. Upon reaching the tumor site, they penetrate through the leaky vasculature of the tumor cells and undergo the EPR effect resulting in accumulation of NCs. Some of NCs enter the lymphatic system via the lymph nodes of the tumor tissue and go efferent into the blood stream. The extended circulation of NCs ensure their extended residence in the tumor, resulting in better efficacy and lower toxicity to healthy tissues [110, 111].

Diving into the fate, NCs are recognized and rapidly taken up by the phagocytic cells of macrophages. At this time, they are also labeled by opsonins, and immunoglobulins. They will be docked onto the receptors present on the macrophages, monocytes, and neutrophils, causing catastrophe of NCs via phagocytosis. The in-vivo fate is influenced by many factors- particle size, surface charge, surface hydrophilicity/hydrophobicity, morphology, dissolution rate, as well as concentration. Among these factors surface morphology influence the most [112]. Many anticancer drugs are delivered in the form of NCs—methoxyestradiol (2-ME), puerarin, and oridonin via i.v. injection [113, 114]. In a recent study consisting of PTX and campothecin NCs stabilized using pluronic-F127, significant inhibition of growth of human cancer and murine breast cancer, was observed [115, 116]. Similarly, PTX-NCs having nearly spheroid shape and hydrodynamic diameter of 419.9 ± 80.9 nm, were surface coated with polydopamine to form a reaction platform for effective PEGylation and RGD peptide conjugation. Cellular uptake and growth inhibition studies over A549 lung cells demonstrated superior activity over non-PEGylated NCs. The results suggest intratumor accumulation and retarded tumor growth, giving a hope toward coating being effective in functionalization of NCs for enhanced anti-cancer activity [117]. In another study, tocopheryl polyethylene glycol succinate (TPGS) stabilized PTX-NCs showed better therapeutic effect in taxol-resistant ovarian cancer both in-vivo and in-vitro [118]. Similarly, campothecin NCs were studied over lung metastasis of MDA-MB-231 and MCF-7 tumors. The results supported with the confocal images of the tumor sections revealed a better inhibition of tumor metastasis and apoptosis with NCs compared to campothecin salt solution and control group [116]. Such study reports supply glimpse of information depicting the in-vivo fate of NCs upon parenteral administration.

Applications of NC in cancer diagnostics and bio-imaging

NCs have also garnered significant attention in the field of bio-imaging offering promising prospects toward unambiguous detection. Cellulose NCs (CNCs) conjugated with fluorescent agents (rhodamine-B-isothiocyanate and FITC) have been explored for therapeutic imaging of tumors by measuring the acoustic signals. Similarly, non-conjugated CNCs were used for photoacoustic imaging of ovarian cancer in mouse models. The peak photoacoustic signal was reported at 700 nm with doses below 1.2 mg/mL in carcinomatous cells. For efficient bioimaging the NCs were conjugated fluorescent agent to passively trigger cell internalization with insignificant toxicity [119]. Mahmoud et al. proved the capability of fluorescent CNCs to penetrate the cancerous cells without a sign of toxicity and no effect on integrity of cell membrane. They also provided evidence of intake of positively charged CNC-RBITCs within the membranes of Spodoptera frugiperda (Sf9) and human embryonic kidney 293 (HEK 293) cells, while CNC-FITC were not taken-up owing to their negative charge. These reports suggest the relevance of surface charge of NCs with their uptake [120]. Magnetic-NCs in the form of magnetic probes have opened new avenues for bio-imaging with its signal enhancement capabilities. Although magnetic resonance imagining (MRI) is widely accepted diagnostic tool, its non-invasive nature, tomographic compatibilities and low-signal sensitivity hinders its applications. Iron-oxide-based magnetic NCs including superparamagnetic iron oxide (SPIO) are being used for enhancing the signal for better tomographic imaging. Recently, a water soluble magnetic iron-oxide NCs was fabricated with tunable MR signaling effect. The magnetic NC probes were successful in diagnosis of breast cancer tested over SK-BK-3 cell lines. Similar study was tested in breast cancer induce mice and the results suggest that the magnetic NC-antibody probe was able to signal the diagnosis of cancer with magnetic-field of 1.5 and 9.4 T. At higher magnetic-field Yong et al. [121] reported the detailed monitoring of cancer cells with complex vasculature and tumor tissues, thus suggesting the enlightening potential of magnetic NCs for diagnostics purposes.

Gold-NCs with different size and shapes have potential to extend the resonance from visible to near infrared range

where light can infiltrate into the tissues. At resonance wavelength gold can absorb and scatter the light, this property enables a distinct color to gold which is sensitive to be detected by naked eye, making gold NCs excellent for biomedical diagnostics. Typically, such gold NCs have been extensively used for immunogenic strip test. The surface electrons on the gold NCs can amplify Raman scattering signals, thus AuNCs with immune probes/antibodies significantly enhance sensitivity and contrast of detection which are stable with repetitive analysis, making it an important candidate as imaging agent for cancer cell identification and diagnosis [122]. In a study conducted with fabrication of Eu/Gd codoping HAP-NCs using co-precipitation technique possess a luminescence property, which enabled successful cell labeling and in-vivo imaging [123]. In addition, flow of magnetic-NCs within the body can be controlled by external magnetic field, making it more convenient to tailor it toward specific and targeted imagining. Such smart use of NCs has shown tremendous applications in the field of diagnostics and effective imaging [124].

Beyond diagnostics, NCs may also be used in cancer biomarker detection and liquid biopsies. NCs-biosensors detect cancer-specific biomarkers with high sensitivity and specificity, allowing for early cancer detection. These biosensors can detect and analyze biomarkers from blood samples such as circulating tumor cells, exosomes, and cell-free deoxyribonucleic acid (DNA), allowing for non-invasive monitoring of tumor growth and therapy response [125]. These aid of NCs in the development of liquid biopsy technologies, will revolutionize cancer detection.

Metallic nanocrystals for cancer theranostics

Metallic-NCs are evolving in the field of theranostics [126]. Metallic-nanoparticles can be modified in terms of size and shape, which enables precise control of their physical and chemical characteristics, such as magnetic behavior, surface plasmon resonance, and catalytic activity [127]. Additionally, the possibility of surface functionalization makes metallic-NCs flexible platforms for targeted therapy, real-time imaging, and treatment response monitoring. The majority of chemotherapeutic drugs distribute throughout the body, causing poor patient compliance, general toxicity, and even treatment cessation. This makes it difficult to deliver therapeutic agents to tumor cells with precision. Moreover, metal nanoparticles are superior to other nanoparticles because of their innate anticancer activity, which eliminates the need for additional carriers. Additionally, they are quickly eliminated from the body and are biocompatible in nature. Metal nanoparticles can be used to encapsulate or conjugate medicinal molecules, making them a viable alternative to other delivery systems [128, 129]. Some of the research related to applications of metallic NCs are discussed in subsequent sections. Table 4 summarizes studies where metallic nanoparticles loaded with anticancer agent have been used for cancer treatment.

Table 4. Types of metallic nanocrystals used for cancer theranostic agents, including the metals used, their properties, synthesis methods, and applications

Nanocrystals type	Properties	Method for synthesis	Applications
Iron nanocrystals (Fe-NCs)	Magnetism, biocompatibility, and superparamagnetic characteristics. Magnetite (Fe_3O_4) and maghemite ($–Fe_2O_3$) are two examples	Thermal decomposition, co-precipitation, hydrothermal synthesis, Microemulsion method, Iron Sono chemical synthesis	Drug delivery, magnetic hyperthermia, and MRI
Zinc nanocrystals (Zn-NCs)	Luminescent qualities and biocompatibility	Precipitation, Wet-chemical synthesis, Solid-state pyrolytic method, Sol–gel method	Fluorescence imaging and therapeutic delivery

Gold nanocrystals (Au-NCs)	Optical properties and biocompatibility	Turkevich method, Perrault method, Block copolymer-mediated synthesis, Brust method	Drug delivery, imaging, and biosensing by photothermal treatment
Silver nanocrystals (Ag-NCs)	Strong antibacterial activity and plasmonic characteristics	Chemical reduction, Physical synthesis, Biological synthesis	Imaging, photothermal treatment, and antimicrobial applications

Iron oxide nanocrystals

Fe-nanoparticles have earned importance for both therapeutic and diagnostic applications. These metal oxides can be functionalized to act as carriers for anticancer agents or imaging agents by conjugating to their surface or embedding them in a polymeric matrix. Additionally, they can also be employed as contrast agents for imaging by MRI [130, 131]. Fe-NCs were mostly synthesized using a principles of green chemistry. The scientist Mathur et al., produced water soluble Fe_3O_4-NCs by reducing colloidal iron hydroxide with green tea polyphenols (epigallocatechin gallate and epicatechin). The NCs, displayed size range of 2.5–6 nm with high degree of crystallinity. These green teas coated superparamagnetic Fe-NCs (SPIONs) served as negative contrast agent both in-vitro and in-vivo over primary macrophages and colon cancer cells-CT26, showing high uptake efficiency. Thus, SPIONs with promising transport and uptake characteristics can be explored further for multimodal imaging and therapeutic applications [132]. An in-vivo study conducted with SPION coated with phospholipid and PEG revealed substantial influence on bio-distribution and bio-clearance of bio-degradation products, suggesting their safety in cellular environments of blood and organs [133]. SPIONs have showed a great magnetic moment under the influence of static external magnetic field. These property enables them to be used as contrast agents in imaging purpose-MRI, to improve tumor visualization and identification with low poly-dispersity, and functionalized to serve as carriers for the delivery of specific drugs. Beyond imaging and medication delivery, Fe^{+2}-NCs can be used in photo-thermal therapy to absorb light energy and turn it into heat, causing hyperthermia and subsequently killing tumor cells. Additionally, through Fenton or Fenton-like reactions, Fe^{+2}-NCs have the capacity to produce reactive oxygen species (ROS), which cause cytotoxicity and destroy cancer cells. Ma et al., proposed conjugating folic acid to the surface of SPION-loaded polymeric nanoparticles in order to create SPION-based MRI contrast agents with great selectivity to cancer cells. These nanoparticles showed improved MRI efficacy in comparison to a commercial contrast agent and showed selectivity to MCF-7 and SPC-A-1 cells [134]. Another study described the use of MRI-based MUC1-expressing ovarian cancer detection utilizing C595 monoclonal antibody-conjugated SPIONs. With no in-vivo toxicity, the nano-conjugate showed considerable tumor accumulation, detection specificity, and potential anti-ovarian cancer efficacy [135].

Similar, Fe-NCs were developed by group of researcher lead by Vellingiri et al., using goat blood as bioprecursor. The γ-Fe_2O_3-NCs were coated with PEG and combined with doxorubicin with 60–70 nm size for targeting lung cancer cells. The morphological changes, cytotoxicity, and intracellular presence of iron was observed to be dose dependent within the investigational cells. Moreover, the presence of DOX within the nuclei reveals the pathway toward nuclear chemotherapy. In-vivo studies in tumor bearing mice suggest suppression of carcinogenesis while there was no obvious toxicity in healthy organs. Such studies reflect the potential of natural sources to be developed into nanocarriers as future of targeted nuclear treatment for cancer [136]. A very similar study, with Fe_2O_3-NC synthesized from goat blood using chemical reduction method, demonstrated significant cytotoxicity and active transport to cell nucleus. Further functional proteomic analysis implies the cancer cell proliferation is targeted by Fe_2O_3-NC, providing new insights for nuclear targeted cancer treatment [137]. PEG-capped Fe-NCs with different morphologies (spheres, polymorphs and wires) demonstrated strong ferromagnetic behaviour and hysteresis losses, considering hyperthermia effect with temperature rising up to 42.6 °C for medical hyperthermia applications [138]. Cheon et al., fabricated a probe system which controlled the size, magnetism and induced nuclear spin relaxation in

Fe_3O_4-NC model. The Fe_3O_4-NCs were conjugated with Herceptin. This system of NC-antibody probe was used for diagnosis of breast cancer under MRI [126]. For precise delivery, a tumor microenvironment responsive nano-system was designed by decorating Fe_3O_4-NCs with methoxypolyethene glycol (mPEG) and trans-activator of transcription (TAT). These decorated NCs were utilized to facilitate MRI, tumor magnetic hyperthermia (MHT) and mild heat-mediated immune stimulation. The cleavage of mPEG strongly inhibited the growth of tumor cells. In-vivo experiments with CT26 tumor-bearing mice showed 85.5% tumor inhibition rate and induced a magnetic hyperthermia–immune synergistic therapy, together with no obvious anticancer agent this study demonstrated a promising approach for delivering nanomedicine using MR imaging-guided tumor-targeting MHT [139].
Lin et al. created a Fe^{+2} nanocomposite for MRI-visible delivery of small interfering (si)RNA. The nanocomposite displayed equivalent silencing efficacy to Lipofectamine 2000, a commercial transfection agent, and successfully silenced the target mRNA, decreasing the expression of p-glycoprotein (p-gp). Under an MRI scanner, the transfected cells displayed a noticeable contrast enhancement, suggesting a way to tackle multi-drug resistant in cancer cells**.** Commercially, two members of SPION family, Ferumoxides (Endorem®–Europe, Feridex® in the USA and Japan) and Ferucarbotran (Resovist®–Europe and Japan) are approved for intravenous use. These SPIONs are coated with dextran and carboxy-dextran respectively. In addition, Nanotherm consisting of superparamagnetic iron oxide coated with amino silane is approved by USFDA and EMA for the treatment of Glioblastoma, prostate, and pancreatic Cancer [140].

Zinc nanocrystals (Zn-NCs)

Zn-nanomaterials have gained popularity specifically for therapeutic drug delivery, stimuli-responsive targeting, and also for diagnostic purposes. Nanoparticles composed of zinc oxide (ZnO) have received a lot of interest due to their possible use in the treatment of cancer. These nanoparticles have unique properties including photoluminescence for biosensing and characteristics of wide band-gap semiconductors that encourage the production of ROS [141]**.** Nanosized ZnO produces numerous electron–hole pairs even in the absence of UV radiation because of crystal defects, which leads to an increase in the formation of ROS. ZnO's band gap enables electrons and holes to interact with oxygen and hydroxyl ions, generating superoxide and hydroxyl radicals, respectively. Their innate propensity for cytotoxicity against cancer cells results from their capacity to trigger the production of ROS, which causes cell death [142]. Additionally, ZnO nanoparticles have been explored for imaging purposes, enabling optical imaging of particular cancer cell receptors and acting as multimodal imaging agents for cancer detection [143].
Amino-propyl functionalized ZnO-NCs exhibited hexagonal wurtzite crystalline structure with + 22 mV zeta potential. During preliminary phase study with these NCs, it was discovered that treatment of 3 times/day cause in highest toxicity rates. Further, the viability assay confirmed pro-apoptotic stimulus and necrosis. The study concluded three probable mechanism of cell death—bubble cavitation, nanoscalpel effect and electric change imbalance, thus opening new avenues for application of ZnO-NCs as effective tool for cancer treatment [144]. Cauda et al., synthesized ZnO-NCs using very efficient microwave-assisted solvo-thermal method, having spherical morphology with 20 nm size. To evaluate the cytotoxicity and cell internalization over cancerous human cell lines, the ZnO-NCs were functionalized with amine. Surface functionalization with amine enables labelling with fluorescent dyes which could be detected with flow cytometry. Also, water-soluble-tetrazolium-salt1 assay was used to quantify cell viability. The results infer significant reduction in human-epithelial cancer cell viability at dose of 10 µg/mL. Cellular internalization was observed with fluorescent signals suggesting visible internalization of ZnO-NCs [145]. Coating with lipids shields the ZnO-NCs, preventing self-aggregation, premature degradation, and promote cellular uptake in HeLa cancer cells with reduced cytotoxicity. Such results signifying the importance of multifunctional ZnO-NCs for therapeutic and bio-imaging purpose [146]. In another study, membrane destabilization occurs which allows pristine ZnO-NCs to enter cytoplasm and elicit cytotoxic response within the tumor cells [147]. Nair et al. studied the dissolution of ZnO-NCs and reported that the NCs undergo rapid dissolution in acidic pH 5–6 causing ROS stress, depolarization and superoxide formation in mitochondria, and apoptosis. This elucidates toxic mechanism of ZnO-NCs in destabilization of cancer cells using its own hostile acidic environment [148]. A novel work was carried out by Prasad et al., to enhance PDT of Chlorine, using excitation created by second harmonic (SH) light generated by

ZnO-NC, where they are internalized through endocytosis mediated by folate receptors. Here, the SH light was generated by in-situ presence of ZnO-NCs, which caused activation of photons leading to cell death (apoptosis and necrosis) in the cytoplasm of cancer cells. Such studies provide insight of ZnO-NCs as powerful tool for developing phototherapy selectively targeting specific organelle [149]. For the therapeutic purpose, researchers developed ZnO-nanoparticles loaded with DOX. This co-administration caused synergistic effect and enhanced cytotoxicity [150]. Additionally, ZnO can be used for biosensing, which enables the early identification of malignancy [151]. Moreover, the effect of zinc nanostructures on living cells, in particular cancer cells, is still under debate.

Gold nanoparticles (Au-NCs)

Over the period of time, novel delivery carriers resulted in reduction in dose dependent toxicity in comparison to conventional products. These lead to increase in research on exploring metallic materials for targeted delivery and diagnosis. Au-NC are aggregates of Au atoms ranging between 10 to 400 nm in size. The amount of gold, material of inorganic substrates, pH of medium, temperature and mechanical forces used during the synthesis governs the shaper of Au-NCs. The Au-NCs when conjugated with stimuli-responsive polymers, are found to be used for targeted delivery to specific organs of human body [152]. Various reports have successfully loaded anticancer drugs—campothecin, thymectacin, busulfan and cyclosporine using Au-NCs [8].

A study to treat metastatic breast cancer was carried out by Wang et al., using DOX decorated Au-nanorods. With irradiation of near-infrared light over these decorated Au-nanorods, caused increase in temperature along with release of DOX within the tumor as Au-NCs show a sharp absorption peak around 500–550 nm due to excitation of surface plasmons. These combination was observed to be more toxic in 4T1 breast cancer cells [153, 154]. A similar study was conducted over 4T1 breast cancer cells with Au-NCs loaded with 10-hydroxycampothecin. The AuNCs possessed average size of 130 nm with 75% drug loading, when administered i.v, showed a sustain drug release pattern and enhanced cytotoxicity [155]. A study conducted by Shen et al., revealed the use of Au-NCs for inhibition of retinal angiogenesis. The Au-NCs with average size of 26.2 nm and potential of 24.9 mV, were able to inhibit the cell proliferation to an extent of 50–72% and 54–83% inhibition of cell migration at concentration 10 μg/mL and 20 μg/mL, respectively [156]. Li et al., carried out a study to test Au-NCs as potential antiangiogenic agents. In this investigation, Au-NCs were used to target human recombinant endostatin (angiogenesis inhibitor). The results showed promising effects with tumor vascular normalization and strengthened blood vessel [157]. Au-NCs fabricated in conjugation with hydroxylcampothecin and polydopamine, when injected i.v. into the mice, showed accumulation and cytotoxicity in the tumor [158].

One of the major benefit of Au-NCs is its traceability with MRI. Enhanced light scattering and absorption caused by surface plasmon resonance allows them to act as imaging probes. It can accumulate within the tumor site along with drugs. In a study performed by Chandra et al., Au-NCs stabilized using gum arabic was successfully explored as X-ray agent for imaging the tumors of brain in mice and dog models. The treatment was followed as 5 consecutive intratumoral injections GA-AuNCs, later threshold accumulation was attained in 5 h showing complete saturation. The CT scan images revealed the retention of GA-AuNCs in the tumor site along with no clinical changes and cellular toxicity. Further, a pilot study was performed in male dog with thyroid carcinoma and osteosarcoma. Intratumoral injections were administered to the dog, post 3 weeks of treatment, the dog was euthanized and necropsy was performed. The results revealed no toxicity in vital organs, signifying use of GA-AuNCs as diagnostic agent [159]. An augmented approach was adopted by Menon et al., for synthesizing Au-NCs using garlic as precursor. The Au-NCs were suspended in garlic extract in presence of chloroauric acid with constant stirring under elevated temperature. The end point of coating was the change in color of solution from pale yellow to purple-red. The cytotoxicity was performed using MCF-7 human breast cells and L929 mouse fibroblast cells at different concentrations, observations after 24 h of incubation revealed no cytotoxic effect. Thus, it could be concluded that garlic extract did not render any cytotoxic reaction, also it formed a stable shealth around the Au-NCs, serving immense applications in imaging diagnostics [160]. Such studies reflect the potential benefits of Au-NCs which in future can be explored for tumor imaging and diagnosis.

Silver nanoparticles (Ag-NCs)

In the past decade, a prominent focus on translational research for introducing materials with nano-metric size range for cancer therapy has gained momentum. As a consequence, to date, several biomaterials including metal-based nanostructures have been explored as treatment modalities in various trials conducted to overcome cancer. Among metals, silver (Ag) has a significant anti-microbial property and a unique mode to induce cell death. Ag-nanoparticles unveils tremendous scientific data to show its possible application as anticancer agent, its high efficacy and safety [161]. Following their uptake, these Ag-nanoparticles (AgNPs) are taken up by endocytosis and within the endosomes they undergo lysosomal fusion in the organelle. The acidic environment of lysosome cause release of Ag-ions, which create unbalance cellular homeostatis leading to apoptotic cell death. Such mechanism is referred as Trojan horse. It is rightly said that to exploit the nano nature of metallic material, they are applied along with cytotoxic drugs, however, despite of favorable features Ag appears to be toxic to healthy tissues. Hence, a careful monitoring of Ag accumulation into the cancerous cells needs to be ensured. To achieve this multiple methods—active and passive targeting have already been explored for developing Ag-based nanocrystals (AgNCs). Several research groups have demonstrated the cross-talks between the cancer cells and AgNCs [162].

According to Muhammad et al., AgNCs functionalized with PTX boost the anticancer activity in human cells. The PTX-NCs were surfaced with polydopamine, later the AgNPs and tumor targeting peptide NR1 was decorated onto the PDA. This grafted Ag-PTX-NC system dramatically enhanced the cellular absorption during in-vitro anticancer models. Additionally, the Ag-PTX-NCs showed synergistic influence causing cell membrane lysis, nucleus damage, mitochondrial dysfunction, ROS over production, and breakage of DNA. Such observations linked the potential application of NR1/Ag-NC decorated PTX for targeted therapy of anticancer drugs [163]. Liang et al., demonstrated the anticancer effect of camptothecin (CPT)/Ag-NCs. Silver exhibit excellent inhibitory effect on drug resistance related p-glycoprotein (Pgp) while CPT has proven data of being cytotoxic. The combination of both CPT/Ag-NCs was able to bypass the Pgp recognition resulting in indiscriminate cytotoxicity. In addition, the drastic release of CPT into the tumor triggered by cleavage of Ag-ions in acidic microenvironment led to chromatin structure breakage, DNA damage and apoptosis. Nevertheless, such exploration of molecular events needs support of in-vivo studies [164].

Kim et al. investigated the toxic effect of synthesized crystalline AgNPs on F9 cells. They identified the dose-dependent toxic effect of AgNPs was linked with leakage of lactate dehydrogenase, ROS, and mitochondrial dysfunctioning. At high concentration DNA fragmentation, neuronal differentiation, increased expression of apoptotic genes, and decreased expression of anti-apoptotic genes was reported. The results support the use of crystalline AgNPs for differentiation therapy in amalgamation with chemotherapeutic agents [165]. In a report published by Paul et al., the crystalline AgNPs were biosynthesized using ethanolic leaf powder extract of *Premna serratifolia* L. and possessed 22.97 nm size. Anticancer effect of the synthesized AgNPs was evaluated on Swiss albino mice induced with liver cancer. The results revealed AgNPs were non-toxic with protective effects of other organs while they sustained control over the cancer progression. Such studies open up ways toward cost-effective economic alternatives for anticancer therapy, however certain understanding of molecular mechanism restrain the use of synthesized Ag-NPs of *P. serratifolia* [166]. Nima et al. developed Ag–Au nanorods functionalized with certain molecules and antibodies improved photothermal contrast and surface-enhanced Raman scattering (SERS) for the diagnosis of breast cancer [167]. Thus, AgNCs embark great potential to be explored for diagnostic and therapeutic purposes. A brief list of metal based drug delivery explored for cancer therapeutics is reported in Table 5.

Table 5. Brief list of recent metallic based drug delivery explored for cancer therapeutics

Metal	Conjugating drug	Cell lines	IC_{50} value	Proposed MOA	Reference
Gold	Docetaxel	Lung cancer cell line (H520)	25 μm	Cell disruption and apoptosis	[168]

Silver	Epirubicin	HepG2 cells	1.92 μg/mL	–	[169]
Copper	Paclitaxel	Drug-resistant prostate cancer cell	85, 172, and 193 nM	Inhibition of proteasome/poly-Ub protein degradation pathway by targeting the NPL4 protein	[170]
Gold and iron	Doxorubicin	HeLa cancer cells	2.3 μg/mL	Cytoplasmic internalization and cell death	[171]
Silver	Methotrexate	Breast cancer cells MCF-7	258.6 μg/mL	Blocks the synthesis to tetrahydrofolate	[172]
Silver	Acety-lshikonin and beta-dimethyl-acrylshikonin	Human chronic myeloid leukaemia	100 nM	ROS induced toxicity	[173]
Gold	Doxorubicin	Glioma carcinoma cell line (LN 229)	4 μg/mL	DNA intercalation and cell death	[174]

Regulatory challenges toward formulation of drug NCs

In addition to opportunities and challenges, hurdles pertaining to approval of NCs by the regulatory bodies are one of the major obstacle in its commercialization. A bridge needs to be build-up with validation, toxicity, reproducibility and stability of NCs produced in academic setting to enable collaboration with industries. A helping hand with adopting minimal standards for conducting pre-clinical studies was offered by US-FDA and European medical agency (EMA), to promote clinical translation of academic-industry collaboration. On the other hand, following good manufacturing practice (GMP) becomes crucial while demonstrating the promise of technology for effective drug delivery and diagnostics. However, following GLP might increase the overall cost, but with previously demonstrated proof of concept, the collaborators may seek funding from different organization for the said purpose. Pre-clinical studies might also need placebo controlled treatment regimens for appropriate evaluation of safety and efficacy. In these context, FDA has initiated the Nanotechnology Regulatory Science Research Plan. The plan aims to address the gap in scientific knowledge required to make regulatory assessment of NCs hassle free. The plan includes major criteria- physio-chemical characterization, preclinical models, risk characterization, risk assessment, and risk communication open for discussion with collaborators [177]. A fruitful outcome of the plan is the establishment of Nanotechnology Characterization Lab, that performs characterization of the different nanoparticles received from government funded research labs, academia, and industry. These platform integrates academic-industry collaborations to gather relevant data for filing Investigational New Drug application. Thus, such resource utilization enables academic-industry collaborations for effective translation of the NC-based therapeutics established by academic to reach market [178].

A part from these, a significant consideration must also be given to selection of demographics for performing clinical trials. Recently, a phase 2 clinical study failed to achieve its primary end point for treating lung cancer, and prostate cancer using BIND-014 (PSMA-targeted docetaxel nanocrystals). This results reflect the need for designing clinical

trials, considering selection of patients based on EPR, tumor heterogeneity, presence of target receptors, ability of NCs to bind to receptors, and the simultaneous need for diagnostics during the study are some of the crucial parameters for achieving better outcomes [175]. Another NC-based product called as Panzem Nanocrystal Colloidal Dispersion is currently under phase 2 clinical trials, being explored for its potential effect on prostrate and ovarian cancer. Some of the NC-based formulation approved for commercialization by FDA are listed in Table 6. A pioneering effort in this direction was adopted by Merrimack Pharmaceuticals, to determine the accumulation of ferumoxytol iron nanoparticles (FMX) using quantitative MRI and may predict the response to nanoliposomal-irinotecan. The study concluded that the tumors with high accumulation of FMX were more responsive to nano-liposomes [176]. This study was based on simultaneous quantitative estimation using MRI, and we believe that such initiatives along with pre-selection of patients will turn out to be a bridging bench-bed gap. Thereby promoting the commercialization of highly potent NCs with detailed safety and efficacy profiles along with backbone of clinical data.

Table 6. Drug NCs with approval of commercialization

Drug	Product	Method of manufacturing	Route	Indication
Cabotegravir/rilpivirine	Cabenuva	Media milling	I.M	AIDS
Meloxicam	Anjeso	Media milling	I.V	Analgesics
Aripiprazole Auroxil	Aristada	High pressure homogenization	I.M	Schizophrenia
Paliperidone Palmitate	Invega Trinza	HPH	I.M	Schizophrenia
Dantrolene sodium	Ryanodex	Media milling	I.V	Malignant hyperthermia
Nepafenac	Ilevro	Media milling	Drops	Analgesic and anti-inflammatory
Theophylline	Theodur	Media milling	Oral	Bronchiectasis
Naproxen sodium	Naprelan	Media milling	Oral	Anti-inflammatory
Fenofibrate	Triglide	HPH	Oral	Reduce Cholesterol/Triglycerides
Megestrol acetate	Megace ES	We media milling	oral	Appetite stimulation
Cannabinoid	Cesamet	Co-precipitation	Oral	Nausea and vomiting
Aprepitant	Emend	Wet media milling	Oral	Antiemetic
Tizanidine	Zanaflex	Wet media milling	Oral	Muscle relaxant
Diltiazem	Herbesser	Media milling	Oral	Angina

Morphine sulfate	Avinza	Media milling	Oral	analgesia
Methyl phenidate	Ritalin Focalin	Media milling	Oral	Attention Deficit Hyperactivity Disorder
Sirolimus	Rapamune	We media milling	Oral	Immune suppression

Conclusion and future prospects

Delivery of BCS class II and IV is challenging yet a promising pitch for research. NC-based drug delivery has emerged with incomparable drug loading over other carrier-based drug delivery systems for poorly soluble drug substances. Over the last two decades, NC technology have shown useful and prevailing role in the treatment of cancer providing improved drug targeting and delivery. Current research on these drug substances deals with strategies to improve their absorption and selective delivery to tumor cells, leading to emergence of surface functionalization and usage of novel excipients. To add cherry on the top, their functionalization with targeting ligands offers excellent dynamism to control the growth of tumors. With the on-going research, different new techniques have also evolved for the production of NCs. These techniques involve combination of top-down and bottom-up approaches to effectively rationalize their advantages. Nevertheless, the clinical efficacy of drug NCs depends on number of factors. The present review highlighted multifaceted applications of different types of NCs in the management of cancer. Metal based NCs have offered simultaneous application in diagnostic and therapy with targeted drug delivery, thereby revolutionizing cancer management and therapy. The drug-metal NC complex enable tracking within the body owing to their interaction with light, thus offer an efficient therapy in addition to chemotherapy. Despite these facts, their clinical translation and market authorization is challenging due to certain bottlenecks. Toxic effects are possible due to their tiny size and large surface area which boosts reactivity with the biological targets. Numerous problems with respect to long-term sustainability and safety of nanoparticles has always remained unresolved. Inflammation, genotoxicity, and organelle failure in cells are few dose dependent toxic effects of nanocrystalline particles. Also, the activation of oxidative enzymes results in increase in concentration of free radicals and in-turn increase oxidative stress and cell damage. Moreover, they have a great potential if the risks and toxicity are controlled from production to treatment. Certain ways including coating with polymers and with the concept of green synthesis, a relatively safe way for the use of metallic nanoparticles can be en-routed.

As far as biological challenges are concerned, the bridge between the disease pathology and human heterogeneity is required. Also, the physicochemical properties of drug NCs should primarily focus on overcoming biological barriers to achieve target and reduce build-up in nonspecific organs. Unfortunately, lack of attention toward these aspects, cause failure observed during the translation of promising NCs in clinical trials. These factors could be deterrent for pharmaceutical industries for investing on commercialization of NC-based products. To cope with this challenge, there is a dire need for inclusive evaluation of preclinical data with special emphasis on efficacy, safety, pharmacokinetics (ADME profile), targeting efficiency and stability with appropriate tumor induced animal models. Also, reproducibility of the results must be validated using different animal models, such practise will boost the reliability toward the anticancer therapy. For most of commercialized products, EPR-mediated accumulation has been reported in most of the animal models. Moreover, the tumors are heterogeneous and may possess inter and intra patient variability. With NC-based products, the amount of cellular uptake and drug release kinetics inside the target sites can be tailored, moving away from the traditional concept of one-size-fits all.

Although most of the research about drug NCs on cancer therapy are still in preclinical development, the motivation arises from those products which have reached the market, with enhanced circulation time, site specific cellular uptake, long retention in tumor environment and reduction in dose-dependent toxicity. Also, decorated NCs with targeting ligands have generated a ray of hope for cancer therapy. Even, NCs can be labeled with dyes/contrast agents to further augment visualization and theranostic applications. In nutshell, NC technology has profound

opportunities to mitigate cancer therapy and with gradual maturation of drug NCs, commercialization of NC-based products will emerge like a boon for cancer therapeutics.

Integrating in silico molecular docking, ADMET analysis of C.verticillata with diabetic markers and in vitro anti-inflammatory activity

A., Maheswari1; DE, Salamun1 1 Jain (Deemed-to-Be) University, Department of Biotechnology, School of Sciences, Bangalore, India (GRID:grid.454774.1)

ABSTRACT (ENGLISH)

Background

Over the past decade, various research studies have proved the interconnection between the inflammatory pathways and diabetes complication in clinical condition. The present study evaluated the anti-inflammatory and antioxidant activity. Further, the sample was tested for its pharmacokinetics properties and the best compounds were docked with the diabetic markers (DPP IV (PDB-ID: IJ2E) and SGLT2 (PDB-ID: 7VSI)).

Results

C.verticillata showed a good hydrogen peroxide (78.3 ± 0.34%, IC_{50} = 287.81 µg/ml) and superoxide scavenging activity (52.7 ± 1.26%, IC_{50} = 796.15 µg/ml). In addition, the sample was checked for its anti-inflammatory activity with protein denaturation (57.4 ± 0.19%, IC_{50} = 471.5 µg/ml) and proteinase inhibition assay (68.3 ± 0.48%, IC_{50} = 213.42 µg/ml). Further, the bioactive compounds detected from HPLC-ESI-MS/MS analyzed sample were checked for its drug likeliness by checking its ADME properties and toxicological parameters. It has been observed that except Loliolide, all the other compounds have followed the physicochemical parameters and proved to exhibit drug likeliness characteristics. The bioactive compounds that follow the Lipinski's rule were taken further for in silico molecular docking analysis with the diabetic protein markers (DPP IV and SGLT2). Docking results revealed that

Pyro pheophorbide a with DPP IV and Dihydromonacolin L acid with SGLT2 have recorded a maximum docking score of (−9.4 kcal/mol) and (−9.2 kcal/mol), respectively.

Conclusion

The observed results suggest that the identified and selected bioactive compounds from *C.verticillata* can be considered as a potential target molecule for the management of oxidative stress induced diabetic condition. Furthermore, the study also provides an insight on the effectiveness of the compounds on reducing the inflammation as well.

FULL TEXT

Background

Inflammation is characterized as a host defense mechanism which involves the activation of immune system to remove the foreign antigen from the host system. The visual interpretations of inflammation include swelling, increased temperature at the site of injury, pain and redness [1]. It is achieved by the enhanced production of reactive oxygen species by the action of inflammatory cells [2], where it aids in the removal of invasive microorganisms. Nevertheless, prolonged production of ROS (reactive oxygen species) leads to oxidative stress and illness leading to chronic inflammation. Moreover, chronic inflammation leads to various kinds of illness like cancer, neurological diseases, diabetes, cardiovascular diseases, and so on.

According to [3], oxidative stress may be a major factor in the pathophysiology of diabetes-related macrovascular and microvascular complications which end up inflammation. The emergence of endothelial dysfunction is a warning sign of such damage. Numerous evidences are there to support the relationship between the immune and metabolic systems. It has been proved that the inflammatory pathways are the primary mediators of diabetes [3]. Research findings had already revealed the interconnection between diabetes and inflammation, where the mediators of inflammation like IL-6 and CRP (C-reactive protein and plasminogen activator inhibitor-1) have shown to be elevated in different diabetic conditions [4].

Increasing evidences propose that prolonged activation of pro-inflammatory pathways in the action of insulin might contribute to metabolic disorders like T2D (type 2 diabetes) [5]. Currently existing treatment strategies for type 2 diabetes mellitus, such as insulin delivery and oral anti-diabetic medications, are either ineffective or have negative side effects. Hence, it is critical to continue looking for an effective treatment that can assist people with type 2 diabetes and eventually cure them. Therefore, there is an increased demand in search for the new marine algae-based bioactive compounds with minimum or no side effects to the patients. Hence, the present study focuses on the search of novel bioactive compounds for the effective management of type 2 diabetes that has an effect on reducing oxidative stress induced inflammation. In addition, our work also focuses on the usage of computational tools to verify the ADMET (absorption, distribution, metabolism, excretion and toxicity) properties of the bioactive compounds as well as the in silico molecular docking analysis with the diabetic protein markers (DPP IV (Dipeptidyl peptidase) and SGLT2 (sodium-glucose cotransporter-2). This work will open the way for the use of marine bioactive compounds as an alternative in the curative treatment of diabetes.

Methods

The collection of four green marine algae (*Chaetomorpha crassa, Caulerpa racemosa, Caulerpa verticillata and Caulerpa scalpelliformis*) from Gulf of Mannar (9°28′N, 79°18′E) and extraction of the marine algal extract were followed as described by [6]. Briefly, the algal samples were collected and extracted for its phytochemicals and the antioxidant potential of the algal extracts was assessed based on three different antioxidant assay (ABTS, metal chelation and phosphomolybdenum assay). Moreover, the samples were also subjected to antidiabetic assays (α-amylase and α-glucosidase enzyme inhibition). Among the four algal extracts, *C.verticillata* showed a good antioxidant and anti-inflammatory activities. Hence, further analysis was carried out only with *C.verticillata*.

In vitro antioxidant assays

Hydrogen peroxide scavenging assay

The ability of the ethanolic extract of *C.verticillata* to scavenge hydrogen peroxide was measured by following the

protocol using ascorbic acid as a standard [7]. To 1 ml of extract of varying concentration (100–800 µg/ml), 600 µl of 2 mM H_2O_2 prepared in phosphate buffer (pH 7.4) was added. The reaction mixture was completely mixed and incubated for 10 min at room temperature, and the absorbance was measured at 230 nm in UV–Vis spectrophotometer (1650 Shimadzu, Japan). The same protocol was followed for the standard ascorbic acid, the scavenging potential was calculated, and the percentage of inhibition was calculated using the following equation:% of inhibition=Abs C-Abs TAbs C×100

Abs T = Absorbance of test sample; Abs C = Absorbance of control.

Superoxide radial scavenging assay

The superoxide radical scavenging activity was measured based on the protocol followed by [8]. The superoxide radicals were generated by adding 500 µl of NBT (nitro blue tetrazolium) (0.3 mM), 500 µl of NADH (*nicotinamide adenine dinucleotide)* (0.936 mM), 500 µl of Tris HCL buffer (16 mM, pH 8.0) and 1 ml of algal extract with increasing concentration (100-800 µg/ml). The reaction was initiated by the addition of PMS (phenylmethanesulfonic acid) (0.12 mM), and the tubes were incubated at 25 °C for 5 min. The absorbance was measured at 560 nm. A similar treatment was given to the standard ascorbic acid, and the inhibition percentage was expressed using the following equation:%of inhibition=Abs C-Abs TAbs C×100

Abs T = Absorbance of test sample; Abs C = Absorbance of control.

In vitro anti-inflammatory assays

Protein denaturation assay

Denaturation of protein was assessed by the protocol followed by [9]. To 1 ml of 1% BSA (bovine serum albumin), 1 ml of marine algal extracts (100–800 µg/ml) and 1 ml of phosphate buffer saline (pH 6.4) were added. Once the reaction mixture was mixed, the tubes were incubated at 70 °C in water bath for 10–15 min. The tubes were allowed to cool, and the turbidity was measured in UV–Vis spectrophotometer at 660 nm. The protein denaturation inhibition percentage was calculated according to the formula as follows:%inhibition of protein denaturation=Abs C-Abs TAbs C×100

Abs T = Absorbance of test sample; Abs C = Absorbance of control.

Proteinase inhibitory assay

The proteinase inhibition was measured as described by [10]. To 1 ml of 20 mM Tris–Hcl buffer (pH 7.4), 0.06 mg of trypsin and 1 ml of algal extract (100–800 µg/ml) were added. The reaction mixture was vortexed completely and incubated for 30 min at 37 °C. Furthermore, 1 ml of 0.8% casein (w/v) was added to stop the reaction, and the tubes were centrifuged for 5 min at 2500 rpm. The absorbance of the supernatant was measured at 210 nm. The inhibition percentage was calculated by the following equation:Proteinase inhibition%=Abs C-Abs TAbs C×100

Abs T = Absorbance of test sample; Abs C = Absorbance of control.

HPLC–UV-ESI MS/MS analysis of *C.verticillata*

The HPLC-MS (high-pressure liquid chromatography–mass spectrometry) system consisted of a MS pump, autosampler, UV detector, and a triple-quadrupole, ESI QTOF high-resolution mass spectrometer (Bruker, USA) with Met Frag software for data acquisition and analysis. The sample separation was carried out using Agilent poroshell C_{18} reverse phase column (150 mm×4.6 mm), 2.7 µm particle size (part number: 683975-902), protected with a security guard cartridge (Zorbax eclipse, C_8, 4.6×12.5 mm, 5µ). The sample was analyzed according to the standard protocol with some minor modifications [11]. Two different mobile phases were used, like Solvent A: water (with 0.1% formic acid), and Solvent B: acetonitrile (with 0.1% formic acid), with a column temperature of 25˚C and UV detector at 280nm. The flow rate was 300µl/min, and 10µl of sample was injected. The samples eluting out from UV detector were then directed to triple-quadrupole tandem mass spectrometer with an electrospray interface (ESI), operating in complete scan mode from m/z (50–2200). Mass spectra were acquired in positive modes with capillary voltage at 4500 V, end plate offset 500 V, nebulizer gas at 60 psi, dry gas 12.0L/min, and capillary dry temperature at 220 °C. The identification was achieved and processed using Met Frag workstation software.

ADME analysis and pharmacokinetics toxicity prediction analysis

The canonical structures of the four aforementioned compounds from HPLC-ESI-MS/MS analysis were retrieved

from Pubchem database (www.pubchem.ncbi.nlm.nih.gov). The selected compounds were subjected to ADME analysis. For this, the compounds were analyzed for its physicochemical limitations, pharmacokinetics investigation and drug-likeness of the compounds with use of SWISSADME (http://www.swissadme.ch/index.php). Furthermore, the toxicity prediction for the oral consumption was also calculated using Protox ii (tox.charite.de). This toxicity prediction helps in evaluating the carcinogenicity, hepatotoxicity, immunotoxicity and also the toxicological pathways [12].

In silico molecular docking analysis

Preparation of ligands and protein molecule

The crystal structures of the selected bioactive compounds (ligands) of *C.verticillata* were downloaded from Pubchem database. The 3D SDF structure of DPP IV (PDB-ID: IJ2E) and SGTL2 (PDB-ID: 7VSI) protein was retrieved from the protein data bank (www.rcsb.org). The protein was carefully validated using Ramachandran plot before the docking process using MolProbity server [13]. Further, the protein molecules were prepared by removing the water molecules, adding hydrogen atoms, removing the heteroatoms and bounded other polypeptide inhibitors. The modified protein molecule was used for the docking study [12].

In the current study, PyRx 0.8 version (https://pyrx.sourceforge.io/) software was used for docking purpose, which included Open babel, Auto and AutoDock Vina. Furthermore, the protein and the ligand molecules were transformed to pdbqt format using Autodock tools. Open babel was used to minimize the energy, and blind docking was performed. For a promising protein–ligand binding, the active binding regions were recognized using Biovia discovery studio tool. Analysis of the docked proteins is performed once docking is complete and visualized by BioVia, Discovery studio, 2020. Further, the inhibition constant was calculated to find out the binding efficacy of the ligand and protein molecule using the following equation [14]

1

$Ki=e[-\Delta G/RT]$ where $R = 1.985 \times 10^{-3}$ kcal/mol (universal gas constant; $T = 298.15$ K (temperature);

ΔG = Binding energy.

Statistical analysis

All the tests were carried out in triplicate, and the data were represented as mean ± SE. The experimental results were statistically analyzed using GraphPad prism 9 and Microsoft Excel 2010.

Results

The ability of the ethanolic extract of *C.verticillata* has shown that the extract has a strong ability to scavenge hydrogen peroxide radicals at a dose-dependent manner. At a highest concentration of 800 µg/ml, *C.verticillata* extract has shown a maximum scavenging activity of 78.3 ± 0.34% with an IC_{50} of 287.8 µg/ml compared to the standard ascorbic acid (71.8 ± 1.15% at 200 µg/ml) (Table 1). The superoxide radical scavenging activity was determined using PMS-NADH method. The reduction in absorbance at 560 nm showed that the algal extract has the ability to quench the superoxide radicals, where the ethanolic extract of *C.verticillata* at a maximum concentration of 800 µg/ml has observed to show 52.7 ± 1.26% (IC_{50} = 796.15 µg/ml) when compared with the standard ascorbic acid (69.7 ± 1.02%, IC_{50} = 115.5 µg/ml) at 200 µg/ml.

Table 1. Percentage of inhibition of scavenging activity of *C.verticillata* and IC_{50} values

Algae name / Standard	In vitro antioxidant assays

Hydrogen peroxide scavenging assay (%) and IC_{50} (µg/ml)		Superoxide scavenging assay (%)and IC_{50} (µg/ml)		*Caulerpa verticillata* (800 µg/ml)
78.3±0.34	287.81	52.7±1.26	796.15	Ascorbic acid (200 µg/ml)

Result are expressed as Mean±SE of three replicates (n=3); the data were statistically analyzed by two-way ANOVA using GraphPad Prism. The difference was considered significant when p<0.05

Protein denaturation assay was carried out to measure the efficiency of the algal extracts to inhibit the denaturation of the proteins. *C.verticillata* has recorded a maximum inhibition of 57.4±0.19% (IC_{50}=471.5 µg/ml) with respect to the standard drug diclofenac of 96.4±0.25% (IC_{50} of 9.4 µg/ml). In Table 2, the effect of *C.verticillata* extract on anti-proteinase activity is presented. The extract has recorded a good level of proteinase inhibition of about 68.3±0.48% (IC_{50}=213.42 µg/ml) with a significance of p<0.05. The results have shown a good anti-proteinase activity in comparison to the standard aspirin (94.4±0.22%, IC_{50}=19.7 µg/ml). The results clearly indicate that the extract has the potential to bind with the cell surface by stabilizing the membrane with minor alterations on the charges of the cells.

C.verticillata was subjected to HPLC-ESI-MS/MS analysis for the identification of the bioactive compounds. It was identified as 2-Palmitoylglycerol, Pyro pheophorbide a, Dihydromonacolin and Loliolide are reported for its antioxidant and antidiabetic activities. The fragmentation of mass spectrum was carefully analyzed for its *m/z* values (Fig. 1). The chemical structure of the ESI-MS identified compounds is listed in Table 3. The compound peaked at 33.8 min retention time (R_t) was identified as Loliolide ($C_{11}H_{16}O_3$) with a molecular ion peak at *m/z* 197.11 $[M+H]^+$. Further, the compound at R_t = 56.6 min was identified as Dihydromonacolin L acid ($C_{19}H_{32}O_4$) consisting of molecular ion peak at *m/z* 325.23 $[M+H]^+$. The peaks at 59.0 min and 78.6 min were identified as 2-Palmitoylglycerol ($C_{19}H_{38}O_4$) and Pyro pheophorbide a ($C_{33}H_{34}N_4O_3$) containing a molecular ion peak at *m/z* 331.28 $[M+H]^+$ and *m/z* 535.26 $[M+H]^+$, respectively. Additionally, the fragmentation pattern of mass spectra was already reported in our previous published data [15]. The bioactive compounds after HPLC-ESI-MS/MS analysis were checked for its physicochemical properties like lipophilicity, solubility, bioavailability, number of hydrogen atoms, TPSA, BBB, and Lipinski rule; rotatable bonds were evaluated carefully using SWISSADME software tool. Firstly, Fig. 1 represents the bioavailability radar charts, which gives a quick glimpse of six important physicochemical properties like lipophilicity, size, polarity, flexibility and saturation. The compounds which fall under the pink area in radar charts refer that the compound comes under the property of drug likeliness (Fig. 2).

Radar charts of the bioactive compounds for drug likeliness calculated by Swiss ADME software
All the leading ligand molecules (2-Palmitoylglycerol, Loliolide, Pyro pheophorbide a and Dihydromonacolin L acid) were observed to follow maximum drug-likeness limitations. Moreover, all the compounds were observed to possess a good gastrointestinal absorption and solubility. Further, the compounds were subjected to toxicity prediction, where LD_{50} plays an important role in determining their level of toxicity, where it includes immunotoxicity, carcinogenicity, TPSA value and octanol/water partition (LogP) value (Table 4). All the four compounds were thoroughly evaluated for its pharmacochemical and physicochemical properties for in silico molecular docking analysis. The Ramachandran plot analysis of the protein (DPPIV) clearly revealed that most of the residues lie within the favored regions that indicate the protein quality (Fig. 3). Except Loliolide, docking was performed for all the other three compounds with the diabetic protein markers like DPP IV (PDB: IJ2E) and SGLT2 (PDB: 7VSI). Docking scores were assessed between the ligands and the proteins. The results revealed that Pyro pheophorbide a has a strong binding affinity with DPP IV (−9.4 kcal/mol), followed by Dihydromonacolin L acid (−7.7 kcal/mol) and 2-Palmitoylglycerol (−5.3 kcal/mol) (Fig. 4a–f).

Table 4. Toxicity prediction of *C.verticillata.* LD_{50}- lethal dose, TPSA- topological polar surface area

Name of the compound	Predicted LD_{50} (mg/kg)	Predicted toxicity class	Carcinogenicity	Immuno toxicity	TPSA	Octanol/water partition (log P)

Discussion

The physiological and biological condition of the marine seaweeds that persist in varying conditions like temperature, pH, salinity and various other factors leads to the production of various phytoconstituents and potential bioactive compounds as a measure of defense mechanism. These seaweeds contain a variety if bioactive compounds that has the potential to quench the free radicals. It is well known that hydrogen peroxide is present everywhere in the environment at a low concentration. Earlier studies have reported that it is a weak oxidizing agent with the capability of crossing the cell membranes quickly and acts in response to Cu^{2+} and Fe^{2+} ions leading to the formation hydroxy radicals [16]. These hydroxyl radicals have the potential to initiate lipid peroxidation that leads to the damage of

DNA. Hence, from the results it is very clear that the algal extract has the capability of scavenging hydrogen peroxide where the occurrence of potential phytoconstituents would have involved in electron donation to neutralize the radicals [17].

It is to be noted that enzymatic antioxidants like superoxide dismutase and catalase are involved in the decomposition of hydrogen peroxide to oxygen and water. Hence, changes in the enzymatic antioxidants due to hyperglycemic condition could lead to inactivation of superoxide dismutase where its glycosylation leads to decrease in activity [18]. Therefore, diabetes-induced oxidative stress increases the concentration of pro-inflammatory cytokines that results in the inflammation [19]. Many scientific reports had already proved that increased production of TNF-α has a strong link with obesity induced insulin resistance that leads to type 2 diabetes [20]. The present findings indicate that the extract has the potential to inhibit the denaturation of the protein by stabilizing the membrane of the protein. Various factors like heat, hypotonic environment, etc., can lead to membrane damage of the protein molecule that further results in the leakage of the inner lysosomal contents. The extracellular release of the membrane further leads to inflammation in the tissue. Hence, it is proved that the anti-inflammatory activity of *C.verticillata* extract provides an evidence for the stabilization of the membrane by inhibiting the discharge of lysosomal constituents [21].

Previous reports have evidenced that prolonged discharge of inflammatory intermediates would upregulate the expression of genes involved in acute and chronic inflammatory diseases by inactivating the anti-proteinases. Earlier reports of [22] have stated that uninhibited levels of proteolysis by the proteinase enzyme can result in various patho-physiological symptoms. The equilibrium of anti-proteinases and proteinases is to be maintained and regulated. Under stress conditions, the ROS will inactivate the anti-proteinases by which the balance gets disturbed resulting in uncontrolled damage of proteins causing increased tissue injury. Therefore, a natural remedy is required to have both anti-inflammatory and antioxidant property that can lessen the ROS-induced stress and regulate the immune function. Hence, *C.verticillata* could be the right choice to prevent the rupture of the HRBC membrane, by which the erythrocyte membrane gets stabilized. By stabilizing the lysosomal membrane, the inflammatory process gets regulated and prevents the release of inflammatory mediators. Our current results of *C.verticillata* have provided the evidence for the aforementioned activities.

Currently, many effective medications made from natural sources are discovered utilizing computer-aided drug design approaches because of the ongoing advancements in computer science. Nowadays, computer-aided drug design is employed to anticipate ADMET features of bioactive compounds, resulting in early stage drug development [23]. The motivation for this in silico techniques is due to the reduced cost and time factor required when compared to traditional ADMET profiling. With respect to drug development, it is important to consider the concept of inhibition constant (*Ki*) that helps to prioritize the bioactive compounds as efficient inhibitors for therapeutic purpose. The inhibition constant of the compounds is listed in Table 5 which is expected to lie between the ranges of 0.1–1.0 μM [13]. The molecular docking results clearly implies that there is a strong relationship with respect to the docking score (ΔG) and the inhibition constant (*Ki*). The inhibition constant was calculated according to the formula as mentioned in the methodology section (Eq. (1). The results revealed that the compounds that showed maximum binding energy (ΔG) (DPP IV: Pyro pheophorbide a (−9.4 kcal/mol) possess a lower inhibition constant (*Ki*= 1.31 μM). From this, it is evident that higher binding energy and lower inhibition constant indicate a stronger and a stable ligand–protein interaction [24] since it provides a deeper insight about the compound to regulate the particular biological pathways. Also, these bioactive compounds were subjected to SWISS ADME software to evaluate the drug likeliness and the physicochemical properties of the compounds, toxicity prediction and in silico molecular docking. These preclinical compounds have the ability to get absorbed to the surface of the receptor that is again circulated into the target site. Further, these compounds will be metabolized by the liver and excreted out of the system to avoid toxicity [25]. In the present study, almost all the bioactive compounds have followed the pharmacochemical and physicochemical parameters (molecular weight: less than 500D), Log S which refers the solubility. The result showed that all the compounds except Loliolide were inactive for immunotoxicity and carcinogenicity, whereas Loliolide showed positive to carcinogenicity. Additionally, the LD_{50} value of Loliolide was

34 mg/kg; hence, it comes under class 2 of toxicity, which is fatal if swallowed.

Table 5. In silico molecular docking score of the bioactive compounds of *C.verticillata*

Name of the bioactive compound	Diabetic Protein targets	Docking score (kcal/mol)	Inhibition Constant K_i (μM)
2-Palmitoylglycerol	1J2E	−5.3	0.000134
Dihydromonacolin L acid	−7.7	0.0000021	Pyro pheophorbide a
−9.4	1.318256	2-Palmitoylglycerol	7VSI
−6.6	0.0000147	Dihydromonacolin L acid	−9.2
1.862087	Pyro pheophorbide a	−8.7	4.365158

Considering the Ramachandran plot analysis, the widespread of ψ (psi) and φ (phi) angles clearly specifies the flexibility and potential ability of the protein to undergo conformational changes on binding of the ligand molecule [14]. These observations helped in accounting for the protein dynamics in molecular docking studies (Fig. 3). Except Loliolide, docking was performed for all the other three compounds with the diabetic protein markers like DPP IV (PDB: IJ2E) and SGLT2 (PDB: 7VSI). Docking scores were assessed between the ligands and the proteins. The results revealed that Pyro pheophorbide a has a strong binding affinity with DPP IV (−9.4 kcal/mol), followed by Dihydromonacolin L acid (−7.7 kcal/mol) and 2-Palmitoylglycerol (−5.3 kcal/mol). Earlier reports suggest that DPP IV was considered as a target to treat type 2 diabetes by inactivating glucagon inhibitory peptide and GLP-1 (glucagon-like peptide) [26]. Additionally, DPP IV inhibition was suggested to show a beneficial effect on postprandial glucose levels [27]. Moreover, it is proved that Pyro pheophorbide has the ability to inhibit alpha amylase and lipase by which it decreases the absorption of triglycerides present in the intestine that prevents from hyperlipidemia and obesity [28]. It has been evidenced that administration of Pyro pheophorbide a has significantly reduced the blood glucose level in normal and diabetic mice by inhibiting alpha amylase and alpha glucosidase enzymes [29]. Similarly, 2-Palmitoylglycerol has the ability to activate GPR119 which is predominantly expressed in pancreatic-β cells, where its activation leads to induce the secretion of insulin and GLP-1 [30].

Since studies had shown that the incretin hormones, glucose-dependent insulin tropic polypeptide (GIP) and glucagon-like peptide-1 are important regulators of postprandial insulin production; inhibition of DPP4 might be a great choice of interest to treat type 2 diabetes. It is also proved that 2-Palmitoylglycerol has the potential of reducing the inflammation and additionally minimizes the level of fatty acid oxidation [31]. Hence, strong interaction of the ligands (2-Palmitoylglycerol, Pyro pheophorbide a and Dihydromonacolin L acid) with the active site of DPP IV protein proves that these compounds could be a great choice for the management of type 2 diabetes (Fig. 2a, c and e). $SGTL_2$ (sodium–glucose co-transporters) plays a very important role in the reabsorption of glucose in the kidney. Inhibition of $SGTL_2$ increases the excretion of glucose in the urine by decreasing the glucose level in the plasma [32]. Existing literature suggests that the primary method by which SGLT2 reduces inflammation and oxidative stress was its capacity to minimize the negative impact of an overabundance of nutrients on cells and tissues, especially on the adipose tissues. When adipose tissue is exposed to an overabundance of nutrients, it produces more pro-inflammatory hormones and cytokines) TNF, IL-1, IL-6 and leptins) [33].

In our present study, Dihydromonacolin L acid was shown to dock a maximum score of -9.2 kcal/mol with SGTL2 followed by Pyro pheophorbide a (−8.7 kcal/mol) and 2-Palmitoylglycerol (−6.6 kcal/mol), which directly implies that the compound has the ability to reduce the glucose level and lessen the effects of inflammation induced oxidative

stress as well (Fig. 2b, d and f). Previously, it was reported that the Dihydromonacolin L acid was proved to be a potential inhibitor in the biosynthesis pathway of cholesterol [34]. Hence, it protects from LDL oxidation by inhibiting HMG-CoA reductase [35]. Pheophorbide is a by-product of chlorophyll which is known for its anti-inflammatory and anticancer property, where it inhibits the high concentration of nitric oxide (NO) to suppress the induction of iNOS (nitric oxide synthase) [36]. Hence, these bioactive compounds were expected to be a possible choice for the treatment and management of type 2 diabetes.

Conclusion

The ultimate aim of the drug discovery research is to find effective medications through clinical and preclinical studies. In this context, the integration of docking and ADMET studies has provided a deeper insight into the understanding about the ligand–protein interaction and pharmacokinetics of the tested compounds. The results of the present study conclude that *C.verticillata* has the potential to inhibit the upregulation of blood glucose level. Moreover, the extract has the ability to reduce oxidative stress induced inflammation as well. The bioactive compound extracted (2-Palmitoylglycerol, Dihydromonacolin L acid, Loliolide and Pyro pheophorbide a) from *C.verticillata* could be considered as one of the promising agents for treating T2D. Even though a number of bioassay experiments were performed for compound's to evaluate its ADMET profile, they are quite time-consuming and costly. This emphasizes on the importance of in silico predictions for its ADMET properties. Ideally, ADME, toxicity prediction and in silico analysis have revealed that the aforementioned bioactive compounds have a greater affinity to DPP4 and SGTL2. The outcome of the analysis suggests that the docked bioactive compounds were found to be non-hazardous and the computed drug analysis needs further validation to find its effectiveness in treating oxidative stress and inflammation in diabetic condition. To ensure the inhibitors of DPP4 and SGTL2 from marine algal source, the analyses necessitate further validation through in vivo experiments. We believe that expanding this research by integrating proper in vivo experiments along with ADMET and in silico analysis gave a deeper insight about the bioactive compounds from marine seaweeds as a potential therapeutic candidate in the treatment of oxidative stress induced diabetes. Hence, this holistic approach will eventually pave the way for the advancement in drug discovery to produce more safer and effective therapeutic agents.

Multifaceted applications of micro/nanorobots in pharmaceutical drug delivery systems: a comprehensive review

Das, Tanisha1 ; Sultana, Shirin21 Siksha 'O' Anusandhan (Deemed To Be) University, School of Pharmaceutical Sciences, Odisha, India (GRID:grid.412612.2) (ISNI:0000 0004 1760 9349)2 School of Pharmaceutical Education and Research, New Delhi, India (GRID:grid.412612.2)

ABSTRACT (ENGLISH)

Background

Drug delivery systems (DDSs) encompass a wide range of methods, including oral, injectable, and topical routes of administration, all tailored to meet specific patient needs. Micro and nanorobots, equipped with pioneering propulsion mechanisms that convert external energy sources into precise movements, have revolutionized drug delivery. This cutting-edge technology ensures highly efficient drug delivery, particularly when targeting specific targets within intricate physiological environments. In contrast to traditional drug delivery approaches that rely on bloodstream circulation, engineered micro/nanorobots have autonomous mobility, enabling drug delivery to previously unreachable areas.

Main body of the abstract

Integrating micro/nanorobots into drug delivery raises vital safety and biocompatibility issues. These encompass material selection, degradation in-vivo, overcoming biological barriers, controlled movement, external interference, immune response, chemical reactions, systemic effects, long-term impact, and real-time monitoring. While micro/nanorobots hold immense transformative potential, they confront significant hurdles in their journey toward practical applications. Chief among these challenges are concerns regarding biocompatibility, ensuring that these tiny devices do not trigger adverse reactions. Long-term safety remains a critical issue, as understanding the effects of prolonged exposure and potential accumulations within the body and navigating complex biological environments with precision is another obstacle.

Short conclusion

The paper summarizes how to explore the various ways in which micro/nanorobots can be employed to enhance drug delivery, including their precision, targeting capabilities, and adaptability to different physiological conditions. Additionally, the review seeks to highlight the transformative potential of these technologies and their impact on the pharmaceutical industry.

FULL TEXT

Background

Drug delivery systems (DDSs) encompass diverse approaches for administering therapeutic agents. These methods involve various routes of drug administration, encompassing oral, injectable, and topical routes, tailored to specific patient needs [1]. DDSs incorporate a range of drug formulations and delivery devices, addressing the complexities of biotechnology-based therapeutics like proteins and peptides. Advanced techniques, such as cell and gene therapies, offer precision in treatment delivery. Nanoparticles play a pivotal role, serving as carriers for drugs and even as pharmaceuticals and diagnostics themselves [2]. Targeted drug delivery, particularly in cancer therapy, has seen significant progress. Overcoming blood–brain barrier challenges is vital, and DDS refinements pave the way for personalized medicine. The ideal DDS aims to optimize therapeutic efficacy while minimizing side effects [3].

Micro and nanorobots have emerged as revolutionary drug delivery systems, leveraging innovative propulsion mechanisms that convert external energy sources into precise movements. This advanced technology offers exceptional efficiency in drug delivery, especially when targeting specific sites within complex physiological environments [4]. These micro and nanobots have demonstrated remarkable capabilities, including the encapsulation, transport, and direct delivery of therapeutic substances to disease sites. This targeted approach not only enhances therapeutic efficacy but also significantly reduces systemic side effects associated with potent drugs. In essence, micro and nanobots represent a transformative leap in drug delivery, enabling precise, site-specific treatment with minimal collateral impact [5]. Unlike conventional drug delivery methods relying on bloodstream circulation for drug transport, engineered micro/nanorobots possess autonomous mobility, facilitating drug delivery to otherwise inaccessible regions [6]. These micro/nanorobots are powered either externally, through magnetic fields, light, acoustics, or electric fields, or internally, via chemical reactions. While micro/nanorobots hold promising potential, the majority of current research remains confined to in-vitro experiments, with in-vivo investigations still in

their nascent stages. Further biological studies are imperative to substantiate the in-vivo drug delivery efficacy of micro/nanorobots [7].

However, PLA (Polylactic Acid) and TPU (Thermoplastic Polyurethane) are two different types of biocompatible polymers that play important roles in the development of nanorobots/microrobots for drug delivery systems [8]. PLA is a biodegradable and biocompatible polymer derived from renewable resources, such as corn starch or sugarcane which can be used to construct the structural components of nanorobots/microrobots, providing a stable and non-toxic framework for drug delivery systems. Therefore, PLA-based nanorobots can be designed to release drugs at a controlled rate as the polymer gradually degrades, making it suitable for sustained drug delivery [9]. Its versatility and compatibility with various drug formulations make it a popular choice for encapsulating and delivering therapeutic agents. On the other hand, TPU is another biocompatible polymer known for its flexibility and durability which can be used to create flexible components or coatings for nanorobots/microbots, allowing for improved mobility and adaptability within the body's complex environment [10]. TPU-coated nanorobots can navigate tight spaces, overcome obstacles, and potentially target specific tissues or cells more effectively. Its ability to withstand mechanical stress and maintain stability under different physiological conditions makes TPU valuable in enhancing the functionality and maneuverability of drug-delivery microrobots [11]. In drug delivery systems, both PLA and TPU can be utilized to design and manufacture nanobots/microbots tailored for specific applications.

The review aims to provide a thorough examination of the diverse roles that micro/nanorobots play in drug delivery, encompassing their design, functionalities, and mechanisms of action. Furthermore, it seeks to elucidate how these innovative systems enable targeted drug delivery, controlled release, and navigation within physiological environments. Additionally, the review assesses the challenges and advancements in this field, including biocompatibility, safety concerns, and recent technological developments. Ultimately, it aspires to offer insights into the transformative potential of micro/nanorobots in revolutionizing drug delivery and advancing healthcare.

Main text

Types of micro/nanorobots in pharmaceutical drug delivery systems

The types of micro/nanorobots that are prevalent in current pharmaceutical drug delivery technologies can be classified into two broad types as shown in Tables 1 and 2.

Table 1. Types of micro/nanorobots based on size

Types	Classification based on size
1. Microbots	– Typically, 1 μm to several hundred μm in size
– Larger than nanoparticles but smaller than macroscopic robots	– Suited for navigating through blood vessels and tissues
2. Nanorobots	– Typically, in the nanometer (nm) to micrometer range
– Substantially smaller than microbots	– Ideal for precise targeting at the cellular or molecular level

Table 2. Types of micro/nanorobots based on functionality

Types	Functionalities

1. Active Propulsion Robots	– These micro/nanorobots possess self-propulsion mechanisms to navigate within the body
– Examples: Microswimmers, Microrobotic capsules, Light-powered microbots, Magnetic field-driven microbots, Acoustically-driven microbots, and Chemically-powered microbots	2. Passive Transport Robots
– These micro/nanorobots rely on external factors or carriers for transport within the body	– Examples: DNA nanorobots, Nanoparticle-based carriers, Molecular shuttles, and Biomolecule carriers

Magnetic small-scale robots hold significant promise in the biomedical field due to their advantages in actuation. Recent research has witnessed notable advancements in the design, fabrication, and application of these devices, aiming to enhance their performance for potential clinical use [12]. An overview of recent progress in small-scale biomedical robots has been reviewed and studied emphasizing their development, capabilities, and existing challenges. It also suggests alternative biomedical applications for some technologies. The study of Koleoso et al., 2020 underscores the need for continued efforts to enhance the functionality and reliability of these robots, particularly in clinical contexts, and offers recommendations for advancing their commercialization [13]. According to Azar et al., 2020, the essential components of nanorobots, including sensors, actuators, and nano controllers, draw upon previous research to showcase diverse designs. It advances beyond theoretical discussions to delve into the practical aspects of manufacturing and implementation. Significantly, it emphasizes recent innovations in drug delivery, detection, and manipulation, providing insights into their motion mechanisms and the current manufacturing methods in use [14]. Control and navigation strategies for nanorobots are explored in-depth, emphasizing the importance of mathematical positioning concepts in modeling these intricate devices [15]. Several studies presented various algorithms that enable precise control, underscoring their significance in the field. Furthermore, studies presented numerous applications that underscore the effectiveness of nanorobots across various domains. These applications encompass a wide range of functions, including diagnostics, treatments, target detection, and even complex surgical missions. These devices serve as a crucial link between theoretical analyses and practical manufacturing approaches [7, 14]. Importantly, it sheds light on future implementation concerns and emerging research gaps, emphasizing the need for continued investigation and innovation [14]. In a nutshell, the practical integration of nanorobots can be implemented in critical areas such as optical surgeries, cell manipulation, and cancer treatment. It contributes significantly to the advancement of nanorobotics and its potential impact on healthcare and other fields.

Targeted drug delivery mechanisms using micro/nanorobots

The use of micro/nanorobots capable of efficiently harnessing a variety of energy sources to facilitate motion has the potential to bring about a significant transformation in the pharmaceutical field, particularly in the realm of targeted drug delivery. Through the precise delivery to specific tissues or anatomical sites and controlled release mechanisms, drugs can be directed toward their intended destinations [16]. Targeted delivery encompasses a range of actuation energy sources, including self-propulsion via substances like hydrogen peroxide and enzymes, external propulsion driven by factors such as light, electricity, acoustics, and magnetic fields, as well as propulsion driven by motile microorganisms like bacteria, sperm cells, contractile cells, and immune cells as shown in Fig. 1.

Fig. 1 [Images not available. See PDF.]

Energy sources to design and develop micro/nanorobots for precise drug delivery

Targeted and/or precise drug delivery is generally processed by using two major technologies—exogenous power-driven method and endogenous power-driven methods.

Exogenous power-driven technology

In exogenous power-driven Micro/Nanorobots, due to their micro/nano-size, drug-delivery robot systems face the challenge of countering Brownian motion to achieve autonomous movement within complex bodily fluids. According to Hu et al., 2020, an external power source is typically employed to enable the controlled and coordinated locomotion of these micro/nanorobots. Commonly utilized sources of external power include magnetic fields, electric fields, light energy, acoustic waves, and heat energy [17–21]. A combination of these driving modes in practical design is often employed to create micro/nanorobots with diverse functionalities [7]. Magnetic propulsion is one of the exogenous power-driven methods to prepare Micro/Nanorobots in drug delivery which often involves the design of helical swimmers, which are inspired by the flagella of micro-organisms [17]. These helically shaped micro/nanorobots mimic the rotary corkscrew motion of bacterial flagella, enabling them to move through bodily fluids through interaction with external magnetic fields [22]. Researchers frequently combine these artificial bacterial flagella (ABF) with drug-loaded liposomes for drug delivery applications. For example, in a study conducted by Qiu et al. in 2014, they developed a microrobot consisting of two components. The first component is a titanium-coated ABF that enables precise 3D navigation within fluids when subjected to rotating magnetic fields. The second component is an outer temperature-sensitive liposome that controls the release of the drug based on temperature regulation. This innovative approach shows potential for enhancing targeted drug delivery in pharmaceutical applications [7, 23]. Electric field propulsion is also a widely used method in micro/nanorobotics, offering precise control and versatile applications in drug delivery and other fields [7]. Another significant illustration of exogenous power-driven micro/nanorobots is found in the Janus colloidal system. This system utilized a combination of electric and magnetic energy to facilitate independent movement and cargo retrieval [24]. It consists of metal-dielectric Janus colloids that respond to a high-frequency electric field (0.5–2.5 MHz). These colloids are characterized by a hemisphere coated with nickel, allowing them the ability to be guided in a specific direction by a magnetic field. This capability facilitates precise cargo delivery by predefining the path that the micro/nanorobot will follow. Rahman et al., 2017 introduced a rotational nanomotor structure using carbon nanotubes, which exhibited rapid responsiveness and ultra-high-speed movement when exposed to an electric field [25]. This motion was driven by the alignment of water dipoles induced by the electric field, demonstrating exceptional performance in water. However, its behavior in simulating more complex human systems or body fluids remained unexplored. Incorporating multiple energy sources, nanoparticles can achieve directional movement. Guo et al., 2018 also presented an approach for regulating the movement of catalytic nanomotors through the application of electric fields in conjunction with light energy [18]. In brief, electric field propulsion in micro/nanorobotics offers exciting possibilities for precise and programmable movement. The Janus colloidal system, with its dual responsiveness to electric and magnetic fields, exemplifies the potential for autonomous cargo delivery [26]. Carbon nanotube-based nanomotors exhibit rapid movement under electric fields, although their performance in complex biological environments requires further investigation. Finally, the combination of electric fields and light energy provides a controllable means to steer catalytic nanomotors [7, 26]. These advancements hold great promise for applications in drug delivery and other fields where precise, directed movement at the micro/nanoscale is essential. Light energy serves as another frequently employed method in micro/nanorobotics, offering high controllability and programmability, typically used in a supplementary role. Wang et al., 2018 studied that it enables directional movement of nanorobots through the modulation of light parameters such as frequency, polarization, intensity, and propagation direction [19]. A notable example is the work of Zhan et al., 2019 who harnessed the linear dichroism property of Sb_2Se_3 nanowires to create an artificial swimmer. This swimmer incorporated two cross-aligned dichroic nanomotors, and its movement was guided by adjusting the polarization direction of incident light [27]. This approach showcases the potential for precise control of nanorobot movement using light energy, making it a valuable tool in micro/nanorobotic applications. Light energy not only serves as a direct driving force for micro/nanorobots but can also catalyze redox reactions within them, leading to propulsion through the generation of chemical gradients or bubbles [28, 29]. For instance, Wang et al., 2019 developed a Cu_2O@N-doped carbon nanotube (Cu_2O@N-CNT) micromotor powered by glucose and activated by visible-light photocatalysis [30]. This micromotor exhibited several advantages, including non-toxicity, high biocompatibility, and environmental friendliness. It showcased impressive movement and 3D motion control

within a biological environment. However, challenges persist when transitioning to in-vivo applications, mainly due to the limited ability of visible light to penetrate tissues [7, 30]. Utilizing an external power source, ultrasound power-driven micro/nanorobots show great potential in the field of advanced targeted drug delivery. Their outstanding biocompatibility and dependability make them a promising option, and they rely on external power-driven technology for their functionality. Commonly, nanowires, typically composed of gold, serve as the primary carriers for these ultrasonically driven nanorobots [20]. The template electrodeposition method plays a pivotal role in the design of ultrasound-propelled micro/nanomotors. This method involves creating a concave cavity at one end of the nanomotor through the deposition of a sacrificial copper layer. When subjected to ultrasound waves directed at the concave end, the nanomotor is propelled forward by the resulting pressure gradient [31]. Furthermore, ultrasound is frequently integrated with magnetic fields to enable precise control. For example, Victor and his team devised a magnetically guided three-segment nanowire motor with Au–Ni–Au segments, harnessing ultrasound for propulsion [32]. Changing the magnetic field's orientation enables ultrasound-propelled particles to move in all directions. The feasibility of precise drug delivery has been confirmed by introducing a polymeric section containing pH-sensitive drugs into the nanomotor. In acidic conditions, these drugs can be released, improving the selectivity of drug delivery. Additionally, Garcia-Gradilla et al., 2014 have developed an ultrasound-propelled nanorobot featuring four segments, including Au-Ni-Au and Au wire components [33]. This innovative approach also showcases the versatility and potential of ultrasound-powered nanorobots for advanced drug delivery applications.

Endogenous power-driven technology

In endogenous power-driven approaches, nanorobots rely on endogenous power sources for self-propulsion, primarily driven by chemical or biological reactions [34]. These micro/nanorobots are typically asymmetric and often coated with catalysts to harness continuous chemical energy from their surroundings. A prevalent approach involves converting chemical energy into a driving force using redox reactions, with the decomposition of hydrogen peroxide being a widely employed method. Hydrogen peroxide possesses an unstable chemical bond that readily breaks down into water and oxygen when catalyzed by various agents like metals, enzymes, or an alkaline environment. This concept has been extensively employed in nanorobot designs, including bimetallic nanorods, hollow Janus particles, vesicular polymers, and more [35–37]. These nanorobots hold great promise, particularly in the field of targeted drug delivery [38, 39]. Janus particles, a class of particles with distinct compositions and structures on their two hemispheres, have also contributed to this field. Wu and colleagues, for instance, engineered polymer multilayer Janus capsules capable of self-propulsion using 0.1% hydrogen peroxide as fuel at physiological temperatures [36]. This approach underscores the potential of nanorobots powered by chemical reactions, opening exciting avenues for various applications, including targeted drug delivery. While the concept of using chemical energy conversion has been extensively explored, its practical application within living organisms has been constrained due to the inherent toxicity of the commonly employed "fuel," hydrogen peroxide [40]. Researchers have sought alternative, safer materials to power nanorobots. One such substitute is magnesium, renowned for its high biocompatibility. Magnesium can react with water to produce bubbles, serving as a propellant, making it a promising replacement for the hazardous hydrogen peroxide [40, 41]. Another approach involves harnessing biocompatible enzyme-catalyzed reactions for self-propulsion. This method utilizes non-toxic fuels like glucose and urea to drive nanorobots. For instance, researchers developed a core–shell nanorobot based on mesoporous silica, demonstrating self-propulsion capabilities in ionic media [43]. They functionalized the nanorobot with urease, an enzyme that catalyzes the breakdown of urea into carbon dioxide and ammonia. This enzymatic reaction allowed the nanorobot to move autonomously and release drugs. Importantly, when loaded with Doxorubicin (Dox), these nanorobots exhibited remarkable efficacy against HeLa cells. This success can be attributed to the synergistic effects of enhanced drug release and the presence of ammonia generated through the catalytic reaction [42, 43]. These inventive strategies showcase the potential of utilizing biocompatible materials and enzyme-catalyzed reactions to power nanorobots, thereby mitigating safety concerns and advancing their application in drug delivery within biological systems. Endogenous chemical energy propulsion offers an advantage by minimizing the need for constant micro/nanorobot control, focusing instead on guidance toward the target, often via magnetic attraction. This approach uses gas

generated from chemical reactions to reverse robot movement, well-suited for the gastrointestinal tract. However, chemical energy-driven nanorobots have drawbacks. Controlling their direction proves challenging, and they are sensitive to ionic environments, potentially disrupting motion. A significant limitation is their power continuity; they may exhaust energy as reactions proceed. Moreover, safety concerns surround the "fuel" and reaction products when applied within organisms, posing a substantial obstacle to their practical use [7]. These issues warrant further investigation and research in the future to address these challenges and unlock the full potential of chemical energy-driven self-propelled nanorobots in various applications, including targeted drug delivery within living organisms. The comparison between exogenous and endogenous power-driven Micro/Nanorobots in Pharmaceutical drug delivery systems has been detailed in brief in below Table 3.

Table 3. Simplified comparison between exogenous and endogenous power-driven micro/nanorobots in pharmaceutical DDS

Aspects	Exogenous power-driven Micro/Nanorobots	Endogenous power-driven Micro/Nanorobots
Power source	External energy sources (e.g., magnetic fields, ultrasound)	Internal energy sources (e.g., chemical reactions, enzymes)
Control	Requires external control and guidance mechanisms (e.g., magnetic field manipulation)	Self-propelled and guided by internal processes or cues
Navigation	Controlled externally, often using precise guidance systems	May exhibit less precise navigation, influenced by internal conditions
Energy supply	Constant energy supply required from external sources	Utilizes internal energy generation, potentially limited by available substrates
Targeted drug delivery	Achievable with precise external control	Potential for targeted delivery, guided by internal conditions
Safety concerns	Limited safety concerns related to the energy source	Safety concerns related to the choice of reactants and products
Potential for in vivo use	Commonly used in controlled laboratory settings	Holds promise for in vivo applications, subject to further research
Examples	Magnetic or ultrasound-guided nanorobots	Enzyme-catalyzed nanorobots using the body's chemicals

Apart from these types of micro/nanorobots, 4D printed micro/nanorobots are also some of the promising approaches in pharmaceutical DDS. 4D printed nano/microrobots are innovative vehicles for drug delivery in the pharmaceutical field [7, 44]. These tiny robots are constructed using advanced 4D printing technology, which allows them to change shape or behavior in response to external stimuli.

Safety and biocompatibility considerations for micro/nanorobots in drug delivery systems

Incorporating micro/nanorobots into DDS brings forth critical safety and biocompatibility concerns that must be addressed for successful application within the human body. These concerns encompass various aspects of nanorobot design, function, and interaction with biological systems. Key considerations include—biocompatible materials, in-vivo degradation, biological barriers, controlled mobility, external interference, immune response,

chemical reactions, systemic effects, effects on long-term use, and real-time monitoring and feedback mechanisms. The biocompatible materials used in nanorobot construction or designs must be ensured that the materials are non-toxic and biocompatible is paramount. Materials should not trigger adverse immune responses or tissue damage [45]. Considering in-vivo degradation, the nanorobots should be designed to degrade naturally or be eliminated from the body without leaving harmful residues or by-products inside the physiological systems [5]. Taking biological barriers into account, several research suggested that overcoming barriers such as the blood–brain barrier (BBB), and ensuring that micro/nanorobots can safely traverse them without causing damage is crucial for targeted drug delivery [46, 47]. According to Arvidsson and Hansen, 2020, it must be noted that nanorobots must be controlled to prevent unintended movement and potential harm to healthy tissues. Precise navigation and guidance mechanisms are essential for its development [48]. Protection against external interference, such as magnetic fields or other external stimuli, is vital to maintain micro/nanorobot stability and prevent unintended actions [15]. Avoiding excessive immune responses that could neutralize nanorobots or trigger inflammation is critical for long-term functionality. The chemical reactions within nanorobots, especially endogenous energy sources, must be carefully selected to avoid toxicity and ensure safe reaction products [7, 15]. The assessment of potential systemic effects of nanorobot deployment, including impacts on organ functions or overall homeostasis, is essential [48]. Understanding the long-term effects of nanorobot presence in the body is necessary to evaluate safety over extended periods [7, 48]. Implementing real-time monitoring and feedback mechanisms to track nanorobot behavior and address any safety issues promptly [7, 11].

Addressing these safety and biocompatibility concerns is critical to harnessing the full potential of micro/nanorobots in drug delivery systems while minimizing risks to patient's health and well-being.

Overcoming the limitations of endogenous and exogenous power-driven micro/nanorobots

However, endogenous/exogenous systems may have limitations in terms of biocompatibility. 4D-printed microrobots can be designed to carry larger drug payloads due to their controlled and customizable structural properties [7]. This can improve the drug delivery efficiency compared to endogenous/exogenous systems.

4D printing enables the precise fabrication of micro robots, tailoring their size, shape, and material properties to specific drug delivery tasks. These robots can be programmed to navigate through complex biological environments with controlled motion. They can swim, crawl, or even fold and unfold to reach target locations [44]. 4D-printed microrobots can be designed to deliver drugs to precise locations within the body, improving drug efficacy while minimizing side effects. They can respond to various stimuli, such as changes in temperature, pH, or magnetic fields, allowing for on-demand drug release. These microrobots can be multifunctional, combining drug release mechanisms with sensors or imaging capabilities, enhancing their utility in diagnostics and therapy [49]. Using biocompatible materials, 4D-printed nano/microrobots reduce the risk of adverse reactions in the body, enhancing patient safety.

For example, biomaterials such as Polylactic Acid (PLA) and Thermoplastic Polyurethane (TPU) can play important roles in 4D printed nanorobots for pharmaceutical drug delivery systems. PLA can be used as a structural material for 4D-printed nanorobots, providing a stable and biocompatible framework. Its rigidity and strength are useful for maintaining the structural integrity of the nanorobots. It is biodegradable, which can be advantageous in drug delivery systems [8, 9]. The nanorobots can be designed to degrade gradually, releasing the drug payload over time, and making it suitable for sustained drug delivery. Its 4D printing properties allow for the precise fabrication of intricate and customizable shapes, enabling the design of nanorobots with specific geometries for optimal drug delivery performance [9, 11, 44].

While, TPU is known for its flexibility and elasticity, which can be valuable for 4D-printed nanorobots in navigating through the body's complex and dynamic environments [11, 44]. It allows the nanorobots to bend and adapt to obstacles, enhancing their mobility. It can be used as a coating or an outer layer for the nanorobots. This coating can protect the nanorobots from degradation, provide better manoeuvrability, and reduce friction when in contact with biological tissues. TPU coatings can reduce the risk of aggregation of nanorobots in bodily fluids, ensuring a smoother and more efficient drug delivery process [10, 11, 44]. It can be incorporated into the 4D printing process to

create components with shape-changing capabilities in response to external stimuli, improving the nanorobots' ability to reach target locations and release drugs as needed. By leveraging PLA and TPU in 4D-printed nanorobots, pharmaceutical drug delivery systems can benefit from the combination of structural stability, biodegradability, customizability, flexibility, and responsive behavior [9, 10]. These properties make PLA and TPU valuable materials for designing advanced nanorobots capable of precise drug delivery in complex biological environments [8].

The design of 4D-printed nanorobots can minimize immune responses, reducing the risk of rejection or other immune-related issues. They can carry a higher drug payload compared to some traditional drug delivery systems, improving efficiency [50]. The customizability of 4D-printed microrobots offers the potential for personalized drug delivery, addressing individual patient needs. These robots can be engineered to reduce the risk of aggregation in bodily fluids, ensuring smooth drug transport.

4D-printed microrobots are engineered to move with more precision and control in response to external cues, improving their ability to reach target sites effectively [44, 49]. Endogenous systems may not offer the same level of control. 4D printing technology allows for the integration of multiple functionalities into a single microrobot, such as drug release mechanisms, sensors, and imaging capabilities, making them versatile tools for drug delivery. Endogenous/exogenous micro/nanorobots can sometimes aggregate in the bloodstream or other bodily fluids, leading to potential blockages. 4D-printed microrobots can be designed to minimize aggregation risks. 4D printing technology allows for efficient and scalable production of micro robots, potentially reducing costs and improving accessibility compared to endogenous/exogenous systems, which may be more challenging to manufacture.

Recent insights on in-vivo *applications of micro/nanorobots drug delivery*

Several kinds of research are still being undertaken on animal models to demonstrate the use of micro/nanorobots in targeted drug delivery systems, however, the studies on human volunteers are yet to be done to draw clear justification for the use of these technologies in clinical phase trials. A few recent reports on the use of drug-loaded micro/nanorobots have been presented in Table 4.

Table 4. Recent in-vivo studies of nanorobots in pharmaceutical drug delivery

Animal Models	Micro/Nano-robots used	Loaded Drug	Targeted Region	Key Findings	Refs.
Mice	Gold Nanorobots	Doxorubicin (Dox)	Tumor	– Enhanced drug delivery Tumor shrinkage	[51]
Rats	Magnetic Nanorobots	Paclitaxel (PTX)	Bloodstream	– Improved drug circulation Improved efficacy	[52]
Rabbits	Polymer Nanorobots	Methotrexate (MTX)	Joints	– Reduced inflammation Targeted therapy	[53]
Guinea Pigs	Lipid Nanorobots	Insulin	Gastrointestinal	– Controlled insulin release Controlled efficacy	[54]
Monkeys	DNA Nanorobots	Antiviral Drug	Brain	– Enhanced brain drug delivery	[7, 55]

From Table 4, it is evident that micro/nanorobots have emerged as promising tools in pharmaceutical drug delivery, offering precise and targeted delivery of therapeutic substances within the body. These tiny robotic systems, typically at the nanoscale, provide several key advantages in drug delivery, such as, (a) they can navigate through

complex biological environments and deliver drugs directly to the target site, minimizing off-target effects and reducing the required drug dosage [4, 7], (b) they offer unparalleled precision in drug release, enabling controlled and on-demand drug delivery, which is especially valuable for diseases with fluctuating symptoms [7, 16], (c) they can carry poorly water-soluble drugs, enhancing their solubility and bioavailability, thereby improving therapeutic outcomes [56], (d) by reducing systemic exposure to drugs, micro/nanorobots can minimize side effects and toxicity, improving patient tolerance to treatment [7], (e) some of them are equipped with sensors that enable real-time monitoring of physiological parameters, allowing for adaptive drug release in response to changing conditions [7, 16], (f) they facilitate the delivery of multiple drugs simultaneously or sequentially, enabling combination therapies to target multiple aspects of a disease [7], (g) they can traverse biological barriers, such as the blood–brain barrier, enabling the delivery of drugs to previously inaccessible regions [12], and lastly, (h) they can control drug release minimizing the development of drug resistance in pathogens or cancer cells [49]. While micro/nanorobots hold immense potential, challenges related to biocompatibility, navigation, and safety in complex biological systems remain. Ongoing research aims to address these challenges and unlock the full potential of micro/nanorobots for revolutionizing drug delivery in pharmaceutical applications.

Conclusion

The advent of micro/nanorobots in pharmaceutical drug delivery promises a transformative leap in the way we administer and benefit from medical treatments. These minuscule machines, designed to operate at the nanoscale, hold the potential to revolutionize healthcare in numerous ways, encouraging further research and innovation in the field. Reports are elated that micro/nanorobots pave the way for personalized medicine. By tailoring drug delivery to individual patient needs, they can optimize treatment regimens, reducing side effects and enhancing therapeutic outcomes. This approach shifts the paradigm from one-size-fits-all to treatments customized for each patient’s unique biology. Many diseases, such as brain disorders or certain cancers, are challenging to treat due to biological barriers like the blood–brain barrier. Micro/nanorobots can cross these barriers, opening up new possibilities for treating conditions that were once considered inaccessible. Micro/nanorobots enable multimodal therapies by delivering multiple drugs or therapeutic agents simultaneously. This multifaceted approach can tackle complex diseases from different angles, potentially enhancing treatment efficacy and reducing drug resistance. They are also capable of contributing to reduced drug dosages, precise drug targeting, and minimizing toxicity and side effects. Patients can benefit from more effective treatments with fewer adverse reactions.

Encouraging investment in nanorobotics research, fostering multidisciplinary collaborations, and establishing safety and efficacy standards through regulatory bodies are crucial steps. These efforts will drive progress and pave the way for a healthcare future where treatments are not only more effective but also safer and tailored to each patient's unique needs. In summary, micro/nanorobots represent a promising frontier in pharmaceutical drug delivery, offering the prospect of a brighter and healthier future in medicine through innovation, collaboration, and dedicated research endeavors.

Bioanalytical method development and validation for the simultaneous estimation of Olanzapine and Samidorphan in rabbit plasma by using HPLC–MS/MS and application to pharmacokinetic study

Kantipudi, Rambabu1; Pavuluri, Sugandha Kumar11 R.V.R &J.C. College of Engineering, Department of Chemistry, Chowdavaram, Guntur, India

ABSTRACT (ENGLISH)

Background

Samidorphan is an opioid antagonist while Olanzapine is an effective medication for schizophrenia and bipolar disorder. A unique and accurate MS/HPLC approach due to simultaneous measurement of Olanzapine and Samidorphan is, therefore, more urgently required. Simultaneous quantification of Olanzapine and Samidorphan in rabbit plasma using HPLC-MS. Using a buffer composed of 1 mL of formic acid in 1 L of water and a mixture of two components, buffer and acetonitrile in a ratio of 50:50 and a flow rate of 1 mL/min at room temperature, we separated compounds on an Inertsil ODS column (250 × 4.6 mm, 5 m).

Results

Analysis was performed within 8 min over a satisfactory linear concentration range of 2–40 ng/mL for Olanzapine (r^2 = 0.99901 0.024) and 2–40 ng/mL for Samidorphan (r^2 = 0.99927 0.012). The matrix effect recoveries of Olanzapine and Samidorphan at various QC concentration levels were 104.5, 100.51% and 110.36, 99.25%, respectively. The precision and recovery study outcomes fall within the acceptable range. An electrospray ionization source was used to analysis of Olanzapine and Samidorphan at m/z 313.40→192.54, m/z 371.45→220.61 for Olanzapine and Samidorphan, m/z 316.40→237.58, m/z 374.41→223.61 for D_3 Olanzapine and D_3 Samidorphan that were ion pairs

of mass analysis.

Conclusions

Liquid–liquid extraction was used to remove Olanzapine (0.17 mg/kg) and its reference standard (D_3-Olanzapine) from rabbit plasma. Both the active compound Samidorphan (0.17 mg/kg) and its reference, D_3-samidorphan, were isolated from rabbit plasma. We conducted stability studies to ensure that the medications would remain stable in accordance with USFDA regulations.

FULL TEXT

Background

The atypical antipsychotic Olanzapine [1, 2] sold under the brand name Zyprexa is effective in treating schizophrenia [3, 4] and bipolar disorder [5, 6]. Both short-term treatment and long-term upkeep of schizophrenia are possible with this method. It can be injected into the muscle or taken orally [7, 8]. Common side effects include: weight gain [9, 10], movement abnormalities [11], dizziness [12, 13], feeling tired all the time, constipation [14], and dry mouth [15]. Among the other potential side effects include dizziness when standing (low blood pressure) [16, 17], allergic reactions [18], neuroleptic malignant syndrome [19, 20], high blood sugar [21], seizures, gynecomastia [22], erectile dysfunction [23], and tardive dyskinesia [24, 25]. It raises the chance of death in the elderly with dementia who take it. Using during the third trimester of pregnancy increases the risk that the baby will have mobility issues. Although its method of action is unknown, it blocks dopamine and serotonin receptors. As olanzapine/samidorphan (trade name Lybalvi), samidorphan (INN, USAN) (developmental code names ALKS-33, RDC-0313) is a treatment for mental disorders like schizophrenia and bipolar. The effects of olanzapine-induced weight gain are mitigated by samidorphan. Oral use of samidorphan is standard. Samidorphan's side effects include drowsiness [26] and stomach upset [27]. The research and development of samidorphan as a stand-alone drug for use in a variety of conditions has been halted.

The recovery rate is high, the run time is reduced, the accuracy is increased, the cost is decreased, the calibration curves are linear, the MRM transitions are optimised, and our method has been validated in accordance with USFDA criteria [28, 29]. Olanzapine (Fig. 1) and Samidorphan (Fig. 2) detection by HPLC–MS/MS simultaneously in rabbit plasma and its application to pharmacokinetic study is a topic that has not been covered in any published studies as of yet, and only few articles were reported on normal method development, validation and simultaneous determination in human plasma by using RP-HPLC [30–32].The pharmacokinetic research of olanzapine and samidorphan made excellent use of the bioanalytical assay. However, there are no current methods available for the determination of Olanzapine and Samidorphan at the present time. The current study aimed to (a) determine the pharmacokinetics of Olanzapine and Samidorphan following intravenous administration of test extracts to rabbits, and (b) create and validate a precise and sensitive MS/HPLC assay for measuring olanzapine and samidorphan in rabbit plasma.

Chemical structure of Samidorphan

Methods

Chemicals and materials

Olanzapine and Samidorphan ($C_{17}H_{20}N_4S$ and $C_{21}H_{26}N_2O_4$) and D_3-Olanzapine and D_3 –Samidorphan (Internal Standards, ($C_{17}H_{17}D_3N_4S$ and $C_{21}H_{23}D_3N_4S$) with purity levels 99% were obtained from Zydus Cadila, Ahmadabad. Acetonitrile (HPLC–MS Grade, 99.99 purity), Water (Milli Q), and Formic acid (HPLC grade, 99.0% purity) were all supplied by Merck (India) Ltd., Worli and Mumbai, India. All other materials and reagents were of commercial quality AR availability.

Instruments and conditions

The HPLC system (Waters Alliance model) and the mass spectrometer QTRAP 5500 triple quadrupole instrument (SCIEX) were used to construct the bioanalytical assay. Chromatographic separation was performed at room temperature using an isocratic model and an Inertsil ODS (250×4.6 mm×5 m) column. The mobile phase consisted of acetonitrile and formic acid at a ratio of 50:50 (by volume) at a flow rate of 1.0 mL/min. Ten litres of liquid were injected, and the entire cycle lasted eight minutes. For this study, we employed a QTRAP 5500 triple quadrupole mass spectrometer equipped with a positive ion electrospray ionisation interface. Mass ion pair monitoring using MRM mode: m/z 313.40→192.54, m/z 371.45→220.61 for Olanzapine and Samidorphan, m/z 316.40→237.58, m/z 374.41→223.61 for D_3 Olanzapine and D_3 Samidorphan (Internal standards of Olanzapine and Samidorphan). Ion spray voltage 5500 V; source temperature 550 °C; drying gas temperature 120–250 °C; collision gas nitrogen; pressure 55psi; drying gas flow rate 5 mL/min; declustering potential 40 V; entrance potential 45 V; exit potential 15 V; capillary voltage 5500 V; dwell time 1Sec. Table 1 clears necessary information on Instrumentation.

Experimental

Stock preparedness, calibration and quality control specimens

Olanzapine, D_3-Olanzapine (IS), and Samidorphan, D_3-Samidorphan (IS), were dissolved in Formic acid 0.1% in water-ACN (80:20, v/v) to create stock solutions with concentrations ranging from 2.0 to 40 ng/mL. Calibration and quality control samples were made by mixing the aforementioned working solutions with plasma and then distributing the resulting mixture. Eight calibration specimens were used, with values of 2, 5, 10, 15, 20, 25, 30, and 40 ng/mL. The quality control (QC) samples were made in the same way, but their final concentrations ranged from

2 ng/mL (LLOQ) to 30 ng/mL (HQC). Before being brought back to room temperature for examination, all samples were frozen to a temperature of−20 °C.

Preparation a solution for plasma samples

In order to prepare the samples, 500 µL of working standard stock solution and 500 µL of internal standard (IS) were injected into 200 µL aliquots of rabbit plasma samples. After 15 min of vortexing 300 µL of acetonitrile and 500 µL of diluent, centrifuging the samples at 5000 rpm for 15 min, then dividing, collecting, filtering, and injecting the supernatant-managed solution into the HPLC machine, we have our final product.

Animal parameters

In order to conduct this research, female rabbits were procured from Bioneeds India pvt. Ltd. in Bangalore. Six rabbits were used in this study (Table 2 represents average body weights of rabbits). Animal ethics committee (Reg. No. 1074/PO/Re.S/05/CPCSEA) at the institute approved the experiment protocol. The circumstances resemble those of a laboratory, and the animals have access to fresh endive, carrots, and maize. Feed for animals should be kept between 21 and 24 degrees Celsius, with humidity between 50 and 55 per cent. All animals fasted for an entire day and drank water at will before being used in an experiment. Olanzapine and Samidorphan solid dispersion tablets' pharmacokinetics were studied. Olanzapine and Samidorphan were given orally to all rabbits at a dose of 0.2 mg/kg. Blood samples were obtained from rabbits at 1, 2, 3, 4, 5, 10, 15, 20, 25, 30, and 35 h, and the concentrations of Olanzapine (1.62 g/mL) and Samidorphan (1.64 ng/mL) ranged from 1.67 ng/mL to 18.4 ng/mL. The plasma was centrifuged for 30 min at 5000 rpm. Until analysis could be performed, plasma samples were kept at 2–8 degrees Celsius, and the supernatant solution was injected into a chromatographic column.

Table 2. Mean average body weights of rabbits

Group name	Average weight of rabbits
Rabbit-1	2538.32±2.65
Rabbit-2	2521.48±3.84
Rabbit-3	2556.47±2.52

Selectivity

The retention times of Olanzapine, Samidorphan, and IS were measured, and interference from untested samples was tested by analysing rabbit plasma samples from six distinct rabbits to assess selectivity.

Matrix effect

By comparing the peak zone fraction in the post-extract plasma sample of six separate plasma samples devoid of medicine and slick recovery samples, we were able to assess the Effect matrix for Olanzapine and Samidorphan. Six different lots of plasma were tested at MQC levels in duplicate, with satisfactory accuracy (% CV 15%).

Recovery

The recovery was calculated by comparing the peak areas of standards that had not been extracted with those of the extracted Olanzapine and Samidorphan (6 replicates per QC concentration).

Dilution integrity

A matrix with an analyte concentration over the ULOQC must be injected, and the test must be diluted using a blank matrix to prove that the dilution was done correctly.

Carry over

The retention of an analyte in the chromatographic system after the injection of a sample is referred to as carry over and can be identified in subsequent blank or unknown samples.

Precision and accuracy

Quality control replication study was performed on a total of six samples to determine the results at four different

quality control levels: low, medium, and high. Except for the LLOQ, which should be less than 20%, the CV level should be less than 15%.

Stability

Comparing the area response of the analyte in the stability samples with the region response of the sample obtained from the fresh stock solution allowed us to draw conclusions about the stock solution's stability. The effects of LQC and HQC concentrations on plasma stability were tested using six dose replicates. The US Food and Drug Administration (USFDA) define stability as a coefficient of variation (CV) of less than 15% for an analyte. Injected rabbit plasma samples were tested for 24 h of shelf life (bench top stability) after being kept at room temperature. The autosampler stability of increased rabbit plasma was measured over a period of 24 h at 2–8 °C. Extract plasma samples were injected immediately or stored in the autosampler at 2–8 °C for 24 h to assess the stability of the autosampler. Freeze–thaw stability was evaluated by contrasting newly infused quality control samples with those that had been frozen at − 30 °C and thawed three times. Six aliquots were utilised to test the freeze–thaw stability of both the low- and high-quality control concentrations. To evaluate the long-term stability, the 24-h concentration was compared to the starting concentration.

Results

Bioanalytical method development

With this method, atmospheric pressure chemical ionisation (APCI) mode is avoided in favour of ESI's more powerful reaction. Quantifying the ionisation of Olanzapine and Samidorphan with the MRM mode. Ion pair scan of Olanzapine and Samidorphan formed major ions of $[M+H]^+$ at m/z 313.4, m/z 362.5, m/z 234.55, m/z 192.54 and m/z 371.45, m/z 296.82, m/z 220.61, m/z 164.57. D_3-Olanzapine and D_3-Samidorphan, both internal standards, formed high intensity daughter ions of $[M+H]^+$ at m/z 237.58 and m/z 223.61. When compared to ion-negative mode, Olanzapine and Samidorphan exhibit a positive ion response mode. Figures 3, 4, 5 and 6 show the details of the mass spectrums.

Mass spectrum of D_3-Samidorphan

Different buffers were tested with acetonitrile as the mobile phase in isocratic and gradient modes to determine the best conditions for chromatography. With each run, the mobile phase composition was tweaked to achieve higher resolution and shorter retention durations. For the best results with the specified drugs, an isocratic mobile phase of 0.1% formic acid and ACN (50:50 v/v) was chosen. In our optimisation procedure, we made use of a number of stationary phases, such as C18, C8, and CN-propyl. We get reliable peak shapes for Olanzapine and Samidorphan using an Inertsil ODS column with dimensions of 250 mm × 4.6 mm × 5 coupled to a PDA detector. Mobile phase flow rates were at 1 mL/min. Using these parameters, we find that Olanzapine and Samidorphan have retention durations of 2,241 and 5,098 min, respectively. Six replicate injections of Olanzapine and Samidorphan show coefficients of variation (CV) of 0.31 and 0.29 per cent, respectively, demonstrating the high precision of the suggested approach. The current procedure has been proven reliable in accordance with USFDA standards. Figures 7, 8 and 9 show the details of the chromatograms.

Validation of bioanalytical process

Matrix effect

At the Low Quality Control (LQC) and High Quality Control (HQC) levels, Olanzapine and Samidorphan's matrix effect results were 104.5 and 100.51 per cent, respectively (Table 3). The CV% for both compounds was calculated to be 0.77 at the LQC and 0.69 at the HQC. According to the findings, the matrix's effect on analyte ionisation and internal conditions was within acceptable limits.

Table 3. Results of matrix variability and Recovery (%) of Olanzapine and Samidorphan in rabbit plasma

Analyte	Matrix	Matrix factor bias (%)		% Recovery		
LQC	HQC	LQC	MQC	HQC	Olanzapine	Plasma
98.51	99.51	98.33	99.59	99.31	Samidorphan	Plasma

Recovery

Recovery rates for olanzapine and samidorphan in rabbit plasma at 10, 20, and 30 ng/mL are 101.33, 100.59, and 100.31%, respectively, at low, medium, and high focal concentrations. Olanzapine and Samidorphan are clearly effective in their extraction (Table 3).

Linearity, consistency and precision

At its height, emphasis was placed on the region's relative importance in determining adjustment standards. Figures 10 and 11 show that the method had a linearity range of 2.0–40 ng/mL for Olanzapine and 2–40 ng/mL for Samidorphan. Olanzapine and Samidorphan's correlation coefficients at different QC levels were greater than 0.9993, and their presented calibration curves covered the linear concentration range. The linearity and correlation data for Olanzapine and Samidorphan are shown in Table 4, 5 and 6.

They ensured precision and exactness by combining the test results from numerous QC samples. The accuracy results of quality control samples for Olanzapine were 98.24–99.72% and for Samidorphan they were 98.03–99.72%. And %CV of Olanzapine and Samidorphan at various concentrations was 5% for all quality control samples. All exactness and precision results fell within the quantification range. Table 7 displays the results in detail.

Dilution integrity

Spiking the analyte matrix fixation over the ULOQC and diluting this specimen with blank matrix should be used to demonstrate dilution integrity. Olanzapine and samidorphan were both diluted to a concentration of 40 nanograms per millilitre (ng/mL) at a 2ULOQC. Olanzapine and Samidorphan were both tested with six replicate samples at 1:2 dilutions (20 ng/mL, 20 ng/mL) and 1:4 dilutions (10 ng/mL, 10 ng/mL). Two components' and% CV were found to be within a reasonable range. Table 8 displays the results.

Table 8. Results of dilution integrity

Analyte	ULOQC conc (ng/ml)	Calculated conc (ng/ml)	%CV
Olanzapine	40	40.29	0.23
Samidorphan	40	40.17	0.71

Carry over

Carryover refers to any systematic error that might influence the sample's measured value. The following method was used to assess sample retention on an HPLC/MS system set up with Waters Alliance. The waters Z-spray triple

quadruple mass detector underwent a flow injection system blank injection with a volume of 10L containing 0.1% Formic acid and Acetonitrile (50:50). We may conclude that the proposed strategy's accuracy and precision were not affected by the method used here. Olanzapine and Samidorphan sample carry over findings were LLQC (3.21%), ULQC (1.14%), and LLQC (6.78%), ULQC (0.93%), respectively, within the allowable limit. Table 9 displays the outcomes of the carryover.

Table 9. Results of carry over

Concentration	% of carry over	
Olanzapine	Samidorphan	Blank
0	0	LLOQC
4.06	3.70	ULOQC

Re-injection reproducibility

Reproducibility of re-injection was performed to validate the system after the hard product was disabled due to any instrument malfunction during analysis of real-subject samples. If an instrument fails during an investigation of a genuine subject specimen, the batch can be re-infused after 24 h if the results of the re-injection show a per cent change of less than 2.0 per cent at the LQC and HQC levels.

Stabilities

We prepared a stock solution of olanzapine and samidorphan and tested its stability by keeping it at room temperature for 18 h. A stock solution kept in an autosampler at room temperature for 24 h displays stable behaviour in terms of autosampler stability. Stock was maintained at (−28 °C) for 24 h to evaluate freeze–thaw stability, 2–8 °C for 18 h to evaluate wet extract stability, and (−20 ± 3)°C for 18 h to evaluate dry extract stability. Long-term stability was determined by holding the stock for 28 days at (−20 ± 3)°C and injecting it into an HPLC–MS, whereas short-term stability was demonstrated by storing the medicines for 7 days at (5 ± 3)°C. Check the new stock solution's stability against the results of the stock solution prepared more than 24 h in advance. Olanzapine and Samidorphan showed negligible percentage changes of 1.15 and 0.68, respectively, during a 24-h period, demonstrating the stability of these solutions.

Plasma stability at room temperature was demonstrated for both olanzapine and samidorphan. Plasma samples spiked with Olanzapine and Samidorphan were tested and found to maintain their LQC, MQC, and HQC levels after being frozen and thawed multiple times. Olanzapine and Samidorphan were found to be stable at a freezing temperature of −30 °C for 24 h, demonstrating their long-term stability. Tables 10 and 11 display the results for Olanzapine and Samidorphan's overall stability.

Discussion

A stock solution of olanzapine and samidorphan was made and left out at room temperature for 18 h to test their stability. When it comes to autosampler stability, a stock solution kept at room temperature for 24 h in the device exhibits stable performance. The stock solution was stored at 2–8 °C for 18 h to evaluate its damp extract stability, whereas the stock was held at (−20 ± 3 °C) for 24 h to evaluate its dry extract stability. Storage of medicines for 7 days at (5 ± 3 °C) demonstrates short-term stability, while storage of the stock for 28 days at (−20 ± 3 °C) and injection into an HPLC–MS demonstrates long-term stability. Examine the differences between the stability results of stock solutions prepared immediately and those prepared more than 24 h in advance. The results showed that after 24 h, there were only a 1.15 per cent change in Olanzapine and a 0.68 per cent change in Samidorphan in the solution.

Both olanzapine and samidorphan were plasma-stable at room temperature under a range of circumstances. Repeated freezing and thawing had no effect on the levels of LQC, MQC, or HQC in plasma samples that had been artificially spiked with olanzapine and samidorphan. Long-term stability testing showed that both olanzapine and samidorphan could withstand temperatures as low as −30 °C for 24 h. Tables 10 and 11 display the results for the overall stability of Olanzapine and Samidorphan, respectively.

Pharmacokinetic study

After administering 0.17 mg/kg of Olanzapine and 0.17 mg/kg of Samidorphan intravenously to rabbits, respective mean plasma concentration–time profiles (Figs. 12, 13) were obtained for pharmacokinetic analysis. There are notable distinctions between Olanzapine and Samidorphan in intravenous pharmacokinetic studies. One, two, three, four, five, ten, fifteen, twenty-five, thirty, and three-and-a-half hours after the drugs were given, we collected samples

from the rabbits' bodies at varying intervals. The values were recorded after the test sample was prepared and injected into the chromatographic apparatus. C_{max} and T_{max} after intravenous administration of Olanzapine and Samidorphan (18.6740.146 and 18.4010.657), Kel (obvious first request terminal rate constant calculated from semi-log plot of plasma concentration versus time bend, employing the least square relapse technique), and $t_{1/2}$ (terminal half-life as governed by 0.693/Kel ratio) were all determined to be accurate measures of bioavailability. C_{max}, AUC0-24, and AUC0- were all within the acceptable range of 18.70.134, 2652.841, and 2654.282, and 18.40.111, 750.988, and 751.024, respectively. In Table 12, we can see the Olanzapine and Samidorphan pharmacokinetic characteristics.

Table 12. Pharmacokinetic studies of Olanzapine and Samidorphan

Pharmacokinetic parameters[a]	Olanzapine	Samidorphan
$AUC_{0–t}$ (ng h/ml)	265±2.841	75±0.988
C_{max} (ng/ml)	18.7±0.134	18.4±0.111
$AUC_{0–\infty}$ (ng h/ml)	265±1.427	75±1.024
$T_{1/2}$ (h)	30±0.41	10±0.12
T_{max} (h)	5±0.2	2±0.15

[a]All parameters expressed as Mean±SD, (n=6) values except T_{max} and $T_{1/2}$ which are expressed in terms of median value

Conclusion

An innovative HPLC–MS/MS method for assessing Olanzapine and Samidorphan in 8-min rabbit plasma has been developed and validated for the first time. Both Olanzapine and Samidorphan were rapidly absorbed by the rabbit's body after being given intravenously, as would be expected based on their pharmacokinetic profiles. The procedure outlined here is efficient, reliable, and repeatable. It has a good linear concentration range and sufficient precision for application in pharmacokinetic investigations for checking analyte concentrations in bodily fluids. These investigations are essential for the future credibility of our findings as a benchmark.
