A new gas chromatographic method for quantification of Metformin hydrochloride and Vildagliptin in bulk and pharmaceutical dosage form:

development and validation

Mohite, Popat1 ; Bhusal, Ramesh1; Khandre, Yogita2; Pandhare, Ramdas2; Pawar, Anil21 AET's St. John Institute of Pharmacy and Research, Palghar, India2 MES's College of Pharmacy, Ahmednagar, India

ABSTRACT (ENGLISH)

Background

Metformin, an antidiabetic drug, assists in reducing the creation of glucose inside the liver. Vildagliptin, a DPP-4 inhibitor, enhances insulin release from the pancreas and reduces the hormones that elevate blood sugar levels. The combined medications work synergistically to lower blood sugar levels. This study was designed to develop and validate a reliable method of simultaneous assessment of Metformin and Vildagliptin in bulk and pharmaceutical dosage forms. For the chromatographic separation, a Gs-Tek INNOWAX column was utilized. This column has a length of 30 m, an internal diameter of 0.25 mm, and a 1.8 µm film thickness. For the detection, a Flame Ionization Detector was utilized. The ideal conditions included an injection volume of 1 µL with a split mode of 10 to 1 ratio, a flow rate of 1 mL/minute for the nitrogen carrier gas, an injector temperature of 300 °C, a detector temperature of 250 °C, an initial oven temperature of 100 °C that was maintained for seven minutes and then programmed to climb at a rate of 10 °C per minute up to a temperature of 300 °C.

Results

A gas chromatographic method that is simple, precise, accurate, robust, and reliable has been developed and implemented for the simultaneous estimation of Metformin and Vildagliptin in the tablet dosage form. The retention time for Metformin and Vildagliptin was 10.203 and 22.021 min. respectively. Validation studies were performed on the method's Linearity, detection limit (LOD), and quantitation limit (LOQ), as well as its accuracy, precision, system suitability, and robustness, using the norms established by the International Conference on Harmonization (ICH). The mean recovery value for Metformin and Vildagliptin was 100.31% (% R.S.D. = 0.6743%) and 100.33% (% R.S.D. = 0.6900%). All the results are within the acceptable range.

Conclusion

Validation of the developed method revealed that all the results were within an acceptable range, and techniques can be employed to analyze these two medications in combined dosage forms. It is the first method used for simultaneous estimation of these two drugs.

FULL TEXT

Background

Today's worldwide disease, Type 2 Diabetes Mellitus (T2DM), is treated by using drugs like Metformin (MET) and Vildagliptin (VID) [1]. Metformin, an antidiabetic drug, assists in reducing the creation of glucose inside the liver. Vildagliptin, a DPP-4 inhibitor, enhances insulin release from the pancreas and reduces the hormones that elevate blood sugar levels. In Fig. 1, the chemical structures of drugs are shown.

Fig. 1 [Images not available. See PDF.]

Chemical structure of **a** Metformin and **b** Vildagliptin

The combined medications work synergistically to reduce blood sugar levels. Patients with type 2 diabetes (T2DM) who take Vildagliptin, an orally active, potent, and selective inhibitor of dipeptidyl peptidase-IV (DPP-4), see improvements in their glycemic control, primarily because of improved pancreatic islet function [2]. In summary, Vildagliptin has been reported to enhance insulin levels and reduce the elevated glucagon release in type 2 diabetes people when paired with Metformin, a thiazolidinedione, a sulfonylurea, or insulin. Metformin has been used to treat

diabetes for 50 years, and although it has a distinct mode of action and does not resolve ß-cell dysfunction, it is still the primary medication advised by all guidelines [3].

The multiple pathophysiological anomalies and progressive nature of T2DM need various intensification techniques over time. As per recent guidelines, patients need therapeutic combinations much earlier to reach and maintain the ever-stricter glycemic goals. Adverse effects like hypoglycemia can be avoided with careful medicine selection. Metformin and Vildagliptin have merits over conventionally used combinations because they do not raise the probability of weight gain or induce hypoglycemia [4–6]. Compared to other diabetic drugs, the safety and tolerability profiles of the combination of Vildagliptin and Metformin are exceptional, and they appear to have positive effects on beta-cell activity [7, 8].

Various analytical methods were used to analyze Metformin when present alone or combined with other medications, including U.V. [9–12], HPLC [13–16], HPTLC [17] and GC techniques [18]. The analysis of the relevant literature showed that Vildagliptin, either on its own or in combination with other pharmaceuticals, has been evaluated by U.V. [18], HPLC [19], HPTLC [20, 21], and GC–MS techniques [22]. The literature study also suggests that only a few analytical methods are established for the determination of MET and VID in combined dosage forms, such as RP-HPLC [23], HPLC–MS/MS [24], and HPTLC [25]. This pharmacological combination has not yet been investigated using GC, and no attempts have been made to do so. This study proposes and validates a new gas chromatographic approach for the simultaneous detection of MET and VID in both their bulk form and their pharmaceutical dosage form.

Methods

Instrument

The Star Chromatography Workstation version 6.41 software was used to record the data, and the HSGC—Shimadzu 2010 I GC system, which relates to a flame ionization detector (FID), was used for all experiments.

Gas chromatographic settings

The Gs-Tek INNOWAX column, which has a 30 m length, 0.25 mm I.D., and 1.8 µm df, was used for the separation. FID was used to carry out the detection. Injection volume 1 µL in split mode 10:1, nitrogen used as carrier gas at a constant flow of 1 mL/min, injector temperature 300 °C, detector temperature 250 °C, beginning oven temperature 100 °C kept for 7 min, then scheduled to climb at a rate of 10 °C/min up to 300 °C, were the optimal circumstances.

Preparation of standard stock solutions

The standard stock solution was prepared by dissolving accurately weighed 500 mg of MET and 50 mg of VID, in ethanol in a 100 mL volumetric flask. It is further diluted by taking 1 mL stock solution with 10 mL ethanol to get containing 500 µg/mL MET and 50 µg/mL VID respectively.

Assay procedure for tablet formulation

Twenty commercially available Galvus Met Novartis formulation tablets were ground adequately into powder using mortar and pestle. In a 100 mL volumetric flask, we weighed out powder equal to 500.0 mg of MET and 50.0 mg of VID, added roughly 50 mL ethanol, sonicated for 2 min to ensure appropriate dissolution, and then brought the volume up to the mark using the same solvent. Whatman No.41 filter paper was used to filter the sample solution and 5 mL of the filtrate was placed in a 50 mL volumetric flask, with the remainder of the volume filled with ethanol. The method is developed and validated with the help of this stock solution.

Validation of method

The results of the analysis, which included Linearity, precision, accuracy, detection limit (LOD), quantitation limit (LOQ), system suitability, and robustness, were statistically validated and performed following ICH guidelines Q2 (R1) [26].

System suitability

Three injections of a solution containing 500 µg/mL MET and 50 µg/mL VID were used to evaluate the system's suitability. The subsequent factors like Retention time values, peak areas, tailing factor, theoretical plates, and resolution are considered.

Linearity and range

The stock solution was diluted with ethanol to create standard working solutions with concentrations ranging from 125.0 to 750.0 µg/mL for MET and 12.5 to 75.0 µg/mL for VID. Five different concentrations of each chemical were selected using the previously established gas chromatographic conditions, and three injections were performed for each dilution. Regression equations and correlation coefficients were obtained using calibration curves to develop the Linearity of the suggested method.

Study of LOD and LOQ

The ICH guideline describes multiple methods for estimating detection limits and quantitation limits. The LOD and LOQ This study determined the proposed approach's values using Eqs. 1 and 2.

1

LOD=3.3xσ/s

2

LOQ=10xσ/swhere *σ*the standard deviation of the *Y*-intercept. s the slope of the calibration curves.

Precision

Six sample solutions (*n*=6) were produced and analyzed using gas chromatography, with concentrations of 500.0 µg/mL for MET and 50.0 µg/mL for VID, respectively, to ensure intraday accuracy. The same solution was analyzed over three days to evaluate the Interday precision.

Accuracy

Analysis of standard drug additions at three levels, i.e., multiple-level recovery experiments, were used to determine the reliability of the approach. A predetermined amount of the sample was mixed with a reference standard of varying concentrations (80%, 100%, and 120%) before being evaluated for the substance.

Robustness

The method robustness was determined by measuring the percentage relative standard deviation (R.S.D.) of retention time and peak area after the oven starting temperature and flow rate were changed by 2.0 °C and 0.1 mL/sec, respectively.

Results

Chromatography

The INNOWAX column effectively separated drugs. As shown in Fig. 2, the retention times for MET and VID were 10.203 and 22.021 min. respectively.

Fig. 2 [Images not available. See PDF.]

Gas Chromatogram showing the presence of MET (500 µg/mL) and VID (50 µg/mL) in a standard solution

System suitability

It was decided to inject five separate injections for the system suitability study. The acceptance limitations were satisfied for all the system suitability criteria, including the number of theoretical plates, the tailing factor, and the resolution. Also, the relative standard deviation (R.S.D.) of retention time values (Rt) and peak area (drug) for five separate injections does not exceed 2%, indicating that the GC system is suitable for the analysis of MET and VID combinations. Table 1 provides a concise summary of the findings.

Table 1. System suitability parameters

Criterion	MET	VID
% R.S.D. of Rt	0.0247	0.0316
% R.S.D. of area	0.9673	0.8590

NTP	25,381	18,468
Tailing factor	1.03	1.09
Resolution	11.2	

Linearity and range

The parameters of the GC were discussed before they were used, and then the calibration curves for MET and VID were developed by plotting the detector's response against the concentration of the medications. The findings show a strong connection between the detector's response and the drug concentration. The concentration ranges and the slope, y-intercept, and correlation coefficient values for both drugs for MET and VID are provided in Figs. 3 and 4.

Fig. 3 [Images not available. See PDF.]

Calibration curve for MET for 125, 250, 375, 500, 625 and 750 ppm

Fig. 4 [Images not available. See PDF.]

Calibration curve for VID for 12.5, 25.0, 37.5, 50.0, 62.5 and 75.0 ppm

LOD and LOQ value

The Detection limit was found to be 12.14 µg/mL for MET and 2.44 µg/mL for VID, while the Quantitation limit was found to be 36.80 µg/mL for MET and 7.37 µg/mL for VID.

Precision

Table 2 presents the intraday and Interday precision % R.S.D. values, which all came in at less than 2.0%. These results indicate that the approach has an appropriate level of precision.

Table 2. Study of precision

Drug	% R. S. D Intra-day	% R. S. D Inter-day
MET	0.9673	0.9663
VID	0.8590	0.8606

Study of accuracy

Multiple-level recovery experiments were conducted to conduct the three-level recovery test, consisting of conventional standard additions. The mean recovery value for MET and VID was 100.31% (% R.S.D. = 0.6743%) and 100.33% (% R.S.D. = 0.6900%), respectively. Table 3 shows the findings of the accuracy of the developed method.

Table 3. Accuracy for the determination of M.E.T. and VID

Level of % Recovery	% Recovery*		% RSD*	
MET	VID	MET	VID	80
100.77	99.98	0.6576	0.8466	100
99.94	100.37	0.7350	0.6625	120

100.20	100.62	0.6305	0.5610	Mean

*Mean of three estimations (n=3)

Robustness

The procedure's reliability was analyzed by purposefully tinkering with the oven's beginning temperature (2.0 °C) and the flow rate (0.1 mL/min.). According to the data presented in Table 4, these adjustments did not substantially impact the retention times or peak areas.

Table 4. Robustness

Parameter changes		Retention time (Min)		Peak Area	
MET	VID	MET	VID	The initial temperature of the oven	98 °C
10.225	22.045	5,486,025	605,845	100 °C	10.204
22.021	5,475,845	603,654	102 °C	10.189	21.995
5,474,554	602,965	%RSD		0.1772	0.1136
0.1147	0.2489	Flow rate (mL/min)	0.9	10.225	22.052
5,485,445	605,868	1.0	10.205	22.018	5,475,841
603,674	1.1	10.155	22.001	5,467,828	601,964
%RSD		0.3537	0.1179	0.1611	0.3241

Analysis of commercial tablet dosage form

The chromatographic approach assessed the two drugs using their combined tablet formulation (500 mg MET, 50 mg VID) as shown in Fig. 5. The analysis was carried out five times with the tablet formulation. The findings obtained using the suggested strategy are presented in Table 5. The assay results demonstrated good accuracy and precision, and the chromatograms of the tablets exhibited no interfering peaks at any point in the analysis.

Fig. 5 [Images not available. See PDF.]

Gas Chromatogram showing the presence of MET (500 µg/mL) and VID (50 µg/mL) in a sample solution

Table 5. Result of analysis of marketed formulation

Drug	Label claim (mg/tab)	The amount found (mg/tab)	Drug Found * (%)	R.S.D. (%)
MET	500	496.8	99.35	0.0964

VID	50	49.71	99.42	0.1685

*Mean of six estimations (n=6)

Discussion

In this investigation, a novel gas chromatographic method employing the INNOWAX column was developed to simultaneously detect MET and VID in bulk and pharmaceutical dosage forms. In earlier experiments, the individual GC determination of MET and VID in a variety of samples was shown to be possible. How these two analytes are evaluated simultaneously employing GC in a pharmaceutical binary combination has not yet been documented. The established chromatographic approach mentioned here has greater specificity than methods like spectrophotometry, which does not segregate the chemicals being tested for. The HPLC techniques have a disadvantage. They require a significant amount of organic solvents, making them unfeasible for routine analysis in the pharmaceutical industry because of their high cost.

The primary purpose of this research was to establish a method that could make this determination in a quick, dependable, and direct manner with a minimum amount of sample preparation. This method does not involve any complexation or pretreatment of the medications that are the focus of the research, which contributes to its ease of use and cost-effectiveness. Also, this method supports the goal of the work that was done. The developed analytical technique has successfully passed validation regarding Linearity, range, LOD, LOQ, accuracy, and precision. The robustness of the developed analytical method was also verified.

Conclusion

The current study developed a simple, linear, precise, accurate, and robust gas chromatographic technique to evaluate MET and VID in bulk and pharmaceutical formulations. The resolution between the drugs was improved by the developed method. The procedure's performance was validated statistically per the ICH requirements, and the findings were deemed satisfactory. Also, this is the first instance that the gas chromatography technique has been invented and validated for estimating MET and VID in combination dosage form, to the greatest of our knowledge.

GCMS-based phytochemical profiling and in vitro pharmacological activities of plant Alangium salviifolium (L.f) Wang

Hongal, Annapurneshwari M.1; Shettar, Arun K.2; Hoskeri, Joy H.3; Vedamurthy, A. B.11 Karnatak University, P G Department of Studies in Biotechnology and Microbiology, Dharwad, India (GRID:grid.444416.7)2 Cytxon Biosolutions Pvt Ltd, Division of Pre-Clinical Research and Drug Development, Hubli, India (GRID:grid.444416.7)3 Karnataka State Akkamahadevi Women's University, Department of Bioinformatics and Biotechnology, Vijayapura, India (GRID:grid.444416.7)

ABSTRACT (ENGLISH)

Background

There is an urge for traditional herbal remedies as an alternative to modern medicine in treating several diseases. A significant number of modern pharmaceutical drugs are based on or derived from medicinal plants or their extracts. These drugs derived from the plant origin have various antimicrobial, antioxidant, anticancer, anti-inflammatory

activities. *Alangium salviifolium* belongs to Cornaceae family and is well known for its medicinal properties. The present study was carried out to evaluate the antibacterial, antioxidant effect and possible bioactive components present in the chloroform, acetone, ethanol, methanol and aqueous extract of *Alangium salviifolium* leaves.

Methodology

Dried leaves of *Alangium salviifolium* were subjected to serial solvent extraction using increasing polarity of solvents, i.e., chloroform, acetone, methanol, ethanol, and distilled water. Crude extracts were further tested for qualitative analysis of phytochemicals using standard procedure, while GCMS analysis was performed to identify the probable phytocompounds. Antibacterial activity was performed against bacterial pathogens using agar well method, whereas antioxidant activity was performed using in vitro PM, DPPH and FRAP assays.

Results

Phytochemical analysis of the extracts revealed the presence of key phytochemical classes. Using gas chromatography-mass spectrometry, several high and low molecular weight chemical compound kinds were discovered. These chemical substances are regarded as having significant biological and pharmacological effects. All crude extracts had considerable and comparable in vitro antioxidant and antibacterial properties.

Conclusions

According to the findings of this study, *Alangium salviifolium* leaves are a rich source of phytoconstituents that are crucial in stopping the advancement of numerous disorders.

FULL TEXT

Background

Numerous metabolites that are more useful in the field of medicine are naturally produced by plants. More than 80% of the world's population, according to the World Health Organization (WHO), relies on traditional medicine for their primary healthcare requirements [1]. 21,000 plants are known to be used as medicines worldwide, according to the WHO [2]. As plants are the primary source of medicines in Siddha, Unani, and Ayurveda systems of medicine, India has a rich cultural history of ancient medicines [3]. Many of the chemicals produced by these medicinal plants have been shown to have therapeutic benefits [4]. More research works on ethnopharmacognosy were increased due to the result of the emergence of negative effects and microbial resistance to the chemically synthesized medications [5].

Secondary metabolites including tannins, steroids, phenolic compounds, and alkaloids, sometimes known as phytochemicals or phytocompounds, are what give plants their therapeutic potential. Some plant secondary metabolites with medicinal promise include morphine, vincristine, vinblastine, taxol and quinine [6]. Due to fewer side effects as compared to synthetic pharmaceutical chemicals, these phytochemicals have recently gained importance throughout the world and are used in the pharmaceutical industry for the drug development and treatment of major diseases like asthma, arthritis, cancer, and diabetes [7, 8]. These medicines have different antimicrobial, antioxidant, anticancer, and anti-inflammatory effects because they are derived from plants [9]. Antioxidants are substances that slow down or stop oxidative reactions that catalyze free radicals. The presence of phenolic substances such as flavonoids, phenolic acids, tannins, and phenolic diterpenes [10, 11] is primarily responsible for the antioxidant activity of plant products. Plants are protected from oxidative assault by antioxidants like BHT (Butylated Hydroxy-Toluene) and BHA (Butylated Hydroxy-Anisol), which bind oxidative damage to metallic ions, break down peroxides, or destroy free radicals [12]. According to Lobo et al. [13] and the rise in pathogen antimicrobial resistance, infectious diseases account for almost 50% of all deaths [14]. As a need of the hour researchers have created new, efficient antibacterial medications from natural phytochemicals [15, 16] demonstrated the potential of numerous herbs as sources of pharmaceuticals with lower toxicity. By screening a wide range of plant groups, the search for new antibacterial compounds continues. Higher plants are a possible source of novel antibiotic prototypes, according to research on the antibacterial activity of plant extracts and plant products [17, 18]. There is a need for more research into traditional health systems because certain traditional medicines have already developed substances that are effective against bacteria strains that are resistant to antibiotics [19, 20].

Alangium salviifolium, also known as sage leaved alangium or ankola, was chosen for the current study. It is a

member of the Cornaceae family, which is indigenous to China, India, Bangladesh, and the Philippines [21]. This family of plants often grows in arid or hotter climates. It is used to treat a variety of illnesses. According to numerous studies [22–25], it is widely used as a treatment for skin conditions, leprosy, asthma, epilepsy, hepatitis, scabies, and as an antidote for snake and dog bites. According to numerous studies [26–28], roots can be used to cure diarrhea, paralysis, piles, and vomiting. Although *Alangium salviifolium* leaves are a storehouse of many nutrients and bioactive chemicals, the systematic analysis of these leaves is still not sufficient in terms of the specific biological activity of their chemical constituents. The potential benefits of *A. salviifolium* for treating different medical issues should be further investigated. Thus, the objective of the current study was to identify the phytochemical components, antioxidant, and antibacterial properties of various solvent extracts of *A. salviifolium* leaves. Additionally, utilizing GC–MS and FTIR analysis, the bioactive elements of the extracts and the functional groups of the compounds were also found.

Methods

Collection of plant material

The plant *Alangium salviifolium* (L.f) Wang's leaves were collected in the month of February 2022 in Ankola, Uttar Kannada District, Karnataka, India. Dr. K. Kotresha, Professor, Department of Botany, Karnatak Science College, Dharwad, Fresh plant leaves were gathered, cleaned under running water, dried in the shade, and then blended to a coarse powder. For future use, the powder was kept in sealed containers.

Solvent extraction

Alangium salviifolium dry leaves were coarsely pulverized, and then, serial solvent extractions were performed using a Soxhlet apparatus. In increasing order of polarity, the following solvents were used for the extraction: chloroform, acetone, methanol, ethanol, and distilled water. Using a Rota-evaporator, the extracts were further concentrated. The airtight containers used to hold the concentrated extracts were chilled until use.

Phytochemical analysis

The presence of various phytochemical components, including alkaloids, tannins, phenols, sterols, terpenoids, glycosides, saponins, flavonoids, and carbohydrates, were screened for in the crude extracts of *Alangium salviifolium* plant leaves using a standard procedure [29].

Total phenol content (TPC) estimation

Utilizing 1.5 ml of the Folin–Ciocalteu (FC) reagent and 7.5% sodium carbonate (Na_2CO_3) solution, the plant extract of known concentration, i.e., 1 mg/1 ml of respective solvent, was subjected to oxidation. The absorbance reading at 750 nm was obtained during an hour of incubation at room temperature. The experiment was performed in triplicate, and results were expressed as mean ± standard deviation. The quantity was determined using the calibration curve for gallic acid. Gallic acid equivalent (GAE) mg/100 ml of sample was used to express the results [30].

Total flavonoid content (TFC) estimation

The 10% aluminum chloride ($AlCl_3$) and 1 M sodium acetate were combined with the known quantity of plant extract, i.e., 1 mg/1 ml of respective solvent. Following a 45-min incubation in the dark, the absorbance was measured at 415 nm. Using the Quercetin calibration curve, the quantity was determined. Quercetin equivalent (QE) mg/100 ml of sample was used to express the results [31]. The experiment was performed in triplicate, and results were expressed as mean ± standard deviation.

FTIR analysis

Utilizing a Perkin Elmer Spectrophotometer system, an FTIR study of *Alangium salviifolium* was carried out in order to identify the distinctive peaks between 400 and 4000 cm^{-1} and their functional groups. The FTIR's peak values were noted.

GC–MS profiling

The different solvent extracts of *A. salviifolium* were subjected to a GC–MS analysis with instrument model GCMS-QP 2010 Plus, Shimadzu). At an ionization voltage of 70 eV, injector temperature of 250 °C and injector mode was split with linear velocity 36.5 cm/s and pressure was 57.5 kPa. The instrument was run in electron impact mode. Approximately 1 µL of the sample was injected into mobile phase consisting of helium (99.9% purity) at a flow rate of

1 mL/min. The oven's temperature was first set to 60 °C for 2 min of isothermal operation before being raised to 100 °C at a rate of 10 °C per minute and then to 280 °C at a rate of 5 °C per minute for 9 min. The GC ran for 34 min in total. Comparing each component's average peak area to the total areas allowed us to determine the proportional percentage amount of each component. With the help of The National Institute of Standard and Technology-5 (NIST-5), a comparison was made between the spectra of the unknown component and the spectrum of the known components including the compound's name, chemical formula, molecular weight, and structure, which were identified.

In vitro antioxidant activity of *A. salviifolium's* leaves

Phosphomolybdenum assay

Using a standardized process, the phosphomolybdenum method was used to assess the antioxidant activity of the plant extracts [32] and ascorbic acid was used as reference standard. *Alangium salviifolium* extracts of concentration 1 mg/ml were added to each test tube separately along with 3 ml of distilled water and 1 ml of the phosphomolybdate (PM) reagent in varying concentrations ranging from 100 to 500µL. For 90 min, the tubes were incubated in a water bath at 95 °C. Following incubation, these tubes were cooled to room temperature, and the reaction mixture's absorbance was assessed at 695 nm.

2, 2 Diphenyl-2-picryl hydrazyl (DPPH) radical scavenging assay

A. salviifolium plant extracts were subjected to the Rice-Evans et al. [33] method for the DPPH radical scavenging assay. The known concentration of test samples (100 µg) was combined in various concentrations with 100 µl of a DPPH solution made in methanol (40 mM). The combination was incubated for 30 min at room temperature and in the dark to produce the desired color, which was measured at 517 nm along with ascorbic acid as a standard. Each sample’s DPPH scavenging activity was estimated using the formula below:Scavengingactivity%ofDPPH=100 ×Ac-At/Acwhere At is the absorbance of the test sample and Ac is the absorbance of the control reaction (100 µL of methanol plus 100 µL of DPPH solution).

Ferric ion reducing power (FRAP) assay

With a few minor modifications, the Oyaizu [34] method was used to assess the reducing power of ferric ions. The extracts of *A. salviifolium* (1 mg/ml) were pipetted into mixtures containing 2.5 ml of 0.2 M phosphate buffer, 2.5 ml (1% w/v) potassium ferricyanide, and various concentrations ranging from 100 to 500 µL. The mixture was then incubated at 50 °C for 20 min. After cooling the mixture, 2.5 ml of 10% w/v trichloroacetic acid and 0.5 ml of 0.1% w/v ferric chloride were added, and the combination was left at room temperature for 10 min to form a complex that was green in color. The absorbance was calculated using a spectrophotometer at 700 nm. The reference standard used was ascorbic acid.

Antibacterial activity

The antibacterial activity was screened using the agar well diffusion method [35] using *Pseudomonas aeruginosa* and *Staphylococcus aureus* cultures as the test organisms. 100µL of the uniformly diluted saline suspension were swabbed over the sterile agar plates. Along with the control drug Ciprofloxacin (30 µg), various concentrations of the extract (1 mg/ml) (30, 60, 90, and 120 µL/well) were added to the medium. The plates were incubated for 24 h at 37 °C. The diameter of the inhibition zones that formed around the wells after the incubation time was measured in millimeters.

Statistical analysis

The experiments were performed in the triplicate, and the results were expressed as mean ± standard deviation using IBM SPSS Statistics 20.0.

Results

Plant chemical analysis

The qualitative phytochemical analysis of five different solvent extracts of *Alangium salviifolium* revealed the presence of flavonoids, reducing sugar, and carbohydrates in chloroform, acetone, methanol, ethanol, and distilled water; in addition, glycosides, saponins, and tannins were present in aqueous extract. All five extracts contained alkaloids and phenols. The other four extracts, with the exception of methanol, all included lignin The results of

phytochemical analysis was shown in Table 1.

Total crude extraction

The phytochemical examination of *A. salviifolium* leaves revealed a significant amount of the plant secondary metabolites. Using the solvents chloroform, acetone, ethanol, methanol, and distilled water, the total yield of crude extracts from *A. salviifolium* leaves was determined to be 1.8%, 2.1%, 3.8%, 2.4%, and 2.8% (w/w), respectively.

Total phenol and flavonoid content

In terms of phenolic content, ethanol extract had the highest level (82.86 ± 0.04) mg/g GAE, followed by methanol extract (59.13 ± 0.02) mg/g GAE, acetone extract (47.61 ± 0.01) mg/g GAE, chloroform extract (12.51 ± 0.02) mg/g GAE, and aqueous extract (7.92 ± 0.02) mg/g GAE. In case of flavonoid content of all the extracts, chloroform extract had the highest amount of flavonoid content (71.86 ± 0.03) mg/g QE, followed by methanol extract (33.33 ± 0.05) mg/g QE, acetone extract (30.07 ± 0.04) mg/g QE, ethanol extract (16.3 ± 0.02) mg/g QE, and aqueous extract (5.04 ± 0.04) mg/g QE. Total phenolic and total flavonoid concentration in each extract showed a wide range of variance (Table 2).

Table 2. Total phenol and total flavonoid content from *A. salviifolium* (leaf extract)

Extract	Total phenolic content (mg)	Total flavonoid content (mg)
Chloroform	12.51 ± 0.029	71.86 ± 0.037
Acetone	47.61 ± 0.018	30.07 ± 0.046
Ethanol	82.86 ± 0.049	16.3 ± 0.012
Methanol	59.13 ± 0.021	33.33 ± 0.051
Aqueous	7.92 ± 0.020	5.04 ± 0.004

The results are expressed as Mean ± standard deviation

Fourier transform infrared spectroscopy analysis

The FTIR spectra of the all extracts revealed the presence of halogen and nitrogen compounds in common. The chloroform, acetone, and ethanol extracts revealed the presence of alkane and alcohol functional groups; the chloroform, acetone, methanol, and ethanol extracts revealed carbon dioxide and alkene groups; the chloroform extracts revealed the presence of aldehyde and ketone groups; the chloroform, methanol, and acetone extracts revealed amine groups; the acetone and ethanol extracts revealed esters groups; acetone, ethanol, methanol, aqueous extract showed sulfoxide group; carboxylic acid group was found in methanol and aqueous extracts; vinyl ether was found in methanol and aqueous extract revealed sulfonyl chloride groups. The results of FTIR are shown in Tables 3, 4, 5, 6, and 7 (Additional file 1: Figs. S1–S6).

GC–MS analysis

The compounds from the GC–MS analysis of the chloroform, acetone, methanol, ethanol, and aqueous extracts of *A. salviifolium* leaves are shown in Tables 8, 9, 10, 11, and 12. In case of the chloroform extract, the compound Androst-5-ene-3, 17-diol, 17-methyl-, dipropan was found to be major compound, in case of acetone extract the compound Phytol was found to be major compound, for methanol extract the compound ethyl (dimethyl) isopropoxysilane seems to be major compound, in case of ethanol extract diethyl phthalate was found to be major compound, and for aqueous extract benzofuran, 2, 3-dihydro compound was found to be major compound. Overall, the GC–MS results of chloroform, acetone, ethanol, methanol, and aqueous extract showed the presence of 24, 53, 23, 31, and 6 compounds, respectively, and the results are shown in Tables 8, 9, 10, 11, and 12. Additional file 1: Figs. S7–S11 show the GCMS chromatogram for all the extracts.

A. salviifolium's antioxidant activity in vitro

Phosphomolybdenum (PM) assay

On comparison between the all extracts, i.e., for acetone, chloroform, ethanol, methanol, and aqueous extracts in the phosphomolybdenum (PM) assay, aqueous extract has shown the highest activity with higher absorbance, i.e., 0.991 ± 0.004 for 500 µg concentration, whereas standard ascorbic acid has shown 1.078 ± 0.003. The results of all test samples are shown in Table 13 and Additional file 1: Fig. S12.

Table 13. Phosphomolybdenum (PM) assay for *A. salviifolium* leaf extract

Concentration (µg/ml)	Standard ascorbic acid	Acetone	Chloroform	Ethanol	Methanol	Aqueous
100	0.347 ± 0.003	0.178 ± 0.009	0.139 ± 0.004	0.124 ± 0.001	0.291 ± 0.006	0.279 ± 0.004

The results are represented as mean ± standard deviation

Radical scavenging assay using 2, 2 diphenyl-2-picryl hydrazyl (DPPH)

In case of DPPH assay among the selected chloroform, acetone, ethanol, methanol, and aqueous extracts, aqueous extract has exhibited prominent activity with a higher percentage of inhibition, i.e., 84.892% and standard ascorbic acid shown around 86.271%. The study found that when aqueous extract was compared to regular ascorbic acid, it had the comparable antioxidant activity than the remaining extracts (Table 14).

Table 14. DPPH assay for *A. salviifolium* leaf extract

	Concentration (µg)	Percentage of inhibition	IC_{50} in µg
Standard ascorbic acid	10	86.271 ± 0.1016	5.788
Acetone	100	59.111 ± 0.2329	84.53
Chloroform	100	56.649 ± 0.3073	88.77
Ethanol	100	66.808 ± 0.4417	74.93

Methanol	100	76.703±0.3206	65.49
Aqueous	100	84.492±0.3556	58.89

The results are represented as mean±standard deviation

Ferric ion reducing power (FRAP) assay

Using standard ascorbic acid, the ferric ion reducing power (FRAP) assay was carried out on extracts of acetone, chloroform, ethanol, methanol, and distilled water. According to the study's findings (Table 15, Additional file 1: Fig. S13), aqueous extract had the highest antioxidant activity with higher absorbance OD value when compared to the other four extracts.

Table 15. FRAP assay for *A. salviifolium* leaf extract

Concentration (µg/ml)	Ascorbic acid	Chloroform	Acetone	Ethanol	Methanol	Aqueous
100	0.566±0.006	0.104±0.003	0.146±0.001	0.086±0.004	0.198±0.002	0.251±0.003

Antibacterial activity of *Alangium salviifolium* leaves extract

Aqueous extract from the leaves of *A. salviifolium* had the greatest zone of inhibition against *Pseudomonas aeruginosa* and *Staphylococcus aureus* of all the leaf extracts tested for antibacterial activity. With a maximum inhibitory zone of 10 mm, leaf aqueous extract was found to be more effective to *Pseudomonas aeruginosa* than ethanol, acetone, and chloroform (5 mm) or methanol extract (3 mm). With a maximum inhibitory zone of 11 mm, *Staphylococcus aureus* was found to be more sensitive to the aqueous extract than to acetone, chloroform, ethanol, or methanol. Table 16 and Additional file 1: Figs. S14 and S15 display the measured zone of inhibition for leaf extracts produced from various solvents.

Table 16. Zone of inhibition (in mm) for different solvent extracts of leaves of *A. salviifolium*

Type of extract	Inhibition zone (mm)							
Pseudomonas aeruginosa				*Staphylococcus aureus*				30 µg
60 µg	90 µg	120 µg	30 µg	60 µg	90 µg	120 µg	Chloroform	3

Discussion

Numerous chemicals found in plants that are known to be biologically active and to have a variety of pharmacological effects [36, 37]. These plant secondary metabolites include several important natural antioxidant sources that are safer and more efficient than synthetic antioxidants [38]. The most prevalent phenolic molecules that act as natural antioxidants in plants include ascorbic acid, carotenoids, and flavonoids [39].

The phytochemicals found in the plant *A. salviifolium* were extracted in the current study utilizing a variety of increasing polarity solvents, including chloroform, acetone, ethanol, methanol, and distilled water. Different phytochemical tests were used to identify the phytochemicals, which included the presence of reducing sugar, alkaloids, flavonoids, phenols, lignin, glycosides, and tannins. Plants use alkaloids, the majority of which have a severe bitter taste and are very toxic, to protect themselves from herbivory, pathogenic microbial attack, and invertebrate pests. Numerous studies on phenolic compounds have demonstrated the significance of these compounds in demonstrating biologically active properties like anti-inflammatory, antidiabetic, antioxidant, antibacterial, anticancer, etc. [38]. Because of this, the total phenolic and total flavonoid contents of various extracts of *A. salviifolium* leaves were determined, as well as their antioxidant potential by in vitro phosphomolybdenum, DPPH, and ferric ion reducing power (FRAP) assay methods. In the current investigation, chloroform extract (71.86 mg/g QE) and ethanol extract (82.86 mg/g GAE) were shown to have the greatest concentrations of total flavonoid and phenol, respectively. It can be expected that the biological activity of the leaves of *A. salviifolium* may be caused by the presence of flavonoids and phenolic compounds in it based on the measurement of the total phenol and flavonoid content in them.

Based on the peak value ratio, the functional groups of the plant extracts are identified using the FTIR spectrum. Aldehyde, ketones, phenol, alkanes, alkenes, alcohol, aromatic, aliphatic amines, and amine compounds, as well as nitrogen and halogen compounds, were all confirmed to be present by FTIR analysis. For the examination of non-polar components and volatile essential oils, fatty acids, and lipids in the majority of medicinal plants, gas chromatography and mass spectroscopy (GCMS) investigations have become more and more helpful [40]. The existence of diverse bioactive components in all of the *A. salviifolium* extracts was confirmed by GC–MS analysis of the various solvent extracts used in the current study. Stigmasterol, (E)-9-Eicosene, 3, 7, 11, and 15-Tetramethyl-2-hexadecen-1-ol, Phytol were the main compounds identified in the chloroform extract; 9-Eicosene, 1-Nonadecene, 2- 4-hydroxy-4-methyl- Pentanone, and 9-Octadecene in acetone, whereas diethyl phthalate, di-(1-hexen-5-yl) ester phthalic acid in ethanol. Aqueous extract revealed the presence of 2,3-dihydro-Benzofuran and Squalene, as well as 7,1-cyclohex-1H-cyclopenta[b]indol-3(2H)-one, 2-Methoxy-4-vinylphenol, n-Hexadecanoic acid, alpha-D-Galactopyranose, 6-O-(trimethylsilyl) in methanol. Among the identified compounds, most of them are known to possess several biological activities such as stigmasterol was known to have anti-infammatory, antioxidant, antimicrobial, anticancer, antiarthritic, and antiasthama activity [41, 42]; (E)-9-Eicosene was known to have antimicrobial property [43]; 3,7,11,15-Tetramethyl-2-hexadecen-1-ol was known to have antimicrobial and anti-inflammatory property [44], and phytol was known to have antimicrobial, anti-inflammatory, antiallergic, anticancer, diuretic, antidiabetic, cytotoxicity, antiproliferative, cancer preventive properties [41, 45–47], 1-Nonadecene was proven to have antituberculosis, anticancer, antioxidant, antimicrobial and antifungal activities [48–50], and squalene was reported to have antibacterial, antioxidant, antitumor, cancer preventive and immunostimulant property [46, 51]. According to Neha et al. [52], an antioxidant is a chemical that can inhibit or block the oxidation of lipids or other

molecules by avoiding the onset of oxidative chain reactions. As a result, it can stop or undo the harm that oxygen does to the body's cells. Natural antioxidants are more popular these days because of their potential to improve health and fend off diseases. In the current work, three assay methods—the Phosphomolybdenum (PM), DPPH, and ferric ion reducing power (FRAP) assay methods—were used to determine the antioxidant activity of *Alangium salviifolium* leaves extract. Different crude extracts of *Alangium salviifolium* leaves underwent PM, DPPH, and FRAP assays, and the results were compared to ascorbic acid standard. The phosphate-Mo (V) complex is a bluish green color, and its synthesis results in the reduction of molybdate ions, which is evaluated spectrophotometrically in the phosphomolybdenum test [32]. It is a method that is often used in laboratories to evaluate the overall antioxidant activity of plant extracts. Aqueous extract had the highest activity in the current investigation (0.991 ± 0.004) (Table 13, Additional file 1: Fig. S12).

The assessed antioxidant's potential to scavenge free radicals is revealed by the decrease in DPPH solution absorbance during the reaction. *Alangium salviifolium* plant secondary metabolites such as alkaloids, flavonoids, tannins, phenols, and glycosides are abundant in the plant's crude extracts. By contributing a hydrogen molecule, each of these bioactive compounds has the ability to oxidize the DPPH solution [53]. Using chloroform, acetone, ethanol, methanol, and aqueous extract, the antioxidant activity of *Alangium salviifolium* was assessed in the current study and compared to that of conventional ascorbic acid. According to the results (IC_{50} value: 58.89 µg/ml) (Table 14), aqueous extract had the highest level of scavenging activity compared to all other extracts.

The ferric ion reducing power (FRAP) assay is a method that examines how antioxidants in an acidic media reduce ferric ion (Fe3+)-ligand complex to the strikingly blue ferrous (Fe2+) complex. According to this approach, absorption is inversely related to reducing potential; the greater the absorbance, the greater the antioxidants' capacity to reduce [54]. In the current analysis, aqueous extract was proven to be significant than chloroform, acetone, ethanol and methanol extracts in terms of antioxidant activity (0.997 ± 0.002) (Table 15, Additional file 1: Fig. S13). The investigated extracts' antioxidant activity varied greatly among the different solvent extracts, and the results concluded that on comparison among the tested extracts aqueous extract demonstrated a greater overall antioxidant capacity with noticeably superior outcomes. According to research by Shravya et al. [1], the antioxidant activity of *Alangium salviifolium* leaves was found to be superior than that of the plant's roots. However, *Alangium salviifolium* leaf extract demonstrated significant antioxidant activity against the DPPH radical and was comparable to earlier findings for this plant, but there was no relationship between antioxidant activity and TPC for *Alangium salviifolium* leaves [55].

Over the past three decades, pharmaceutical companies have created a variety of innovative antibiotic treatments, but bacteria have grown more resistant to these medications. Plant extracts are a fantastic source of pathogen-fighting antibacterial compounds. They can therefore be utilized to treat a variety of infectious disorders brought on by virulent microorganisms. *Staphylococcus aureus* and *Pseudomonas aeruginosa* were used in this work to test the plant extract from *Alangium salviifolium* for antibacterial activity. In both test organisms (Zone of Inhibition-19 mm and 22 mm), aqueous extract stood out among the extracts for its strong antibacterial activity (Table 16, Additional file 1: Figs. S14 and S15). However, *Alangium salviifolium* stem bark and flower extract have been found in the past to have strong antibacterial activity against a variety of bacteria [56, 57]. Additionally, there are not many reports on the antibacterial properties of *Alangium salviifolium* leaf extract. The results of the current investigation make it abundantly evident that water extract proven to be have significant antibacterial activity, whereas acetone, chloroform, ethanol, and methanol have noticeable antibacterial properties. Our study's findings indicate that *Alangium salviifolium* leaves can act as a natural antioxidant to stop the onset and spread of a variety of ailments. To isolate and purify the plant chemicals for this antioxidant and antibacterial properties, more research is required.

Conclusions

In the present study, the plant *Alangium salviifolium* was selected and using phytochemical and GCMS analysis the different solvent extracts of the plant have shown the presence of several metabolites such as phenols and alkaloids, GC–MS analysis has shown the presence of several compounds which are having industry and medicinal applications. Among the different solvent extracts, ethanol and chloroform extract have shown the presence of

highest phenolic and flavonoid content, respectively. Further, all selected extracts were screened for biological activities such as antioxidant and antibacterial activity. The results concluded that aqueous extract of plant *Alangium salviifolium* proven to be having potent properties in all performed assay. Hence, in future the molecular level of studies and animal model can be studied to understand its pathway studies.

ABSTRACT (ENGLISH)

Background

Hypertension is one of the burning topics in today's world. Natural product can open a new window in the treatment as they are lesser side effect compared to synthetic compounds. *Paederia foetida* a naturally occurring plant has proven its biological importance in many aspects. In this present study, the ethanolic extract of *Paederia foetida* has effectively proven its antihypertensive activity against Amphetamine-induced hypertension.

Results

The study was carried out for 4 weeks with five different groups where the groups receiving *Paederia foetida* (400 mg/kg) for 4 weeks result in decrease in blood pressure and was found helpful in maintaining the sodium and potassium balance in rat's serum. Amphetamine induces decreasing sodium level that can be countered by *Paederia foetida* whole plant extract. Geniposide, an active ingredient present in this plant, is having

antihypertensive activity, so it was docked against different PDB IDs (3OLL, 3OLS, 5DX3, 5DXE &6PIT), to find its anti-hypertension effectiveness through computational chemistry. The docking investigations identified that estrogen receptor (PDB ID: 3OLS) exhibited the highest possibility to be the site of action. Docking score of Geniposide with 3OLS was -8.91 which is quit comparable with the internal ligand Estradiol.

Conclusion

To assess the binding affinity of Geniposide with the estrogen receptor, an additional molecular dynamics simulation was conducted. The result strongly suggests that Geniposide has the potential to function as an activator of estrogen receptor through of β-ligand binding. This key finding reveals that Geniposide may serve as a potential in the treatment of hypertension by modulating the activity of the estrogen receptor.

FULL TEXT

Background

A chronic medical condition known as hypertension causes raised blood pressure in the arteries, also known as arterial hypertension. Above 140/90 mmHg of systolic and diastolic blood pressure is often considered as hypertension. Since high blood pressure is one of the major risk factors for coronary artery disease and other consequences, including heart failure, stroke, kidney disease, and diabetes, it is one of the main causes of mortality, globally [1]. According to the Global Burden of Disease study, hypertension is also regarded as the main risk factor for disability-adjusted life years, globally [2]. According to the World Health Organization, by 2025, 1.5 billion people will have hypertension, and the condition is projected to be a factor for more than 7 million fatalities annually [3]. Numerous research are focused on development of novel antihypertensive medicines and new therapy options because of the massive prevalence of hypertension, worldwide [4, 5]. There are different classes of antihypertensive medications, including angiotensin-converting enzyme (ACE) inhibitors, beta-blockers, and calcium channel blockers used in management of blood pressure, through the control of cardiac output, peripheral vascular resistance, and circulating blood volume [6, 7]. These antihypertensive medications are widely used to treat hypertension and associated cardiovascular disorders; however, these drugs also have undesirable side effects [6]. On account of the fact that natural herbal products made from medicinal plants are thought to have lesser adverse effects, thereby can be an alternative treatments and can be preferred over the existing medication [5]. Recently, it has been revealed that medicinal herbs can reduce hypertension and can be used empirically as antihypertensive medicines [8, 9]. Oxidative stress can be considered as an early warning sign for both hypertension and cardiovascular disorders so plants as an natural antioxidant can have the capability to enhance their antihypertensive effects [10, 11]. Diuretics have a significant role in the clinical management of hypertension. These medications influence the renal tubular segments' salt re-absorption to boost kidney urine production [12, 13]. NCC (Sodium chloride co-transporters) and NKCC2 (Na–K-2Cl co-transporter) are the main targets of diuretics. Recent research has demonstrated that the NKCC2-oxidative stress-responsive kinase 1 (OSR1)-with-no-lysine kinase (WNK) signaling pathway is crucial for controlling blood pressure [14]. WNK may control sodium chloride co-transporters (NCC) through the intermediate kinases OSR1 [15, 16]. A Rubiaceae family member *Paederia foetida*, also known as Prasariniin in Sanskrit, is a climbing plant with a strong foetid odor. Its Hindi name is Gandhaprasarini, and its English name is Chinese Flower [17]. Numerous scientific studies have been conducted to examine the activity of *Paederia foetida* in the management of rheumatic diseases, anti-inflammatory, hepatoprotective, and chemolithotripsy encourages sexual energy, boosts physical strength, semen production, and creates a young glow [18–25]. *Paederia foetida* possesses paederolone, paederone, sitosterol, paederoside, and asperuloside, along with their glycosides it has been identified through phytochemical studies [26–28]. The leaves of the plant are a good source of vitamin C, alkaloids, ketone alcohol, and beta-carotene [29]. Important constituents such asasperuloside, beta-sitosterol, and lupeol are well quantified in leaves, too [30]. Asperuloside, scandoside, and paederoside are iridoid glucosides that are present in the plant's aerial portions [31]. Friedelin, campesterol, ursolic acid, hentriacontane, hentriacontanol, ceryl alcohol, palmitic acid, and methyl mercaptan ellagic acids are other components of *P. foetida*. [32]. Another Iridoid glycosides are also found in roots of this plant known as Geniposide [33]. Our focus of this study is on Geniposide.

Yang Fu et al. [14] demonstrated the ability of Geniposide to increase urine production and the excretion of salt and chloride ions. They further revealed that the antihypertensive effects of Geniposide were considered due to their inhibition of the activation of the WNK signaling pathway, which is mediated by the estrogen receptor. So, considering this key finding we performed molecular docking and molecular dynamics (MD) simulations studies of Geniposide and various PDB IDs based on the structure of estrogen receptor.

Molecular docking, a computer-based method, can be employed to predict the non-covalent interactions between a macromolecule and a small molecule [34]. Based on the scoring method molecular docking analyses, the energy and binding strength of the complexes are observed [35]. This technique is frequently employed to conduct preliminary screening of small compounds by analyzing their binding characteristics to drug target. This creates the necessary foundation for rational drug design of novel drugs that can have higher specificity and greater efficacy [36]. Molecular dynamics (MD) simulations rely on general physics model guiding inter-atomic interactions and predict the motion of each molecule in a molecular system. Molecular dynamic simulations can determine the stability and dynamic properties of these protein–ligand complexes by analyzing the statistical parameters of these simulations [37, 38].

The present study evaluates the antihypertensive activity of the ethanolic extract of *Paederia foetida* against Amphetamine-induced hypertension in Wistar rats. Subsequently, an *in silico* molecular docking and dynamic simulation studies were conducted using the key phytochemical constituent, Geniposide to evaluate the potential of Geniposide and to consider it as a medication to lower blood pressure in the near future.

Materials and Methods

All the chemicals and reagents used were of analytical grade. Amphetamine and Hydralazine were purchased from Sigma-Aldrich, Mumbai, India. All drug solutions were freshly prepared in saline water before each experiment. Concentrated sulfuric acid, potassium bismuth iodide, Wagner reagent, Hagers reagents, sodium hydroxide, copper sulfate, hydrochloric acid, hydrogen peroxide, 4-aminoantipyrine, 4-chlorophenol, phosphotungstic acid, sodium dihydrogen phosphate, citric acid, potassium sulfate, and trichloracetic acid were purchased from Deshpande Laboratories Pvt Ltd, Bhopal, India.

Collection and authentication of plant material

The whole plant of *Paederia foetida* was collected and dried in 2022 from Bankura, West Bengal, India, with the GPS coordinates of 22°59′51.7′′N 87°OO’39.4′′E. The plant was authenticated by department of Botany, Bankura Christian College, West Bengal, India. The whole plant was shade-dried under room temperature and grinned to a fine powder.

Preparation of extraction

A whole plant powder (100 g) of *Paederia foetida* was extracted by maceration in 400 mL of ethanol for 14 days with frequent agitation. The mixture was filtered through clean muslin cloth followed by double filtration with Whatman No. 1 filter paper and the filtrate was concentrated by rotary evaporator with the vacuum at 50 ºC, poured into glass Petri dishes, and brought to dryness at 60ºC oven.

Phytochemical screening of different extract

Preliminary phytochemical screening was performed to identify the phytoconstituents present in the extracts. Phytochemical tests, such as Molish test, Dragendroff test, Mayers test, Wagner test, Hager test, Biuret test, Million test, ferric chloride test, lead acetate test, gelatin solution test, Shinoda test, alkaline reagent test, Legal test, Bajlets test, and Liebermann-Burchard test, were performed to determine the carbohydrates, alkaloids, proteins, tannins, flavonoids, glycosides, saponin, and steroids from ethanolic extract of *Paederia foetida.*

Procurement of animals

The experiments were carried out according to the guidelines of the CPCSEA, New Delhi, India. The study protocol was approved by the Institutional Animal Ethical Committee of Aditya Bangalore Institute of Pharmacy Education and Research Bangalore, Karnataka, India (approval number: 64/1611/CPCSEA). Female Wistar rats (Wistar strain) weighing between 150 and 200 g were obtained from local vendor, Bangalore, Karnataka. Animals were housed into five groups under standard laboratory conditions, i.e., 25 °C ± 1 °C/45–55% RH and 12/12 h light and

dark conditions in the animal house of Aditya Bangalore Institute of Pharmacy Education and Research, Bangalore, Karnataka, India. The rats are kept with free access to food (Hindustan Lever, India).

Antihypertensive activity

The rats were divided into five groups and each group contain six rats (n = 6). Group I was for positive control, received 0.9% saline p.o, group II marked for negative control, and received Amphetamine 5 mg/kg/day, (i.p.). Groups III and IV were allocated as test 1 and test 2 and received Amphetamine (5 mg/kg/day, i.p.) along with *Paederia foetida* (200 mg/kg/day, p.o.) and Amphetamine (5 mg/kg/day, i.p.) along with *Paederia foetida* (400 mg/kg/day, p.o.) for 4 weeks, respectively. Group V was marked as standard and received Amphetamine (5 mg/kg/day, i.p.) and Hydralazine (25 mg/kg., i.p.).

Blood pressure monitoring

Blood pressure was determined by placing an animal in the supplied restrainer. The tail-cuff warming chamber was attached and selected the number of test cycles and then pressed auto-calibrate to run. The tail-cuff method required the minimum amount of heat to measure blood pressure.

Noninvasive method of blood pressure determination

The cuff consists of latex balloon measuring 5 cm × 2 cm with 0.5 mm thickness. This balloon was placed in a circular plastic case having a diameter of 23 mm with a central hole of 12 mm diameter. The balloon was kept in such a manner that it remains in contact with the inner surface of the plastic case around the central hole so that this balloon encircles the tail. One end of the triway was connected with the balloon (tail-cuff) and the other two ends were connected to an inflating–deflating pump and sphygmomanometer. The system measured the systolic BP by determining the cuff pressure (reflected on the sphygmomanometer) and the blood flow (pulse) to the tail was eliminated. This elimination of blood flow (pulse) was recorded by a pulse transducer connected to a single-channel physiograph through a suitable coupler. The animals were acclimatized and kept in restrainers. The tail was passed through the hole of the newly designed cuff and the pulse transducer was tied around the tail distal to the cuff. As the system was switched on and the pulse was recorded on the physiographic paper. The cuff was inflated by the pump and the pressure in the cuff was raised until the pulse was eliminated. The pressure at which the pulse was eliminated, and noted as the systolic BP of the animal. The systolic BP and pulse were also recorded by the NIBP system of ADI for comparison.

Estimation of electrolytes

Method for assessment of serum electrolyte

Wistar rats were used for the biochemical analysis of serum. The rats were provided with the usual diet and the blood samples were collected for the determination of the amount of electrolytes present in blood (Na^+, K^+).

Sodium and potassium ion estimation

Sodium and potassium determination was performed in an automated Roche 9180 electrolyte analyzer (Basel, Switzerland). The 2 ml of blood samples was collected from rats through retro-orbital plexus after anesthetizing through a diethyl ether inhaler. The blood samples were kept for 30 min then centrifuged in a cooling centrifuge at 5000 rpm for 10 min to obtain the serum. The calibration of the instrument was performed, then run a control sample as mentioned. Finally, the serum sample was run to obtain the results.

In silico analysis

Ligand and protein preparations

The selected compound Geniposide and Estradiol (Internal ligand) were utilized for the molecular docking analysis for estrogen receptors. The three-dimensional structures of Geniposide and Estradiol were acquired from the PubChem database (https://pubchem.ncbi.nlm.nih.gov) (accessed on 20 April 2023) in SDF MOL format. The SDF MOL format was converted into PDB format by using OpenBableGUI 3.1.1 software. Three-dimensional structures (mainly crystal) of different PDB ID like 3OLL [40], 3OLS [40], 5DX3 [41], 5DXE [41], and 6PIT [42] were chosen for the investigation acquired from RCSB Protein Data Bank (PDB). 3OLL-Crystal structure of phosphorylated estrogen receptor beta ligand binding domain, 3OLS-Crystal structure of phosphorylated estrogen receptor beta ligand binding domain, 5DXE-Estrogen Receptor Alpha Ligand Binding Domain Y537S Mutant in Complex with Stapled

Peptide SRC2-P4 and Estradiol, 5DX3-Estrogen Receptor Alpha Ligand Binding Domain Y537S Mutant in Complex with Stapled Peptide SRC2-P3 and Estradiol &6PIT-Estrogen Receptor Alpha Ligand Binding Domain Y537S Mutant in Complex with SRC2 Stapled Peptide 41A and Estradiol. The process of getting ready the proteins involved accessing the PDB ID to retrieve the protein from the server, uploading the molecule, adding hydrogens, applying specific turning to residues, examining interactions and geometry for all atoms, and acquiring the finished protein file. Estradiol was isolated from the protein's binding pocket as an internal ligand to reveal the grid coordinates throughout the active region. The stabilized structure was stored after being downloaded from the server in PDBQT format for the purpose of protein–ligand docking.

Molecular docking of protein and ligand

The Autodock-4.2.6 program (ADP) was used to carry out molecular docking of Geniposide &Estradiol with estrogen receptors. ADP tools were used to prepare the protein and ligands. The coordinate values used in grid settings were acquired from re-docking studies, and the dimensions of the grid box were 60 × 60x60 in the x, y, and z directions. In each case, the spacing of the grid point was 0.375". Auto grid-4.2 was utilized to create the map files. For search criteria, a genetic algorithm (GA) was employed. Autogrid and Autodock operation were the last step of docking analysis and were performed in Autodock-4.2.6. The molecular docking of individual ligands on the appropriate protein was carried out using Autodock-4.2 and Autogrid-4.2, respectively. Interactions between molecules and binding energy (kcal/mol) were measured and analyzed.

ADME profile

The Swiss ADME online server (http://www.swissadme.ch/index.php) was used to assess the drug-likeness patterns and pharmacokinetic characteristics of the investigated compounds, where SMILES format of the compounds was uploaded to the webpage and the assessment procedure was completed.

Toxicity profile

The ProTox-II online server (https://tox-new.charite.de/protox_II/index.php) was used to predict the toxicities of the investigated compounds, where SMILES format of the compounds was uploaded to the webpage and the assessment procedure was completed.

Molecular dynamic simulation

Molecular dynamics (MD) simulation was carried out using GROMACS 2022.2. The following steps were utilized.

(a) Preparation of enzyme

The 3-dimensional (3D) models of the Estrogen receptor in complex with Geniposide were exported to PDB format using Pymol. The dynamic behavior of the complex was evaluated using molecular dynamic (MD) simulation in the GROMACS package program (version 2022.2) [43–45]. Protein topology was constructed by pdb2gmx with the CHARMM27 force field [46], and ligand topology was generated using the SwissParam server [47].

(b) Setting up a system for simulation

After applying the force field, the complex was inserted into the system. It was solvated with the TIP3P water model [48] in a cubic box greater than 1 nm from the edge of the protein with periodic boundary conditions. The system was neutralized by adding Na + ions, and energy minimization was done for 50,000 steps using the steepest descent algorithm. It was then followed by 100 ps of NVT simulation at 300 K and 100 ps of NPT simulations to equilibrate the whole system. The Leapfrog algorithm was employed in the constant-temperature, constant-pressure (NPT) ensemble to separately couple each component like protein, ligand, water molecules, and ions [49]. The Berendsen temperature and pressure coupling constants were set to 1 and 2, respectively, to keep the system in a stable environment (300 K temperature and 1 bar pressure) [50]. Finally, MD simulation for 100 nswas performed in isothermal and isobaric condition ensemble at 300 K. The pressure coupling with time-constant was set at 1 ps to maintain pressure constant at 1 bar, and the LINCS algorithm [51] was used to constrain the bond lengths. The Van der Waals and Coulomb interactions were truncated at 1.2 nm, and the PME algorithm [52] inbuilt into GROMACS was used to minimize the error from truncation.

(c) Visualization and analysis of simulation

The trajectory file was visualized through VMD (Visual Molecular Dynamics) 1.9.2 [53] and analyzed by the tool Hero

MD Analysis [54, 55] and Xmgrace 5.1.25 [56, 57].

Results

Preparation of extract and phytochemical screening

The crude ethanolic extract was prepared by maceration process for a period of 14 days and finally the yield was calculated. Nearly 100 gm of the whole plant was extracted and the yield was found to be 12.16 g. An appropriate concentration of the extracts was made in distilled water for further studies. Preliminary phytochemical screening of ethanolic extract of *Paederia foetida* was performed and revealed the presence of different phytoconstituents, proteins, amino acids, alkaloids, phenolic compounds, carbohydrates, alkaloids, tannins, flavonoids, and glycosides. The results of all these tests are summarized in Table 1.

Table 1. Phytochemical screening of *Paederiafoetida*

Serial no	Test	Result
1	Proteins and amino acids	+
2	Alkaloids	+
3	Phenolic compounds	+
4	Carbohydrates	+
5	Glycosides	+
6	Saponins	−
7	Flavonoids	+
8	Fixed oils and fats	−
9	Terpenoids	−
10	Sterols	−

The symbol (+) denotes presence and (−) denotes absence of phytoconstituents

Measurement of blood pressure by noninvasive (indirect) method after administration of Paederia foetida whole plant extract

The drug-induced hypertension in rats was acquired by administration of Amphetamine for 4 weeks (negative control) in rats, and produced a significant elevation in the systolic blood pressure (SBP) as measured by tail-cuff method on 1st, 2nd, 3rd, and 4th week, respectively, when compared to the control rats. Rats that received *Paederia foetida* whole plant extract (200 and 400 mg/kg/day, p.o., test 1 &2) for 4th weeks along with Amphetamine was found to reduce the SBP significantly in 3rd and 4th week when compared to Amphetamine-induced hypertensive rats, thus implying an antihypertensive activity. The detailed antihypertensive study is summarized in Table 2 and Additional file 1: Figure S1.

Table 2. SBP of Amphetamine-induced rat along with *Paederiafoetida* and Hydralazine

Treatment groups (mg/kg)	Mean SBP (mm/Hg)				
0 week	1st week	2nd week	3rd week	4th week	Control
108.32 ± 2.34*	109.43 ± 2.10*	114.12 ± 1.19*	112.23 ± 1.03*	110.15 ± 0.34*	Amphetamine (5)

Estimation of sodium and potassium ion in serum of rats

The blood sample from different groups was collected and serum was separated to carry out the estimation of sodium and potassium levels in the serum of rats. The normal control (Group I) test 1, (Group III), test 2 (Group IV) &standard (Group V) exhibited normal values of sodium, whereas the negative control group (administered with Amphetamine) showed a relative decrease in Na^+ level in blood serum for 4 weeks in rats. Our findings also satisfy the literature survey as it was mentioned by Suzanne et al. 2002 [39] that Amphetamine toxicity can relatively decrease the Na^+ level than the normal value in blood serum. The result of the study is represented in Table 3 and Additional file 1: Figure S2. In the case of the serum potassium level in rats, no significant changes were noticed in all the four groups (Table 4 and Additional file 1: Figure S3).

In silico activity of Geniposide and Estradiol against estrogen receptor

Molecular docking of Geniposide and Estradiol

The literature survey reveals that Geniposide is an active ingredient which can effectively reduce the blood pressure by inhibiting the activation of WNK signaling pathway mediated by the estrogen receptor [14]. The goal of the

molecular docking study was to examine at the binding energy and molecular interactions of Geniposide and Estradiol in the active site of the estrogen receptor, to achieve a strong rational correlation through computational studies. In addition, each compound's binding mechanism was examined for molecular interactions. The results showed that Geniposide had very close significant binding energy compared to the internal ligand Estradiol (Table 5). Among all the interactions (3OLS, 3OLL, 5DX3, 5DXE, 6PIT), PDB ID: 3OLS, Geniposide was found to have a very good docking score. The result of the binding and molecular interaction between PDB ID: 3OLS &Geniposide (Fig. 1c) revealed that Geniposide formed hydrogen bonds with HIS475, GLU3O5, LEU298, LEU339, and ARG346 through oxygen groups having bond lengths of 3.10, 2.76, 2.46, 3.33 &3.07 Å, respectively. In the case of internal ligand Estradiol, it showed hydrogen bond interaction between HIS475 &ARG346 through oxygen atoms having bond lengths of 3.10 &3.17 Å, respectively (Fig. 1d). All other interactions are shown in Fig. 2. 2D molecular interactions of Geniposide and Estradiol with respect to all PDB ID are given in Additional file 1 (Figure S4- Figure S8).

ADME profile

The pharmacokinetics, physicochemical, and drug-likeness parameters of the compounds Geniposide (Plant derived) &Estradiol (Internal Ligand) were evaluated using the freely available online server Swiss ADME (http://www.swissadme.ch/index.php). The overall results of Swiss ADME prediction (Table 6) elucidated that the examined compounds showed a predicted log Po/w value in the range of -1.25 to 3.40 and disclosed no alerts for Pan Assay Interfering Substances (PAINS). Geniposide has poor solubility in water, but Estradiol was practically insoluble in water. Geniposide does not show BBB permeability, but Estradiol shows BBB permeability. This parameter was well understood from the boiled egg chart (Fig. 3). Both of these compounds follow Lipinski rule of five. Estradiol was found to be a CYP2D6 inhibitor, whereas Geniposide does not inhibit the enzyme CYP2D6 that suggests that Geniposide does not interfere with the metabolism of other drugs associated with CYP2D6. Lastly, the oral bioavailability radar charts (Fig. 4) showed good oral bioavailability as it is polar in nature, whereas Estradiol is nonpolar in nature. This result reflects Geniposide a favorable compound for good pharmacokinetic features. Along with this features, Geniposides also possess greater flexibility, lesser lipophilicity, and higher solubility when compared to Estradiol. This proves that Geniposide is having better ADME profile than Estradiol.

Table 6. ADME properties of the selected compounds predicted using SwissADME web server

Property	Geniposide	Estradiol
MW	388.37	272.38
Consensus LogPo/w	-1.25	3.40

Toxicity profile

The toxicity parameters of Geniposide (Plant derived) &Estradiol (Internal Ligand) were evaluated using the online server ProTox-II (https://tox.new.charite.de/protox_II/index.php) and the result is depicted in Tables 7 and 8. It was observed that Geniposide is safer in comparison with Estradiol and it is clearly understood from the toxicity radar chart and toxicity table that all the toxicity parameters were inactive except immunotoxicity in case of Geniposide, whereas several toxicity parameters were found active in Estradiol. The immunotoxicity of Geniposide was found to be 0.52, whereas that of Estradiol was 0.99. This refers that Geniposide is safer option than that of Estradiol. Geniposide is much safer compare to Estradiol for the target androgen receptor, from the toxicity profile study of both these drugs depleted in Additional file 1: Figure S9.

Molecular dynamic simulations of estrogen receptorin Apoprotein form and in complex with molecules, Geniposide and Estradiol

In order to evaluate the binding of molecule, Geniposide and Estradiol inside the β-ligand binding domain of Estrogen receptor, we have carried out MD simulations for a period of 100 ns for the three models, A) Apoprotein, B) Geniposide-3OLS, and C) Estradiol-3OLS complex (Fig. 5). Their simulations were evaluated using various statistical parameters including: root-mean-square deviation (RMSD), root-mean-square fluctuation (RMSF), h-bond interactions, and its %occupancies over the time.

Fig. 5 [Images not available. See PDF.]

Graphical representation of **A** Apoprotein form, **B** Geniposide and **C** Estradiol bound inside the active site of Estrogen receptor, where protein is shown in cartoon representation and the ligand is shown in CPK representation

RMSD analysis

Analyzing the protein-RMSD can give insights into any structural conformation that protein undergoes during the simulation. The multiplot for protein Cα and ligand RMSD versus time is shown in Figs. 6 and 7, respectively. The protein CαRMSD plot indicates that the Apoprotein and the complexes (protein and ligand) have thoroughly followed the equilibrium RMSD value of around 0.17 nm.

Fig. 6 [Images not available. See PDF.]

Graphical representation of the plots showing protein Cα RMSD (nm) versus time (100 ns) for different models

Fig. 7 [Images not available. See PDF.]

Graphical representation of the plots showing ligand RMSD (nm) versus time (100 ns) for Geniposide-3OLS and Estradiol-3OLS complex

The ligand RMSD plot revealed the stability of both Geniposide and Estradiol in their binding to the estrogen receptor during the entire simulation. Geniposide and Estradiol achieved RMSD values of approximately 0.1 nm and 0.025 nm, respectively.

RMSF analysis

Protein RMSF proves valuable for assessing local changes in the protein chain. The multiplot for protein RMSF (nm) versus residue number index is depicted in Fig. 8. Encouragingly, the plot indicates fluctuations of less than 0.15 nm for most of the protein sequence, with the exception of the loop region between ASN407-SER422 in all three cases—Apoprotein, Geniposide-3OLS, and Estradiol-3OLS. Although this loop region exhibits fluctuations of around 0.35 nm, it does not impact ligand binding, as no residue in this region contributes to the ligand's binding cavity. The residues within the binding cavity remain stable with fluctuations of significantly lower magnitude.

Fig. 8 [Images not available. See PDF.]

Graphical representation of the plots showing protein RMSF (nm) versus residue index number of protein for different models

H-bond interaction

Molecular interactions, especially h-bond interactions, are sensitive to distance and angle variations, susceptible to disruption under dynamic conditions. In this study, we scrutinized the ligand–protein interactions in both complexes. Figure 9 presents the plot of the number of hydrogen bonds versus time. Notably, Geniposide exhibited up to three stable h-bond contacts during the simulation, while Estradiol displayed up to two stable contacts.

Fig. 9 [Images not available. See PDF.]

Pictorial representation of the number of h-bond contacts formed by Geniposide and Estradiol in complex with Estrogen receptor (3OLS)

Figure 10 illustrates the %occupancies histogram of h-bond contacts formed by the ligand Geniposide in complex with the Estrogen receptor. The most stable interaction was observed with residue GLU305, exhibiting an occupancy of 114.98%. This indicates that the ligand established multiple stable h-bond contacts with this residue (see Fig. 11), while Geniposide weakly interacted with other residues, including LEU298, LEU339, GLY472, and HIS475, with %occupancies of 3.55, 4.63, 2.57, and 2.16%, respectively. In comparison, the ligand Estradiol interacted with residues HIS475 and GLU305, with occupancies of 72.26% and 42.27%, respectively. Other residues, such as MET295, LEU298, and GLY472, exhibited interactions with occupancies of 2.4%, 2.06%, and 1.01%, respectively. In summary, similar to Estradiol, Geniposide efficiently activates the Estrogen receptor, demonstrating effective binding within the β-ligand domain. Estrogen receptor activation is known to promote vasodilation and exert antihypertensive effects by modulating the renin–angiotensin–aldosterone system [58].

Total energy

The total energy profiles obtained from the MD simulations of the Geniposide-3OLS and Estradiol-3OLS complexes offer valuable insights into their stability and energetic characteristics. Across the 100 ns simulation period, both complexes displayed minor fluctuations in total energy, indicating the attainment of a relatively stable equilibrium state (Fig. 12). These fluctuations remained within acceptable ranges, indicative of a well-equilibrated simulation that faithfully captured the dynamic behavior of the complexes.

Fig. 12 [Images not available. See PDF.]

Graphical representation of the total energy (KJ/mol) versus time (100 ns) for 3OLS-Geniposide and 3OLS-Estradiol complex

Discussion

Hypertension is also regarded as the main risk factor for disability-adjusted life years globally, according to the Global Burden of Disease study [2]. Numerous research are focused on development of novel antihypertensive medicines and new therapy options because of the massive prevalence of hypertension, worldwide [4, 5]. Recently, it has been revealed that medicinal herbs can reduce hypertension and can be used empirically as antihypertensive medicines [8, 9]. Diuretics have a significant role in the clinical management of hypertension. These medications influence the renal tubular segments' salt re-absorption to boost kidney urine production [12, 13]. NCC (Sodium chloride co-transporters) and NKCC2 (Na–K-2Cl co-transporter) are the main targets of diuretics. Recent research has demonstrated that the NKCC2-oxidative stress-responsive kinase 1 (OSR1)-with-no-lysine kinase (WNK) signaling pathway is crucial for controlling blood pressure [14]. A Rubiaceae family member *Paederia foetida*, also known as Prasariniin Sanskrit, is a climbing plant with a strong foetid odor. Its Hindi name is Gandhaprasarini, and its English name is Chinese Flower [17]. Various types of phytochemicals are present in the *Paederia foetida*,

among these one Iridoid glycosides known as Geniposide present in the root of this plant [33]. Yang Fu et al. [14] demonstrated that the ability of Geniposide to increase urine production and the excretion of salt and chloride ions. They further revealed that the antihypertensive effects of Geniposide was considered due to their inhibition of the activation of the WNK signaling pathway, which is mediated by the estrogen receptor. So, considering this key finding we performed molecular docking and molecular dynamics (MD) simulations studies of Geniposide and various PDB IDs based on the structure of estrogen receptor. *Paederia foetida* whole plant extract has an antihypertensive action in Amphetamine-induced hypertensive rats which is evident by a considerable decrease in blood pressure. Amphetamine induces decreasing sodium level that can be countered by *Paederia foetida* whole plant extract, whereas sodium &potassium level remains to be same in all the four groups of rats. The goal of the molecular docking study was to examine the binding energy and molecular interactions of Geniposide and Estradiol in the active site of the estrogen receptor, to achieve a strong rational correlation through computational studies. In addition, each compound's binding mechanism was examined for molecular interactions. The results showed that Geniposide had very close significant binding energy compared to the internal ligand Estradiol. The result of ADME study reflects that Geniposide is a favorable compound for good pharmacokinetic features. Along with these features, Geniposides also possess greater flexibility, lesser lipophilicity, and higher solubility when compared to Estradiol. This proved that Geniposide is having better ADME profile than Estradiol. Geniposide is safer in comparison with Estradiol and it is clearly understood from the toxicity radar chart and toxicity table that all the toxicity parameters were inactive except immunotoxicity in case of Geniposide, whereas several toxicity parameters were found active in Estradiol. The molecular dynamics revealed that Geniposide forms stable interactions with key amino acid, GLU305 of β-ligand binding domain of estrogen receptor, suggesting its potential as an activator of estrogen receptor. After overall evaluation of all the data, we can say that Geniposide is a potential drug candidate for the treatment hypertension through the modulation of estrogen receptor.

Conclusion

The present work concludes, *Paederia foetida* whole plant extract has an antihypertensive action in Amphetamine-induced hypertensive rats which is evident by a considerable decrease in blood pressure. Amphetamine induces decreasing sodium level that can be countered by *Paederia foetida* whole plant extract, whereas sodium &potassium level remains to be same in all the four groups of rats. According to the OECD (Organization of economic co-operation and development 425 guidelines) *Paederia foetida*, whole plant extract was safe for administration at 200 and 400 mg/kg. Among the two dosages tested for *Paederia foetida*, whole plant extract 400 mg/kg body weight exhibited the highest considerable antihypertensive effect. Geniposide, a natural moiety found in this plant, is having antihypertensive activity. Docking study was carried out on different PDB ID to find out the potency of the compound as an antihypertensive. Geniposide, an antihypertensive agent present in this plant, is used for in silico study to define its potential as an antihypertensive agent. The ligand structure was docked with different PDB IDs (3OLL, 3OLS, 5DX3, 5DXE &6PIT). The docking studies revlealed the PDB ID: 3OLS to be most suitable in terms of its comparison with the internal ligand, Estradiol. Further molecular dynamics simulation study was carried out to evaluate the binding between Geniposide and estrogen receptor. The findings indicate that Geniposide forms stable interactions with key amino acid, GLU305 of β-ligand binding domain of estrogen receptor, suggesting its potential as an activator of estrogen receptor. Thus, Geniposide can be a useful compound for the treatment of hypertension through the modulation of estrogen receptor.

Acknowledgements

The authors would like to acknowledge the Aditya Bangalore Institute of Pharmacy Education and Research for extending the facility for the manuscript. The authors also would like to acknowledge Bishal Banerjee (Assistant Professor, IQ City Institute of Pharmaceutical Scienes, Durgapur, West Bengal, India) and Priyanka Chandra (Research Scholar, BIT Mesra, Ranchi) for their suggestions for the manuscript.

Author contributions

Conceptualization, supervision, formal analysis, writing, review and editing were done by Suddhasattya Dey and Arijit Mondal; Ravi Rawat, Dibya Lochan Mohanty, Deeparani Urolagin, Ameeduzzafar Zafar, Padma Charan

Bahera, and Chanchal Koley helped in investigation; Naresh Kumar Rangra, Volkan Eyupoglu, Ravi Rawat, Arijit Mondal, Suddhasattya Dey, and Anjan Mondal were involved in software, methodology, and validation. All authors have read and agreed to the published version of the manuscript.

Funding

Availability of data and materials

The data that support the findings of this study are available from the corresponding author upon request.

Declarations

Ethics approval and consent to participate

The study protocol was approved by the Institutional Animal Ethical Committee of Aditya Bangalore Institute of Pharmacy Education and Research Bangalore, Karnataka, India (approval number: 64/1611/CPCSEA). Female Wistar rats (Wistar strain) weighing between 150 and 200 g were obtained from local vendor, Bangalore, Karnataka. Animals were housed into five groups under standard laboratory conditions, i.e., 25 °C ± 1 °C/45–55% RH and 12/12 h light and dark conditions in the animal house of Aditya Bangalore Institute of Pharmacy Education and Research, Bangalore, Karnataka, India. The rats are kept with free access to food (Hindustan Lever, India).

Consent for publication

Not Applicable.

Competing interests

The authors declare that they have no known competing interests or personal relationship that could have appeared to influence the work report in this paper.

Investigation of the antidiabetic and probiotic properties of lactic acid bacteria isolated from some ethnic fermented foods of Darjeeling District

Ghosh, Amlan Jyoti1; Ghosh, Supriyo1; Adhikari, Manab Deb2; Saha, Tilak1 1 University of North Bengal, Immunology and Microbiology Laboratory, Department of Zoology, Siliguri, India (GRID:grid.412222.5) (ISNI:0000 0001 1188 5260)2 University of North Bengal, Department of Biotechnology, Siliguri, India (GRID:grid.412222.5) (ISNI:0000 0001 1188 5260)

ABSTRACT (ENGLISH)

Background

Indigenous communities residing in the Darjeeling Himalayan region and its adjacent hilly areas have a deeply rooted cultural tradition of consuming a diverse range of vegetable and milk-based fermented products, believed to confer various health advantages. With this traditional knowledge, lactic acid bacteria (LAB) were isolated from popular fermented foods such as Chhurpi (derived from *Bos grunniens* milk), Gundruk (made from *Brassica juncea* leaves), Sinki (derived from *Raphanus sativus* taproots), and Kinema (produced from *Glycine max* beans). This study aimed to investigate the probiotic properties of the prevalent LABs, including aggregation properties, bile salt hydrolase activities, survival under gastro-inhibitory conditions, safety evaluations, and their potential health-promoting attributes, with a specific focus on inhibiting α-amylase and α-glucosidase enzymes.

Results

Five of the LAB isolates demonstrated notable viability rates exceeding 85% when exposed to gastro-inhibitory challenges. Based on 16S rRNA gene sequencing, these isolates were identified as *Pediococcus pentosaceus* (isolate GAD), *Lactobacillus plantarum* (isolates KAD and CAD), *Lactobacillus brevis* (isolate SAD), and *Lactiplantibacillus plantarum* (isolate CMD). These LAB isolates exhibited versatile carbon source utilization, significant auto- and co-aggregation, and bile salt hydrolase (BSH) properties. Auto-aggregation capacity notably increased over time, ranging from 30 to 150 min, with percentage increments from 4.83 ± 1.92% to 67.60 ± 5.93%. *L. brevis* SAD displayed the highest co-aggregation increment (%) against *Staphylococcus aureus*, while *L. plantarum* KAD demonstrated potent antimicrobial activity. *In vitro* analyses postulated potential health benefits related to antidiabetic properties, particularly inhibiting α-amylase and α-glucosidase enzymes. *L. brevis* SAD exhibited the highest α-glucosidase inhibitory activity, while *L. plantarum* KAD displayed the most potent α-amylase inhibitory activity. Comprehensive safety assessments, including antibiotic susceptibility profiling, hemolytic activity evaluation, and *in vivo* acute toxicity studies, confirmed the suitability of these LAB isolates for human consumption.

Conclusions

The isolates show promising probiotic characteristics and significant potential in addressing metabolic health. These results carry substantial scientific implications, suggesting the pharmaceutical-based applications of these traditional fermented foods. Further *in vivo* investigation is recommended to fully elucidate and exploit the health benefits of these LAB isolates, opening avenues for potential therapeutic interventions and the development of functional foods.

FULL TEXT

Background

The beneficial effect associated with consuming fermented food products containing probiotic microorganisms is conventionally recognized. This has intrigued researchers to isolate and characterize novel probiotics from diverse sources. Fermented foods function as rich repositories of probiotics, rendering them valuable as dietary supplements for health benefits. Certain ancient societies have a longstanding tradition of incorporating fermented foods into their diets, and some are still produced through traditional methods [1, 2]. The microbial fermentation of raw ingredients in these foods facilitates the production of highly nutritious components, including bacterial metabolites, which are believed to confer health-promoting effects [3].

Research on identifying and characterizing new probiotic isolates and developing probiotic supplements with health-enhancing properties has gained increasing significance, especially in metabolic disorders such as diabetes. One strategy to mitigate the glucose load involves the delayed metabolism of carbohydrates, leading to a more balanced glucose profile. Studies have shown that inhibiting α-glucosidase and α-amylase enzymes can delay glucose absorption, resulting in a gradual increase in postprandial blood glucose levels [4, 5]. Notably, certain *Lactobacillus* spp. have demonstrated effective inhibition of α-glucosidase and α-amylase enzyme activity in vitro [6].

In the sub-Himalayan regions of West Bengal, India, particularly in the Darjeeling district, various fermented dishes

are regularly consumed [7]. Several communities residing in the Darjeeling district and neighboring hilly areas of northern West Bengal traditionally prepare and consume different fermented milk and vegetable-based dishes. Examples include “Sinki” which is fermented radish (*Raphanus sativus*) taproot, “Gundruk” which is fermented leaves of certain *Brassica* species (*Brassica juncea*), “Kinema” which is fermented soybean (*Glycine max*) seeds, and “Chhurpi” which is a fermented cheese product made from the milk of Himalayan *Bos grunniens*. These preparations are reported to foster the growth of LAB isolates [8, 9]. However, further research is necessary to elucidate the antidiabetic, probiotic, and safety attributes of the LABs.

In this study, LAB strains from some popular ethnic fermented foods of Darjeeling have been isolated, and their *in vitro* antidiabetic and probiotic potentials, along with safety aspects, have been investigated.

Methods

Sample collection, processing, and isolation of LAB

Fermented food samples were collected from two different villages in the Darjeeling district of West Bengal, India, during March and April 2022. Chhurpi, a dairy-based fermented product, was collected from Tukdah Forest village, while soft Chhurpi and vegetable-based fermented preparations, namely Gundruk, Kinema, and Sinki, were collected from Bijanbari village. The samples were collected separately in sterile 50mL centrifuge tubes and transported to the laboratory in thermally insulated ice boxes to maintain their integrity. Standard procedure was followed for the collection of the samples [10].

Similar to the traditional processing for consumption, Kinema, Gundruk, and Sinki were mixed with distilled water and incubated at 37 ℃ for 20 min. Then, 200µL sample from these liquid mixtures was taken and added to separate De-Man, Rogosa, and Sharpe (MRS) (Hi-Media, India) broth and incubated at 37 ℃ for 48 h. Hard and soft Chhurpi was directly used as inoculum for MRS broth and incubated following the same process. After 48 h of incubation, all the inoculated broths were serially diluted up to 10^{-7} in phosphate buffer saline (PBS) (SRL, India) and spread on MRS agar plates separately. These plates were then incubated at 37 ℃ for 48 h. Plates with a suitable number of colonies (neither too many nor too few) were selected, and their colony numbers were counted in terms of colony-forming units (CFU). Bacterial load of all the food samples was calculated in CFU per milliliter (mL) or CFU per gram (g) unit. Colonies with distinct physical characteristics were then selected and streaked onto fresh MRS plates to make single colonies and to isolate pure cultures.

The isolated pure colonies were then transferred to MRS agar slants for experimental use and stocked in 40% glycerol for storage. The isolates were named based on the source (C for Chhurpi, G for Gundruk, K for Kinema, and S for Sinki), the month of collection (M for March, A for April), and the district of collection (D for Darjeeling), followed by sequential numbers to represent each isolate from each source. The slants were stored at 4 ℃ and sub-cultured every 15 days, not exceeding 2 passages (the transfer of organisms from an established culture to a fresh medium), while glycerol stocks were stored at – 20 ℃ and restocked every 2 months (not exceeding 5 passages) [11].

Preliminary screening of the isolates based on gastro-inhibition tolerance activity

In order to identify the most resilient LAB from the initial isolates, the isolates were exposed to conditions resembling the harsh environment of the human gastrointestinal (GI) tract. These conditions included lysozyme-mediated degradation, acidic pH, and high bile concentration [12]. After the preliminary screening, tolerance to alkaline pH was also evaluated for the selected strains.

To assess lysozyme tolerance, a standard protocol was followed [13]. Briefly, overnight-grown bacterial cells were subjected to lysozyme tolerance testing. The cells were harvested, washed, and resuspended in Ringer's solution. A suspension of 10 µL was inoculated into a sterile electrolyte solution containing lysozyme at a concentration of 100 mg/L (SRL, India). A control broth without lysozyme was also prepared. The samples were then incubated at 37 °C, and after 2 h, the viable cell count was determined as a measure of lysozyme tolerance (in terms of Log CFU/mL).

For the analysis of acid and bile tolerance, standard protocols with certain experimental adjustments were followed [14, 15]. To assess acid tolerance, the isolates were cultured in acidic MRS broths (Test) adjusted to pH 3.0 with

1 M hydrochloric acid, alongside control MRS broth with normal pH. Here, a direct endpoint method was employed. This involved determining the survival percentage by comparing the bacterial count (expressed as log CFU/mL) in the control broth (not subjected to acidification) with that in the test broth (acidified to pH 3.0). For the experimental assessment of bile, acid, and lysozyme tolerance, *L. plantarum* MCC 2156 served as the positive reference strain [16]. The assessment was performed after a fixed incubation time of 3 h, utilizing an overnight-grown culture as the inoculum at a concentration of 1% V/V. Similarly, for the bile tolerance assay, a test broth containing 2% (w/v) deoxycholic acid (SRL, India) was used, and again, Log CFU/mL values of the 'Test' broth were compared with those of the 'Control' broth involving the same incubation parameters. The survivability of the isolates was calculated by comparing the Log CFU/mL values of the 'Test' and the 'Control' broths, and the survivability for each isolate was expressed as 'Percent Survival' (% Survival) using the following formula:PercentSurvival(%Survival)=LogCFUpermL ofTextLogCFUpermLofControl×100

Isolates showing survival values≥85% for the GI conditions (lysozyme, acid, and bile tolerance) were selected for further analysis. The chosen cut-off value of "85%" was selected because scoring more than 85% of all three parameters creates a probability of success (85%×85%×85%) and reinforces the strains' potential to thrive in the harsh GI environment, making them promising candidates for probiotic use.

After preliminary screening, survival of the selected isolates in alkaline pH was further assessed, taking alkaline-tolerant *Escherichia coli* K12 strain as control. Briefly, broths with pH levels of 8.5, reflecting the maximum pH detected in the human gastrointestinal tract [17], were prepared alongside control broths with unaltered pH. Inoculums were incubated for 12 h at 37 °C, and the % OD change of the individual broths was measured at 600 nm in a spectrophotometer (Shimadzu UV-1900I, Japan) indicating the extent of growth inhibition due to alkaline pH.

Molecular identification of the LAB isolates

The selected LAB isolates were identified by analyzing the partial sequences of their 16S rRNA genes through molecular phylogeny. The genomic DNA of each isolate was separately extracted following standard protocols outlined by De et al. [18]. The partial 16S rRNA gene was then amplified using universal primers 27F (5′-AGAGTTTGATCCTGGCTCAG-3′) and 1492R (5′-TACGGTTACCTTGTTACGACTT-3′) as described in a previous study by Frank et al. [19]. For amplification, reaction mixture was prepared using reagents from Promega (USA) and Eurofins Genomics, India (primers) following the manufacturer's instructions. Thermal cycling was carried out in a Mastercycler® Nexus GX2 thermal cycler (Eppendorf instrumente gmbh, Germany). The PCR products were visualized on an ethidium bromide-agarose gel under a UV transilluminator (Hi-Media, India). The PCR products were purified and sequenced using Sanger's method at Heredity Biosciences, India. The resulting sequences were aligned in the NCBI-BLAST (https://blast.ncbi.nlm.nih.gov/blast.cgi) for similarity analysis and to infer functional and evolutionary relationships between sequences. The raw sequences obtained were trimmed and aligned using the MEGA 11 version 11.0.13 package with similar sequences retrieved from the database for drawing the phylogenetic relationship [20]. Finally, the curated sequences were deposited in the GenBank (https://www.ncbi.nlm.nih.gov/websub/) for public access. Phylogenetic tree and evolutionary relationships were constructed using the neighbor-joining method in the MEGA 11 (v. 11.0.13) package, with *Leuconostoc gasicomitatum* strain Tb1-10 serving as the outgroup [20]. To assess the accuracy of the tree topologies, bootstrap analysis with 100 repetitions was performed [21].

Assessment of probiotics properties

Carbohydrate fermentation profiling and esculin hydrolysis

A good probiotic strain should have the ability to utilize multiple carbohydrate sources, which ensures its survival in the host's digestive tract [22]. To identify the patterns of sugar fermentation, and esculin hydrolysis of the LAB isolates, a standard carbohydrate fermentation kit (Hi-Lacto Identification Kit, KB020-10KT, Hi-Media, India) was used. For the assessment, 50 µL of overnight-grown cultures was aseptically applied to each of the specific designated wells of the kit by surface inoculation method, and then, the kits were again sealed off and incubated at 37 °C for 24 h, and after the incubation, the results were interpreted as per the instruction manual (as positive, + or negative, −).

Auto-aggregation assay

Modified version of the auto-aggregation assay developed by Del Re et al. [23] was used to test the capacity of the isolated LAB isolates to auto-aggregate. Briefly, 2 mL of bacterial suspension from overnight-grown cultures was vortexed, and then, the mixture was allowed to stand in static condition at 37 °C, and at regular intervals (30 min, 60 min, 90 min, 120 min, and 150 min) 100 µL of liquid from the upper surface from each bacterial culture was taken and combined with 900 µL of PBS (0.1 M), and then, the absorbance was measured using a microplate reader (SPECTROstarNano, BMG Labtech, Germany) at 600 nm (A_{600}). The auto-aggregation (%) of all the LAB isolates was then calculated by the formula:Auto-aggregation(%)=A0-ATA0×100where A_0 is A_{600} at 0 h and A_T represents the A_{600} of cell suspension at different time intervals (30 min, 60 min, 90 min, 120 min and 150 min). For comparison and analysis, the percentage value of each time frame was compared with the previous time frame for individual LAB isolates.

Co-aggregation assay

For co-aggregation assay, four commonly used laboratory strains were used as control. These were *Escherichia coli* K12 ATCC® 29425™, *Pseudomonas aeruginosa* CCEB-481 ATCC® 10145™, *Staphylococcus aureus* NCTC-8532 ATCC® 12600™, *Bacillus cereus* CCM-2010 ATCC® 14579™. For assessing the co-aggregation properties, standard protocols were followed with some modifications [24]. For this assay, overnight cultures of LAB isolates were mixed with the overnight cultures of the above-mentioned laboratory strains in equal volumes to form a cell suspension of a definite bacterial count (10^9 CFU/mL). The mixed suspensions were then incubated at 37 °C for 2 and 8 h. 2 mL of pure bacterial suspensions (for each bacterium) was taken as control. After the defined time duration, the optical density was measured at 600 nm. The following formula calculated the percentage values of co-aggregation of all the LAB isolates:Co - aggregation(%)=100×ALS+ALAB2-AmixALS+ALAB2where A_{LS} and A_{LAB} stand for the OD_{600} of the pure cultures of the laboratory strains (LS) and LAB (LAB) isolates, respectively. A_{mix} is the OD of the mixed suspension different LAB and LS. Percent co-aggregation of the 8th h was compared with that of the 4th h (for each LAB to each LS).

For the auto- and co-aggregation assays too, *L. plantarum* MCC 2156 served as the reference strain [16] for comparing the performance of the isolated LABs.

Bile salt hydrolase activity (BSH)

One of the most potent health-promoting features of any LAB is the BSH activity, which determines its ability to break down conjugated bile salts [25]. For the assessment of BSH activity, one of the standard protocols laid down by Hernández-gómez et al. [26] was used with few modifications. Briefly, bile salt (Oxbile, Hi-Media) and $CaCl_2$ were added to MRS agar at 0.5% (w/v) and 0.37 g/L, respectively. Sterile disks made from filter paper were spot inoculated with 10 µl of overnight-grown LAB cultures in MRS broth, and finally, the disks were laid over modified MRS agar plates and then incubated at 37 °C for 48 h (to give ample amount of time for the deposition of detectable amount of precipitate). It was considered positive when bile acid precipitations started to form surrounding the disk in a diffused manner.

Cell surface enzyme characteristics

Extracellular enzyme activities like proteolytic, lipolytic, and amylolytic properties were evaluated following standard protocol [27].

For proteolytic property assessment, skim milk powder (SRL, India) was dissolved in 100 mL of bacteriological agar media to create skim milk agar plates. Then fresh overnight cultures of LAB isolates were inoculated onto skim milk agar plates, which were then incubated for 24 h at 37 ℃. The bacteria showing translucent haloes around the colonies were thought to have proteolytic properties.

Tributyrin supplement (SRL, India) was employed as a source of lipids to assess extracellular lipase activity. Tributyrin was autoclaved at 120 ℃ for 15 min. It was then diluted by 1/100 mL and added to Tributyrin Supplement Agar (TSA; SRL, India). The resultant colloidal medium was plated, allowed to dry, streaked with the LAB isolates, and then incubated for 24 h at 37 °C. Positive result was interpreted by the presence of a clear zone and the emergence of broken lipid droplets around the colonies.

For amylolytic activity assessment, 1 g starch is added in 100 mL of sterile nutrient agar media (SRL, India) and autoclaved at 121 ℃ for 15 min. The starch agar plates were streaked with cultures of the LAB isolates, incubated for 24 h at 37 °C, and after that, the plates were flooded with 1% iodine solution. Clear zones around the streaked lines indicated the presence of extracellular amylase enzyme, while the absence of such zones indicated negative results.

Antimicrobial properties

In order to check the antimicrobial activity, indicator strains, viz. *E. coli* K12ATCC® 29425™, *E. coli* HB101 ATCC® 33694™, *P. aeruginosa* CCEB-481 ATCC® 10145™, *S. aureus* NCTC-8532 ATCC® 12600™, *B. cereus* CCM-2010 ATCC® 14579™, were used and the experiment was conducted following a standard protocol [15] with experimental modifications. The overnight cultures of LAB isolates were centrifuged for 5 min at 8000×*g* (Eppendorf 5430R, Eppendorf Instrumente GmbH, Germany), the cells were pelleted out, and the cell-free supernatant was utilized to assess the antibacterial activity. A sterile borer was used to make 6-mm-diameter wells in Muller Hinton Agar (MHA) plates (SRL, India) that had been surface inoculated with overnight-grown culture suspensions of the indicator organisms (100 mL). Each well received 150 mL of cell-free supernatant of all LAB isolates, after which the plates were kept at 37 °C for a day and checked for zones of inhibition (ZOI). Results were interpreted as no inhibition = −, ‘+’ = ZOI: 1–3 mm; ‘++’ = ZOI: 3–8 mm; ‘+++’ = ZOI: ≥ 8 mm (the ZOI was calculated after subtracting the well diameter size, i.e., 6 mm).

Cell surface hydrophobicity (CSH) assessment

One of the most commonly used methods to evaluate CSH activity is to find the hydrocarbon attachment propensities of the bacteria in question. CSH of the LAB isolates was determined using a standard protocol [28] with certain modifications. Briefly, after 24 h of incubation bacterial cultures were washed twice in PBS and then resuspended to a concentration of ~ 10^9 CFU/mL, and the initial absorbance at 600 nm value was determined (A_0). A two-phase system was then created by adding 3 mL of cell suspension with 1 mL of solvent (Xylene, Ethyl acetate, Acetone). It was then vortexed for 2 min. After 20 min of incubation, the aqueous phase was removed, and its absorbance at 600 nm was measured (A_1). CSH or ‘% adhesion’ or hydrophobicity was calculated according to following formula:CSHorAdhesion(%)=A0-AaA0×100where A_0 is the OD_{600} of bacterial culture before solvent mixing and A_1 is the OD_{600} of bacterial culture after solvent mixing.

In vitro antidiabetic assessment

Partial or complete inhibition of carbohydrate-hydrolyzing enzymes determines the glucose-lowering activity of any LAB isolates because it reduces the amount of available free glucose in peripheral circulation.

α -amylase inhibitory activity

The ability of the isolated LAB strains to inhibit α-amylase was assessed following standard protocol [29]. Briefly, 250 µL of cell-free supernatant of each overnight LAB culture was mixed with 250 µL of 0.5 mg/mL α-amylase (Merck, India) solution and then incubated for 10 min at 25 °C. After that, 250 µL of starch solution (1% w/v in 0.02 M sodium phosphate buffer) was added to the reaction mixture and again incubated at 25 °C for 10 min. The reaction was then terminated with the addition of 500 µL of 3,5-dinitrosalicylic acid (DNS) color reagent (Merck, India) (96 mM DNS and 5.31 M sodium potassium tartrate in 2 M sodium hydroxide solution). The reaction mixture was heated for 5 min, cooled at room temperature, and diluted four times, and then, the absorbance was measured at 540 nm. The reaction mixture without bacterial supernatant was taken as a control. The inhibition propensity (%) was calculated according to the following formula:where A_C is the absorbance of the control reaction mixture and A_B is the absorbance of the reaction mixture with bacterial supernatant.α-amylaseinhibitoryactivity(%)=(AC-AB)AC×100

α -glucosidase inhibitory activity

The α-glucosidase inhibition activity was carried out following standard protocol [30]. Briefly, 25 µL of cell-free supernatant from each overnight LAB culture was mixed with 150 µL 0.01 M of potassium phosphate buffer (pH 6.8) and incubated for 10 min. To this mixture, 50 µL of α -glucosidase (Merck, India) enzyme was added and again incubated for 15 min at 37 °C. Then to this reaction mixture, 75 µL of 5 mM p-nitrophenol-D-glucopyranoside (pNPG) (Merck, India) substrate was added and incubated for 30 min at 37 °C; the enzymatic reaction was stopped with the

addition of 1 mL of 0.1 M Na_2CO_3. The absorbance of the reaction mixture was measured at 540 nm. The reaction mixture without bacterial supernatant was taken as a control. The inhibition propensity (%) was calculated according to the following formula: α-glucosidaseinhibitoryactivity(%)=1-ABAC×100 where A_C is the absorbance of the control reaction mixture and A_B is the absorbance of the reaction mixture with bacterial supernatant.

Several strains *of L. plantarum* have been documented for their significant anti-diabetic properties, alongside notable *in vitro* inhibition of α -amylase and α -glucosidase enzymes. Hence, *L. plantarum* MCC 2156 has been employed as a reference strain to validate the experimental protocols and to assess the performance of the isolated LABs in these assays [31, 32].

Safety assessment

Antibiotic susceptibility profiling

Antibiotic susceptibility of a potent probiotic is linked with host safety. Antibiotic susceptibility of the selected isolates was carried out on MHA plates using antibiotic discs (Hi-Media Combi IV Octadisc, Hi-Media, India) of standard antibiotics, ampicillin (amp) 10 µg, cephalothin (cep) 30 µg, chloramphenicol (c) 30 µg, clindamycin (cd) 2 µg, erythromycin (e) 15 µg, gentamicin (gen) 10 µg, oxacillin (ox) 1 µg, vancomycin (va) 30 µg, streptomycin (str) 10 µg, kanamycin (kana) 15 µg, and tetracyclin (tet) 20 µg standard antibiotics. The results obtained were interpreted according the standard methods [33]. Briefly, the obtained ZOI diameter values were grouped into 2 subsection, "+" (having ZOI≤8) and "−" (having ZOI≥8) and the result was interpreted in a table.

Hemolytic activity

The hemolytic activity of bacteria is its capacity to degrade red blood cells and release hemoglobin, and it is required for the safety assessment of a putative probiotic. For this assay, standard protocol with slight modification was used [34]. Briefly, overnight cultures of LAB isolates were spread onto Blood Agar Plates (tryptone soy agar plate containing 5% human blood) and incubated for 24 h. The plates were then examined for patterns of hemolysis that is whether complete (beta), partial (alpha), or absence of visible (gamma) destruction of RBCs indicated [35] by a clear zone around the colonies. *E. coli* K12 was taken as positive hemolytic indicator strain to define the experiment's accuracy.

In vivo acute toxicity test

To ensure the safety of the LAB (probiotic isolates), acute oral toxicity study was conducted on Swiss albino mice (20±2 g) aged 6–8 weeks. The mice were sourced from a licensed animal dealer (Chakraborty Enterprise, Kolkata, India; Regd. No. 1443/PO/Bt/s/11/CPCSEA) and housed in controlled conditions with specific temperature, humidity, and light–dark cycle. They were acclimatized for two weeks in the animal house keeping them in cages and with free access to pellet diet and water. The study was approved by the Institutional Animal Ethical Committee (IAEC) of the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA) of the University as per rules, under the animal ethical approval number IAEC/NBU/2022/27. The mice were randomly divided into six groups a vehicle group and five groups with dietary LAB supplementation. Each group received a single dose of bacterial suspension (6×10^9 CFU/Kg body weight). Observations of various parameters such as aggression, food and drink intake, sedation, diarrhea, fur loss, and lethargy were recorded at regular intervals over 2 weeks. Particular attention was given to identifying any late signs of toxicological effects within the first four hours of each day. The investigation followed the OECD guideline for acute oral toxicity testing [36, 37].

Statistical analysis and graphical interpretation

All *in vitro* experiments were repeated three times. The data were represented by the replicate value's mean and standard deviation. GraphPad prism software package Version 8.0.2 was used for statistical analysis for data normality (Shapiro–Wilk test), statistical differences (ANOVA), multiple-comparison post hoc testing (Dunnet's or Tukey's test for significance test), and data visualization. $p \leq 0.05$ were considered significant.

Results

Isolation and screening of the isolates for tolerance to gastro-inhibitory conditions

Colony counts with respect to the weight of the source sample led to the enumeration of bacterial load in the food samples. In Gundruk it was 3.83×10^7 CFU/g, in Kinema it was 6.52×10^8 CFU/g, in Soft Chhurpi it was 1.65×10^7

CFU/g, in Hard Chhurpi it was 1.51×10^7 CFU/g, and in Sinki it was 6.03×10^8 CFU/g. A total number of 20 isolates were obtained from different food sources. From Gundruk, 4 isolates, from Kinema 4 isolates, from Soft Chhurpi 6 isolates, from Sinki 4 isolates, and from Hard Chhurpi 2 isolates were acquired. All the 20 isolates were subjected to screening based on their gastro resistant properties. The results are depicted in Fig. 1.

Fig. 1 [Images not available. See PDF.]

Lysozyme, acid, and bile tolerance (in terms of % survival) of 20 bacterial isolates from fermented foods of Darjeeling

Isolates GAD1, KAD3, CAD3, SAD1, and CMD1 showed ≥ 85% survival in all the tolerance tests involving lysozyme, acid, and bile. These five isolates have no significant differences in comparison with the control strain for the gastro-inhibitory (bile, acid and lysozyme tolerance) tests and their influence on host body weight (refer Additional file 1: Fig. S1 and S2 for the results of gastro-inhibitory parameters and influence on host body weight respectively). For tolerance to alkaline pH, four of these isolates except CAD3 showed noteworthy reduction in survival rates compared to the reference *E. coli* K12 strain (refer Additional file 1: Fig. S3 for the results of alkaline tolerance of the isolates). These five isolates, subjected to further analysis were subsequently named as GAD, KAD, CAD, SAD, and CMD for easy understanding.

Molecular identification and phylogenetic analysis

The concentration of the isolated DNA from the five isolates was 44 µg/mL. 16S rRNA gene amplicons of the five isolates were compared to those of the strains listed in GenBank using NCBI-BLAST. Isolate GAD (Acc. No. OQ306562) showed highest percent identity (99.05%) with *Pediococcus pentosaceus* isolate 4412 (Acc. No. MT544941.1); isolate KAD (Acc. No. OQ306564) showed highest percent identity (98.18%) with *Lactobacillus plantarum* strain 6415 (Acc. No. MT515856.1); isolate CAD (Acc. No. OQ306566) showed highest percent identity (99.39%) with *L. plantarum* strain 1887 (Acc. No. MT597711.1); isolate SAD (Acc. No. OQ306549) showed highest percent identity (99.45%) with *L. brevis* isolate gp71 (Acc. No. KM495920.1); and isolate CMD (Acc. No. OQ306547) showed highest percent identity (99.52%) with *Lactiplantibacillus plantarum* strain thankcomeLP1 (Acc. No. MZ045749.1).

A phylogenetic tree constructed using the neighbor-joining approach with a bootstrap test (100 repetitions) depicts the proportion of duplicate trees in which the linked taxa clustered together (Fig. 2).

Fig. 2 [Images not available. See PDF.]

Phylogenetic tree demonstrating the evolutionary relationship of isolated five LAB strains from fermented foods of Darjeeling, as inferred by the neighbor-joining approach based on the 16S rRNA gene sequences in MEGA11. The evolutionary distances were computed using the Maximum Composite Likelihood method. This analysis involved 37 nucleotide sequences and 1551 positions

Probiotic assessment

Carbohydrate fermentation pattern and esculin hydrolysis

All the isolates could ferment carbohydrate sources present in the kit, viz. xylose, cellobiose, arabinose, maltose, galactose, mannose, mellibiose, raffinose, sucrose, and trehalose. For esculin hydrolysis, all showed positive properties.

Auto-aggregation assay

Auto-aggregation values of all five LAB isolates increased significantly starting from 30 min up to 150 min (from 4.83 ± 1.92 to 67.60 ± 5.93%). Most isolates tended not to collapse after forming clumps during the incubation period. Longer incubation times resulted in higher and significant auto-aggregation percentages (Fig. 3a). *L. plantarum* strain KAD showed highest percent aggregation amongst these five isolates. Overall, it can be seen that auto-aggregation values of all the LAB isolates increased significantly in each successive time frame after initial dissociation.

Fig. 3 [Images not available. See PDF.]

Aggregation properties of isolated five LAB strains. **a** Auto-aggregation measured at successive intervals of 30 min reveal significant increase in all strains (adjusted *p* value ≤ 0.0001). **b** Heatmap showing co-aggregation properties of the strains against known intestinal commensals. Key: A, GAD; B, KAD; C, CAD; D, SAD; E, CMD; 1, *E. coli* K12; 2, *P. aeruginosa*; 3, *S. aureus*; 4, *B. cereus*

Co-aggregation assay

All the five LAB isolates have shown the ability to co-aggregate with the intestinal commensal strains tested. Highest percent co-aggregation at 2nd hr was seen in the case of CMD (39.55 ± 1.16%) with *E. coli* K12, and the least was seen in the case of SAD (9.35 ± 4.80%) with *S. aureus*., whereas in the case of the 4th hr, the isolate SAD showed the highest co-aggregation percentage (84.76 ± 0.44%) with *E. coli* K12, and during the same time frame, the least percent co-aggregation value was seen in the case of CMD (23.50 ± 2.22%) with *B. cereus*. Maximum percent co-aggregation increment (2nd–4th h) is seen in association with *S. aureus* with the isolates KAD (18.96 ± 6.46–66.74 ± 0.37%), CAD (9.97 ± 0.74–70.26 ± 1.05%) and SAD (9.35 ± 4.80–71.21 ± 1.82%) (Fig. 3b).

The five LABs exhibited no significant overall variances compared to the positive strain for the auto-aggregation and co-aggregation properties (Additional file 1: Fig. S1). However, in three specific instances (% auto-aggregation at 90, 120, and 150 min), positive strain yielded higher values.

Bile salt hydrolase (BSH) activity

All five LAB isolates displayed BSH-positive results, which was consistent with the isolates' earlier documented bile salt tolerance results. SAD showed the highest precipitation zone (6.66 ± 2.51 mm), while CMD showed the lowest (2 ± 1 mm). All of the other isolates displayed values that are more or less in the middle, falling between 2.33 mm and 3.66 mm (Fig. 4a, b).

Fig. 4 [Images not available. See PDF.]

Bile Salt Hydrolysis (BSH) assay of isolated five LAB strains **a** MRS medium containing bile salt showing BSH activity of the LAB strains as evidenced by the development of a precipitation zone around the colony. **b** Graphical representation of the BSH activity of isolated five LAB strains. The diameters of the precipitation zones are given in millimeters (excluding the diameter of the disc)

Cell surface enzyme characteristics

The five LAB isolates displayed cell surface enzyme features to varied degrees (Table 1). GAD displayed the highest levels of proteolytic activity; CAD and SAD showed highest lipolytic activities; GAD and KAD showed highest amylolytic activities. None of the LAB isolates showed positive results in all the three parameters.

Table 1. Cell surface enzyme characteristics and antimicrobial profiling of isolated five LAB isolates

Isolates	Cell surface enzyme characteristics			Antimicrobial profiling against pathogens				
Proteolytic activity	Lipolytic activity	Amylolytic activity	*E. coli* K12	*E. coli* HB101	*P. aeruginosa*	*S. aureus*	*B. cereus*	GAD
+++	−	++	++	++	−	++	++	KAD
++	−	++	+	++	+	++	++	CAD

−	++	−	+	++	+	+	++	SAD
−	++	−	−	+++	+	++	++	CMD

[a]'+++' = highly positive; '++' = moderately positive; '+' = weekly positive; '−' = negative

[b]'−' = no inhibition; '+' = ZOI: 1–3 mm; '++' = ZOI: 3–8 mm; '+++' = ZOI: ≥ 8 mm

Antimicrobial properties

In the case of antimicrobial properties, it was seen that all the five LAB isolates showed the highest antimicrobial properties against *E. coli* HB101, whereas the least antimicrobial activity against *P. aeruginosa.* Among LAB isolates, KAD and CAD showed antimicrobial activity against all the strains tested. The complete absence of antimicrobial activity was seen in the case of GAD (against *P. aeruginosa*), SAD (against *E. coli* K12), and CMD against (*P. aeruginosa*) (Table 1).

Cell surface hydrophobicity (CSH) assessment

Microbial adhesion to solvents (MATS) serves as an illustration of the association between surface hydrophobicity and adhesion nature. The highest hydrophobicity (adhesion/CSH %) for all the LAB isolates was seen in the case of ethyl acetate, followed by acetone and then by xylene. On the other hand, among all the isolates tested with all the solvents, isolate KAD showed the highest adhesion/CSH % (75.15 ± 0.57%) with ethyl acetate, whereas the lowest was seen in the case of CMD (4.53 ± 3.64) with ethyl acetate. Overall, on the basis of solvents, SAD showed the highest adhesion/CSH % with xylene (28.97 ± 13.96%), isolate KAD with ethyl acetate (75.15 ± 0.574%), and isolate GAD with acetone (41.87 ± 3.56) (Fig. 5).

Fig. 5 [Images not available. See PDF.]

Graph showing cell surface hydrophobicity (Adhesion/CSH %) of isolated five LAB strains with various solvents

In vitro antidiabetic assessment

α-amylase and α -glucosidase inhibitory activity

In the present study, it was found that the α-amylase inhibitory activity for all five isolates ranged from 53 to 63%. Where KAD showed highest inhibition (63.16 ± 1.91%) followed by isolate SAD (62.45 ± 0.53). Isolates GAD and CAD showed similar inhibitory pattern (58.42 ± 0.41% and 58.38 ± 1.64%, respectively). The least inhibition was shown by isolate CMD (53.37 ± 1.47%) (Fig. 6a). In the case of α -glucosidase inhibitory activity, it was seen that the values ranged from 34 to 39%. The highest inhibition was seen in the case of isolate SAD (39.75 ± 2.78%) followed by isolate CMD (37.30 ± 2.40%); isolate GAD and KAD showed similar pattern of inhibition (36.54 ± 3.50% and 35.47 ± 2.06%, respectively). The least activity was seen in the case of isolate CAD (34.86 ± 2.78%) (Fig. 6b).

Fig. 6 [Images not available. See PDF.]

α-Amylase and α -glucosidase inhibitory activity of isolated five LAB strains

All the five LABs exhibited negligible variances in the % inhibition in α-amylase and α-glucosidase activities compared to the positive strain (Additional File 1: Fig. S1).

Safety assessment

Antibiotic susceptibility profiling and hemolytic activity

All the selected LAB isolates showed varying degrees of susceptibility against a panel of standard antibiotics. Isolate-wise resistance was observed against certain antibiotics. Isolate GAD showed resistance against gentamicin, vancomycin, streptomycin, and kanamycin; isolate KAD showed resistance against erythromycin, oxacillin, vancomycin, streptomycin, kanamycin; isolate CAD showed resistance against all antibiotics except oxacillin and tetracycline; isolate SAD showed resistance against chloramphenicol, clindamycin, streptomycin, and tetracycline; isolate CMD showed resistance against ampicillin, cephalothin, oxacillin, vancomycin, kanamycin, and tetracycline

(Table 2; Additional file 1: Table S1 for the antibiotic susceptibility assessment of LABs in terms of zone of inhibition).

Table 2. Antibiotic susceptibility assessment of the isolated five LAB isolates

Isolate	Antibiotics[a,b]										
Amp	Cep	C	CD	E	Gen	Ox	Va	Str	Kana	Tet	GAD
−	−	−	−	−	+	−	+	+	+	−	KAD
−	−	−	−	+	−	+	+	+	+	−	CAD
+	+	+	+	+	+	−	+	+	+	−	SAD
−	−	+	+	−	−	−	−	+	−	+	CMD

[a] *Amp* ampicillin; *Cep* cephalothin; *C* chloramphenicol; *CD* clindamycin; *E* erythromycin; *Gen* gentamicin; *Ox* oxacillin; *Va* vancomycin; *Str* streptomycin; *Kana* kanamycin; *Tet* tetracycline

[b] "+" denotes resistance &"−" denotes susceptibility

In case of hemolytic activity, all the five LAB isolates displayed a pattern of gamma hemolysis which indicates lack of hemolysis as in this case there should be no reaction in the surrounding medium, whereas the *E. coli* K12 strain showed beta hemolysis (Fig. 7).

Fig. 7 [Images not available. See PDF.]

Hemolytic activity assessment of isolated five LAB strains (compared with hemolysis-positive *E. coli* K12)

In vivo acute toxicity test

After oral treatment of a predetermined high dosage of bacterial suspension (6×10^9 CFU/Kg body weight) of each isolate to separate male and female mice, there was no mortality or side effects noted during the first 24 h. During the subsequent 14-day observation period in each group, there was no mortality or deviation in the way the animals appeared or behaved or changes in their feeding habits or body weight gain (Additional file 1: Fig. S2).

Discussion

All five LAB isolates have primary probiotic attributes like gastro-tolerant activities, tolerance to alkaline pH which may enable them to survive in the harsh intestinal microenvironment [38]. Their ability to utilize multiple carbon sources enhances their persistence in conditions like food deprivation or dietary changes. Furthermore, the capacity of LAB isolates to auto and co-aggregate with similar and other bacterial strains provides protection against external pressures, including host immune attacks, ensuring prolonged persistence in the GI tract [39]. In the present study, all LAB isolates showed BSH-positive results, indicating their capability to degrade conjugated bile salts, contributing to the lowering of serum cholesterol levels [24]. Notably, the LABs' production of deconjugated bile salts suggests reduced reabsorption and increased excretion of free bile acids in the stool. Additionally, all the LAB isolates exhibited cell surface enzyme characteristics needed for the breakdown of proteins, lipids, and carbohydrates. This may be linked to improved food digestibility and nutritional quality associated with health benefits of consuming these fermented foods.

Phylogenetic analysis of these isolates revealed that they group with the members of the family *Lactobacillaceae*. Such bacteria are known for producing short-chain fatty acids (SCFAs) which are reported to have beneficial effects on physiological and metabolic homeostasis of mammals [40–43]. These LAB isolates also demonstrated potent antimicrobial properties against common pathogens, producing organic acids, bacteriocins, and hydrogen peroxide to resist the growth of pathogenic microbes [44–46]. The ability of LAB isolates to bind to the intestinal mucosa

enhances their survival and growth in the GI tract. Higher CSH% (cell surface hydrophobicity) indicates strong adhesion abilities and competitive exclusion of other microbes, fostering interactions with bacterial communities in the GI tract [47]. Moreover, CSH activity determines the ability of cells to attach and separate from surfaces. A probiotic strain's intestinal colonization, or adherence and persistence, is measured by the hydrophobicity of its cell surface. High hydrophobicity indicates more colonization capability [48]. The LAB isolates also fulfil these criteria by showing higher CSH% values. In respect with the of the antidiabetic activity, the isolated LAB displayed significant inhibitory activity against α-glucosidase and α-amylase enzymes, which can potentially slowdown glucose absorption and reduce postprandial blood sugar levels. This highlights their potential as therapeutic hypoglycemic agents as well as hyperglycemia-preventive supplements. Regarding antibiotic resistance, some LAB isolates showed resistance to vancomycin, streptomycin, and kanamycin [49]. Moreover, lack of hemolytic activity of the isolates demonstrated their safety. The results from acute toxicity tests reaffirmed the safety of these LAB isolates, establishing their status as "Generally Recognized as Safe" [50].

Conclusion

This investigation highlights the probiotic attributes of five LAB isolates, namely *P. pentosaceus* isolate GAD, *L. plantarum* isolate KAD, *L. plantarum* isolate CAD, *L. brevis* isolate SAD, and *L. plantarum* isolate CMD. All the five isolates show potential for probiotic applications and as naturally derived pharmaceutical agents, owing to their gastro-tolerance, metabolic activities, adhesion capabilities, antimicrobial properties, and hypoglycaemic effects. These findings support their safety as health-beneficial LABs. However, further *in vivo* investigations are essential to validate and establish their suitability to be used as dietary supplements.

ABSTRACT (ENGLISH)

The pharmaceutical sector has recently witnessed a transformative improvement and shift toward artificial intelligence (AI) in its drug and pharmaceutical delivery process and procedures. Hence, this research delves into the benefits and obstacles pharmaceutical firms face in utilizing AI in China. Globally, China is recognized as a dominant pillar in research and development in the pharmaceutical industry. The country has incorporated AI approaches and technologies to improve the drug industry's cost, efficiency and development. Therefore, this study applies the case study method and evaluation of prior studies to assess AI's potential benefits and challenges in the drug and pharmaceutical enterprises. The research provided an in-depth evaluation of AI in the various phases of the drug discovery process. The research outcome indicated that AI's benefits include drug repurposing, target identification, clinical trial optimization, quality assurance, and control and efficient drug distribution method. However, the analysis revealed that China faces several challenges that impact the pace and extent of integration of AI in its pharmaceutical industry. These challenges include a lack of standardized data, a shortage of skilled labor or professionals, and data and privacy concerns. In addition, the research provides three case studies that focused on f XtalPi-AI-Enhanced Drug Discover, BioMap: Accelerating Drug Development Through AI and iCarbonX: AI-Driven Precision Medicine and provided a comprehensive analysis of how these firms have used AI to stimulate their drug discovery process. The study also provides policies that can help improve the integration of AI in the pharmaceutical and drug delivery process.

FULL TEXT

Background

In recent years, integrating artificial intelligence (AI) into various industries has catalyzed transformative changes, with the pharmaceutical sector no exception [25]. This study delves into the profound implications of AI in drug discovery and development, with a specific focus on pharmaceutical companies operating in China. Sufyan, Shokat, and Ashfaq [44] asserted that as technological advancements continue redefining traditional methodologies, it becomes imperative to assess the comparative strategies employed by pharmaceutical enterprises in harnessing AI to enhance drug discovery and development processes. Lengthy and resource-intensive drug development pipelines have long characterized the pharmaceutical industry. The introduction of AI promises to expedite these processes, potentially revolutionizing the landscape of drug discovery [29]. However, the adoption and implementation of AI technologies vary among pharmaceutical companies, and a comparative analysis provides an understanding of the diverse approaches employed by industry players in China [29]. This research seeks to unravel the intricacies of AI utilization, evaluating the impact on efficiency, cost-effectiveness, and overall success rates in drug discovery and development. Thus, this research provides a novel approach that can help understand the opportunities and challenges faced by pharmaceutical in China. Moreover, as indicated by Kim et al. [20], China has become a center for the advancement of drugs. As AI applications advance in sophistication, it will become strategically imperative for firms looking to gain a competitive advantage to integrate them into their drug development processes.

Moreover, implementing AI tools, including machine learning and data analytical approaches, is revolutionizing drug and pharmaceutical enterprises to identify and initiate a new therapeutic in contemporary times [19]. Compared to the traditional methods used for drug discovery and pharmaceutical process, Sultana and Rangareddy [46] recounted that AI has offered firms the ability to process huge amounts of clinical, biological, and chemical data in a timely and sustainable manner. As the demand for novel and effective therapeutics continues to rise, so does the pressure on pharmaceutical companies to innovate and streamline their drug discovery and development pipelines. AI presents a unique opportunity to augment human capabilities, offering the potential to uncover hidden patterns in data, predict potential drug candidates, and optimize clinical trial designs [3]. This exploration into the utilization of AI in drug discovery and development processes among pharmaceutical companies sheds light on the current state of the industry but also lays the groundwork for understanding the future trajectory of pharmaceutical innovation in the era of artificial intelligence [3].

The research problem at the core of this investigation revolves around identifying the key determinants that influence

the adoption and efficacy of AI in drug discovery among pharmaceutical companies in China. By conducting a comparative analysis, we aim to uncover patterns, trends, and success factors that distinguish the strategies of various enterprises. Moreover, this study seeks to address potential challenges and ethical considerations associated with implementing AI in drug development, contributing to a comprehensive understanding of the evolving landscape in the context of the Chinese pharmaceutical industry. As AI technologies evolve rapidly, staying abreast of the dynamic relationship between pharmaceutical companies and these innovations is paramount [5]. The findings of this research endeavor are poised to offer valuable insights not only for industry stakeholders but also for policymakers, researchers, and the broader scientific community. Ultimately, by scrutinizing the impact of AI in drug discovery and development within the unique context of Chinese pharmaceutical companies, this study contributes to the ongoing discourse on the role of artificial intelligence in shaping the future of healthcare and innovation.

This research significantly contributes to the evolving field of pharmaceuticals and artificial intelligence. By focusing specifically on China, the study provides valuable insights into the utilization of AI in drug discovery and development processes within the Chinese pharmaceutical industry. This geographical focus is crucial, as China has emerged as a major player in the global pharmaceutical market, and understanding how AI is integrated into its drug development practices is essential for academic and industry stakeholders [51]. The novelty of this research lies in its comparative analysis, which allows for a comprehensive understanding of the different approaches adopted by pharmaceutical companies in China regarding AI in drug discovery. The study explores various AI techniques, algorithms, and technologies these companies employ, shedding light on the diversity of strategies within the Chinese pharmaceutical sector. This comparative aspect contributes to the existing body of knowledge by highlighting variations in AI adoption and implementation across different companies, offering a nuanced perspective on AI integration in drug development.

The practical significance of the research is evident in its potential to inform policymakers, industry professionals, and researchers about the current landscape of AI in drug discovery in China. The findings can guide decision-makers in developing targeted policies and strategies to foster AI's responsible and effective use in the pharmaceutical sector. Moreover, pharmaceutical companies can benefit from the insights by understanding their counterparts' successful AI applications and challenges, potentially optimizing their drug discovery and development processes. This research holds practical implications for advancing the intersection of artificial intelligence and pharmaceuticals, with potential global implications given China's growing influence in the industry.

Literature review

AI: a transformative tool for advancing pharmaceutical product lifecycle

AI has emerged as a transformative force in advancing the pharmaceutical product life cycle across various stages, from drug discovery to post-market surveillance [53]. One notable contribution of AI is in drug discovery, which accelerates the identification of potential drug candidates. By leveraging machine learning algorithms, AI can analyze vast datasets, including genomic information and chemical properties, to predict how different compounds might behave and interact [9]. This expedites the discovery process, significantly reducing the time and costs traditionally associated with bringing a new pharmaceutical product to market. In the development phase, AI is crucial in optimizing clinical trials [2]. Machine learning algorithms can analyze patient data to identify suitable trial candidates, predict potential adverse effects, and optimize the trial design. This enhances the efficiency of clinical trials and improves patient outcomes by ensuring that the right individuals are enrolled, leading to more robust and reliable results [33]. Additionally, AI can assist in the monitoring and analysis of real-world evidence, providing insights into the long-term efficacy and safety of pharmaceutical products [43].

Once a drug is approved and enters the market, AI contributes to its life cycle by enhancing manufacturing processes [17]. AI-powered systems can monitor and optimize production, ensuring consistency and quality while minimizing waste. Predictive maintenance powered by AI can also reduce downtime in manufacturing facilities, improving overall efficiency [40]. These manufacturing advancements benefit pharmaceutical companies and contribute to a more reliable and accessible supply of medications for patients. In the post-market phase, AI facilitates pharmacovigilance and drug safety monitoring. According to Deng et al. [12], AI can promptly identify

possible adverse responses and new security vulnerabilities by examining vast amounts of data, such as online communities and medical records.

AI can quickly detect potential adverse reactions and emerging safety concerns by analyzing large-scale data, including electronic health records and social media [12]. This makes it possible for pharmaceutical firms and regulatory organizations to act quickly, protecting the welfare of patients and upholding the general public's trust in pharmaceuticals. Over every phase of the life cycle, a more proactive and instantaneous policy regarding pharmaceutical security is made possible by AI's constant surveillance features. [7]. Floresta et al. [14] revealed that AI helps provide personalized medicine by evaluating the patient data to recognize specific biomarkers and genetic markers that may affect the therapy responses. This enables the improvement of customized or targeted medicines that optimize efficacy while minimizing the adverse effects.

Furthermore, AI aids in personalized medicine by analyzing patient data to identify specific genetic markers and biomarkers that can influence drug response. This allows for the development of targeted therapies tailored to individual patients, maximizing efficacy while minimizing adverse effects [14]. A substantial advancement in the life progression of medical products, tailoring therapy regimes based on a patient's genetic profile, represents an essential turning point in the medical field. According to Gupta et al. [15], AI can greatly accelerate the lifespan of pharmaceutical products. Knake [21] advances the discussion by indicating that AI has an enormous effect on every stage of the product life cycle, from accelerating the discovery of new drugs to streamlining clinical trials, boosting post-market monitoring and facilitating targeted therapy. As technology evolves, the pharmaceutical industry is poised to benefit from further innovations and improvements, ultimately leading to more efficient, effective, and patient-centric healthcare solutions [42]. In Fig. 1, Paul et al. [36] identified various AI networks and decision tree algorithm that helps improve pharmaceutical products.

Artificial intelligence: a sustainable approach to drug discovery

AI has emerged as a sustainable and revolutionary approach to drug discovery, offering unprecedented opportunities to streamline and enhance the traditionally time-consuming and resource-intensive process [48]. Hence, Bhattamisra et al. [6] mentioned that AI's important enhancement to drug development is its speedy digestion of enormous amounts of medical and scientific information. Thus, AI enables health practitioners to identify prospective drug candidates more accurately and efficiently than they could using the conventional approach when they employ ML. Thus, complex compositions can be examined and explored using ML. AI's capacity to substantially reduce the cost and time connected with bridging new drugs to the market demonstrates the sustainability of this kind of drug delivery process. Therefore, AI expedites the initial drug discovery phase by promptly recognizing novel compounds and forecasting their physiological impact on patients. AI's capacity to significantly reduce the time and cost associated with bringing new drugs to market demonstrates the sustainability of this kind of drug development. AI expedites the initial phases of drug discovery by promptly recognizing novel compounds and forecasting their physiological effects. This increases the likelihood of successful and noteworthy pharmaceutical product launches and helps pharmaceutical businesses allocate resources more wisely, both of which support stability in the healthcare sector.

The sustainable aspect of AI in drug discovery is evident in its potential to significantly reduce the cost and time required to bring new drugs to market. By expediting the identification of promising compounds and predicting their biological activity, AI accelerates the initial phases of drug discovery. This allows pharmaceutical companies to allocate resources more efficiently and increases the likelihood of bringing successful and impactful drugs to market, promoting sustainability within the pharmaceutical industry [47]. Furthermore, AI contributes to sustainability by facilitating a more targeted and personalized approach to drug development. Machine learning models can analyze patient data, identifying specific genetic markers and biomarkers influencing individual medication responses [35].

This personalized medicine approach not only enhances the effectiveness of treatments but also minimizes adverse effects, reducing the overall environmental impact associated with the production and disposal of pharmaceuticals. In addition to its role in the early stages of drug discovery, AI supports sustainability in optimizing clinical trials [32]. By analyzing patient data, AI can help identify suitable trial candidates, predict potential adverse effects, and optimize trial designs. This ensures that clinical trials are more efficient, with reduced resource requirements and a higher likelihood of success. Streamlining clinical trials contributes to the overall sustainability of drug development processes [4].

Hence, the integration of AI in drug discovery also aligns with sustainable practices by improving the efficiency of drug manufacturing. AI-powered systems can monitor and optimize production processes, reducing waste and ensuring consistent product quality [4]. Predictive maintenance, enabled by AI, minimizes downtime in manufacturing facilities, contributing to a more sustainable and resource-efficient pharmaceutical production ecosystem [24]. Moreover, AI enhances sustainability in drug discovery through its contribution to pharmacovigilance and drug safety. By continuously analyzing real-world data, including electronic health records and social media, AI can quickly detect and assess potential adverse reactions and safety concerns [49]. This proactive monitoring ensures patient safety and builds trust in pharmaceutical products, promoting the industry's long-term sustainability. Accordingly, integrating AI in drug discovery represents a sustainable approach that addresses various challenges in the pharmaceutical industry [24]. AI's impact is multifaceted, from expediting drug discovery and optimizing clinical trials to supporting personalized medicine and improving manufacturing efficiency. As the field continues to evolve, the sustainable application of AI in drug discovery holds the promise of transforming the pharmaceutical industry toward more efficient, effective, and environmentally conscious practices [45]—Table 1 provides a list of some prominent AI tools used in drug discovery.

Table 1. Examples of AI tools in drug discovery

AI tools in drug discovery	Explanation	References
IBM Watson for drug discovery	IBM Watson for Drug Discovery leverages AI to analyze biomedical literature, clinical trial data, and other relevant information to help researchers identify potential drug candidates and biomarkers	Chen et al. [10] and Hatz et al. [18]
Atomwise	Atomwise uses deep learning for the virtual screening of potential drug compounds. It analyzes molecular structures to predict their binding affinity with target proteins, expediting the identification of potential drug candidates	Carpenter and Huang [8]
DeepChem	DeepChem is an open-source platform that provides a collection of deep-learning tools for drug discovery	Korshunova et al. [23]
In silico medicine	In silico medicines aims to provide aging research and medicine discovery by applying AI. It also utilizes biological data and seeks promising medication options that focus on sickness, which comprises neurological conditions and cancer	Shaker et al. [41]

Recursion pharmaceuticals	Recursion Pharmaceuticals screens and analyzes biological pictures with artificial intelligence (AI) to find possible medication prospects. Their approach enables rapid screening of biological abnormalities by combining machine learning and computer vision	Malandraki-Miller and Riley [31]
OpenEye scientific software	OpenEye provides a suite of AI tools for cheminformatics research and structural architecture. Their software helps with drug candidate optimization, biological attribute forecasting and chemical-based dataset assessment	Cox and Gupta [11] and Rifaioglu et al. [38]
Schrodinger	Schrodinger offers a system for molecular interaction modeling, digital screening, and discovery of medicines package that integrates AI. It helps scientists optimize tiny compounds to create medications and estimate binding capacities	Adelusi et al. [1]

Advancing pharmaceutical product and drug discovery in China: the role of AI

AI is transforming China's life science and healthcare enterprises as it has become essential for creating medication and pharmaceutical products. Given China's growing pharmaceutical industry, it has recognized the potential of AI to revolutionize conventional drug research methods, leading to improved creativity and efficiency [45]. AI has significantly improved China's drug discovery process by speedily and accurately analyzing large amounts of data, accelerating the recognition of promising potential medicines.

According to Deshmukh [13], in the drug discovery process, AI algorithms can be used to evaluate complex chemical information and biological analysis comprising proteomics, genomics and chemical composition. Chinese medicinal product companies use AI to improve the accuracy of target authentication, which raises the effectiveness rate of pharmaceutical research initiatives [28]. The application of AI in this phase is particularly crucial for addressing diseases prevalent in China and globally, providing a tailored and efficient approach to drug development. Furthermore, AI is optimizing the clinical trial process in China, another critical phase in pharmaceutical product development. Machine learning algorithms are employed to analyze patient data, identify suitable clinical trial participants, and predict potential adverse effects [28]. This personalized approach to clinical trials accelerates the testing process. It ensures that drugs are tailored to diverse genetic profiles, contributing to developing more effective and safer pharmaceutical products [30].

China's commitment to AI in pharmaceuticals extends to manufacturing processes. AI-powered systems are being integrated into production facilities to monitor and optimize manufacturing, ensuring consistency, quality, and efficiency [39]. Predictive AI-powered maintenance minimizes downtime, contributing to China's more reliable and sustainable pharmaceutical manufacturing ecosystem. These advancements benefit local pharmaceutical companies and position China as a global leader in adopting cutting-edge technologies for drug production [39]. AI can quickly identify potential adverse reactions and safety concerns by analyzing real-world data from diverse sources, including electronic health records and social media. This continuous monitoring enhances patient safety and regulatory compliance, contributing to the sustainable growth of the pharmaceutical industry in China [36].

Moreover, AI is fostering international collaborations and partnerships in drug discovery. Chinese pharmaceutical companies are increasingly collaborating with global AI and biotech firms to access cutting-edge technologies and expertise [22]. These collaborations facilitate knowledge exchange, talent development, and the integration of diverse perspectives, ultimately contributing to a more robust and globally connected pharmaceutical ecosystem in China [16]. Therefore, the integral role of AI in advancing drug discovery and pharmaceutical products in China underscores the nation's commitment to embracing innovative technologies [24]. AI is reshaping the entire

pharmaceutical product life cycle, from accelerating drug discovery and optimizing clinical trials to improving manufacturing processes and ensuring post-market safety [34]. As China continues to invest in research, development, and collaborations, the synergy between AI and pharmaceuticals is poised to drive transformative changes in healthcare, benefiting both the nation and the global community [26].

A case study on the utilization of AI in drug discovery and development processes among pharmaceutical companies

Case of iCarbonX: AI-driven precision medicine

iCarbonX, a prominent entity in the Chinese healthcare sector, specializes in AI-driven precision medicine, leveraging advanced technologies to analyze diverse datasets, including genomics, lifestyle factors, and clinical records. By forming strategic alliances with academic institutions, iCarbonX collects large amounts of genomic data and uses AI algorithms for predictive modeling to find individual treatment plans. Machine learning is then used to detect biomarkers and help create targeted medicines. A global pioneer in precision medicine, iCarbonX can now produce medicines with more efficacy and fewer side effects thanks to the successful integration of AI. This has led to advancements in personalized medicine. But the business also has to deal with issues like data protection, moral dilemmas, and the need for smooth communication between AI specialists and healthcare professionals. Constant endeavors center on guaranteeing adherence to regulations and fostering public confidence. [26]. Figure 2 shows IsoLight, a precision medical tool invented by iCarbonX for profiling the cells of single-cell chips and software products.

Fig. 2 [Images not available. See PDF.]

IsoLight precision medical tool

Case of BioMap: accelerating drug development through AI

The dynamic biotechnology startup BioMap was founded in China and is dedicated to utilizing state-of-the-art AI-driven methods to hasten medication development. With a focus on efficiency enhancement, the company uses artificial intelligence (AI) to assess complicated biological datasets, including pharmaceutical interactions, proteomics, and genomes. BioMap's strategy approach combines AI algorithms for lead optimization and target discovery with real-time data analytics and predictive modeling to speed up drug development. Collaborations between AI firms and academic institutions expand their technological capabilities. Because of this, BioMap's implementation of AI has significantly decreased the time and expenses related to drug development, allowing for the quicker identification of viable drug candidates and creating a more effective development pipeline. The firm has successfully brought innovative treatments to market in a record time. Notwithstanding these achievements, BioMap still has issues with its AI infrastructure's scalability and integration of various datasets. To keep personnel updated on the latest developments in AI technology, ongoing efforts are being made to solve these issues and provide them with ongoing education and training. A sample picture of the BioMap tool used for accelerating the drug development process is captured in Fig. 3.

Fig. 3 [Images not available. See PDF.]

BioMap AI tool for drug delivery

Case of XtalPi: AI-enhanced drug discovery

XtalPi, a pioneering pharmaceutical technology company in China, specializes in advancing drug discovery through AI-enhanced methodologies. Their strategic focus is leveraging computational approaches to optimize drug formulations and accurately predict properties. XtalPi's distinctive approach integrates quantum mechanics and AI algorithms, enabling the modeling of molecular interactions, prediction of drug solubility, and optimization of drug formulations. Through partnerships with global pharmaceutical firms, XtalPi enhances its access to diverse datasets, facilitating virtual screening of compounds and expediting the lead optimization process. Moreover, Xtalpi has listed these objectives as their mandate in improving health care and drug delivery systems, and they include:

1. Target characterization and identification of binding modes
2. Ideation and exploration of novel chemical space
3. Accurate forecasting of potency and properties
4. Formulation, synthesizing and evaluation strategies
5. AI-enhanced physics based on computational modeling

The incorporation of AI at XtalPi has transformed drug discovery, markedly reduced preclinical development timelines, and identified more stable and effective drug formulations. Despite these successes, XtalPi grapples with challenges related to the intricate nature of quantum mechanics simulations and the continual validation of AI models. Ongoing efforts are directed at ensuring seamless integration with existing pharmaceutical workflows [37]. Figure 4 indicates the collaborative approach adopted by Xtalpi with partners to power macromolecule programs that can create custom-based solutions integrated into their AI machine called the ID4 platform.

Fig. 4 [Images not available. See PDF.]

AI machine-ID4 platform

Evaluating the benefits and challenges of AI in the drug discovery and pharmaceutical product

Potential benefits of AI in drug discovery and pharmaceutical product

Drug repurposing

AI is essential to drug repurposing because it provides a strong and creative method for finding novel therapeutic applications for already-approved medications. AI's capacity to evaluate large and varied historical data, comprising genetic, surgical, and pharmacologic statistics, is one of the primary benefits of medication repurposing [52]. AI algorithms can find possible interconnections and links through examination that might not be readily evident using more conventional techniques. AI can quickly treat existing medications with an opportunity to alleviate various ailments by employing ML models to go through complex data and unearth novel findings [52]. Specialists can bypass some phases of expansion, such as assurance of safety, which was already completed after the drug's first acceptance, by using AI to repurpose existing pharmaceuticals [20]. To meet patients' immediate healthcare demands, it is very important to streamline the clinical trial process because it enables clients to receive therapies more quickly.

Sufyan et al. [44] denoted that AI systems can track subtle patterns and connections in data that may escape human scrutiny. Thus, the ability to make coincidental discoveries broadens the scope of repurposing medication, revealing possible remedies for ailments other than those for which they were originally designed. Moreover, AI-driven medication repurposing multidisciplinary perspective facilitates a more comprehensive comprehension of the biological causes of disease, opening the door to novel and unanticipated methods for therapy [19]. In summary, AI is essential for drug repurposing because it can transform the drug development process by providing quicker, more efficient and creative measures to find new therapeutic uses for already-approved medications. This has the potential to find novel answers to urgent medical challenges and expedite the delivery of therapies to patients.

Target identification

The technique of finding a medicine involves a critical called pinpointing the target. Because of its numerous advantages, AI plays a significant role in the success and efficacy of this procedure. Since AI can sift through vast amounts of complex biological information and data, it is essential for target identification [22]. AI algorithms can find

possible treatment targets more speedily than conventional techniques since they can evaluate proteomics, genomes and other omics data. Moreover, AI helps find fresh pathways and interconnections in information essential to the target assessment process. ML algorithms recognize patterns and correlations that may be challenging for human researchers to identify [28]. This capability allows AI to reveal potential targets that may have been overlooked using conventional approaches. By simultaneously considering many factors, AI enhances the comprehensiveness and accuracy of target identification, opening up new avenues for developing targeted and effective therapeutic interventions.

The essence of AI in target identification is further underscored by its role in personalized medicine. AI can analyze large-scale patient data, including genetic information, to identify specific disease-associated biomarkers [26]. This personalized approach allows for identifying effective targets in treating a particular disease and is tailored to individual patient profiles, potentially improving treatment outcomes and minimizing adverse effects [27]. In essence, AI in target identification brings a level of precision and efficiency that has the potential to revolutionize the drug discovery process and pave the way for more effective and personalized therapeutic interventions [50].

Clinical trial optimization

ML algorithms can analyze diverse data sources, including electronic health records and real-world data, to identify suitable candidates for clinical trials. By streamlining the recruitment process and matching patients with specific trial criteria, AI accelerates the enrolment phase, reducing delays and ensuring that trials progress more swiftly [16, 22, 36]. Another critical role of AI in clinical trial optimization is in the design and management of trials. AI systems can assess historical data, enhance trial protocols and predict medical challenges confronting patients. AI also help to maximize client satisfaction and participation in clinical studies. AI provided the platform to evaluate patient input from various reports, including patient forums and social media platforms, using sentiment analysis and processing of natural language. With these insightful data on patient experience, trial administrators will be better equipped to quickly resolve issues, strengthen their interaction plans and increase participant engagement. By providing a data-driven, patient-centered approach, the integration of AI in clinical trial optimization marks a paradigm shift and the ability to expedite procedures, lower costs and more quickly bring novel therapies to the marketplace [24, 26, 34].

Quality control and assurance through AI

Mahato [30] revealed that with its enhanced ability to improve efficiency, precision, and the overall quality of the product, AI is becoming a more vital component of quality assurance and control throughout a wide range of industries. AI ensures that products satisfy strict requirements by automating quality control operations in production. Large production of data sets can be evaluated by ML algorithms to locate abnormalities and trends, enabling real-time prompt corrections and monitoring. This predictive capability helps improve the overall quality of the production process by assisting in the detection and prevention of possible flaws [52]. In pharmaceuticals and healthcare, AI transforms quality assurance by streamlining processes and ensuring compliance with rigorous standards. Large volumes of data about pharmaceutical production, testing in labs, and experimental treatments can be analyzed by AI-powered systems, which can then spot variations and discrepancies from forecasted outcomes. This lowers the potency that client will receive defective medicals by enabling prompt identification of such issues [20]. Additionally, AI contributes to regulatory compliance by automating documentation processes, facilitating easier traceability, and ensuring that every step in the production and testing phases aligns with established quality standards.

Kulkov [25] reported that using AI software to control and quality assurance medical products is a common practice. Testing tools engineered by AI can automatically find vulnerabilities in the software, security issues, and operational problems. Thus, software development cycles can be accelerated while upholding rigorous standards of quality because of these technologies' ability to carry out complicated test situations more quickly than conventional

approaches. Likewise, Hasselgren and Oprea [17] espoused that through ML, these systems can learn from previous testing situations and improve their ability to recognize possible problems with every iteration. This improves the effectiveness of the testing procedure while also adding to the general resilience and dependability of software offerings.

AI in drug distribution

AI is instrumental in route optimization and logistics planning. Through advanced algorithms and machine learning models, AI can analyze various factors such as traffic conditions, weather, and transportation costs to optimize the delivery routes of pharmaceutical products. This ensures timely and cost-effective distribution and minimizes the environmental impact associated with transportation. AI-driven route optimization can lead to more sustainable drug distribution practices, aligning with broader efforts to reduce carbon footprints in the pharmaceutical industry [9]. Additionally, AI improves the accuracy and efficiency of order fulfillment processes in drug distribution. AI-powered automated systems can handle order processing, packing, and labeling with high precision, reducing the likelihood of errors and enhancing overall operational efficiency [2]. These AI-driven systems can adapt to fluctuating demand, prioritize critical orders, and provide real-time tracking information, ensuring that healthcare providers and patients receive the proper medications at the right time. Integrating AI in drug distribution is thus instrumental in achieving precision, reliability, and sustainability in the pharmaceutical supply chain [33].

Ongoing challenges facing the implementation of AI among pharmaceutical industries in China

While promising, the adoption of artificial intelligence (AI) in the pharmaceutical industry in China faces several challenges that impact the pace and extent of integration. One primary challenge is the *lack of standardized data*. The pharmaceutical sector has vast and diverse datasets, including clinical trial data, patient records, and genomic information. The absence of standardized formats and interoperability issues among these datasets can impede the seamless integration of AI solutions, making it challenging for pharmaceutical companies to harness the full potential of AI in data-driven decision-making processes [17, 40, 43].

Moreover, the *demand for experts proficient in pharmaceutical sciences* and AI technologies exceeds the current supply [12]. The development, application, and upkeep of AI-driven approaches in drug research, clinical trials, and other pharmaceutical industries are hampered by this shortage. It will take targeted educational initiatives and training programs to close this talent gap and give experts the multidisciplinary skills necessary for sustainable AI integration [7]. Regulatory issues further hamper the extensive use of AI in the Chinese pharmaceutical sector. The healthcare industry's legal framework is always changing, and pharmaceutical companies need to maneuver through intricate procedures to maintain conformance. Adoption may be slowed by the absence of precise and uniform criteria, which could lead to ambiguities and delays when applying for regulatory clearances for AI-driven technologies. [14].

Privacy and data security concerns also pose a big obstacle to using AI in healthcare. There is a greater emphasis on guaranteeing data privacy and protection since healthcare data, such as genetic knowledge and records of patients, are delicate [14]. To alleviate these concerns and promote the broad adoption of AI in pharmaceutical operations, businesses need to invest in cybersecurity safeguards and build confidence with all relevant parties, including clients and regulatory authorities. [15]. Therefore, even if AI has a lot of prospective advantages for the Chinese pharmaceutical business, its wide-ranging implementation will need to address issues, including data harmonization, talent shortages, regulatory complications, and data security concerns [48].

Research conclusion and policy directions

Conclusions

Exploring the influence of AI in drug discovery and the development of pharmaceutical enterprises in China has

revealed a substantial shift toward using innovative approaches to promote and enhance the health sector in the country. The current analysis has provided a comprehensive understanding of the potential transformative of applying AI tools in reducing cost, enhancing efficiency and streamlining drug development pipeline policies. The current assessment has revealed that the strategic application and adoption of AI reflects an expanding recognition of its capacity to expedite the invention of new therapeutics, thereby improving and advancing health care and medical science. In addition, this research has shed light on the assumption that China's drug and pharmaceutical industry is at the forefront of outlining cutting-edge tools for research and development which can foster a culture of collaboration and innovation. The report emphasizes the tremendous steps Chinese pharmaceutical businesses have taken in incorporating AI. Still, it also emphasizes the necessity for continued research, international cooperation, and regulatory frameworks to address issues and guarantee AI's moral and responsible application in drug creation. Amidst the paradigm shift in the pharmaceutical industry, stakeholders need to exercise caution when navigating the ethical, legal, and societal ramifications of incorporating artificial intelligence (AI) into the complex drug development processes. In the end, the comparative research indicates that the pharmaceutical business could undergo a revolution if AI technologies are successfully incorporated, with China establishing itself as a key participant in this revolutionary process.

Policy directions

Based on the study's outcome, the research proposes that certain policy recommendations must be implemented to optimize AI's impact on drug discovery. Firstly, fostering collaboration between pharmaceutical companies and research institutions is crucial. Establishing a framework for data sharing and joint projects can leverage collective knowledge and resources, accelerating the pace of drug discovery.

Secondly, there is a need for standardized regulatory guidelines governing the ethical use of AI in pharmaceutical research. Developing a comprehensive set of regulations ensures the responsible and transparent deployment of AI technologies, addressing concerns related to data privacy, bias, and the potential misuse of AI-generated insights. Establishing clear ethical boundaries allows trust in AI applications within the drug development process to be cultivated among industry stakeholders and the public. Furthermore, incentivizing AI research and development through government policies can stimulate innovation. Offering tax breaks or research grants to pharmaceutical companies investing in AI technologies encourages the industry to explore and implement cutting-edge solutions. This bolsters the competitive edge of Chinese pharmaceutical companies in the global market and positions the nation as a leader in AI-driven drug discovery.

Moreover, educational initiatives should be prioritized to bridge the gap between AI developers and pharmaceutical researchers. Promoting interdisciplinary programs that combine expertise in both AI and pharmaceutical sciences can cultivate a new generation of professionals equipped to harness the full potential of AI in drug discovery. Collaboration between academic institutions and industry players can facilitate knowledge exchange, fostering an environment conducive to continuous learning and adaptation. In addition, creating a centralized AI platform that aggregates and anonymizes data from various pharmaceutical companies can enhance the industry's collective intelligence. This platform could serve as a hub for shared insights, best practices, and AI algorithms, using advancements in drug discovery on a broader scale. Such a collaborative approach mitigates the fragmentation of efforts and maximizes the benefits of AI technologies across the entire pharmaceutical ecosystem.

Lastly, ongoing monitoring and evaluation mechanisms should be established to assess the impact of AI interventions in drug discovery and development. Regular audits can ensure compliance with ethical standards, measure implemented policies' effectiveness, and identify improvement areas. This adaptive approach enables the refinement of policies based on real-world outcomes, ensuring that the integration of AI in pharmaceutical processes

aligns with societal expectations and ethical considerations. In conclusion, a comprehensive and collaborative approach, anchored by robust regulations and incentives, is essential to harness the full potential of AI in drug discovery among pharmaceutical companies in China.

Limitations and future research directions

Integrating AI in drug discovery and development has undeniably revolutionized the pharmaceutical landscape, particularly in China. However, this technological advancement is not without its limitations. One major challenge lies in the availability and quality of data for training AI models. The success of AI algorithms in drug discovery heavily depends on access to comprehensive and reliable datasets, which can be a bottleneck in regions where data sharing and standardization practices may vary. Additionally, the interpretability and explainability of AI-generated insights remain significant concerns, especially in the highly regulated field of pharmaceuticals. Future research in this domain should address these limitations by establishing robust data-sharing frameworks, improving the transparency of AI algorithms, and enhancing the collaboration between pharmaceutical companies, research institutions, and regulatory bodies. Moreover, exploring the potential ethical implications of AI-driven drug discovery and development is crucial to ensuring responsible and equitable deployment of these technologies in advancing healthcare solutions.

Bioanalytical method development and validation for quantification of amivantamab in rat plasma by LC-MS/MS

Gaddey, Pridhvi Krishna1; Sundararajan, Raja1 1 GITAM School of Pharmacy, GITAM (Deem ed to Be University), Department of Pharmaceutical Analysis, Visakhapatnam, India (GRID:grid.411710.2) (ISNI:0000 0004 0497 3037)

ABSTRACT (ENGLISH)

Background

Amivantamab is a monoclonal bispecific anti-EGFR-MET antibody used to treat non-small cell lung cancer. There were no published methods using a liquid chromatographic—tandem mass spectrometric approach to develop and validate a feasible, novel, and thoroughly validated method for quantifying amivantamab in rat plasma.

Results

The liquid–liquid extraction method was used to extract the analyte from rat plasma. The analyte was separated using acetonitrile–ammonium formate buffer (40:60) as a mobile phase on waters, alliance e-2695 model high-pressure liquid chromatographic system having Agilent eclipse C_{18}, 150 mm × 4.6 mm, 3.5 µm column. The overall runtime was 6 min at a 1.0 ml/min flow rate. The method showed significant sensitivity and acceptable linearity over the 5.00–100.00 ng/ml concentration range. Accuracy was proved by mean percent recovery ranging from 98.03 to 99.99%. The intraday precision coefficient of variation (%) ranged between 0.31 and 5.43. Also, the findings such as C_{max}, t_{max}, AUC_{0-t}, $AUC_{0-\infty}$, and half-life values of amivantamab showed that the technique was helpful for pharmacokinetic studies.

Conclusions

All the validated parameters were found to be within the acceptable range. The validated method was found to be simple, accurate, precise, and reproducible and hence can be used for the routine analysis of amivantamab, such as in-process quality control by liquid chromatographic—tandem mass spectrometry.

FULL TEXT

Background

One of the most frequent malignancies linked to occupational exposures is lung cancer. Mesothelioma and lung cancer incidence have been related to the usage of asbestos in manufacturing and industries [1]. The two main subtypes of the disease are small cell lung carcinoma and non-small cell lung carcinoma (NSCLC), which account

for 15% and 85% of all instances of lung cancer, respectively. Three other subtypes of NSCLC include squamous-cell carcinoma, adenocarcinoma, and large-cell carcinoma [2]. The prevailing type of lung cancer, advanced non-small cell lung cancer (NSCLC), has a terrible prognosis and no recognized treatment. Due to the few therapy choices available, survival times are frequently brief [3]. There are risk factors for NSCLC that can be prevented and some that cannot be avoided. Tobacco inhalation is the most prevalent preventable risk factor for NSCLC [4]. Alcohol consumption, environmental exposure to second-hand smoke, asbestos, radon, arsenic, chromium, nickel, exposure to ionizing radiation, and polycyclic aromatic hydrocarbons are other causes of lung cancer [5]. One of the treatments for non-small cell lung cancer is the epidermal growth factor receptor (EGFR) gene. The tyrosine kinase cell-surface receptor EGFR can open up pathways that are involved in cell growth and proliferation when it is active [6]. EGFR mutations in malignancies lead to unregulated cell division because of persistent activation. 10–15% of people with lung cancer adenocarcinoma with European and Asian ancestry, those who never smoked, and female patients had EGFR gene mutations [7]. The first targeted treatment for non-small cell lung cancer patients, amivantamab, is a monoclonal bispecific anti-EGFR-MET antibody [8].

The quantitative assessment of drugs and their metabolites in efficient and robust techniques is important for the fruitful evaluation of biopharmaceutical, preclinical, and clinical research. The protocol referred to in the demonstration of a technique for quantitative assessment of analytes in biological matrices such as plasma, urine, blood, and urine is called bioanalytical method validation [9]. These techniques are dependable and repeatable. A review of the literature was conducted. Bioanalytical methods for the determination of amivantamab in biological samples have not yet been reported. There were no analytical methods reported for determination of amivantamab in pure form and in different matrices. The goal of this work was to create a sensitive and specific analytical approach for the quantitation of amivantamab in rat plasma. The developed technique was validated by ICH M10 regulations [10]. The results of this study provide a robust and reliable analytical strategy for the rapid identification of amivantamab and provide a helpful basis for further research.

Methods

Solvents and chemicals

The amivantamab sample (99.99% purity) was provided as a gift sample from Shree Icon Labs, Vijayawada, Andhra Pradesh, India. All other chemicals, including HPLC grade acetonitrile and methanol, were purchased from Merck Chemical Division in Mumbai. The Milli-Q water purification system's HPLC-grade water was used throughout the study. All chemicals and reagents were used as received without further purification. Trastuzumab (99.98% purity) was used as an internal standard (IS). It was obtained from Glenmark Pharmaceuticals Pvt Ltd, Mumbai, India.

Instrumentation

The liquid chromatography system comprised of Waters, alliance e-2695 model HPLC armed with column oven, autosampler, and degasser was employed for analysis. The SCIEX QTRAP 5500 mass spectrometer was connected to the HPLC system. REMI centrifuge was used for centrifugation. Cyclo Mixer was used for mixing.

Chromatographic conditions

The autosampler was maintained at ambient temperature. An Agilent eclipse C_{18}, 150 mm × 4.6 mm, 3.5 µm column was used for elution. Isocratic elution was employed with a mobile phase comprising acetonitrile and 0.1 M ammonium formate in the proportion of 40:60. With an injection volume of 10 µl, the chromatographic flow rate was set at 1.0 ml/min.

Mass spectrometer conditions

The mass spectrometric system comprised a SCIEX QTRAP 5500 mass spectrometer armed with an electrospray ionization interface ionization mode. The collision gas used was nitrogen. The compound-specific parameters working are displayed in Table 1. The ions were detected using multiple-reaction monitoring mode (MRM). Sciex Analyst software was used to process the data.

Table 1. Compound-specific parameters

Parameter	Value
Declustering potential (DP)	40 V
Collision energy (CE)	14 V
Entrance potential (EP)	10 V
Collision cell exit potential (CXP)	7 V
Source temperature	550 °C
Drying gas temperature	120–250 °C
Drying gas flow stream	5 ml/min

Selection of internal standard (IS)

Trastuzumab was selected as an internal standard to reduce the inaccuracy at the processing level or the ongoing analysis level caused by the instrument for quantifying both analytes by technique. Trastuzumab was chosen as the IS due to its near molecular weight with the analyte.

Preparation of solutions

Preparation of amivantamab stock and working solutions

Five milligrams of amivantamab working standard was weighed and transferred into a 100-ml volumetric flask and then diluted to volume with diluent. Further, 1 ml from the above solution was transferred to a 10-ml volumetric flask and made up with diluent. 0.4 ml of the above solution was taken into a 10-ml volumetric flask and made up to the mark with diluent.

Preparation of internal standard stock solution (200 ng/ml)

Five milligrams of trastuzumab working standard was weighed and transferred into a 100-ml volumetric flask and, then, diluted to volume with diluent. Further, 1 ml was pipetted into a 10-ml volumetric flask and made up with diluent. 0.4 ml of the above solution was taken into a 10-ml volumetric flask and made up to the mark with diluent. This IS added to the sample processing (50 µl) resulted in a final concentration of 50 ng/ml corresponding with the MQC concentration of amivantamab.

Preparation of plasma samples

Transferred 500 µl of amivantamab stock solution into a 2-ml Eppendorf tube. To this, 200 µl of plasma, 500 µl of internal standard, 300 µl of acetonitrile, and 500 µl of diluent were added (50 ng/ml). Calibration standards were prepared by spiking blank rat plasma with appropriate amounts of amivantamab and trastuzumab. Calibration standards for final concentration were 5.00, 12.50, 25.00, 37.50, 50.00, 62.50, 75.00, 100.00 ng/ml for amivantamab. The preparation of calibration standards and QC samples are displayed in Tables 2 and 3.

Table 2. Preparation of standards

Stock solution (ng/ml)	Volume taken (µl)	Made up to volume (µl)	Final concentration (ng/ml)	Identification
200	50	2000	5.0	Standard 1
200	125	2000	12.5	Standard 2

200	250	2000	25.0	Standard 3
200	375	2000	37.5	Standard 4
200	500	2000	50.0	Standard 5
200	625	2000	62.5	Standard 6
200	750	2000	75.0	Standard 7
200	1000	2000	100.0	Standard 8

Table 3. Preparation of QC samples

Stock solution (ng/ml)	Volume (µl)	Made up to volume (µl)	Final concentration (ng/ml)	Identification
200	750	2000	75.0	HQC
200	500	2000	50.0	MQC
200	250	2000	25.0	LQC
200	50	2000	5.0	LLQC

Diluent

Mobile phase of acetonitrile and ammonium formate in the ratio 40:60 was used as diluent.

Sample preparation

The 2000 µl samples prepared above were vortexed with the vortex cyclo mixture. The solution was centrifuged at 4000 RPM for 15 to 20 min. Then, the supernatant fluid was collected in an HPLC vial. Double blank samples (i.e., without analyte and IS) were prepared by mixing 1000 µl of acetonitrile with 200 µl of rat plasma samples.

Bioanalytical method validation

Method validation was done according to ICH M10 guidelines.

System suitability

Six replicates of high-quality control (QC) standard solution were injected into the chromatographic apparatus to analyze the system suitability parameters.

Linearity

The calibration curve was generated by analyzing eight concentrations of amivantamab in plasma. Samples were measured by comparing the peak area of amivantamab to that of trastuzumab. The plot of peak area ratios vs plasma concentrations was made.

Specificity

The specificity of the developed approach was evaluated in the current study by analyzing the chromatograms of blank plasma and spiked plasma samples (amivantamab, trastuzumab).

Sensitivity

The method's sensitivity was assessed by analyzing 6 replicates of rat plasma comprising a lower limit of quantification (LLOQ) sample (5.0 ng/ml) of amivantamab.

Accuracy and precision

Four QC samples—LLOQ, low-quality control (LQC), medium-quality control (MQC), and high-quality control (HQC)—each with six replicates were used to assess the proposed bioanalytical method's precision and accuracy. The precision and accuracy of the proposed method were represented as mean accuracy (%) and coefficient of variance (CV) (%), respectively.

LOD and LOQ

The signal-to-noise ratio was used to calculate the bioanalytical method's limit of detection (LOD) and limit of quantification (LOQ).

Autosampler carryover

Autosampler carryover was assessed by injecting a blank sample, followed by an HQC sample and then an LLOQ sample followed by a blank sample.

Dilution integrity

The dilution integrity of plasma samples was evaluated by evaluating amivantamab samples above ULQC. Those samples were taken and diluted with a blank matrix to MQC and ULQC.

Matrix effect

The matrix effect of plasma on the response of amivantamab was assessed by blank plasma samples that were extracted from six different lots and reconstituted to form working standards of LQC and HQC. These samples in triplicate were quantified against the calibration curve.

Recovery of analyte

Six replicates of the amivantamab QC low-, medium-, and high samples were created by spiking the relevant concentrations of the drug and an internal standard into either unextracted or supernatant-recovered blank rat plasma (extracted). Recovery was calculated by comparing its response in multiple samples to neat standard solution responses.

Recovery of internal standard

Trastuzumab (50.0 ng/ml) samples in blank plasma were prepared and examined in six repetitions.

Ruggedness

Low, medium, and high QCs of amivantamab in plasma samples were reinjected into the system. % CV and accuracy were assessed to determine ruggedness.

Reinjection reproducibility

Low, medium, and high QCs of amivantamab in plasma samples were reinjected into the system. % CV and accuracy were assessed to determine reinjection reproducibility.

Stability studies

Benchtop stability

Amivantamab's stability in rat plasma was assessed by exposing six replicates of three different concentrations (LQC, MQC, and HQC) for 8 h on a benchtop and injecting them into the system.

Short-term and long-term stability

Short-term and long-term stability was assessed for amivantamab. Three different analyte concentrations were spiked into six duplicates of rat plasma for QC. LQC, MQC, and HQC samples were prepared and stored at 5 ± 3 °C for 7 days, and short-term stability was assessed. LQC, MQC, and HQC samples were prepared and stored at −20 ± 3 °C. These samples were injected from day 1 to 28 days for every seven days (as day 1,7,14 21, and 28), and long-term stability was assessed.

Freeze–thaw stability

The stability of amivantamab was evaluated after freeze–thaw cycles, respectively. Each LQC, MQC, and HQC had six duplicates that were held at −20° C, totally thawed at ambient temperature, and then immediately refrozen at −20° C. After this cycle was done twice, the samples were removed for injection into the LC-MS.

Autosampler stability

LQC, MQC, and HQC samples of amivantamab in plasma were injected at one-hour up to 24-h intervals. Mean accuracy (%) and CV (%) were calculated.

Dry extract and wet extract stability

Wet extract stability was evaluated by assessing the six sets of LQC, MQC, and HQC after 12 h and 18 h that were stored at 2–8 °C. The dry extract stability test used six sets of LQC, MQC, and HQC after 12 h and 18 h that were stored at 22 °C.

Assay

Assay was done to define the applicability of the bioanalytical method to the marketed formulation. MQC (50.0 ng/ml) sample was prepared from the marketed formulation (Rybrevant) and injected into the LC-MS system.

Method applicability to rats

Six healthy white female albino rats (body weight in between 250 and 350 g) were taken from Flair Labs, Gujarat, India. Before the experiment was directed, rats were adapted to laboratory environments for seven days. Diet was restricted for 12 h before the experiment, although water was freely available. A single dose of amivantamab (0.83 mg/ml) was administered to six rats. Samples were collected at different intervals, such as 10, 20, 30, 40, 50, and 60 min. K2 EDTA vacutainer tubes were used to collect blood at each interval. A predose sample was also taken to check for any potential plasma interferences. The plasma was obtained by centrifuging the collected samples kept at 10 °C. The liquid–liquid extraction method was used to isolate amivantamab in rat plasma. The animal study protocol was approved by the Institute of the Animal Ethics Committee (Reg.No: 1250/PO/RcBi/S/09/CPCSEA). Phoenix Win Nonlin (Version 5.2) software was used to analyze the data.

Results

Method development

MS/MS analysis

The mass spectra of amivantamab and trastuzumab were obtained by preparing each analyte in diluent and injecting it into the liquid chromatography-tandem mass spectrometer with positive ionization mode. Scan displayed that precursor ions of amivantamab and an m/z value of 145.66 were chosen. During MRM optimization, the product ion 112.10 showed the best response and was selected as the daughter fragment. The collision energy was optimized as 14 V using the edit ramp function. The scan presented that precursor ions of trastuzumab have an m/z value of 148.57. During MRM optimization, the product ion 126.01 showed the best response and was chosen as the daughter fragment. The mass transitions are shown in Figs. 1 and 2.

Fig. 2 [Images not available. See PDF.]

Product ion scan of trastuzumab using positive polarity

Liquid chromatography

Several elution conditions were tested for the chromatographic separation. An isocratic flow profile was devised to get the finest peak separation with a minimal overall run time for all the analytes. The liquid chromatographic settings were improved to prevent the matrix effect, provide better peak shapes for all analytes, and increase sensitivity. Agilent eclipse C_{18}, 150 mm × 4.6 mm, 3.5 µm column, was chosen as the stationary phase for the analyzed compounds. Acetonitrile and 0.1 M ammonium formate buffer (40:60) were used for the mobile phase. The optimized method chromatogram is presented in Fig. 3. The finest outcomes were found with a flow rate of 1.0 ml/min.

Fig. 3 [Images not available. See PDF.]

LLOQ chromatogram of amivantamab

Optimization of the sample preparation

Based on the pKa value of the compound and the ease of sample extraction, the liquid–liquid extraction method was chosen for sample preparation. Acetonitrile was selected as the extractant because of its low ionization suppression

and excellent extraction efficiency compared to other organic solvents frequently employed in LC-MS/MS analysis. High sensitivity, linear calibration range, and low matrix effect were attained for amivantamab.

Bioanalytical method validation

System suitability

System suitability was examining a set of reference standards to determine an instrument's performance, which was conducted before the analytical run. The CV (%) for amivantamab and trastuzumab area ratio was 0.13. The CV (%) of retention time of amivantamab and trastuzumab was found to be 0.63 and 0.23, respectively. The system suitability parameters like tailing factor, plate count, and resolution were within the limit. System suitability parameters are displayed in Table 4.

Table 4. System suitability results of amivantamab

	Name	Retention time	Area	USP tailing	Theoretical plate	USP resolution
1	Amivantamab	2.128	3265124	1.07	6594	
2	Trastuzumab	4.136	4485769	1.01	7318	8.19

Linearity

The peak area obtained from the analysis was used to calculate the area response ratio. A calibration curve was plotted by taking concentration on the X-axis and area response ratio on the Y-axis. The slope, intercept, and correlation coefficient were obtained from the plot. The best linearity of the calibration curve for amivantamab was secured over the concentration ranges of 5.0−100.0 ng/ml. The correlation coefficient was 0.99949. The linearity range of solutions and respective area response ratios are tabulated in Table 5. A representative calibration curve for amivantamab is presented in Fig. 4.

Table 5. Linearity results of amivantamab

Concentration (ng/ml)	Area	Area response ratio
0	0	0
5	0.345×10^5	0.082
12.5	0.852×10^5	0.202
25.0	1.754×10^5	0.416
37.5	2.601×10^5	0.616
50.0	3.457×10^5	0.819
62.5	4.305×10^5	1.020

Intercept	0.00584
R^2 value	0.99949

Fig. 4 [Images not available. See PDF.]

Calibration curve of amivantamab

Specificity

Specificity results exhibited that the process developed was highly selective for amivantamab. No discernible endogenous chemicals interfered at the retention times for amivantamab and trastuzumab were seen in six different types of blank plasma. The ability to clearly distinguish the analyte in biological fluids, which comprised various components, including the matrix, was known as specificity. The specificity results are tabulated in Table 6.

Table 6. Specificity results of amivantamab

S. no	Sample ID	Intensity (cps)		% Interference		Pass/fail
Amivantamab	Trastuzumab	Amivantamab	Trastuzumab	1	Std Blank 1	0
0	0	0	Pass	2	LLOQ 1 (5 ng/ml)	0.369×10^5

0	0	0	Pass	12	LLOQ 6 (5 ng/ml)	0.364×10^5

Sensitivity (LLOQ)

The current approach achieved an LLOQ of 5.00 ng/ml for amivantamab in rat plasma. The CV (%) and mean accuracy (%) were 6.30% and 93.10%, respectively. Table 7 displays the sensitivity test results.

Table 7. Sensitivity results of amivantamab

Replicate number	LLOQ (5.0 ng/ml)
1	4.3 ng/ml
2	4.9 ng/ml
3	4.4 ng/ml
4	4.9 ng/ml
5	4.9 ng/ml
6	4.5 ng/ml
Mean	4.7 ng/ml
SD	0.3
% CV	6.3
% Mean accuracy	93.1%

Accuracy and precision

Accuracy was shown as % mean recovery and precision as % CV. The degree to which the experimental value and the actual value were similar depends on the accuracy of the analytical approach. LLQC, LQC, MQC, and HQC solutions were prepared in replicates and injected into the system. The intraday accuracy and precision of amivantamab were 94.2–99.9% and 0.9–5.3, respectively. Results were summarized in Table 8.

Table 8. Precision and accuracy results of amivantamab

Replicate no	HQC (75.0 ng/ml)	MQC (50.0 ng/ml)	LQC (25.0 ng/ml)	LLQC (5.0 ng/ml)

0.7	0.5	0.3	0.3	% CV
0.9	1.0	1.0	5.3	% Mean accuracy

Autosampler carryover

The chromatograms of standard blank samples were observed, and no significant carryover of amivantamab was detected. Similarly, carryover of trastuzumab was also not found.

LOD and LOQ

The LOD (1.67 ng/ml) solution was prepared so that the S/N ratio ranged around 3:1. Respective chromatograms of LOD and LOQ (5.0 ng/ml) are shown in Figs. 5 and 6. The method was found to be sensitive and specific.

Fig. 5 [Images not available. See PDF.]

Chromatogram of LOD

Fig. 6 [Images not available. See PDF.]

Chromatogram of LOQ

Dilution integrity

Dilution integrity was the evaluation of the sample dilution technique to ensure that it does not affect the precision and accuracy of the measured concentration of the analyte, as needed. The CV (%) and mean accuracy (%) for MQC and ULQC were found to be 0.5, 0.5, and 100.1 and 98.5, respectively. The results are displayed in Table 9.

Table 9. Results for dilution integrity

Replicate number	MQC (50.0 ng/ml)	ULQC (100.0 ng/ml)
Concentration		1

49.9	97.8	2
49.9	98.4	3
49.9	99.0	4
49.9	99.0	5
50.6	98.4	6
49.9	98.4	Mean
50.1	98.5	SD
0.3	0.5	% CV
0.5	0.5	% Mean accuracy

Matrix effect

A matrix effect describes the changes observed in detecting or quantifying an analyte when other substances are present in the sample. The CV (%) for LQC and HQC was observed to be 0.73 and 1.20, respectively. The mean accuracy was 99.71% for low-quality control samples and 99.88% for high-quality control samples. Data was included in the Additional file 1.

Recovery of analyte

The effectiveness of separating analytes from samples was described by recovery. The CV (%) for extracted and unextracted samples at the HQC level was found to be 0.99 and 0.98, respectively. The mean recovery (%) for extracted and unextracted samples at the HQC level was found to be 99.79 and 99.94%, respectively. Data was incorporated in the Additional file 1.

Recovery of internal standard

The CV (%) of unextracted and extracted methods was found to be 0.17 and 0.19, respectively. The CV (%) of trastuzumab's recovery was around 15.00%. Data was integrated in the Additional file 1.

Ruggedness

Ruggedness is a measure of the susceptibility of a method to small changes that might occur during routine analysis, like small changes in pH values, mobile phase composition, temperature, analysis, etc. The mean accuracy (%) for LQC, MQC, and HQC was 99.13–99.88%. Data was included in the Additional file 1.

Reinjection reproducibility

Six duplicates of low, medium, and high QCs of amivantamab were reinjected into plasma samples to see if samples could be reinjected in the event of instrument failure or other issues. The % CV for HQC, MQC, and LQC was found to be 0.7, 0.3, and 0.9%, respectively. Data was added in the Additional file 1.

Stability studies

Bench-top stability

Bench-top stability is the stability of an analyte in a matrix under sample handling conditions during sample processing. The CV (%) of HQC, LQC, and MQC was found to be 0.9, 1.3, and 0.5, respectively. The mean accuracy (%) of HQC, LQC, and MQC was found to be 99.7, 98.8, and 98.4%, respectively. The results of bench top stability are shown in Table 10.

Table 10. Bench top stability results of amivantamab

0.7	0.3	0.3	% CV
0.9	1.3	0.5	% Mean accuracy

Short-term stability and long-term stability

Long-term stability assesses the degradation of an analyte in the matrix relative to the starting material after periods of frozen storage. The results showed that amivantamab QC low, medium, and high samples were stable in short-term and long-term stability. Short-term stability results are displayed in Table 11, and long-term stability results are summarized in Tables 12, 13, 14, 15, 16.

Freeze–thaw stability

Freeze–thaw stability refers to the stability of the analyte in the matrix upon freezing and thawing. The CV (%) of HQC, LQC, and MQC was found to be 1.2, 1.9, and 0.8, respectively. The mean accuracy (%) of HQC, LQC, and MQC was found to be 99.75, 99.94, and 99.94%, respectively. The results are tabulated in Table 17.

Autosampler stability

Autosampler stability is the stability of the analyte in the processed sample under the conditions in the autosampler. The CV (%) of HQC, LQC, and MQC was found to be 1.09, 0.46, and 1.24, respectively. The mean accuracy (%) of HQC, LQC, and MQC was found to be 99.7, 98.3, and 99.9%, respectively. The outcomes are summarized in Table 18.

Assay

The developed method's applicability for quantifying amivantamab in the marketed formulation was assessed. The

assay (%) of amivantamab was found to be 99.96%. The results of the assay are shown in Table 23.

Table 23. Results of assay

Injection	Area counts
1	3.439×10^5
2	3.474×10^5

Method application to rat plasma samples

The developed and validated procedure was applied to study in rats. The concentrations of amivantamab in rat plasma samples are tabulated in Table 24. The pharmacokinetic parameters of amivantamab were calculated using Phoenix Win Nonlin (Version 5.2) software. The results of pharmacokinetic parameters are tabulated in Table 25. The recovery plot of amivantamab in rat plasma is shown in Fig. 7.

Table 24. Concentration of amivantamab in rat samples

Recovery plot for amivantamab in rat plasma

Discussion

LC-MS/MS is a sensitive method for the quantification of monoclonal antibodies. Several elution conditions were tested for the chromatographic separation. In trial 1, a mobile phase composition of acetonitrile and triethylamine buffer in the ratio 60:40 was used. Peak splitting was observed, so further trial was carried out. In trial 2, a mobile phase ratio of acetonitrile and ammonium formate buffer (60:40) was used. The plate count was not within the limit. Hence, further trial was carried out. A mobile phase ratio of acetonitrile and ammonium formate buffer (50:50) was used in trial 3. Peak heights were not within the limit, so further trial was conducted. In trial 4, a mobile phase ratio of acetonitrile and ammonium formate buffer (40:60) was used. System suitability parameters were within the limit, so this method was validated. The developed method quantified amivantamab in a biological matrix. The system was deemed suitable for usage if the area ratio's CV (%) was less than five and the retention time's CV (%) was less than 2. It thus passed the system suitability test. The calibration curve was deemed agreeable when % accuracy for all calibration curve standards ranged from 85.00 to 115.00%. The correlation coefficient (R^2) was 0.99 or better. The method was found to be linear. The response of any interfering peaks at the analyte retention time was to be ≤ 20.00% of amivantamab at LLOQ and ≤ 5.00% of that in LLOQ in the case of trastuzumab. The method was found to be specific and selective. Sensitivity acceptance criteria were to be as 4 out of 6 samples, or at least 67.00%, fell within the 80.00–120.00% range. The recommended range for mean accuracy (%) was 80.00–120.00%. The CV's (%) accuracy was to be 20.00%. The outcomes fell within the permitted range. The method was found to be sensitive. The standards for data acceptance included accuracy (%) within 85.00–115.00% of the actual values and precision within 15.00% relative standard deviation (RSD). These findings demonstrated that the accuracy and precision were reproducible and dependable for quantifying amivantamab in rat plasma. If the analyte concentration detected in the double blank sample was less than 20.00% for amivantamab, carryover was deemed significant. Hence, there was no carryover effect. CV (%) and mean accuracy in dilution integrity were within the limits for amivantamab. The minimum acceptance standard required that two out of three samples at every level fell under the 85.00 to 115.00% range. The matrix lot was to be within the agreeable criteria in at least 80.00% (5 out of 6 cases). The results were within the tolerable range. Hence, the matrix effect was found to be negligible. For each QC level, the CV (%) of recovery was to be under 15.00%. For all QC levels, the mean recovery CV (%) was to be under 20.00% overall. All of the results fell within desirable limits. The overall mean recovery (%) and CV (%) were less than 20.00% for all QC levels. The range of the mean accuracy for low-, medium-, and high-quality control samples was between 85.00 and 115.00%. The results were found within tolerable limits. The results were within the tolerable range. This specifies that the extraction technique used was effective. The limitations were all met in reinjection reproducibility. The method was found to be reproducible. The CV (%) of low- and high-quality control samples was ≤ 15.00%. The CV (%) and mean accuracy were within the standard limits. Any condition, time period, or analyte concentration examined had less than 15.00% of CVs. All the stability results were within the tolerable range. The range for the LQC and HQC samples' mean concentration accuracy was between 85.00 and 115.00%. LQC and HQC samples were to have a CV (%) of less than 15.00%. The results showed that amivantamab was stable in rat plasma. CV (%) and mean accuracy (%) were within the limits. Samples were deemed stable if the CV (%) for the low-, medium-, and high-quality control samples was less than 15.00%. It showed that the stability of the autosampler was determined to be within limits. Moreover, the mean accuracy and CV (%) were within limits. The CV (%) and mean accuracy (%) for amivantamab passed the wet and dry extract stability. As a result, the approach was accurate in various conditions. Through the study of three QC samples of amivantamab the application of various storage conditions, stability of the drug was evaluated. The findings were consistent throughout the studies conducted. These stability results indicate that amivantamab was stable during benchtop, freeze–thaw, autosampler,

short term, long term, wet extract, and dry extract stability studies. Also, amivantamab was stable during the storage and handling of samples in rat plasma matrix. The study confirmed that the bioanalytical method was accurate and can be used to study pharmaceutical dosage forms. The validated technique was sensitive enough to quantify analyte in plasma samples in experimental rats accurately. The pharmacokinetic findings illustrate less absorption and metabolism effects on amivantamab in rats. These findings will be helpful in further pharmacokinetic assessments.

Conclusions

This was the first fully validated stability, indicating that the LC-MS/MS technique was developed to measure amivantamab in pharmaceutical preparations and rat plasma. A precise, easy, and repeatable method for measuring amivantamab in rat plasma was developed and validated by ICH M10 guidelines. The validation parameters' findings inferred that the current analysis technique could be used to carry out bioavailability studies with high sensitivity, precision, and accuracy. Also, from the recovery studies, it was found that there was less interaction from the matrix to monoclonal antibody and less absorption or distribution in the rats. It was strongly advised to evaluate the quality of medications during routine analyses or stability studies. Rat plasma samples can be analyzed in clinical investigations using this fully validated approach.

ABSTRACT (ENGLISH)

Background

Cucurbitacins are present in some common vegetables as secondary metabolites and are used by the plants against harmful microbes. Exploration of this capability of natural product based substances against wide variety of microbes seems relevant due to the ease of availability of the resources and safety. In this regard, considering the current pandemic, the antiviral properties of these molecules with a subset of Cucurbitacin I structural derivatives have been screened. The inhibition potential of the phytochemicals was assessed by the stability of the protein–ligand complex formed with the nucleocapsid protein (PDB ID: 7CDZ) of SARS-CoV-2 by computational methods. The proposition of an alternate antiviral candidate that is cost-effective and efficient relative to existing formulations is the main objective of this work.

Results

Server-based molecular docking experiments revealed CBN19 (PubChem CID: 125125068) as a hit candidate among 101 test compounds, a reference molecule (K31), and 5 FDA-approved drugs in terms of binding affinities sorted out based on total energies. The molecular dynamics simulations (MDS) showed moderate stability of the protein-CBN19 complex as implied by various geometrical parameters RMSD, R_g, RMSF, SASA and hydrogen bond count. The ligand RMSD of 3.0 ± 0.5 Å, RMSF of C_α of protein with less than 5 Å, and smooth nature of SASA and R_g curves were calculated for the adduct. The binding free energy (−47.19 ± 6.24 kcal/mol) extracted from the MDS trajectory using the MMGBSA method indicated spontaneity of the reaction between CBN19 and the protein. The multiple ADMET studies of the phytochemicals predicted some drug-like properties with minimal toxicity that mandate experimental verification.

Conclusions

Based on all the preliminary in silico results, Cucurbitacin, CBN19 could be proposed as a potential inhibitor of nucleocapsid protein theoretically capable of curing the disease. The proposed molecule is recommended for further in vitro and in vivo trials in the quest to develop effective and alternate therapeutics from plant-based resources against COVID-19.

FULL TEXT

Background

After claiming nearly 7 million people, the virus responsible for COVID-19, SARS-CoV-2 is still propagating [1, 2]. Even though the vaccines have helped to contain the pandemic to some extent, effective and safe drugs are still in the experimental phases [3, 4]. One of the alternatives to existing pharmaceuticals is the phytochemical-based therapeutics that need to be designed and developed for proper treatment and cure of the disease in a cost-effective manner. Various natural products have been reviewed in terms of their potential to fight the disease, taking into consideration the specific targets [5]. Cucurbitacins, tetracyclic triterpenoids occur in regularly consumed vegetables like cucumber, gourds, squash, and pumpkins as secondary metabolites and act in the plant's defense mechanisms [6]. The molecular structure of Cucurbitacin I is shown in Fig. 1. These vegetables contain multi-sized nutrients, antioxidants, vitamins, amino acids, and small anti-nutrients [7]. It carries non-trivial ethnobotanical significance and has been in use in the treatment of multiple diseases since ancient times [8–12] with weaker side effects, good safety, and multiple healing pathways [13]. Especially, cucurbitacin B has been found to possess anti-Herpes simplex virus 1 biological activity with IC_{50} of 0.94 ± 0.2 μM [14] and forms the basis for the selection of this class of organic compound with possibly similar pharmacophore. Therefore, the adaptation of local practices by scientific research in developing a new type of compound as a drug with molecular-level understanding seems relevant

considering this class of organic compound having known biological activity and the requirement of the present global context.

Fig. 1 [Images not available. See PDF.]

Molecular structure of a parent molecule, Cucurbitacin I

Out of twenty-nine proteins in the viral genome of SARS-CoV-2, a structural protein, nucleocapsid (N), seems to be a good target for small ligands since it is responsible for RNA encapsidation, transcription and replication of the viral genome [15, 16]. Therefore, its involvement in the assembly, budding, cell cycle regulation, immune system modulation, and cessation of host cell translation makes it one of the prominent functional entities [17, 18]. If a guest molecule binds effectively to it then its normal functioning will be disrupted, which would result in the deceleration or halting of the viral replication, ultimately leading to the cure of the disease caused by it. A recent study involving NMR and mass spectroscopic techniques has shown the protein to be druggable and possesses greater availability [19]. A compound K31 [4-(3-Bromophenyl)-3a,4,5,9b-tetrahydro-3H-cyclopenta[c]quinoline-6-carboxylic acid, PubChem CID: 2872351] has been recently reported to bind to it with EC_{50} of 1.7 ± 0.2 μM [15]. Alectinib has been proposed to be capable of inhibiting nucleocapsid protein by prohibiting phosphorylation from in vitro studies [20]. Using in silico approach, Curcumin, Apigenin, Cinnamic acid, Simeprevir, and Grazoprevir have been found to bind successfully with the nucleocapsid protein in different studies [21–23]. Suramin, an antiparasitic drug, has been proposed based on experimental and in silico studies to disturb the association of N-terminal domain (NTD) with RNA, leading to the cessation of viral replication [24]. These results establish the selected protein as a good therapeutic target and therefore, has been chosen for this work.

The relative strength of the binding of the test molecule and its orientation at the orthosteric site of the receptor can be determined by molecular docking calculations as that performed with Cucurbitacins against multiple target proteins of SARS-CoV-2 [25]. The assessment of the stability of the protein–ligand adduct by monitoring the conservation of the initial docked pose of the ligand at the active pocket by molecular dynamics simulations is required. The spontaneity of the forward reaction inferred from binding free energy changes would help to design a molecule that can effectively inhibit the protein by binding to it in a thermodynamically and geometrically stable manner. The safety and bioavailability of the drug-like candidate from ADMET predictions would help to establish the test compound as a good and safe drug against the disease [26]. The computational approach stands as a viable tool in designing a drug that would prevent later failures in high-throughput experiments and clinical trials. One objective of this work is a quick screening of safe, natural product-based molecules with Cucurbitacin I as a scaffold against SARS-CoV-2. The other is an extension of traditional medicinal knowledge into the modern concept of rational drug design and development with molecular-level understanding.

Since the nucleocapsid protein is of utmost importance in functioning at various stages in the viral life cycle [27] and is druggable, it has been adopted in this research work for exploring its possible interactions with Cucurbitacins I scaffold derivatives. The antiviral capabilities of a slightly different structure of Cucurbitacin B have added to the rationale of small molecule selection [14].

Objectives of the work

- a. To explore the phytochemicals from regularly used vegetables with known biological activities against a specific viral target by cost-effective computational methods.
- b. To identify a drug-like and safe molecule with potential inhibitory capabilities of the functioning of the nucleocapsid protein.
- c. To recommend a hit molecule for in vitro and in vivo trials in the course of developing it as an effective nutraceutical/pharmaceutical against SARS-CoV-2.

Experimental/methodology

Ligand and receptor preparation

The parent molecule, Cucurbitacin I (PubChem CID: 5281321) and its substructure derivatives were taken in sdf file format from the PubChem webpage (https://pubchem.ncbi.nlm.nih.gov/, accessed 12 July 2023) [28] and converted to pdb format using *obabel* command (The Open Babel Suite, version 2.3.1 http://openbabel.org, accessed 12 July 2023) [29] and the PyMol program [30]. The N-terminal domain of nucleocapsid protein of SARS-CoV-2 as a drug target (PDB ID: 7CDZ, X-ray diffraction, resolution 1.80 Å, Escherichia coli BL21 expression system) (https://doi.org/https://doi.org/10.2210/pdb7CDZ/pdb) was retrieved in pdb file format from the RCSB website (https://www.rcsb.org/, accessed 4 July 2022) [31], verified and preprocessed for molecular docking.

Molecular docking calculations

The DockThor web-server (https://dockthor.lncc.br/v2/, accessed 12 July 2023) [32] was used in molecular docking calculations with center coordinates of (−6, 22, 16), discretization of 0.25, and grid size of ($20 \times 20 \times 20$ $Å^3$) of the active pocket. The genetic algorithm search settings involved 1,000,000 evaluations with 750 population size for 24 number of runs deemed suitable for capturing the local minima in a complicated potential energy surface. The affinity prediction was done for each ligand based on the total energy, which was calculated for its different binding modes. It involved inter-molecular, intra-molecular, and torsional energies and were clustered to finally yield the best value [32, 33].

Molecular dynamics simulations and thermodynamics

The docked pose with the best binding affinity was taken for molecular dynamics simulations (MDS) of 90 ns production run at 310 K using the GROMACS version 2021.2 program [34]. The force-field (charmm27) [35] was obtained from the SwissParam server (https://www.swissparam.ch/, accessed 12 July 2023) [36], and all the other parameters as reported by Sharma et al. [37] were adopted. Multiple parameters like root mean square deviation (RMSD), radius of gyration (R_g), root mean square fluctuation (RMSF), solvent accessible surface area (SASA), and number of hydrogen bonds between ligand and residues were determined from MDS trajectory using inbuilt commands of GROMACS. Binding free energy change of complex formation was calculated using MMGBSA method [38] with GB7 option [39] for the best-docked pose using gmx_MMPBSA module (100 frames) [40] in GROMACS and also using the fastDRH server (http://cadd.zju.edu.cn/fastdrh/, accessed 15 July 2023, ID4638) [41]. The differences in the fluctuation of the residues upon ligand binding were determined in terms of RMSF difference from the MDS of 10 ns duration using the CABSflex2 web-server (http://biocomp.chem.uw.edu.pl/CABSflex2/, accessed 15 July 2023) [42].

Pharmacokinetics and pharmacodynamics

The SMILES strings of the molecules were used as input in determining various parameters. The ADMET prediction [43] was made using the pkCSM (https://biosig.lab.uq.edu.au/pkcsm/prediction, accessed 24 October 2023) [44] and the ADMETboost (https://ai-druglab.smu.edu/, accessed 25 October 2023) [45] servers. Various toxicity end-points and the rule of five (RO5) or Lipinski's rule were calculated along with other physicochemical parameters of selected Cucurbitacin I derivatives.

Programs and resources

The structures were visualized using the Biovia Discovery Studio visualizer v21.1.0.20298 [46] and the Avogadro2 v1.93.0 [47] programs. The graphical representations were made with the GNUPLOT 5.2 patch level 8 [48] and the Grace-5.1.25 [49] software. The SMILES strings were converted into 2D molecular structures by the online Marvin JS structure editor (https://chemaxon.com/products/marvin-js). The computational experiments were carried out in different machines with multi-core processors, GPU accelerator, RAM 128 GB, and storage 6 TB. The operating

systems were Ubuntu 20.04 LTS and Windows 8. Data analysis, visualization and interpretation were carried out on a PC with minimal configuration.

Results

Binding affinities and orientation of the docked molecule

The 2D representations of selected test molecules and a reference are shown in Fig. 2. The binding affinities of the top five Cucurbitacin I derivatives, a reference compound (K31) and that of FDA-approved drugs are shown in Table 1.

Fig. 2 [Images not available. See PDF.]

Molecular structures of the top compounds and a reference

Table 1. Top five Cucurbitacin I derivatives, a reference compound and 7 commercial drugs in terms of binding affinities with NTD of nucleocapsid protein

Molecules (PubChem CID)	Affinity (kcal/mol)	Total energy (kcal/mol)	Commercial drugs	Affinity (kcal/mol)	Total energy (kcal/mol)
CBN19 (125125068)	−10.27	92.01	Simeprevir	−10.56	5227.5
CBN36 (162939996)	−10.20	73.67	Vapreotide	−10.45	212.33
CBN85 (138107616)	−10.16	83.82	Atazanavir	−9.66	82.34

The compound CBN19 in its docked pose with the receptor is displayed in Fig. 3A. Figure 3B depicts the hydrophobic surface of the active pocket of the protein that interacts with the ligand from two viewing angles 180° apart.

Fig. 3 [Images not available. See PDF.]

Docked pose of **A** CBN19 (ball and stick model) with the nucleocapsid protein (ribbon representation) and **B** CBN19 in the active pocket enveloped with hydrophobic surface viewed at 180° apart

It is evident from the data that the drugs, Simeprevir and Vapreotide lead among all the compounds, and the former,

along with Grazoprevir, has been reported by Bhowmik et al. [23] from computational screenings as better candidates. However, the top five test candidates possess better affinities than the other five FDA-approved drugs. The compound CBN19, with the best binding affinity could be considered a hit candidate among the pool of the studied molecules. The highest total energy, however, imply that the reference compound K31, possessed weaker binding (−8.86 kcal/mol) than that of the test compounds and was bound to the N-terminal domain of nucleocapsid protein as inferred experimentally [15]. Apart from the molecules mentioned above, Emetine and Glycyrrhizin have also been found to possess good docking properties against nucleocapsid protein [50, 51]. The computational results show promising properties of the selected molecules derived from a molecular scaffold suitable for further characterization and trials.

Druglikeness and toxicity assessment

The drug-like characteristics in terms of RO5 were found to be acceptable for most of the compounds, inferring good bioavailability and permeability (data presented in supplementary information as ADMET_predictions.xls file). The pharmacokinetics of various Cucurbitacins have been reported by Delgado-Tiburcio et al. [9]. The toxicity in terms of the AMES test, hERG I/II inhibition, hepatotoxicity and skin sensitization showed negative results for the test molecules. The permeability of BBB and CNS are poor or absent, with suitable excretion parameters. The results from the pkCSM server showed that Cucurbitacins possess acceptable drug-like properties with relatively safe end-points.

The ADMET predictions from another server (ADMETboost), to validate the earlier results, were analyzed for different properties. The output, however, showed that Caco2-permeability and aqueous solubility lay outside the acceptable range, whereas all the other properties were predicted to be similar to those from the pkCSM server.

Geometrical stability of complexes

The binding affinity based on a scoring function provides a clue towards the strength of interactions between the ligand and the protein and can be used as a comparative property. It may not necessarily reflect the binding efficacy considering the time the ligand stays at its initially docked position and may not be a measure of the absolute property. To determine the conservation of pose and position of the ligand with time and to determine the geometrical stability of a system, molecular dynamics simulation of 90 ns duration was carried out and various parameters like RMSD, SASA, RMSF, R_g, and hydrogen bond count were extracted from the trajectory. These parameters provide a numerical assessment of the structural stability and are analyzed thoroughly in this section. The RMSD of the ligand and that of the protein are shown in Fig. 4 as subplots A and B, respectively.

Fig. 4 [Images not available. See PDF.]

Multiple parameters extracted from MDS trajectory **A** RMSD of ligands with respect to protein backbone **B** RMSD of protein backbone with respect to protein backbone (CBN19 = dark, CBN36 = red, CBN85 = green, CBN76 = blue, and CBN96 = indigo)

The RMSD of ligand CBN19 with respect to the protein backbone (dark curve) was *ca.* 2 Å and was moderately smooth with small fluctuations at 55 ns and 70 ns regions. It remained flat from 75 to 85 ns, similar to the initial part of the trajectory up to 45 ns. The results hint at near preservation of the docked pose during the simulation period. Similar values have been reported for approved drugs against nucleocapsid CTD [52]. The compounds with CBN36 and CBN96 showed unsteady behavior, both attaining equilibrium after 60 ns with RMSD larger than 6.8 Å. Another compound CBN85 showed an RMSD of *ca.* 4 Å or lower with multiple spikes during the production run. It did not attain steady state, as shown by a deep at 85 ns and necessitates a longer simulation run. The complex of CBN76 showed an RMSD of *ca.* 3 Å with a rise at 85 ns. The unsteady curve implies significant ligand motion at the active

site, and the stability could only be confirmed from extended production runs. Multiple curves showed a rise at 70 ns except CNB36, indicating a common factor in the structural modulation. The lack of such a feature in the protein backbone may be attributed to the function of temperature leading to similar coincidental atomic spatial evolution of the docked ligands and may not be relevant in assessing the stability of the adduct. The nature of the ligand RMSD curves suggests the formation of moderately stable protein–ligand adducts, with most of them attaining equilibrium after *ca.* 75 ns.

The multiple RMSD of protein backbone with respect to the protein backbone, as shown in Fig. 4B, are less than 3 Å except that in the case of CBN36, which was sometimes higher in magnitude. The relatively flat and smooth nature of the curves hints at greater stability of the protein structure during the production run. The overall geometry of the receptor and the active pocket can be inferred to remain intact, capable of binding the ligand effectively. Out of five complexes studied, since CBN19 showed comparatively promising stability, other structural features related to it were only derived and analyzed.

The RMSF plots of alpha carbon atoms of the protein in the adduct and in the receptor alone were extracted from two separate MDS trajectories and are given in Fig. 5 as subplots A and B, respectively. Figure 5B shows large fluctuations *ca.* 6.5 Å from residue number 45 to 65 in the two chains out of four of the protein. In the adduct, as shown in Fig. 4A, it is seen to be reduced to *ca.* 5 Å. Similar values have been published for cases with other types of organic molecules against the NTD domain of nucleocapsid protein [53]. A decrease in RMSF in the red curve and an increase in the dark curve in the same region can be seen, which corresponds to two other chains of the protein. Overall, the ligand binding to the protein has resulted in some reduction of RMSF of the alpha carbon atoms of the protein that could be proposed as induction of stability to the system. The presence of large fluctuations in some parts of the structure could be responsible for the wavy nature of the ligand RMSD curve since the residues undergo significant motion during the simulation. The twisted geometry of the anti-parallel beta sheets at the proximity of the docked ligand might also be a determining factor. Large RMSF has been reported for the protein in complex with the hit molecules [23, 54]. The difference in RMSF of the residues from 10 ns server-based MDS as shown in Additional file 1: Fig. S1, reveals the presence of more peaks at the negative side relative to that at the positive side, with the overall value being negative. This implies that the fluctuation of residues is reduced when a ligand binds to it, providing further support for the stability of the adduct from a different approach.

Fig. 5 [Images not available. See PDF.]

RMSF of amino acid residues of protein in **A** nucleocapsid-CBN19 adduct and **B** apo structure of nucleocapsid protein derived from two separate 90 ns MDS (the four colors correspond to the four chains of the receptor and NOT to the ligands as in the other figures)

The R_g of protein in protein-CBN19 complex (dark curve of Fig. 6A) of *ca.* 2.5 nm is similar to that reported by Suravajhala et al. [21] and is smaller than that reported by Ribeiro-Filho et al. [55]. SASA (brown curve of Fig. 6A) of *ca.* 273 nm^2 is slightly outside the range 230–260 nm^2 as reported for the Curcumin molecule and nucleocapsid receptor complex [21]. Both the geometrical parameters suggest inherent intactness (no significant expansion or contraction) of the protein in the adduct during the production run.

Fig. 6 [Images not available. See PDF.]

A Radius of gyration (dark) of protein and SASA (brown) of protein in the adduct **B** Variation of hydrogen bond count in the adduct during 90 ns production run

The number of hydrogen bonds between the receptor and the ligand in the adduct during the MDS changed from

null up to 10, as shown in Fig. 6B, with maximum frames having 4 or 5. The number of hydrogen bonds stayed up to 5 ± 1 at the equilibrated part of the trajectory and contributed significantly to the non-covalent binding of the ligand CBN19 with the protein. It might be the causative factor in the appearance of a smooth curve (dark color) after *ca.* 77 ns up to 85 ns in the RMSD plot, Fig. 4A. The presence of small bumps along the RMSD curve of CBN19 might be due to the fluctuations from the protein backbone. A rise at *ca.* 70 ns in the hydrogen bond count to 10 is reflected by multiple curves (RMSD, SASA and R_g) showing change in ligand orientation and the protein backbone. Similar hydrogen bond count and other parameters have been reported by Dhankhar et al. [53], and therefore, the reliability of the results can be justified. Nonetheless, the lack of appreciable change in the number of hydrogen bonds during the simulation indicated a near-steady nature of interactions between the ligand and the amino acid residues.

The snapshots of nucleocapsid-CBN19 adduct at the active pocket at different time intervals are shown in Fig. 7. The center of mass of the ligand and the structure of the protein backbone are seen to be nearly conserved (comparing snapshots at 1 ns and 90 ns) with a slight variation in the orientation of the ligand. The progressive display of the ligand at the orthosteric site of the receptor during the MDS shows the absence of translational motion. The twisted anti-parallel beta sheets (yellow) seem to show some geometrical changes along with the loop (green) attached to it. The disappearance of the alpha helix structure at the left side of the frame at 30 ns could be correlated to a decrease in hydrogen bond count and is reflected by slightly increased RMSD. The pose of the ligand seems to be maintained with minor variation, which might be due to a change in the location of the protein backbone as a function of temperature. Similar geometrical analysis have been reported on the docked complex of quinoline derivative with M^{pro} of SARS-CoV-2 using snapshots by Singh et al. [56]. Also, Nguyen et al. have studied the druggable targets of dengue and malaria using multiple frames at different times during MDS [57]. The snapshots have revealed that the active site of the protein is capable of holding the docked ligand for sufficient time, which could lead to the disruption or deceleration of metabolic reactions.

Fig. 7 [Images not available. See PDF.]

Snapshots of the active region of the protein-CBN19 complex at different times during MDS (the numbers represent times in nanoseconds)

Spontaneity of the adduct formation reaction

The binding free energy change (ΔG_{BFE}) of complex formation from the protein and the ligand was calculated to be − 47.19 ± 6.24 kcal/mol from the MDS trajectory and − 34.06 kcal/mol from the server-based approach. The spontaneity of the reaction was revealed by the negative values obtained from both the methods. It showed the feasibility of the nucleocapsid-CBN19 adduct formation and the usefulness of the MMGBSA method in estimating the free energies. The multiple components of the free energy changes are shown in the Additional file 2: Table S1.

The in silico results obtained from MDS in terms of RMSD, SASA, R_g, RMSF and hydrogen bond count have established the effectiveness of molecular docking in providing adequate models and parameters reflecting the geometrical stability of the system studied. The thermodynamic parameter has complemented this finding. A comprehensive suggestion would be that the ligand and the protein could form a moderately stable compound in which the docked pose is fairly conserved, that may be suitable for effective inhibition of the protein functioning.

Molecular level analysis of non-covalent interactions in the adduct

The cumulative interactions between the ligand and the amino acid residues of the protein are presented in Fig. 8 in terms of 2D representation. An earlier figure, Fig. 3A, shows the docked position of the ligand at the orthosteric site of the receptor calculated by blind docking and verified again by 5 different ligands. The findings of nondeep cavities

unsuitable as a well-defined active region in the NTD domain for RNA binding have added to the ambiguity of the active site [58]. One side of the pocket is completely hydrophilic (exterior), and the other is hydrophobic (interior). Therefore, the lack of bonding involving electrostatics is seen at the hydrophobic part of the protein and is compensated by the involvement of multiple residues with more than 25 van der Waals interactions.

Fig. 8 [Images not available. See PDF.]

Protein-CBN19 interactions in the 2D projection of the complex with different types of interactions and distances (Å)

The molecular level understanding of the interactions constitutes the knowledge of key amino acid residues involved. There is a presence of disruptive interaction (acceptor-acceptor) from residue THR101 with simultaneous associative interaction through very weak hydrogen bonding at 4.37 Å with different oxygen atoms of the ligand. Another weak hydrogen bonding with THR30 at 3.92 Å and alkyl-related interaction with ARG49 at 5.10 Å are also present. Different sets of key residues have been reported to be involved in binding Ceftriaxone sodium and RNA separately by Luan et al. [58]. The poses with the best binding affinities sorted out based on total energies seem to be acceptable as these form stable complexes with a few non-covalent interactions good enough for inhibiting the protein's functioning. It could be compared with the performance of Ceftriaxone sodium, reported to be an inhibitor of NTD of nucleocapsid protein. For comparative purposes the 2D representation of the adduct formed by the receptor with the reference compound K31 depicting various types of interactions is shown in Fig. 9.

Fig. 9 [Images not available. See PDF.]

Protein-K31 interactions in the 2D projection of the complex with different types of interactions and distances (Å)

The involvement of a common amino acid residue ARG49 with alkyl related hydrophobic interactions and THR101, ILE111, and VAL112 with other different types of binding interactions in both the adducts support the inference that the orthosteric pocket was occupied by the ligands. The presence of larger number of van der Waals bonding with the hit candidate compared to that with the reference ligand could be attributed to better binding affinity and stability of the complex. The 2D representations of other adducts are shown in Additional file 1: Figs. S2–S5.

Discussion

Relative strength of binding of ligands by the protein and stability of adduct

The hit molecule, CBN19, have been found to bind with sufficient strength with the receptor protein relative to other 100 Cucurbitacins, five FDA-approved drugs, and a reference molecule. The strength of interactions is reflected by the binding affinities and the stability of the adduct with time is shown by various geometrical parameters extracted from the MDS. The poses at different times during the MDS production run supported this inference. The presence of weak hydrogen bonding and van der Waals' interactions between the ligand and the amino acid residues seems to be the contributing factor in the conservation of the docked pose at the orthosteric site of the receptor. The molecule could thus be proposed to be a potential inhibitor of the nucleocapsid protein.

Druglikeness and safety

The test compounds seem to have drug-like properties with no observable toxicity. These compounds are present in regularly consumed vegetables, and the administrable dose of each component has to be precisely determined to formulate it as a safe drug candidate that is free from any adverse effects. The proximity of toxic dose amount to its biological activity could be exploited for better therapeutics [59]. The time and dose-dependent cytotoxicity has been reported for Cucurbitacin B [60]. Therefore, the toxicity from the curative effect has to be distinguished by various in vitro and clinical trials [61] and is highly recommended for the future work involving Cucurbitacins.

Validation by thermodynamic parameter

The negative values of binding free energy changes, ΔG_{BFE} obtained from two different methods clearly showed that the adduct formation was spontaneous in nature. It provided additional support for the geometrical stability of the nucleocapsid-CBN19 adduct at the physiological conditions. Therefore, the feasibility of the forward reaction determined from the calculation of the thermodynamic parameter, ΔG_{BFE} strengthened the inferences derived. It supported the molecular docking methodology, observations derived from it, and the geometrical parameters extracted from the MDS. Similar results have been obtained from the models of protein and approved drugs by Chauhan et al. [52]. The findings of this research is in par with the current literature and thus validates the employment of many types of computational methods.

In the end, the results showed that the server-based molecular docking calculations could provide quick and reliable models that could be used further for the stability assessment. The molecular dynamics trajectory of the adduct formed by CBN19 with the target protein hinted at the sufficient sturdiness of the complex as revealed by multiple parameters. However, pharmacokinetics of the molecule and toxicity predictions obligate mandatory experimental verification for the safety of the hit candidate present in different edible sources. The stability analysis of adducts formed by other different classes of organic molecules with nucleocapsid protein would provide comparative basis against the performance of Cucurbitacins. It is being explored along with the derivatives of compound K31 for finding effective and safe drug-like candidates for fighting COVID-19 and related diseases.

Conclusions

Different computational tools were used in screening the phytochemicals (substructures of Cucurbitacin I) of common vegetables for proposing the potential inhibitors of nucleocapsid protein of SARS-CoV-2. A Cucurbitacin, CBN19, was found to be a hit candidate better than 100 other Cucurbitacins, five approved drugs, and a reference molecule based on ligand binding affinity obtained from molecular docking calculations and from geometrical as well as thermodynamic parameters derived from molecular dynamics simulations. Additional experiments are recommended to confirm the drug-like properties and safety of the proposed molecule in terms of toxicity. In summary, accelerated computational assessment of natural product-based bio-active compounds could be systematically performed in low resource settings for designing therapeutics against COVID-19 and extended to other related diseases in accordance with the modern rational drug discovery process.

ABSTRACT (ENGLISH)

Background

The intricate molecular frameworks of natural products with biological activity towards human targets offer academic and industrial chemists an important starting point for next generation drug discovery. With a focus on natural products for the production of diverse small-molecule libraries and the evaluation of uncharted chemical space, several strategies have emerged for achieving selective modulation of disease-associated targets. This review highlights some of the significant and more recent synthetic strategies inspired by naturally occurring molecular frameworks, aiming at the discovery and development of novel bioactive molecules. We underscore the potential of these innovative strategies with representative examples to forecast their role in addressing the enduring drug design challenge.

Main text

In this review, we discuss these newer natural product-inspired synthetic approaches, among them diversity-oriented synthesis, biology-oriented synthesis, hybrid natural products, diverted total synthesis, pruning natural products, ring distortion of natural products and integrating natural product framework with a bioactive molecule. Selected representative examples associated with these strategies are given to demonstrate how they have been applied to afford desired bioactivity.

Conclusion

This review elaborates several pioneering and emerging strategies inspired from natural product which allows access to the unexplored chemical space to identify novel molecules possessing noteworthy bioactivity. The corresponding examples highlight the success of these strategies in the discovery of novel bioactive molecules which can be further developed in drug discovery and can be novel probes for chemical biology. Although there are

limited number of successful examples, the selectivity, activity, and efficacy associated with natural product-inspired molecules accentuate their importance.

FULL TEXT

Background

Continuing efforts towards the discovery of novel molecules to systematize and expand our knowledge and to understand the biological pathways and modify disease aetiology is of prime importance towards sustaining the quality and longevity of human life [1]. A total of 893 mammal- and pathogen-related molecular targets have been identified upon which marketed drugs act [2]. Meanwhile, the corresponding chemical space is estimated to comprise about 10^{60} drug-like structures/molecules that follow Lipinski's rule of five [3, 4]. Hence, although apparently important, it is very arduous to identify a new molecule out of this vast chemical space which specifically interacts with the defined molecular target [5].

In the early 2000s, combinatorial chemistry became a primary tool for drug discovery [6]. The idea of producing a large library of compounds that can be screened against numerous targets in a brief period of time seemed appealing to pharmaceutical companies and initiated significant industrial efforts [7]. Although substantial investment was made in relation to this concept, the overall success was less than anticipated with a few exceptions, such as the discovery of sorafenib, which is a multikinase inhibitor for the treating advanced renal cancer [8]. The constrained impact of this strategy can be attributed to the fact that molecules obtained by it were concentrated on a relatively small area of chemical space, and potential molecular diversity remained unexplored. Conversely, the chemical space occupied by natural products encompasses a vast chemical space [9].

For centuries, nature has been the source of medicinal compounds for the treatment of a wide spectrum of diseases [10]. The stunning structural and chemical diversity offered by natural products has revitalized, in multiple phases, the interest of medicinal chemists to take advantage of such chemotypes for drug discovery [11]. Natural products may differ significantly from easily accessible synthetic drug candidates [12]. They often feature versatile structural and physical properties such as a large number of stereogenic centres, sp^3-hybridized atoms and variable molecular mass as well as octanol–water partition coefficient. Moreover, they also tend to have a high oxygen content and to contain aliphatic ring systems and therefore display an intricate three-dimensional geometry [13]. Thus, the innovative design of a library of molecules based on natural product frameworks can in principle be propelled by applying specific strategies to synthesize arrays of novel bioactive compounds [14]. To achieve this goal, in the past two decades, several named concepts have been developed to address the unceasing drug discovery challenge [15]. In this review, we discuss these newer natural product-inspired synthetic approaches, among them diversity-oriented synthesis (DOS), biology-oriented synthesis (BIOS), hybrid natural products(HNPs), diverted total synthesis (DTS), pruning natural products (PNP), ring distortion of natural products(RDNPs) and integrating natural product framework with a bioactive molecule (iNPBM). Selected representative examples associated with these strategies are given to demonstrate how they have been applied to afford desired bioactivity.

Diversity-oriented synthesis (DOS)

Shortly after the period of thorough investigation of the potential of combinatorial chemistry, efforts were made towards increasing functional and structural diversity of the prepared compounds [16]. Generally speaking, diversity-oriented synthesis (DOS) was developed to rapidly generate libraries of compounds of high structural and skeletal variety [17]. DOS utilizes multicomponent reactions, complexity-generating transformations, stereoselective synthesis and branching pathways. It also includes so-called forward synthetic analysis in order to enter a comparatively large chemical space [18]. Typically, no more than five transformations, efficient as well as modular synthesis and scaffold diversity within the library of compounds are anticipated to provide novel hit compounds to accelerate drug discovery (Fig. 1) [19].

Fig. 1 [Images not available. See PDF.]

Schematic representation of the concept of diversity-oriented synthesis. (To generate a small-molecule collection

with a high degree of structural, and thus functional, diversity that interrogates large areas of chemical space simultaneously.) [16].

Generally, DOS was soon able to generate diverse libraries of compounds in a short span time; the molecules were screened across several targets randomly and were not directed towards specific biological targets or disease. In recent years, utilizing natural product frameworks as an origin or synthesis of a natural product-like DOS libraries has transformed the traditional DOS strategy. Natural product-based DOS library is more markedly directed towards a specific biological target. There must be, like in all cases of desired changes of the function of a protein or other target, a structural fit between the target and the modulating ligand. Identification of the binding site is helpful and crucial when it comes to narrowing the chemical space of the synthesized bioactive molecule [20]. The following are two representative examples of DOS modulating a specific biological target, as by disrupting protein–protein interaction and the discovery of new antibiotics to emphasize the potential of natural product-inspired diversity-oriented synthesis (DOS) as a dynamic tool for the discovery of novel bioactive molecules.

Many cell functions, physiological processes, and disease mechanisms comprise protein–protein interactions involving electrostatic interactions and other intermolecular forces. Thus, modulating protein–protein interaction is one of the attractive drug discovery concepts [21]. However, multiple binding sites, a high number of non-specific binding interactions and also a lack of generally applicable reliable screening assays make protein–protein interactions difficult basic strategy of drug discovery [22].

One such a protein–protein interaction pathway, named Hedgehog signalling pathway involving the protein *Sonic Hedgehog (Shh),* regulates cell proliferation as well as differentiation and is crucial for proper embryonic development. The Hedgehog signalling cascade is initiated by auto-cleavage of full-length Shh to an active N-terminal fragment (ShhN) upon its binding to 12-pass transmembrane receptor Patched (Patch1). It results into the reversal of the inhibitory effect on Smoothened (Smo) and releases Glioma (Gli) transcription factor. This mechanism regulates the transcription of gene Gli1 and Ptc1. The aberrant Shh pathway activity due to mutation of the gene is associated with the initiation of tumorigenesis [23]. The discovery of novel molecules which can modulate Shh signalling pathway have been proposed as one of the potential therapeutic strategy for treating the pancreatic cancer, basal cell carcinoma (BCC), medulloblastoma, prostate cancer and associated disorders (Fig. 2) [24, 25].

Fig. 2 [Images not available. See PDF.]

Schematic diagram showing robotnikin inhibits the induction of the Shh pathway [25]. (Robotnikinin is a small molecule capable of binding to and inhibiting the activity of Sonic Hedgehog (Shh) signaling up stream of Smoothened)

The bioactive, naturally occurring macrolactones such as pikromycin, erythromycin, enterobactin, and epothilones are known to act through changing different protein–protein interactions. Based on macrolactone framework **1**, Schreiber et al. synthesized a library of about 2070 small molecules (SM) and screened it for its binding with bacterially expressed protein—N-terminal sonic hedgehog protein (ShhN) to identify several new bioactive macrolactone structures (Fig. 3) [26]. Lead optimization on the initial hit compound **2** by ring contraction resulted in the identification of robotnikin (**3**), which displays strong and concentration-dependent inhibition of Gli expression with an EC_{50} value of 4 μM and EC_{max} reaching 91% (Fig. 3). This pronounced activity renders **3** a promising small-molecule probe of the Hedgehog signalling pathway [27].

Fig. 3 [Images not available. See PDF.]

Small-molecule modulators of Shh pathway discovered by DOS strategy with enhanced bioactivity

In another notable example of utilizing natural product frameworks in DOS, Spring and coworkers have discovered new antibiotics against the methicillin-resistant *Staphylococcus aureus* (MRSA) [28]. Since discovery of Penicillin in the 1930s, antibiotics have revolutionized modern medicine and played in important role in improving the quality of life as well as the life expectancy [29].

However, over-prescription of antibiotics and their use without professional advice have given rise to drug-resistant microbes also termed ‘superbugs’ [30]. The alarming increase in resistance warrants immediate discovery of novel antibacterial compounds against multidrug-resistant bacteria such as MRSA [15, 31].

Spring and co-worker have synthesized a DOS library of about 242 molecules of 18 different natural product-like frameworks (**8**–**25**) from a solid-supported phosphonate (**4**) as a starting material [28]. Reaction of **4** with different aldehydes was done in step 1 to synthesize twelve different α,β-unsaturated acyl-imidazolidinones (Fig. 4). In the second step, pluripotent **5** is diversified via [3 + 2] cycloaddition, dihydroxylation, and [4 + 2] cycloaddition to generate further branch point substrates **7**–**9**. These molecules serve as intermediate compounds for the series of versatile organic reactions. Compounds **7** and **8** were further diversified into **10**–**13** and **14**/**15**; norbornene intermediate **9** was transformed into the five different scaffolds **16**–**20**. In step 4, further complexity and diversity was added to generate **21**–**25**. In the final step of purification, the compounds were hydrolysed from the silyl-polystyrene solid support resin and evaluated with regard to their *in vitro* bactericidal activity against two UK epidemic methicillin-resistant strains (EMRSA 15 and EMRSA 16) as well as three different strains of *S. aureus*: a methicillin-susceptible S. aureus (MSSA). In particular, they discovered three novel compounds (**26**–**28**) with growth inhibition against the three strains of *S. aureus*.

Library of 242 DOS compounds synthesized to study antibacterial activity [20]. Reagents and conditions: **a** LiBr, 1,8-diazabicyclo[5.4.0]undec-7-ene, R1 CHO, MeCN; **b** (R)-QUINAP, AgOAc, iPr2NEt, THF, 788C!258C; **c** AD-mix, (DHQD)PHAL, THF/H2O (1:1); **d** chiral bis(oxazoline), Cu(OTf)2, 3 E M.S., CH2Cl2, C5H6; **e** R2 COCl, DMAP, pyridine, CH2Cl2; **f** R3 CHO, BH3·pyridine, MeOH; **g** SOCl2, pyridine, CH2Cl2, 40 8C; **h** R4 Br, Ag2O, CH2Cl2, 40 8C; **i** R5 C(O)R5, TsOH, DMF, 658C; **j** R6 CHO, TsOH, DMF, 65 8C; **k** NaN3, DMF, 1008C then dimethyl acetylenedicarboxylate, PhMe, 658C; **l** mCPBA, CH2Cl2 then MeOH, 658C; **m** CH2=CHCO2Bn, PhMe, 1208C, Grubbs II, CH2=CH2; **n** OsO4, NMO, CH3C(O)CH3/ H2O (10:1); **o** RNH2, Me2AlCl, PhMe 1208C; then NaH, R11X, DMF, THF; then PhMe, 1208C, Grubbs II, CH2=CH2; **p** NaIO4, THF/H2O (1:1); then R7 NH2, NaB(OAc)3H, CH2Cl2; **q** NaIO4, THF/H2O (1:1); then R8 NHR8, NaB(OAc)3H, CH2Cl2; **r** R9 CHO, DMF, TsOH, 60 8C; **s** R10C(O)R10, DMF, TsOH, 608C. DMF = N,N-dimethylformamide, THF = tetrahydrofuran, DMAP = N,N-dimethylaminopyridine, (DHQD)PHAL = hydroquinidine 1,4-phthalazinediyl diether, mCPBA = meta-chloroperbenzoic acid, Ts = para-toluenesulfonyl, Grubbs II = 1,3-(bis-(mesityl)-2-imidazolidinyl-idene) dichloro (phenylmethylene) (tricyclohexylphosphine) ruthenium, NMO = 4-methylmorpholine-N-oxide, OTf = CF3SO3, Bn = benzyl, QUINAP = 1-(2-diphenylphosphino-1-naphthyl)isoquinoline

One compound named gemmacin (**26**) was found to be a broad-spectrum antibiotic to inhibit the Gram-positive bacteria and to exhibit lower cytotoxicity against human epithelial cells (Table 1).

Table 1. Antibiotic activity of compounds synthesized from DOS strategy [20]

Based on these two examples, one can see that diversity-oriented synthesis (DOS) of libraries of natural product (NP)-like molecules is capable of providing efficient skeletal diversity to explore biorelevant chemical space and opens a new direction for the discovery of bioactive molecules.

Hybrid natural products (HNP)

In developing potential therapeutics, it is important to limit the number of biologically inactive molecules; that is, synthetic efforts should ideally be focused and not produce irrelevant compounds. Taking advantage of the activity and specificity of known, naturally occurring systems, Tietze [32] and Mehta [33] have proposed the concept of hybrid natural products for drug discovery. In fact, in nature, there are several such naturally occurring natural product hybrids. One such an example is the indole alkaloid vincristine (**29**) which is used for the treatment of lymphatic leukaemia [34]. It is a hybrid of vindoline (**31**) [35], which belongs to the *Aspidosperma* alkaloid family and catharanthine (**30**) [36], which belongs to the *Iboga* class of alkaloids (Fig. 5). The individual monomers exhibit no significant activity, whereas **19** possesses pronounced bioactivity as well as specificity.

Fig. 5 [Images not available. See PDF.]

Naturally occurring hybrid molecules. (Molecular structure of ibogaine, vindoline, vincristine). The structure of vincristine, two vinca alkaloids, are formed by two polycyclic moieties, namely vindoline (red) and catharanthine (blue). The catharanthine portion is also the basic motif found in the ibogaine molecule.)

Generally speaking, artificially linking two or more natural products may result in the creation of hybrid molecules with improved bioactivity that differs from those of its parent molecules. Based on this concept, natural product hybrid of geldanamycin (**32**) and estradiol (**33**) have been prepared and evaluated for its bioactivity, in particular, antimicrobial activity (Fig. 6). Compound **32** is an ansamycin antibiotic isolated from *Streptomyces hygroscopicus* and also effectively inhibits human epidermal growth factor receptor (HER2) kinases [37]. On the other hand, **33** induces selective degradation of certain oestrogen receptors (ER) [38]. The estradiol-geldanamycin hybrid compounds **34** were found to be more selective than **32** in inhibiting HER2 and ER in breast cancer cell line MCF7 [39].

Fig. 6 [Images not available. See PDF.]

Hybrid natural products synthesized from geldanamycin and estradiol

Many such natural product (NP) hybrids display exceedingly higher biological activity than their isolated parent natural molecules. Nonetheless, covalent linkage of two bioactive compounds does not necessarily lead to a overall improved desired properties. The oxindole containing natural product quinocarcin (**35**) [40] is isolated from *Streptomyces melunovinuceus*, displaying prominent antitumour activity [41]. It inspired Williams and coworkers to combine **35** with the natural product netropsin (**36**). However, the quinocarcin–netropsin hybrid **37** was found to display lower biological activity than its parent molecules (Fig. 7) [42].

Fig. 7 [Images not available. See PDF.]

Hybrid natural product synthesized from quinocarcin and netropsin

The hybrid natural product is one of the newer natural product-inspired synthetic approaches, which can provide access to unique combinations of existing natural fragments. Although only a limited number of hybrid molecules have been synthesized to date, mainly for the development of new antibiotics and anticancer agents, the bioactivity associated with these hybrid molecules emphasizes the promising role of HNP for future drug discovery.

Biology-oriented synthesis (BIOS)

Combinatorial chemistry and DOS generate very large libraries to be screened against multiple different targets and hence potentially make the overall process highly expensive [43]. Therefore, to limit the number of molecules for biological studies, a unique structure-based approach named biology-oriented synthesis (BIOS) was introduced by Waldman and co-workers (Fig. 8) [44]. This approach takes into account the structural conservatism during evolution of the chemical space of target proteins and also natural products (NP) modulating them. The structural conservatism within protein families limits the number of small molecules and binding sites. The systematic structural analysis of proteins, namely 3D structure, sequence homology and classifying the small molecules which modulate them, is supposed to lead to the discovery of novel bioactive molecules. The applications lie, more generally speaking, in chemical biology as well as medicinal chemistry [45]. Waldmann and coworkers have invented a cheminformatics tool ‘structural classification of natural products’ (SCONP). Relatively complex natural products (such as **38** and **39**) are reduced to core scaffolds by holding bioactivity as a main guiding principle. Decorating the cores with new groups generates a so-called natural product structural tree, which is investigated in terms of target modulation and also further improved [46].

Fig. 8 [Images not available. See PDF.]

Schematic representation of the concept of biology-oriented synthesis depicting scaffold-substituent analogy between small molecules and protein adapted from ref. 44 (https://doi.org/10.1002/anie.201007004) with permission). (The small-molecule scaffold determines the spatial orientation of the substituents, whereas the protein

subfold arranges the amino acid side chains spatially. Binding occurs when compatible substituents match in their spatial positioning so they can interact.)

Thus, a library of a limited number of molecules (**40**,**41**) synthesized based on the BIOS concept may have added relevance to specified target/s and thus increases chances of displaying the desired bioactivity [47]. This BIOS strategy has been effectively applied for discovery of several novel bioactive molecules, as exemplified in the following [48].

The progressive degeneration of neuron and loss of neural activity is associated with many neurodegenerative disorders. Discovery of novel molecules which can promote neurite growth and restore neuronal viability or which can prevent neuronal decline is utmost important [49]. Towards the development of novel neurite growth-promoting compounds, Waldmann and coworkers have utilized the BIOS approach based on the iridoid scaffolds silphinene (**42**) as well as harpagide (**43**) and rhynchophylline (**44**), which belongs to the secoyohimbane class of compounds (Fig. 9) [50]. All of these are known to possess neurotropic and neuroprotective activity [51].

Fig. 9 [Images not available. See PDF.]

Iridoid and secoyohimbane scaffold-inspired synthesis of BIOS library for discovery of neurite growth-promoting compounds

A library of 54 iridoid analogues (**48**) were synthesized by a [3 + 2] cycloaddition/Baeyer–Villiger oxidation sequence, and library of 56 secoyohimbane-related compounds (**52**) by enantioselective and organocatalysis. They were screened in phenotypic assays with respect to the modulation of neurite outgrowth. These assays were able to identify several new molecules (**53**–**56**) possessing growth-promoting properties, and which can be used as chemical probes for studying neurodevelopmental process (Fig. 9) [52].

The enzyme 11β-Hydroxysteroid dehydrogenase type 1 (11βHSD1) is NADPH-dependent enzyme which activates glucocorticoid hormones (GCs). Glucocorticoids regulate various physiological processes including glucose and lipid metabolism, and increased levels may result in various metabolic syndromes, such as hypertension, type 2 diabetes, and dyslipidemia [53]. Thus, selective inhibition of 11βHSD1 is an important strategy for the treatment of these syndromes [54]. The BIOS approach, by combining protein structure similarity clustering (PSSC) [55] and SCONP, was applied to the discovery of novel and selective 11βHSD1 inhibitors (Fig. 10) [56]. Analysis of PSSC of 11βHSD1 and dual specificity phosphatase (Cdc25 A) and acetylcholine esterase (AChE) revealed that the active site and position of the catalytic amino acid residue show very good overlap in these three proteins. Although the functions of 11βHSD1, Cdc25 A and AChE are different, the similarity of active sites indicates that the molecules which can modulate the Cdc25 A and AChE have the potential to modulate 11βHSD1. Generating PSSC analysis and SCONP analysis of related natural products can therefore lead to the identification of novel 11βHSD1 modulators [57]. Consequently, a SCONP tree was constructed by the software, based on the natural product dysidiolide (**57**) [58], which is known to inhibit Cdc25A, and glycyrrhetinic acid (**58**), which is a known 11bHSD ligand.

Fig. 10 [Images not available. See PDF.]

SCONP analysis of natural products dysidiolide and glycyrrhetinic acid for identification of selective 11bHSD1 inhibitor using BIOS [44] and PSSC analysis of the superimposed catalytic sites of Cdc25A (red), 11_HSD1 (green), and AChE (blue) [46]

This analysis of multicyclic natural products led the researchers to identify decalin scaffolds **IV** and **VI**, which were presumed to be privileged cores associated with activity changes in 11βHSD1, Cdc25 A, and AChE. A natural product-inspired library of 483 compounds was synthesized and screened for their activity against 11βHSD1. Combining PSSC and SCONP led to the discovery of several new 11βHSD1 inhibitors **59**–**62**, acting at the nanomolar concentration level in vitro. Additionally **59** displays selective in vivo cellular inhibition of 11βHSD1 [46]. These representative examples emphasize the importance of the BIOS strategy in the efficient discovery of novel bioactive molecules [55].

Diverted total synthesis (DTS)

Danishefsky *et al.* purported a different concept 'diverted total synthesis', for discovery of novel bioactive compounds [59]. It is based on developing a smaller library of compounds by using and diverting the intermediates formed during the total synthesis of small-molecule natural products (SMNPs) [60]. Starting from building blocks **A**, the complexity and diversity associated with synthetic intermediates **B**, obtained during total synthesis of natural product (NP) **C** will allow access towards uncharted chemical space (Fig. 11). Such space would otherwise not be accessible due to limitations levied by biosynthetic pathways or by direct modification of parent natural products **C**.

Fig. 11 [Images not available. See PDF.]

Schematic representation of the concept of diverted total synthesis

Therefore, molecules obtained by DTS might exhibit a upper order of complexity (**D**) or a lower order of complexity (**E**) than **C.** These can be evaluated for their potential biological activity [61].

Such a library of compounds was produced by Danishefsky and coworkers based on the total synthesis of epothilone B (**63**) (Fig. 12). The natural product epothilone B is isolated from mycobacterium *Sorangium cellulosum* and found to exhibit strong in vitro cytotoxicity in multidrug-resistant (MDR) cell line by promoting stabilization of microtubule polymerization, thereby interrupting the cell division and apoptosis. However, in vivo studies revealed that epothilone B was highly toxic to mice, which inspires editing of the epothilone B framework to reduce its toxicity and increase the desired bioactivity. In the course of DTS, compound dEpoB (**64**), lacking the epoxy group, was made and shown to possess remarkably lesser toxicity as anticancer agent. Likewise, 9,10-dehydro-dEpoB (**65**) with added unsaturation was prepared and displayed improved survival rate in mice. Furthermore, fludelone (**66**) was obtained by installing a trifluoromethyl group, resulting more effective for tumour reduction in comparison with all the previous molecules. Eventually, alteration of the heterocyclic moiety leads to the identification of isofludelone (**67**), a promising candidate intended for cancer treatment and currently under pre-clinical trials [59].

Fig. 12 [Images not available. See PDF.]

Discovered novel anticancer compounds from the diverted total synthesis of Epothilone B with modulating the bioactivity

Pruning biomolecules and natural products (PBNP)

The structure of natural products (NPs) varies from simple frameworks to highly complex 3D architectures. The preparation of bioactive natural products with higher complexity poses a enormous challenge for the synthetic organic chemist. In the course of biosynthesis, the biochemical machinery can easily vary the substitution of the core structure in terms of side chains and functional groups, which can lead to different structures and activity of the natural product(s). In many cases, the simplified natural product framework retains substantial bioactivity [62]. Thus, pruning of biomolecules and natural products (PBNP) by systematic identification of the pharmacophore can address the synthetic challenge by reducing the number of chemical steps and may lead to the discovery of novel bioactive molecules [63]. To a certain extent, this approach is related to BIOS but relies primarily on cutting off substituents.

The discovery of eribulin (**69**) from the complex marine natural product halichondrin B (**68**) by Eisai Pharma and Kishi is a prominent example of PBNP for the discovery of anticancer drugs (Fig. 13). Halichondrin B (**68**) was isolated from marine-sponge *Halichondria Okadai*, which is a polyether macrolide [64]. During its total synthesis and biological evaluation, it was found that the right half of the molecule displays cell growth inhibition. The hydrolyzable ester functionality of **68** changed to a non-hydrolyzable bioisostere enhanced the in vivo efficacy. Further synthetic efforts and clinical studies led to the identification of **69** for treating of late-stage breast cancer resistant to other anticancer drugs [65].

Fig. 13 [Images not available. See PDF.]

Pruning of natural product halichondrin B for the discovery of anticancer drug halaven

Another prominent example of PNBP is the discovery of novel migrastatin analogues. Migrastatin (**70**) is macrolactone isolated from *Streptomyces sp.* MK929-43F1 [66] which was found to inhibit cancer cell migration (Fig. 14). During its synthesis and bioevaluation, it was found that its truncated analogue **71** possesses increased activity as compared to the **70** and can be a promising candidate in cancer therapy to address metastasis (Fig. 14) [67].

Fig. 14 [Images not available. See PDF.]

Discovery of novel migrastatin analogue by pruning of natural product

Another example of PBNP is the development of antihypertensive agent rostafuroxin (**73**) (Fig. 15). The natural product ouabain (**72**) from the bark the tree of *Acokanthera ouabaio* is being used as an arrow poison by some of the African tribes. It was also found to be useful for the treatment of cardiac conditions. Ouabain binds to the plasma membrane and inhibits the Na+/K+ATPase in vivo. [68] However, it also has several side effects. The simplified analogue **73** was found to inhibit Na+/K+ATPase more selectively, without interacting with other receptors which regulate blood pressure; it is now being studied in clinical trials for treating hypertension [69].

Fig. 15 [Images not available. See PDF.]

Pruning of natural product ouabain for the discovery of hypertension drug

Such truncated or simplified natural product obtained by PBNP will also not only help to gain insight into the role of the natural product during its evolution and biological processes but also directs the discovery of novel modulators of the biological targets.

Ring distortion of natural products (RDNP)

In order to rapidly generate a novel library of drug-like small molecules from a natural product with relatively high structural and complexity, Hergenrother has reported a ‘ring distortion strategy’. In this approach, natural products with of a given framework, such as the 5,6,6-fused tricyclic system **74**, are converted into different core scaffolds by applying a minimum number of steps (Fig. 16). In this process, a distinct series of molecules is synthesized by taking inspiration from the biosynthetic pathway, which often creates diverse compounds from a common intermediate [70]. The ring distortion approach involves chemoselective transformations such as ring cleavage, expansion, fusion, as well as rearrangement, leading to systematically altered scaffolds such as **75**–**78** [71]. This strategy was exhibited for the production of different analogues of three readily available natural products, namely gibberellic acid (**79**), adrenosterone (**80**), and quinine (**81**) (Fig. 17). The RDNP produced 19, 18, and 12 diverse compounds, respectively, from these natural products.

Fig. 16 [Images not available. See PDF.]

Schematic representation of strategy ring distortion of natural product. (Ring-distortion reactions can be used readily to convert natural products into complex and diverse scaffolds.)

Fig. 17 [Images not available. See PDF.]

Natural products for the synthesis of novel library of compounds by RDNP

These compounds were studied by cheminformatics techniques for correlation between structural features and potential biological activity [72]. The detailed results of bioactivity studies have not been disclosed yet.

Indole-containing compounds are abundant in nature, interacting with numerous biological targets and therefore displaying diverse biological activity. The alkaloid yohimbine (**82**), isolated from the bark of *Pausinystalia johimbe*, is known to inhibit the α2-adrenergic receptor (Fig. 18). This readily available natural product, which contains a complex multicyclic structure with a fused indole system, was the starting point for an extended RDNP study to rapidly generate a library of 70 diverse and complex compounds. The yohimbine ring distortion (RDNP) library was screened for bioactivity in processes linked inhibition to cancer, inflammation, and against pathogenic bacterial strains, whereby several hit compounds were identified (Fig. 19). One of the compounds, **83**, was found to exhibit

promising anti-inflammatory as well as hypoxia-inducible factors to display (HIF)-dependent anticancer activity [73]. Furthermore, the compounds **84** and **85** were found to be activators of the Nrf2-ARE pathway. The transcription factor Nrf2 (Nuclear erythroid 2-related factor 2) selectively binds to antioxidant responsive element (ARE). Activation of Nrf2/ARE signalling pathway generally protects mammalian cells from impending oxidative stress-induced cell death. Thus, compounds which have ability to modulate Nrf2/ARE can be prophylactive agents against cancer [74].

Fig. 18 [Images not available. See PDF.]

Ring distortion of yohimbine for the discovery of novel bioactive molecules [75]

Fig. 19 [Images not available. See PDF.]

Bioactive compounds from RDS of yohimbine

Conversely, Nrf2/ARE inhibitors render cancers cells more susceptible to chemotherapy. The compounds **86**–**88** were found to be selective inhibitors of Nrf2/ARE [75].

Although the availability of pure natural products isolated from natural resources limits the scope of RDNP, the systematic application of this strategy offers a convenient approach towards expanding biorelevant chemical space.

Integrating natural product framework with bioactive molecules (*i*NPBM)

Pandey et al. have introduced a distinct methodology of integrating natural product framework with synthetic bioactive molecules (*i*NPBM) [76]. This concept takes into consideration that increased bioactivity may result from the designed structural combination of a natural product with a synthetic pharmacophore. Schematically, this is exemplified in Fig. 20; a natural product framework (**A**), that possess limited biological activity against specified target, is integrated with a synthetic bioactive molecule (**B**), featuring one common structural motif, to afford the integrated molecules (**C** and **D**).

Fig. 20 [Images not available. See PDF.]

Schematic representation of strategy integrating natural product and bioactive molecule for the discovery of novel bioactive molecules

The resulting molecules ideally combine the bioactivity as well as selectivity of both molecules to exhibit highly enhanced therapeutic activity in comparison with their parent compounds.

The widely distributed five distinct human muscarinic receptors (M1-M5) belong to family of G-protein-coupled receptors (GPCR) and are proven to regulate numerous essential processes of the central and peripheral nervous system. Gephyrotoxin (**89**) is an alkaloid obtained from the frog *Dendrobates histrionicus* and exhibits mild-antimuscarinic activity (Fig. 21). For the discovery of novel muscarinic receptor modulators, this natural product gephyrotoxin was combined with isoindolines (**90**) [77] which display a wide spectrum of bioactivities. The presence of the common pyrrolidine ring was the basis for the design of integrated multicyclic molecules, such as **91** and **92**. A library of these integrated structures was synthesized and screened against various muscarinic receptors. A few of them turned out to be hit molecules featuring specific modulation of muscarinic receptor.

Fig. 21 [Images not available. See PDF.]

Schematic representation of *i*NPBM strategy for identification of isoindolyl-gephyrotoxin frameworks for the discovery of novel muscarinic receptor modulators [76]

Compound **93** was found to be a potent M2 agonist with activity of <4 nM and to be helpful in alleviating cognitive deficiency in a mouse model (Fig. 22) [78]. Moreover, compounds **94** and **95** are moderate and selective M2 agonists. On the other hand, compounds **96** and **97** act as selective M3 antagonist with activity of <1 nM and might be further improved for treating respiratory disorders [79]. As illustrated by this study, the *i*NPBM approach suggests an unique strategy towards the discovery of receptor protein modulators alongside promising therapeutic implications.

Fig. 22 [Images not available. See PDF.]

Selective muscarinic receptor modulators discovered by iNPBM strategy

Miscellaneous strategies

Waldmann and co-workers reported designed pseudo-natural products by using different combination of natural products and fragment-based compound development to afford novel performance-based diverse natural products displaying varying biological activity [80]. A natural product library of 244 member pseudo-natural products are designed by using indole-containing or chromanone containing fragments with natural product quinine, quinidine, sinomenine, and griseofulvin (**98–102** Fig. 23).

Fig. 23 [Images not available. See PDF.]

Combination of indole and chromanone with natural product fragments of quinine and quinidine

These fusion of NP fragments with different combinations provided pseudo-natural product compounds which spans over wide chemical space to display diverse bioactivity. The cheminformatic analysis suggests several compounds could exhibit both drug-like and natural product-like properties.

Recent updates

In additional example, Duttwyler and coworkers fused boron clusters with natural products to explore bioactivity of resultant natural product-boron cluster hybrids [81]. Stereoselective B-H activation was achieved to afford asymmetric boron cluster by fusing natural products camphanic acid and menthol **103–106 (**Fig. 24). Several of resulting compound displayed excellent bactericidal properties against Gram-positive as well and Gram-negative bacterium strains with bioactivity up to 2-ug/Ml.

Fig. 24 [Images not available. See PDF.]

Fusing natural product camphanic acid and menthol with boron clusters

These results open up new space for the discovery of novel bioactive dodecaborate cages having diverse antimicrobial properties by fusing with suitable natural products (NP).

Zou and coworkers have recently reported efficient construction of 1,3-indanedione-based tetrahydroquinolines based on biology-oriented synthesis (BIOS). Spirocyclic tetrahydroquinoline and Spiroindane-1,3-dione were selected natural products for guiding the BIOS approach. Various 2-arylidene-1,3-indanediones reacted with different vinyl benzoxazinanones by using Pd catalyst to provide novel library of spirocyclic tetrahydroquinolines (Fig. 25).

Fig. 25 [Images not available. See PDF.]

1,3-Indanedione-based tetrahydroquinolines based on biology-oriented synthesis (BIOS)

Two of the synthesized products **114** and **115** display remarkable activity by inducing apoptosis in A549 human lung cancer cells [82].

Natural products and molecular modelling for drug discovery

Bioactive natural products are vital starting points for crafting newer and improved analogues through advanced medicinal chemistry techniques like molecular modelling. Natural products and its analogues are rigorously studied through SAR analysis and molecular modelling to enhance potency, reduce toxicity, and optimize pharmacokinetics. Interactions with various ligands/target proteins are crucial in determining biological activity. The most promising analogues undergo synthesis and thorough evaluation via in vitro and in vivo assays, culminating in the development of optimized drug candidates. The overall process of molecular modelling involves in silico ligand construction and preparation, target preparation, docking, identification of hit molecule, and optimization of hits [83]. Software like Schrödinger, AutoDock Vina, Discovery Studio and optimization software such as Chimera, Chem 3D Ultra, and Avogadro are employed for molecular modelling. Initially, optimized 3D structures of ligands/targets in PDB format can be obtained from databases like PUBCHEM, while ZINC database provides access to structures of

known natural products. In silico ligand construction involves geometry optimization to achieve minimal energy levels before docking. After energy minimization, the binding site for natural ligands within the target must be defined during target preparation. Subsequently, the 3D structures of natural products and their analogues are docked against the specified target using docking software to assess binding energy and analyse intermolecular binding interactions. The docking simulation results are then scrutinized to identify the top interactions. Based on interaction rankings, hit molecules exhibiting high affinity towards the target are identified. Further optimization of hit involves studying various analogues of hit molecules with improved drug-like properties using QSAR software, including stability, pharmacokinetic, and pharmacodynamic properties. Thus, molecular modelling enables the identification of potential hits for a target biological activity and facilitates establishing a robust structure–activity relationship (SAR) during lead optimization. This process effectively narrows down the pool of compounds for real testing through bioassays [84].

Very recently, Stefan Gahbauer and coworkers utilized computational design to discover potent inhibitors targeting the NSP3 macrodomain of SARS-CoV-2 with low- to sub-micromolar affinity. Ligands were designed by amalgamating small-molecule fragments and employing ultra-large library docking of 450 million molecules. In total, 160 ligands across 119 different scaffolds were identified, accompanied by the determination of 152 Mac1-ligand complex crystal structures. This approach led to the discovery of several selective and cell-permeable molecules, paving the way for developing novel antiviral therapeutics for SARS-CoV-2 (Fig. 26) [85].

Fig. 26 [Images not available. See PDF.]

Discovery of ligands that bind to the NSP3 macrodomain of SARS-CoV-2 (Mac1)

Conclusions

Natural products (NPs) have always been a source of inspiration for designing novel drug-like molecules which largely relied on trial and errors assisted by serendipity. The systematic development of synthetic strategies based on logical hypothesis inspired from natural product has revived interest of medicinal chemists in utilizing them for innovative drug discovery. Recently, there has been major advancement in synthetic methodology with development of modern catalyst, advanced reagents which allows rapid derivatization of organic compounds. These coupled with contemporary development in computational tools for designing molecules, docking software, and biological screening allow swift detection of hit molecule for further drug development. This review elaborates several pioneering and emerging strategies inspired from natural product which allows access to the unexplored chemical space to identify novel molecules possessing noteworthy bioactivity (Table 2). The corresponding examples highlight the success of these strategies in the discovery of novel bioactive molecules which can be further developed in drug discovery and can be novel probes for chemical biology. Although there are limited number of successful examples, the selectivity, activity, and efficacy associated with natural product-inspired molecules accentuate their importance. Acknowledging the need for substantial further advancement, we anticipate that integrating natural product-inspired synthetic strategies with advance computational techniques involving molecular modelling will become a prevalent approach in modern drug discovery.

Author contributions

PP was involved in conceptualization, methodology, data curation, and drafting the paper; Dr SG was responsible for study, drafting the paper, and critical revision; Dr AJ contributed to data curation, conceptualization, and formal analysis; and all authors have read and approved the final manuscript.

Funding

This work was not supported by any funding agencies.

Availability of data and materials

The data that support the findings of this study are available from the corresponding author, upon reasonable

request.

Declarations

Ethics approval and consent to participate

Not applicable.

Competing interests

The authors declare no competing interests.

Abbreviations

ARE
Antioxidant responsive element
BCC
Basal cell carcinoma
BIOS
Biology-oriented synthesis
DOS
Diversity-oriented synthesis
DTS
Diverted total synthesis
ER
Oestrogen receptors
EMRSA
Epidemic methicillin-resistant strains
GCs
Glucocorticoid hormones
GPCR
G-protein-coupled receptors
HNPs
Hybrid natural products
HER2
Human epidermal growth factor receptor
11βHSD1
11β-Hydroxysteroid dehydrogenase type 1
iNPBM
Integrating natural product framework with a bioactive molecule
MRSA
Methicillin-resistant strains
MSSA
Methicillin-susceptible *S. aureus*
PDB
Protein data bank
NP
Natural product
PNP
Pruning natural products
QSAR
Quantitative structure–activity relationship
RDNPs
Ring distortion of natural products

SARS-CoV-2
Severe Acute Respiratory Syndrome Coronavirus 2
SM
Small molecules
ShhN
N-terminal sonic hedgehog protein
SCONP
Structural classification of natural products

Publisher's Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

ABSTRACT (ENGLISH)

Background

Docetaxel (DTX) finds extensive use in treating various cancers, but its limited solubility, side effects, and multi-drug resistance (MDR) hinder its effectiveness. To enhance DTX's properties, the study aimed to formulate DTX-loaded mixed micelles (MMs) and evaluate their anticancer potential using Quality by Design (QbD) approach. Using solvent evaporation, DTX-loaded MMs were prepared and optimized via a 3^2 full factorial design.

Results

The optimized formulation (R5) displayed a % entrapment efficiency (%EE) of 74.81 ± 4.27%, % drug loading capacity (%DLC) of 29.27 ± 0.70%, and mean particle size (MPS) of 71.4 ± 1.24 nm. TEM images confirmed well-dispersed spherical MMs. Analytical studies (IR, DSC, and *P*-XRD) showed no adverse drug-excipient interactions. The MMs were converted into vacuum foam-dried (VFD) products for enhanced stability. The optimized VFD products exhibited low residual moisture, rapid reconstitution, consistent drug content, and high %EE. Notably, sustained drug release from the VFD product reduced hemolysis and in vitro cytotoxicity against B16F10 melanoma cells.

Conclusion

This study creatively tackled DTX's challenges through targeted MM development, transformed them into VFD products, demonstrating the potential for melanoma treatment. The QbD approach ensures the formulation's safety, efficacy, and quality, underscoring the promising VFD technology and multifunctionality of mixed micelles.

FULL TEXT

Background

Docetaxel (DTX), a BCS Class IV drug, possesses challenges in oral absorption due to its low solubility and low permeability, leading to poor bioavailability [1]. Its narrow therapeutic index and potential side effects necessitate cautious formulation to minimize toxicity and enhance patient tolerability [2]. Improving efficacy with reducing adverse effects on healthy tissue are difficult aspects of targeting cancer cells. Besides, large-scale production transition poses difficulties in maintaining consistency and quality. These considerations are crucial in optimizing docetaxel pharmaceutical properties for effective cancer treatment [3]. Efforts to enhance drug effectiveness have led to advancements in drug delivery technologies. Targeted medication delivery entails selective and effective localization of a pharmacologically active ingredient at a preselected target in therapeutic concentration while limiting

its access to nontarget areas, hence increasing the treatment's effectiveness [4]. Mixed micelles (MMs) refer to micellar systems composed of multiple amphiphilic components that offer targeted drug delivery, enhanced drug loading capacity, and better control over drug release kinetics [5]. Many researchers have formulated DTX MMs to enhance the properties of DTX in various applications. However, these formulations pose challenges due to certain limitations these include MPP, TPGS, and CSO-SA copolymers by thin film hydration method for enhanced oral absorption [6]. However, difficulties with achieving constant film thickness and managing the size and stability of MMs occur when employing the thin film hydration approach for the formulation. A PF127 and Tween 80 MMs gel to address stability and solubility challenges [7]; DTX MMs with TPGS and Poloxamer 188 [8]; a Pluronic P105 and F127 polymeric MMs against taxol-resistant lung cancer [9]; a monomethylol poly(ethylene glycol)-poly(d,l-lactic acid) (MPP) and Pluronic copolymer MM for enhanced bioavailability and overcoming multidrug resistance [10]; and DTX MMs with TPGS and Pluronic F108 for overcoming MDR in cancer [11]. But, TPGS, a surfactant, and solubilizer, have limitations regarding stability, efficacy, and solubility. Besides, Tween 80, another surfactant, may pose concerns about cytotoxicity and adverse effects [12]. Compatibility and phase separation issues should be addressed when employing multiple Pluronic copolymers, like Pluronic P105 and F127. Moreover, it is crucial to note that the MPS of TPGS and Pluronic F108 MMs was observed to be 233 ± 3 nm which exceeds 100 nm, which hinders their ability to leverage the Enhanced Permeability and Retention (EPR) effect for tumor targeting [13]. Hence, careful selection and optimization of MMs composition and method of preparation help to tailor the properties of drug delivery systems to specific cancer treatment needs.

The scalability of solvent evaporation for mixed micelles (MMs) is vital for large-scale production, offering ease of optimization for reproducibility [14]. The cost-effectiveness of this method, coupled with the novel combination of Soluplus® and PF108, enables the modulation of drug release kinetics, addressing challenges associated with maintaining a constant film thickness and managing particle size [15, 16]. By avoiding the use of Tween 80, concerns regarding cytotoxicity and adverse effects are minimized, while ensuring that the MMs achieve a size below 100 nm [17]. Furthermore, in cancer treatment product development, the application of Quality by Design (QbD) principles is pivotal, offering a systematic approach to optimize formulation, manufacturing, and analytical methods for consistent and high-quality cancer therapeutics, ensuring proactive identification and mitigation of risks for safer and more effective treatments [18].

Previous literature shows that nanoparticles, including micelles, often face long-term stability issues, such as aggregation and chemical degradation [19]. To enhance micelle stability, methods like lyophilization, spray drying, membrane extrusion, and coacervation are employed [20], but they face challenges. Lyophilization and spray drying may lead to changes in micelle size [21] and structure, while membrane extrusion can result in the loss of active ingredients [22]. Coacervation may pose difficulties in controlling particle size and stability [23]. Addressing these challenges is crucial for advancing micellar formulations with improved stability and functionality. To overcome these challenges and further enhance the stability of the developed MMs, novel methods like vacuum foam drying (VFD) have been explored in product development. VFD involves the use of foam structures, formed by mixing drug-loaded micelles with a foaming agent, which are then subjected to a VFD [24]. This method allows for the production of solid, porous materials that maintain the structure and stability of micelles, preventing drug leakage and preserving their therapeutic properties [25]. Retaining drug encapsulation effectiveness, improving stability, extending shelf life, and being simple to handle and store are some benefits of VFD.

The objective of this research was to develop DSP-MMs loaded with novel pluronic polymers Soluplus® and PF108 using the solvent evaporation method, for enhanced treatment against melanoma. To accomplish this goal, a QbD approach was employed for the formulation process, focusing on optimizing the MM's quality, efficacy, and stability as given in the Additional file 1: Supplementary Data S1 - Quality by Design Parameters for Formulation Optimization (see Additional file 1 for details). Additionally, the research was focused on exploring the application of VFD as a means to further improve the stability of the DSP MMs, ensuring their suitability for long-term storage and sustained effectiveness in melanoma treatment.

Methods

Materials

Docetaxel was purchased from IQGEN-X Pvt. Ltd, Mumbai, India. Soluplus® was graciously gifted by BASF, India. PF108 was sourced from Sigma-Aldrich, Mumbai. Other chemicals were obtained from Molychem, Mumbai.

Culture medium and cell line

In this study, the B16F10 murine melanoma cell line (ATCC, USA) was obtained from the American Tissue Culture Collection. The stock cultures were then maintained at 37 °C in Dulbecco's Modified Eagle Medium (DMEM) supplemented with fetal bovine serum, and streptomycin (100 µg/mL) under a 5% CO_2 atmosphere. The cells were seeded in a microplate within an artificial womb with 5% CO_2 and incubated at 37 °C for 24 h [9].

Critical micelle concentration determination

The CMC of Soluplus® and PF108, both individually and in combination, was determined using the Iodine (I_2) UV-visible spectrophotometric method. A standard KI/I_2 solution was prepared by dissolving 2 gm of potassium iodide (KI) and 1 gm of iodine (I_2) in deionized water. Solutions of Soluplus®, PF108, and their mixtures at concentrations of 0.00001, 0.00005, 0.0001, 0.0005, 0.001, 0.005, 0.01, 0.05, and 0.1 mM were prepared in double-distilled water (DDW), to which the KI/I_2 solution was added. The samples were stored in the dark at room temperature for 12 h. Subsequently, the absorbance at 366 nm was measured using an Agilent 1800 UV spectrophotometer [12].

Development and optimization of MMs

The development of DTX-loaded Soluplus® with PF108 MMs (DSP-MMs) involved the utilization of the most efficient and scalable solvent evaporation method. Sonication was employed for 5 min to dissolve a combination of DTX and copolymer in methanol, which was gradually added drop by drop to distilled water under continuous stirring. The evaporation of methanol at room temperature was facilitated through continued stirring until a clear supernatant of DSP-MMs was obtained after centrifugation. Blank MMs were also prepared without the addition of DTX.

For optimizing the DSP-MMs, a highly efficient 3^2 full factorial design was employed. The design focused on two independent variables the concentration of Soluplus® (X_1) and PF108 (X_2). The study considered two dependent variables, namely % entrapment efficiency (%EE; Y_1) and mean particle size (MPS; Y_2). To determine suitable levels of the independent variables, a preliminary screening was conducted, and each factor was assigned values of − 1, 0, and + 1, as for the concentration of Soluplus® (X_1), levels were set at 182 mg, 364.5 mg, and 547 mg. Likewise, for the concentration of PF108 (X_2), levels were defined as 22 mg, 44.5 mg, and 67 mg. The statistical analysis was carried out using Design Expert® VR software. Analysis of variance (ANOVA) was employed to assess the significance of the model. The coefficients of magnitude were calculated based on the polynomial equations, and p values were used to determine the statistical significance (p <0.05) [9].

Evaluation of DSP-MMs

Entrapment efficiency and drug loading capacity (DLC)

The concentration of DTX in DSP-MMs was measured by diluting 1 mL of DSP-MMs supernatant with methanol to 10 mL and sonicating for 5 min. The resulting solutions were spectrophotometrically scanned at 230 nm using a UV–visible spectrophotometer (Model UV-1900, Shimadzu) equipped with a high-quality quartz UV cell designed to accommodate standard cuvettes with a 1 cm path length, facilitating accurate estimation of the DTX concentration. Substituting values in the following formulae, the %EE and %DLC of DSP-MMs were determined [26]. The %EE and %DLC of DSP-MMs were calculated by substituting values in Eq. 1 and Eq. 2 respectively [26].

1

%EE=Weight of drug in micellesWeight of drug taken initially×100

2

%DLC=Weight of drug in micellesWeight of drug fed initially+Weight of copolymers×100.

Mean particle size (MPS) and zeta potential (ZP):

The Horiba particle size analyzer (Horiba SZ-100, ver. 2.40) was used to determine the MPS and ZP of DSP MMs. The dynamic light scattering method was employed to analyze particle size, and

Laser Doppler Anemometry technology was used to measure zeta potential. Each experiment was carried out in triplicate at 25±5 °C [26].

Drug-excipient compatibility study

Fourier transform infrared spectroscopic analysis (FTIR)

FTIR analysis was conducted to investigate the compatibility of DTX with Soluplus® and PF108. FTIR spectra were recorded for plain DTX, Soluplus®, PF108, and a physical mixture of DTX, Soluplus®, and PF108. Samples for FTIR were prepared following a methodology based on the principles outlined by Patravale et al. This involved maintaining a specific 1:0.5 ratio of active pharmaceutical ingredient (API) to solubilizers, mainly Soluplus® and PF108. Each unit of the API was combined with 0.5 units of Soluplus® and PF108. The FTIR measurements were performed using an Agilent Alpha 100508 instrument over a wave number range of 4000 to 400 cm^{-1} [27].

Differential scanning calorimetry (DSC) analysis

The thermal characteristics and interactions between DTX and the co-polymer were examined through DSC analysis. Both plain DTX and optimized DSP-MMs were subjected to the analysis using a DSC instrument Thermo Gravimetric Analysis–Differential Thermal Analysis–Differential Scanning Colorimetric (TGA–DTA–DSC) instrument with make TA instruments and model SDT Q600 V20.9 build 20. The samples were heated from 0 to 500 °C at a scan rate of 10 °C/min. An empty aluminum pan was used as the reference material for the measurements [9].

Processing of mixed micelles by vacuum foam drying

The product development process involved the careful transfer of precise 1 mL portions of DSP-MMs formulations into 3 mL glass vials. These vials contained a solution with 15% sucrose and 3% citric acid. The vials were partially sealed and then placed on the shelf of a Labconco lyophilizer (FreeZone 2.5® model). The lyophilizer condenser temperature was set to − 50 °C. Vacuum concentration of the DSP-MMs compositions took place for 4 h below 10 °C, maintaining a vacuum above 100 mBar. During this step, the composition's viscosity and surface area were carefully adjusted to ensure foam stability and efficient removal of water through evaporation during bubble formation. Subsequently, further drying of the viscous solutions occurred under vacuum conditions ranging from 1.650 to 0.030 mBar, with varying holding times to complete a 24 h cycle. Secondary drying was conducted at a temperature between 10 and 20 °C and 0.024 mBar for 2 h. As a result of this process, the dried products exhibited a highly porous thin bubble film inside the vials. The next step involved fully stoppering the vials under vacuum, and the finished product, known as the vacuum foam-dried DSP-MMs (DSP-MMs VFD product), was stored in a refrigerator at 4–8 °C until further analysis [25].

Characterization of DSP-MMs VFD product

After processing, the final product was further subjected to characterization to assess PS, ZP, PDI, %EE, %DLC, moisture content, and reconstitution time [25].

Comparative analysis of DSP-MMs and DSP-MMs VFD product

Morphological characterization using TEM and SEM analysis

The surface morphology of optimized DSP-MMs and DSP-MMs VFD products was analyzed using TEM and SEM. The SEM was done on the Scanning Electron Microscope with Jeol Ltd., Japan, and model JSM 6360 A. For TEM analysis, two drops of each sample were placed on a nitrocellulose-coated copper grid and air-dried for over 12 h at room temperature. Following this, the samples were stained with a 2% w/v phosphotungstic acid solution and examined using a Transmission Electron Microscope with Jeol and model JM 2100 to analyze morphological characteristics [28]. For SEM, samples were fixed on a brass stub, made electrically conductive by platinum coating in a vacuum using a Hitachi Ion Sputter, and analyzed with ImageInside Ver. 2.32 [29].

Powder X-ray diffraction analysis

The crystallinity behavior of the formulations was assessed using *P*-XRD analysis. Diffractograms of standard DTX, optimized DSP-MMs, and DSP-MMs VFD products were obtained using an X-ray Diffractometer (Bruker D8 Advance). The X-ray diffractometer operated with Cu-K radiation ($\lambda = 1.54$) at a voltage of 40 kV and 50 mA, incrementing in steps of 0.02° from 5° to 60° diffraction angle ($2°\theta$) at 1 s/step. A zero background was used during the scanning of all samples [9].

In vitro drug release study

In vitro drug release behavior of DTX from DSP-MMs, plain DTX, and DSP-MMs VFD products was investigated

using the dialysis tube method. Dialysis bags containing DTX dispersion and DSP-MMs equivalent to 2.5 mg DTX were immersed in phosphate buffer solution (PBS) pH 7.4 with tween 80, maintained at 37 °C, and stirred at 150 rpm. At pre-determined intervals (0, 2, 4, 6, 8, 24, 48, 72, and 96 h) samples were extracted, replaced with fresh medium, and analyzed using a UV–visible spectrophotometer at wavelength 230 nm. The drug release study results were analyzed by correlating the percentage cumulative drug release against time and; mathematical kinetic models viz. zero-order, first-order, Higuchi, and Korsemeyer-Peppas to understand the drug release mechanism of the MMs formulations [30].

In vitro hemolysis study

The hemolytic effect of pure DTX, blank DSP-MMs, DSP-MMs (optimized R5 formulation), and DSP-MMs VFD products were evaluated using human blood. Fibrinogen was removed from a 5 mL blood sample through centrifugation, and the RBC pellets were cleaned and redispersed in 0.9% NaCl injection water. A 2% erythrocyte pellet solution was prepared and mixed with the above samples in flasks, with the volume adjusted to 10 mL using 0.9% NaCl. Besides, negative and positive controls were also prepared. The flasks were incubated at 37 °C for 2 h, followed by centrifugation and absorbance measurement at wavelength 420 nm. The percentage hemolysis was calculated using Eq. 3 [31]:

3

$$\%\text{Hemolysis} = \frac{\text{Abs of sample} - \text{Abs of negative control}}{\text{Abs of positive control} - \text{Abs of negative control}} \times 100.$$

In vitro cytotoxicity

The cytotoxicity of plain DTX, blank DSP-MMs, and DSP-MMs was evaluated using the murine melanoma cell line (B16F10) through a 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) dye reduction test. The stock cultures were stored for 18 h at 2–8 °C before the cells were seeded. Cells were seeded in a 96-well microtiter plate, and after the formation of a partial monolayer, various test drug doses were added. Following a 48 h incubation period, MTT reagent was added, and the formazan was dissolved using DMSO. Absorbance was measured at wavelength 590 nm, and the percentage growth inhibition was calculated. The IC_{50} values were determined using dose–response curves for each cell line [9].

Stability study of MMs and DSP-MMs VFD product

According to the ICH stability testing requirements for biologicals short-term stability studies on the improved DSP-MMs and DSP-MMs VFD products were conducted for 6 months. The optimized MMs composition was filled in vials and stored at 2–8 °C and 60% RH. The product appearance, MPS, and %EE of the dried composition were assessed [25].

Results

This research aimed to prepare DSP MMs containing Soluplus® and PF108 by leveraging the essential properties of the excipients. The additional application of VFD was employed to overcome various challenges associated with previous methods. Soluplus®, a novel polymer renowned for its exceptional solubilization properties, particularly for poorly soluble APIs, was combined synergistically with PF108. The selection of PF108 was based on its outstanding foaming capacity, strategically intended for use in the novel VFD process. Simultaneously, Soluplus® was chosen strategically to facilitate the solubilization of the drug and achieve the formation of mixed micelles (MMs) with a size below the accepted threshold of 100 nm.

CMC of polymers and mixture

In this study, the iodine UV–visible spectrophotometric method was used to determine the CMC. Iodine served as a hydrophobic probe, and its conversion from I_3 to I_2 in the solution indicated the formation of micelles. This method is preferred over the cloud point method, because the reliability of the cloud point method is compromised by temperature sensitivity, making it less robust without strict control [32]. Additionally, its subjective nature, relying on visual observation, can introduce variability in results due to individual interpretation. The CMC values of pure Soluplus®, PF108, and Soluplus® + PF108 mixture were 0.0031 mg/mL, 0.01047 mg/mL, and 0.001 mg/mL, respectively, as shown in Fig. 1. The lower CMC of the Soluplus® + PF108 mixture is indicative of enhanced drug loading capacity, drug delivery efficiency, and significant in vivo stability which is crucial for pharmaceutical

applications [12].

Fig. 1 [Images not available. See PDF.]

CMC of Soluplus®, PF108, and Soluplus®+PF108 mixture

Development and optimization of MMs

In the pursuit of product development, preliminary experiments were conducted, followed by formulation optimization using a 3^2 full factorial design. Two independent variables, Soluplus® concentration (X_1) and PF108 concentration (X_2), were investigated at three different levels, resulting in nine possible combinations of DSP-MMs as presented in Table 1. The impact of independent variables was assessed with two dependent variables %EE (Y_1) and MPS (Y_2). Through optimization, batch R5 emerged as the most promising, exhibiting %EE of 74.81 ± 1.35%, MPS of 71.4 ± 0.2 nm, and drug loading of 29.27%.

Table 1. Formulation compositions using 3^2 full factorial design and results of their characterization

Batch code	Drug (mg)	Soluplus® (mg)	PF108 (mg)	% EE (%)	MPS (nm)	DLC (%)
R1	2.5	182	22	60.79 ± 2.23	80.5 ± 1.40	20.43 ± 0.75
R2	2.5	182	45	64.51 ± 1.22	74.8 ± 2.89	23.75 ± 0.91
R3	2.5	182	67	65.73 ± 3.56	74.7 ± 4.59	26.14 ± 1.27
R4	2.5	365	22	72.06 ± 2.27	72.8 ± 03.27	28.02 ± 1.41
R5	2.5	365	45	74.81 ± 4.27	71.4 ± 1.24	29.27 ± 0.70
R6	2.5	365	67	74.64 ± 1.82	72.3 ± 3.81	25.11 ± 0.69
R7	2.5	547	22	73.04 ± 2.43	72.4 ± 4.78	21.23 ± 0.34
R8	2.5	547	45	72.54 ± 4.65	72.7 ± 3.25	19.46 ± 1.25
R9	2.5	547	67	70.70 ± 1.28	77.8 ± 4.7	18.12 ± 0.89

The results are the mean ± SD (n = 3)

Effect of formulation variables on %EE

The effect of Soluplus®(X_1) and PF108 (X_2) concentrations on the %EE was estimated using a contour plot, Fig. 2A, and a 3D surface response plot Fig. 2B.

Fig. 2 [Images not available. See PDF.]

A Contour plot of %EE, **B** 3D surface plot of %EE, **C** contour plot of particle size, **D** 3D surface plot of particle size

The %EE of DTX in MMs was observed to be increased with an increase in the concentration of both PF108 and Soluplus®. However, at a medium Soluplus® concentration (365 mg), a substantial increase in %EE was observed that ranged from 72 to 74.81%. The %EE of the DSP-MMs also increased with an increase in concentrations of both the components up to medium concentrations. Beyond this point, further increases in Soluplus® and PF108 concentrations led to a decrease in %EE [33]. This can be attributed to establishing a saturation point within the carrier system at elevated concentrations, which diminished the progressive advantages

of additional Soluplus® and PF108. Moreover, apprehensions about potential aggregation or precipitation of these components emerged as concentrations increased, significantly compromising their efficacy in enhancing encapsulation efficiency. The simultaneous increase in solution viscosity due to heightened concentrations was also recognized as a pertinent factor contributing to this phenomenon, potentially obstructing the unobstructed diffusion of the DTX into the MMs.

The final %EE equation in terms of coded components is given below in Eq. 4:

4

%EE=+74.59I+4.21A+0.8633B-1.82AB-5.95A2-1.13B2

Equation (4) shows a positive value indicating an increase in %EE owing to an increase in the concentration of Soluplus® and PF108. The Model F-value of 153.92 and a *p* value of 0.0008 being < 0.05 indicates that the model terms are significant.

Effect of formulation variables on particle size

The effect of Soluplus® (X_1) and PF108 (X_2) concentrations on the MPS was revealed using a contour plot, Fig. 2C, and a 3D surface response plot, Fig. 2D.

The MPS of DSP-MMs formulations were in the range of 71.4 ± 0.2 nm to 80.5 ± 1.4 nm. The concentration of PF108 and Soluplus® significantly affected MPS. The MPS of the DSP-MMs goes on decreasing with the increase in the concentration of both variables up to a certain extent after which it further goes on increasing with the increase in the concentration [34].

5

MPS=+70.76I-1.18A-0.1500B+2.80AB+3.32A2+2.12B2

The model *F*-value 41.77 and a *p* value 0.0056 < 0.0500 indicates that the model terms are significant [31].

Mean particle size and zeta potential:

The MPS of the MMs in the absence of DTX was found to be 74.4 nm, as shown in Fig. 3A. The MPS and zeta potential of DSP-MMs optimized batch R5 are presented in Fig. 3B and C were found to be 71.4 ± 0.2 nm and − 17.6 mV, respectively. TEM analysis confirmed the MPS estimated by dynamic light scattering [9].

Fig. 3 [Images not available. See PDF.]

Drug-excipient compatibility study

FTIR analysis

Figure 4 displays the overlain FTIR spectra of DTX, PF108, Soluplus®, and the optimized formulation DSP MMs. In product development, FTIR analysis is pivotal for studying drug-excipient interactions and assessing formulation stability. DTX FTIR peaks include O–H, N–H stretching at 3630, 3444, and 3355 cm^{-1}, aromatic C=C stretching at 1699 cm^{-1}, and C–O–C stretching at 1157, 1251 cm^{-1}. PF108 shows C–H stretching at 2875 cm^{-1}, C–H bending at 1462 cm^{-1}, and C–H bending at 840 cm^{-1}. Soluplus® exhibits O–H, N–H stretching at 3656 cm^{-1}, C–H stretching at 2886 cm^{-1}, C=O at 1731 cm^{-1}, and C–O, C–O–C stretching at 1102 cm^{-1}[34].

Fig. 4 [Images not available. See PDF.]

FTIR spectrums: **A** Docetaxel, **B** PF108, **C** Soluplus® and **D** DSP MMs

DSC analysis

DSC analysis is vital in product development, offering insights into thermal transitions and formulation properties. The overlain DSC thermograms in Fig. 5I depict DTX and DSP MMs VFD products. DTX exhibits an endothermic peak at 178–188 °C, while DSP MMs VFD product shows a peak at 308.16 °C, indicating polymer melting and a solid-to-liquid transition. Notably, the DTX melting point peak disappears in DSP MMs VFD products, suggesting a transition from a crystalline to a partially amorphous state, crucial for optimizing drug delivery properties in pharmaceutical development [35].

Fig. 5 [Images not available. See PDF.]

(I): DSC thermograms: **A** DTX, **B** DSP-MMs (R5), and **C** VFD product and (II) *P*-XRD: **A** Plain DTX, **B** DSP-MMs, and **C** DSP-MMs VFD product

Characterization of DSP-MMs VFD product

The DSP-MMs VFD products were a lightweight, porous material with a high surface area that was obtained under reduced pressure conditions. The product formed facilitates rapid drying by removing moisture at lower temperatures than traditional drying methods. The resulting product typically exhibits characteristics such as enhanced porosity, improved rehydration capabilities, and a unique texture, as shown in Fig. 6A. The DSP-MMs VFD products underwent characterization to evaluate MPS, zeta potential, PDI, EE, drug loading, moisture content, and reconstitution time. The MPS was 82.7 ± 0.98 nm (Fig. 3D), zeta potential was − 14.1 ± 0.9 (mV) (Fig. 3E), PDI was 0.073 ± 0.011, %EE was 79.98 ± 0.97%, DLC was 98.2 ± 1.3%, moisture content was 2.25 ± 0.36%, and reconstitution time was 46 ± 5 s (Fig. 6B). These findings provided valuable insights into the physical properties and performance of the final product.

Fig. 6 [Images not available. See PDF.]

DSP-MMs product: **A** VFD product and **B** reconstituted VFD product

Morphological characterization using TEM and SEM analysis

The morphological characteristics of the optimized R5 formulation DSP-MMs structure and DSP-MMs VFD product are validated by TEM analysis Fig. 7A and B. The self-assembled MMs were observed to be spherical in shape. TEM images confirmed the nanoscale of generated MMs, which was comparable with the results, obtained using Zetasizer [36]. The SEM images revealed a highly porous structure of DSP-MMs VFD product (Fig. 7C and D). This porous nature facilitates the rapid reconstitution of DSP-MMs VFD products into micellar solutions [37].

Fig. 7 [Images not available. See PDF.]

TEM images: **A** DSP-MMs, **B** DSP-MMs VFD product and SEM images: **C** DSP-MMs, **D** DSP-MMs VFD product

Powder X-ray diffraction analysis

The *P*-XRD patterns of the plain DTX, DSP-MMs, and DSP-MMs VFD products are displayed in Fig. 5II. Plain DTX showed characteristic strong, high-energy diffraction peaks, indicating crystallinity. In the case of optimized DSP-MMs, these peaks were dramatically broadened with reduced peak intensities indicating partial amorphization. These characteristic peaks disappeared in the diffractogram of VFD products, indicating the amorphization of DSP-MMs VFD products [38].

In vitro drug release study

Illustrated in Fig. 8I are the release profiles of DTX from different formulations: plain DTX DSP-MMs and DSP-MMs VFD products. When dissolved in methanol, plain DTX exhibited an impressive release rate of over 90% after 8 h in PBS (pH 7.4) with 0.5% w/v tween 80, maintaining the sink condition. Comparatively, the DTX release from DSP-MMs after 96 h was measured to be 81.95 ± 1.3%. However, the DSP-MMs VFD product showcased even more remarkable sustained release capabilities, reaching 83.23 ± 1.5%, outperforming plain DTX in terms of sustained release performance [9].

Fig. 8 [Images not available. See PDF.]

(I)In vitro drug release study from DTX, DSP MMs (R5), and DSP-MMs VFD product, (II) Drug release kinetics for DSP-MMs VFD Product, and (III) In vitro cytotoxicity against B16F10 cell line

The drug release pattern was analyzed by fitting the %CDR data from the release profile into various models, including zero-order, first-order, Higuchi, and Korsmeyer-Peppas models. Among these models, the Higuchi model demonstrated the highest correlation coefficient (R^2), as depicted in Fig. 7II. Consequently, this model was selected as the best fit for the data, indicating that the main drug release mechanisms from DSP-MMs involve dissolution and

diffusion [39].

In vitro hemolysis study

The hemolysis assay was performed to assess the biocompatibility and safety of the formulations. The results of in vitro hemolysis in plain DTX, blank Soluplus®/PF108 MMs, DSP-MMs, and DSP-MMs VFD products are presented in Fig. 9. The positive control displayed complete hemolysis, while the negative control showed minimal hemolysis. Plain DTX exhibited a higher percentage of hemolysis compared to DSP-MMs and DSP-MMs VFD products at the same dose. Compared to Taxotere, a marketed formulation of the DTX and previously prepared docetaxel nanoformulations, DSP-MMs VFD product exhibits reduced hemolysis, providing evidence of the enhanced quality of the developed product. This indicates that encapsulation of DTX in DSP-MMs and the subsequent DSP-MMs VFD product significantly reduced the hemolytic potential of the formulation. The reduced hemolytic activity indicates a decreased risk of red blood cell damage and supports the potential for safe and effective delivery of DTX using DSP-MMs and DSP-MMs VFD products intravenously [40].

Fig. 9 [Images not available. See PDF.]

Hemolysis study of DTX, DSP blank, DSP-MMs, and DSP-MMs VFD product

In vitro cytotoxicity study

All the test samples showed a cytotoxic effect on the B16F10 cell line that was concentration-dependent (Fig. 8III and Table 2). At the same doses, both plain DTX and DSP-MMs demonstrated virtually comparable cytotoxicity against cancer cells. On the B16F10 cell line, the simple DTX displayed a lower IC_{50} value of 0.2155 µM than DSP-MMs with an IC_{50} value of 1.170 µM. In comparison to conventional DTX, DSP-MMs displayed a slightly higher IC_{50} value, indicating lesser cytotoxicity against the B16F10 cell line. The sustained release of DTX from DSP-MMs, as seen in the in vitro release study, can be attributed to reduced cytotoxicity. The sustained release of DTX from MMs corresponded to a previous study described by Patil et al. [9].

Table 2. In vitro cytotoxicity study of formulations

Formulation	IC_{50} value against B16F10 cell lines (µM)
Plain DTX	0.2155 ± 0.005
DSP blank MMs	0.7100 ± 0.007
DSP MMs	1.170 ± 0.028

Stability study of DSP-MMs and DSP-MMs VFD product

The comparison between the stability of the developed formulations, DSP-MMs, and DSP-MMs VFD products under accelerated storage conditions is depicted in Table 3. The table showcases key physical properties at two distinct time junctures: initial time (time zero) and following a 3-month storage period. This evaluation provides valuable insights into the endurance of the formulations over time and in the face of adverse storage conditions [25].

Table 3. Stability study of DSP-MMs

Sampling time	DSP MMs			DSP MMs VFD product				
%EE (%)	MPS (nm)	%DLC (%)	%EE (%)	MPS (nm)	Moisture content (%)	Reconstitution time (sec)	%DLC (%)	0 Day

74.81 ± 0.27	71.4 ± 0.52	29.27 ± 0.70	79.98 ± 0.97	82.70 ± 0.98	2.25 ± 0.36	46 ± 5	98.2 ± 1.3	1 Month
72.5 ± 0.16	75.8 ± 1.12	29.07 ± 1.80	79.51 ± 1.12	82.84 ± 0.75	2.40 ± 0.51	49 ± 4	98.1 ± 0.9	2 Months
70.19 ± 0.32	79.2 ± 2.26	28.87 ± 0.90	78.87 ± 0.58	82.84 ± 0.75	2.80 ± 0.76	52 ± 3	97.4 ± 1.1	3 Months

Discussion

Soluplus®, a versatile polymer in drug delivery, offers advantages like high solubilization capacity, biocompatibility, and improved drug bioavailability [41]. In this current study, a composite formulation comprising PF108 and Soluplus® was employed. The inclusion of PF108 was driven by its foaming capacity. Nonetheless, prior research revealed that PF108 single micelles commonly exhibited a moderately higher particle size. In light of this limitation and with the objective of achieving a reduced particle size, the collaborative incorporation of PF108 with Soluplus® was employed. As a result, the resultant mixed micelles exhibited a decrease in particle size compared to the micelles composed of PF108 alone. When combined with PF108, these benefits are further amplified in MMs. The combination of Soluplus® and PF108 in MMs results in smaller MPSs compared to individual micelles of either polymer. This reduction in MPS facilitates the extravasation of MMs through the leaky tumor vasculature [42], leading to enhanced accumulation at the tumor site through the EPR effect [43]. Additionally, the mixed micelles formed by Soluplus® and PF108 can accommodate a higher drug payload, maximizing the amount of drug delivered to the target site, further improving the therapeutic effect [44]. Previously, Patil KS et al. developed DTX-MMs using TPGS and PF108, achieving a MPS of 233 ± 3 nm and %DLC of 2.06 ± 0.08 [12]. In contrast, this research demonstrated that MMs formed by combining Soluplus® and PF108 resulted in a significantly smaller MPS, measuring 71.4 ± 0.2 nm, and a substantially higher %DLC of 29.27%. Hence, the combination of Soluplus® and PF108 proves to be a superior choice for the development of docetaxel MMs. Further, QbD principles were crucial in product development, starting with defining the QTPP and identifying CQAs through pre-formulation studies [45] as given in the Additional file 1. A factorial design was employed to systematically vary critical factors, including polymer concentrations and other formulation parameters, through multiple experimental runs [46]. The effects of these variations on the MPS and %EE were evaluated. The objective of this optimization phase was to determine the optimal formulation that would yield MMs with the desired attributes, ultimately resulting in a high-quality product. Through this optimization R5 batch demonstrated promising characteristics, indicating an efficient encapsulation of the drug within the micellar structure, a desirable MPS for enhanced drug delivery, and an appropriate drug loading content; hence, it was used for further analysis [47].

In the previous research by Patil et al., DTX micelles had a zeta potential of − 7.4 mV, while the product developed in this research achieved a higher zeta potential of − 17.6 mV [9]. This increase can be attributed to the ionizable hydroxyl (–OH) groups present in both Soluplus® and PF108. These groups dissociate, releasing H+ ions, and maintaining the negative charge. The elevated zeta potential in the new research offers several advantages in continuous flow. Firstly, it enhances electrostatic repulsion between particles, preventing aggregation and ensuring uniformity during storage and circulation. Secondly, the increased zeta potential provides better control over drug release kinetics. The higher repulsive force between MMs slows down drug release, resulting in sustained and controlled drug delivery over an extended period [48].

FTIR spectroscopic studies were conducted to investigate potential drug-excipient interactions between DTX, TPGS, and PF108. The DSP MMs VFD product displayed characteristic peaks of the drug, suggesting no significant evidence of chemical interaction between the drug and excipients. This finding ensures the compatibility of the drug with its MMs formulation. DSC studies revealed a transformation from a crystalline to a partially amorphous state. Further for enhancing the stability of the liquid product, converting it into a solid form is a common approach.

Traditionally, lyophilization and spray drying were used, but they presented drawbacks, such as lengthy processing times, potential loss of bioactivity, and limited control over MPS [49]. A drawback of lyophilization is the potential formation of a compacted cake at the bottom of the product container during the drying process. This cake can be difficult to reconstitute as it may resist the absorption of water or solvent. As a result, reconstitution might require more vigorous shaking or mixing to break down the cake and achieve a uniform solution. This can be time-consuming and lead to inconsistencies in the reconstituted product, affecting its usability and quality. Hence, as an innovative alternative, this research tried using novel VFD for DSP-MMs [50]. VFD's ability to operate under mild conditions helps maintain the stability and efficacy of the final solid product. The solid product formed after lyophilization is a cake form whereas VFD gives a porous product hence reconstitution becomes easy as well as there is less percentage of moisture content. The product formed after VFD was further used for different in vitro tests.

The sustained release behavior of DSP-MMs and DSP-MMs VFD products hinders premature drug release, reducing exposure to healthy tissues and potentially enhancing DTX accumulation in tumors via the EPR effect for improved treatment efficacy [51]. The finding of reduced hemolysis demonstrates that the DSP-MMs VFD product formulation is a promising candidate for further development and potential clinical application. It highlights the positive impact of the vacuum foam drying process on the quality and safety of the developed DSP-MMs, reinforcing the importance of this manufacturing approach in producing improved drug delivery systems for melanoma treatment.

The stability of DSP-MMs and DSP-MMs VFD products was assessed at regular intervals. Over time, the MPS of the MMs increased from 71.4 to 90.7 nm due to slight aggregation of the cores of the hydrophobic micelles [52]. After 3 months, the liquid MMs showed precipitation and a significant decrease in %EE. In contrast, DSP-MMs VFD products exhibited stability with only a slight increase in MPS and a minor reduction in %EE. This comparison highlights the superior stability of DSP-MMs VFD products, as they demonstrated minimal changes in MPS and %EE compared to the liquid formulation.

Conclusion

In this research, DSP-MMs loaded with Soluplus® and PF108 were successfully developed to enhance melanoma treatment. Employing QbD principles, the formulation optimization process yielded an efficient encapsulation of the drug, desirable MPS, and appropriate drug loading content. The nanoscale size of the MMs facilitated drug accumulation in tumors through the EPR effect, improving therapeutic efficacy. IR spectroscopic studies indicated no significant drug-excipient interactions, ensuring the stability of the drug within the MM formulation. DSC studies revealed a transformation from a crystalline to a partially amorphous state, indicating potential changes in drug properties. VFD significantly improved the stability of DSP-MMs, reducing MPS growth and maintaining encapsulation efficiency over time. Moreover, DSP-MMs VFD products demonstrated superior stability compared to liquid MMs, exhibiting minimal changes in MPS and encapsulation efficiency. The sustained release behavior of DSP-MMs VFD product minimized premature drug release and enhanced drug accumulation in tumors, contributing to improved treatment efficacy. The applied QbD approach will ensure the safety, efficacy, and quality of the formulation improve the stability of docetaxel-loaded mixed micelles, and enhance their efficacy for melanoma treatment. Further, a novel VFD technique was applied to liquid mixed micelles formulation and converted to a foam-dried product that exhibits improved stability and therapeutic potential. The study of novel vacuum foam drying techniques is a budding phase for the pharmaceutical industry as a whole. This section of the study is interesting and acts as a lamppost for numerous researchers on the stability perspective of nanoformulations.

Acknowledgements

We extend our gratitude to SWVSM's Tatyasaheb Kore College of Pharmacy, Warananagar and Bharati Vidyapeeth College of Pharmacy, Kolhapur, for providing essential facilities and equipment for our research. Special thanks to BASF for the generous gift of Soluplus®, and to Shivaji University, Kolhapur for granting access to SEM, *P*-XRD, and DSC facilities, enhancing the comprehensive analysis of our study.

Author contributions

KP and RC: conceptualization, investigation, data curation, software, methodology, visualization, formal analysis, supervision, writing—original draft, writing—review and editing. JD, AH, NJ, and PK: formal analysis, writing—review and editing.

Funding

This research was conducted without any external funding support.

ABSTRACT (ENGLISH)

Background

Artificial intelligence (AI) revolutionized the formulation and development of modern pharmaceuticals. With the help of AI, researchers can now optimize drug design, develop formulations, and streamline clinical trials in a much accurate and efficient way. Drug development might be greatly expedited and time-consuming procedure; however, with the help of AI this are significantly reduced.

Main body of abstract
The main advantages of AI in pharmaceutical formulation are its capacity to analyse vast amounts of data and spot patterns and connections that human researchers would miss. Various tools and technologies, such as ANN, fuzzy logic, neuro-fuzzy logic, and genetic algorithm are used for analysing the date, of which ANN is popular and mostly used. AI enables the discovery of novel pharmacological targets and the creation of more potent medications. AI may also be used to improve medication formulations by forecasting the solubility, stability, and bioavailability of drug candidates, increasing the likelihood that clinical trials will be successful.
AI is also applied in designing clinical trials, reducing the time and cost of the process by identifying patient populations that are most likely to benefit from the treatment. Additionally, AI can monitor patients during clinical trials, detecting real-time adverse effects and adjusting dosages to improve patient outcomes.
Conclusion
AI is a potent pharmaceutical formulation and development tool, allowing researchers to analyse vast amounts of data, optimize drug formulations, and streamline clinical trials. As technology develops, experts anticipate that AI will increasingly show a crucial part in drug development, enabling faster, more efficient, and more effective treatments for various diseases.

FULL TEXT

Background

The phrase "Artificial Intelligence" (AI) is a general term that describes the least amount of human intervention possible when utilizing a computer to imitate intelligent behaviour. AI is the subfield of computer science that deals with programming to solve issues [1]. It has developed into a discipline that addresses problems in business, engineering, and healthcare. The creation of expert systems is one use for AI. An inference engine, an information base, and a user interface make up an expert system. AI possesses distinctive characteristics that enable it to reason and execute actions with the highest probability of accomplishing a specific objective. AI accomplishes this through a combination of algorithms that simulate even the most fundamental human intellectual capabilities. Nowadays, AI is gaining momentum across multiple sectors, and the pharmaceutical industry is at the forefront of this trend. In the past, formulators have favoured statistical methods, for example response surface approach, for analysing design space. However, optimization using this approach has the potential to be deceptive, especially when dealing with a complex formulation. Two methods that can tackle the issue at hand have been developed as a result of recent developments in mathematics and computer science. The first technique involves using neural networks to replicate how the human brain processes information. The second technique is genetic algorithms, which mimic biological systems' self-organizing and adaptive natures through an evolutionary method. The practical requests of AI in the pharmaceutical production house are highlighted in this paper, including drug research and development (R&D), drug repurposing, increasing pharmaceutical output, clinical testing, etc. These applications reduce the need for human labour and accelerate the drug development process [2]. Over the past few years, the pharmaceutical manufacturing company has significantly improved its data digitalization. To answer challenging clinical problems, acquiring, examining, and applying this knowledge is difficult due to this digitization. AI is used to address this since it can manage enormous volumes of data with increased automation. However, it does not endanger the physical existence of humans. AI uses hardware and software to analyse input data and learn from it in order to accomplish specified goals. This review explains that its services in the pharmaceutical sector are constantly growing. The rapid advancement of AI-guided automation, according to the McKinsey Global Institute, will fundamentally alter how society views labour. Every stage of the pharmaceutical product life cycle, including drug discovery, optimization, formulation development, characterization, quality testing, marketing, and post-marketing surveillance, can integrate AI to improve its efficacy [3].

Tools, technology, and networks

Artificial neural networks (ANN)

Machine learning (ML) is an essential subdivision of AI. A big part of ML is deep learning, which involves ANN. The ANN is made up of multilayer functional units that mimic how electrical impulses are transmitted in the human brain,

i.e. it mimics a human brain. They are mainly biologically motivated systems. It takes input and learns directly from input data; primarily, neurons work mainly on the summation of all information and express an output [4].
The fundamental component of biological neural systems is the neuron. Neurons are electrochemical cells; they receive signals from one neuron and transmit signals to other neurons [4]. Like humans, the ANN system has a primary component known as a "perceptron" or node. Nodes are arranged into layers, and artificial neurons analyse input to create an output that is sent to the following perceptron. It is categorized into two states, supervised learning (SL) and unsupervised learning. In unsupervised learning, the network receives input data and identifies patterns or structures within the data thereby condensing the data into a more compact form [5].
In SL, the network is "taught" by receiving guidance during the learning process. In this SL, the network is given the relevant input and output data. The connection between the input and output data is established via the network. SL is considered the most popular and valuable network for formulation purposes [4, 5].
The arrangement of interconnected neurons in a neural network is called network architecture. There are various types of network architecture; among them, a multilayer perceptron (MLP) network is one of the best suitable examples.
X1, X2 &X3 are input variables, and Y is the output. The number of input, output, and hidden layers depends on the condition and the researcher's plan depicted in Fig. 1 [6].
Fig. 1 [Images not available. See PDF.]

Schematic diagram of artificial neural network

Fuzzy logic

Another tool of AI is fuzzy logic. People extensively use fuzzy logic in problem-solving. When ANN accompanies it, it cooperates to understand the formulation and optimization process [4]. Conventional sense relies on either 'true' or 'false.' So, this hypothesis falls between either in actual or wholly false part. Since the premise is true, the membership function in the true set is 1; otherwise, it is 0 in the false set [4].

Neuro-fuzzy logic

The main motto of fuzzy logic is to give in simple forms. Neural network modelling is necessary to form it. Neuro-fuzzy logic, by its name, is understood that neuro-fuzzy logic is composed of neural networks and fuzzy logic. It combines ANN's learning capacity with generality and fuzzy logic's ability to explore complex concepts. Neuro-fuzzy logic is tightly well suited to process data mining. It can develop good models from data and express the linguistic IF_THEN rules [4, 5].

Genetic algorithm

John Holland introduced genetic algorithms (GA) in the 1970s [5]. Like ANN, GA is also a biologically motivated system. Natural selection, the primary tenet of its genetic variation, imitates the fundamental principles of evolution over a generation. We create a genetic algorithm to select the best and most effective solution. They provide a 'search' strategy that is excellent for optimisation. An iterative procedure would be used to advance the trial population. As part of this procedure, we form a starting population and evaluate each member's fitness [4]. The fittest solutions change into 'parents' of the subsequent generations. It becomes a more ideal answer by including some introduction of recombination and mutation, which produces a larger degree of new stuff in the population. The genetic algorithm needs a criterion of "fitness." It is variable from problem to problem [5].
The best solution is found by creating a number of potential solutions when an ANN and a genetic algorithm are combined. These candidates are selected based on their fitness according to predefined criteria. Generating a new population of solutions is accomplished by utilizing the most effective solution and incorporating crossover and mutation techniques. The process persists until it fulfils the desired requirements, at which juncture the repetition is terminated [4].
An optimization technique is needed to develop a pharmaceutical product to find the best combination of ingredients and techniques. Researchers have proven that the combination of ANN and GA possesses the requisite solutions for developing dosage forms.

Evolutionary computing

It is just a definition of a computational technique that uses heredity, recombination, mutation, and selection to solve a problem. One particular branch of evolutionary algorithms has been used in formulation research [5].

Life cycle of pharmaceutical products

AI can support decision-making, enable rational drug design, determine the best course of a patient's treatment with personalized medications, accomplish the clinical data produced, and utilised that data to create new drugs in the future [7]. From the lab to the bedside, it is logical to assume that AI will contribute to creating pharmaceutical products. Eularis created the E-VAI analytical and decision-making AI platform, which employs ML algorithms and a user-friendly interface to create analytical roadmaps based on rivals, crucial stakeholders, and the market share currently held to forecast critical factors in pharmaceutical sales [8]. This boosts sluggish sales and gives marketing directors the ability to foresee where to make expenditures. It also helps them allocate resources for optimum market share growth. Figure 2 presents an overview of several AI uses in drug discovery and development.

Fig. 2 [Images not available. See PDF.]

Applications of AI in various pharmaceutical business subfields, including pharmaceutical product management and drug development

AI in drug discovery

The research and development of new drugs is a challenging, expensive, and lengthy task. On average, the R&D cycle spans around 10–15 years. Despite the significant financial investment made by the pharmaceutical industry, pursuing the next blockbuster drug persists. This R&D is since only one in every ten potential drug candidates completes phase I clinical trials and attains regulatory approval [9, 10]. The cost and time constraints associated with developing newer therapeutic compounds may be a contributing factor in the pharmaceutical industry's acceptance of AI [11].

The tools and technologies employed by AI are valuable in rapidly identifying hit and lead materials, validating drug targets, and optimizing drug structure design, potentially benefiting the healthcare industry by reducing the cost and timeline associated with discovering novel molecules. However, despite these advantages, AI must still overcome significant data hurdles, including the data's complexity, growth, diversity, and ambiguity [12, 13].

The chemical structure that would elicit the desired reaction at the target location may be predicted using a variety of in silico approaches. This structure can then be improved to meet a variety of criteria, such as potency, safety, solubility, permeability, and synthetic tractability. These methods also make it possible to plan the production of the compound and anticipate the molecule's physicochemical characteristics [13, 14].

By utilizing both structure- and ligand-based methods, along with all available data, it is feasible to hasten the elimination of non-lead compounds. Recently, researchers have employed the quantitative structure–activity relationship (QSAR) modelling device for screening potential pharmacologically active compounds from a pool of one million candidates. Moreover, the deep learning approach, an evolution of the earlier ML approach, can now handle the massive amount of data gathered throughout the drug discovery and development procedure [15, 16].

Using a computer model based on the QSAR, large quantities of compounds or certain physicochemical qualities, such as log P or log D, may be swiftly predicted. These models, however, are far from being able to forecast with any degree of accuracy complex biological traits like a compound's efficacy and undesirable side effects. Additionally, QSAR-based models have issues with limited exercise groups, erroneous investigational facts, and a need for more trial validations. To address these problems, researchers can employ newly developed AI methodologies, such as Deep Learning (DL) and pertinent modelling lessons, to assess the safety and effectiveness of pharmaceutical molecules through extensive data showing and study [17, 18].

DL models beat traditional ML techniques in 15 drugs candidate-related absorption, distribution, metabolism, excretion, and toxicity (ADMET) data sets regarding predictability. Drug metabolism sites are identified using artificial intelligence (AI) techniques like XenoSite, FAME, and SMARTCyp. By displaying molecule distributions and properties, the huge virtual chemical space suggests the existence of a molecular topographic map. Chemical space

visualization's idea is to collect positional information on nearby molecules to hunt for bioactive compounds; thus, virtual screening (VS) helps choose appropriate molecules for future investigation. PubChem, ChemBank, DrugBank, and ChemDB are a few open-access chemical databases.

For the purpose of locating prospective novel drugs, AI-based QSAR approaches, such as decision trees, support vector machines, random forests, and linear discriminant analysis (LDA), have evolved from QSAR modelling tools [15, 19, 20].

We have included a list of a few AI technologies used throughout the drug development phase in Table 1 to help readers understand. Figure 3 summarizes the various AI models used during drug development methods. Physicochemical characteristics, bioactivity, toxicity, target proteins, drug interactions, drug-protein binding interactions, and de novo synthesis of certain organic synthetic compounds are all predicted by these models [21].

Table 1. The AI techniques/tools used in the drug discovery process

Name of tools	Application
Reinforcement learning	Used to optimize drug combinations and dosages by considering multiple interacting variables and maximizing desired outcomes
DeepChem	Open-source library for deep learning in chemistry and drug discovery
DeepTox	Open-source deep learning framework specifically designed for toxicity prediction and assessment
Neural graph fingerprints	Method for encoding molecular structures as fixed-length feature vectors using neural networks, suitable for various applications in drug discovery, such as virtual screening, lead optimization, and property prediction
PotentialNet	Ligand-binding affinity prediction based on a graph convolutional neural network (CNN)
Predictive ADME/Tox modelling	Tools employ ML techniques to model and predict the absorption, distribution, metabolism, excretion, and potential toxicity of drug candidates
Natural language processing (NLP) tools	Assist in extracting and analysing information from scientific literature, patents, and clinical trial data
Cheminformatics tools	Tools enable the analysis and manipulation of chemical structures and properties
QSAR/QSPR modelling	Correlate molecular properties and structures with biological activities or properties, enabling the prediction of compound behaviour
Deep learning (DL)	Applied in tasks like virtual screening, de novo drug design, and predicting drug properties

Machine learning (ML)	Help predict drug-target interactions, analyse biological activity, and optimize lead compounds

Fig. 3 [Images not available. See PDF.]

Different applications of AI in drug discovery

AI in drug development

An acceptable dosage form with the essential delivery qualities must then include a unique medicinal component. In this case, AI can take the place of the conventional approach of trial and error [22]. With the use of QSPR, a variety of computational techniques may resolve issues in the formulation design area, such as instability issues, dissolving, porosity, and many more [23]. Decision-support technologies use rule-based algorithms to choose the kind, nature, and amount of the excipients depending on the physicochemical properties of the drug. They also use a feedback loop to keep an eye on and occasionally tweak the entire process [24].

Piroxicam direct-filling hard gelatin capsules were designed using a hybrid method that combines expert systems (ES) and ANN in order to achieve the necessary dissolving profile. Based on the input parameters, the Model Expert System (MES) delivers judgements and recommendations for formulation development. Contrarily, ANN make use of backpropagation learning to link the formulation parameters to the desired outcome, enabling trouble-free formulation creation. The control module collaboratively manages this process [22].

Using a variety of mathematical methods, including computational fluid dynamics (CFD), discrete element modelling (DEM), and the finite element method (FEM), researchers have investigated the effects of the powder's flow property on the die-filling and tablet compression processes [25, 26]. CFD may also be used to examine how tablet shape affects the profile of the tablet's disintegration [27]. Integrating these mathematical models with AI may have a huge positive impact on the rapid manufacturing of pharmaceutical products. Technologies incorporating AI have evolved into versatile tools that find wide application in various stages of drug development. These stages include identifying and validating drug targets, designing new drugs, repurposing existing drugs, enhancing R&D efficiency, aggregating and analysing biomedicine data, and making informed decisions regarding patient enrolment in clinical trials [17, 28, 29]. These prospective applications of AI offer the chance to mitigate bias and human interference while addressing the inefficiencies and uncertainties resulting from traditional drug development approaches [30]. Drug repurposing [31], pharmacological features [32], protein characteristics and efficacy [33], drug combination, drug-target interaction [34], and prediction of potential synthetic methods for drug-like molecules [35] are other uses of AI in the pharmaceutical industry. In addition, the identification of associations between drugs and illnesses and the development of novel biomarkers and therapeutic targets allow for the identification of new pathways and targets utilizing omics analysis [36, 37].

AI in drug formulation

Pharmaceutical sciences have seen various formulations, for example solid dispersions, extrudates, pellets, nanoparticles, and liposomes, arise in addition to standard dosage forms. The name "formulation techniques" is given to these techniques because they empower the development of formulations or incorporate functionality into common dosage forms such as tablets. AI applications in formulation techniques are even more worthwhile to investigate in order to create next-generation drug products with desired efficacy and health outcomes because these methods can successfully address a variety of API issues, such as low solubility, stability, bioavailability, and production capability [6].

Controlled-release tablet formulation

Researchers utilize pharmacokinetic simulations and ANN to develop controlled-release formulations [5]. The ANN model learns sophisticated and specialized abilities from the input and output data units with the use of Chem software. In order to anticipate the best tablet formulations based on two ideal *in vitro* dissolution-time profiles and two desirable *in vivo* release profiles, researchers use a sophisticated ANN model. Dissolution is the rate-limiting step in the *in vivo* absorption of the drug since it is linearly proportional to the amount of the drug taken *in vivo*. *In*

vitro release patterns are often detected using the difference factors (f_1), and similarity factor (f_2) [38].

Immediate-release tablets formulation

To boost tablet strength, Turkoglu developed a direct compression tablet formulation utilizing hydrochlorothiazide [39]. In a different study, Kesavan and Peck developed a model of a caffeine tablet formulation to describe the diluting agent and binder content in each formulation, processing variables (type of granulator, method of adding binder), and granule and tablet properties (disintegration time, hardness, and friability). These two analyses demonstrated that neural networks performed better than traditional statistical methods. Kesavan and Peck's findings have so been re-evaluated by academics employing a variety of genetic algorithms and neural networks [40]. This presentation illustrated how the relative relevance of the output attributes and the restrictions placed on the several tiers of components and processing factors determined the ideal formulation [41]. Researchers used neuro-fuzzy computing to analyse the same data and frequently created helpful rules that highlighted the most important aspects of any item [5].

Hard gelatin capsule shell formulation

Developing hard gelatin capsule formulations involves using executive tools like ANN and expert systems (ES). ANN stimulate human mental processes, such as generalization, learning, prediction, and abstraction from domain knowledge. With ANNs, the data and statistics collected during investigative work may be transformed into knowledge very quickly, enabling the manufacturer to generate few domain-specific strategies for forthcoming occurrences or forecast the theoretical preparation’s characteristics [22]. By extending the Expert Network and conducting analysis, Wendy I. Wilson in 2005, created a capsule shell manufacturing of Biopharmaceutical Classification System II drugs, such as carbamazepine, ketoprofen, naproxen, and ibuprofen. Capsugel's expert system, for the formulation of powders in hard gelatin capsules, was used all over the world despite the drawback of just providing a proposed composition. During the initial test, researchers discovered that the system exhibited low prediction accuracy and a significant error rate. Researchers retrained the ANN using a new dataset, resulting in models with an R2 of less than 70%. Lastly, for the model drugs, the smart hybrid system predicted the quantity of drug soluble around 5%. By using only 10% of the newly generated data for cross-validation, the researchers showed that the system was capable of creating a formulation that satisfied its performance requirements. Researchers presented the system's ability to analyse several BCS class II drugs by considering wettability and intrinsic dissolving properties [42].

Solid dispersions (SD)

One or more APIs dispersed in a solid matrix describe solid dispersions [43, 44]. They are currently a practical and affordable approach for enhancing solubility and bioavailability [45]. They have been extensively employed in academics and industry to overcome concerns with API poor solubility. Many AI-based SD studies have used ANNs to optimize the formulations [46–48]. Researchers utilized ANNs to enhance the floating and drug release characteristics of SD of Nimodipine prepared with PEG and effervescent mixtures [46]. ANNs were employed to elucidate the relationship between variables such as API concentration, the molar mass of PEG, and temperature in a SD formulated with PVP [49]. Researchers recently developed a model using ML approaches to expect the stability of SD. They employed twenty molecular descriptors to compare eight ML methods. Among these methods, the RF model exhibited the highest estimate precision and provided insights into every input. The top five contributing parameters among the twenty descriptors they picked were the drug loading ratio, relative ambient humidity, storage temperature, preparation temperature, and molecular weight of polymers [50].

Emulsions, microemulsions, and nanoemulsions

Emulsions are biphasic systems with water and oil phases spread over each other and stabilized by an emulsifier [51]. The utilization of micro- and nanoemulsions has the potential to provide a variety of advantages, including increased API bioavailability, superb optical clarity, and improved long-term stability [52–55]. Researchers have published studies on these systems that utilize AI approaches. Kumar et al. regulated the fatty alcohol content with the use of ANNs to produce a steady o/w emulsion. Particle size, zeta potential, conductance, and viscosity were among the emulsion product properties that the ANNs could accurately predict. They also made it possible to

quantify the relative significance of the inputs [56]. Gasperlin et al. successfully predicted the structures of microemulsions by creating two ANNs that can determine the kind of microemulsion from the desired composition or a differential scanning calorimetry (DSC) curve, respectively [57]. Additionally, Agatonovic-Kustrin et al. developed a stable microemulsion formulation for the oral administration of rifampicin and isoniazid using ANN model data for treating the ongoing stage of TB [58]. Amani et al. used ANNs to study potential influences on nanoemulsion particle size and discovered that the final particle size's most important factor was the total energy provided during preparation [59]. In addition, Seyed et al. looked into the component concentrations of nanoemulsion to catch the most stabilized structure with minimum cytotoxicity. They found that emulsifier concentration, which was shown to be the primary determinant of nanoemulsion stability, had no effect on cytotoxicity [60].

Self-emulsifying drug delivery systems (SEDDS)

Drugs, oils, surfactants, and occasionally cosolvents are combined in isotropic ways to create SEDDS [61]. SEDDS offer several advantages due to their physical stability, ease of production, and ability to address concerns regarding low drug bioavailability [62]. SEDDS can effectively tackle various API concerns, including enzymatic degradation, gut wall efflux, solubilization, and bioavailability [63]. Fatouros et al. utilized AI techniques such as neuro-fuzzy networks to create a dynamic lipolysis model that simulates medication absorption and predicts the *IVIVC*. Without requiring complex settings, the model showed significant prediction skills, indicating its potential for application in forecasting the *in vivo* behaviour of formulations made of lipids [64]. Utilizing ANNs coupled with I-optimal design, Parikh and Sawant optimized the crucial elements that determine the droplet size of SEDDS. When compared to the quadratic model based on I-optimal design, the ANN-coupled replicas showed the comparative contributions of every factor and were more accurate [65]. Li et al. used multiple linear regression (MLR) and ANN approaches to create quantitative structure-property relationship (QSPR) models that relate the molecular structures of the surfactant, co-surfactant, oil, and drug used in SEDDS with the drug solubility. The researchers found that key factors influencing drug solubility were the ratios of surfactant and oil, as well as the dipole moment and energy of the highest occupied molecular orbital [66].

Other formulation techniques

In addition to these formulation techniques, researchers have applied AI methods to beads and pellets [67–71], microparticles and nanoparticles [72–85], microspheres and nanospheres [86–88], liposomes and nanoliposomes [89], colloidal systems [90], micelles [91, 92], and liquid, solid dosage forms [93].

Scaling up AI across the pharmaceutical value chain

AI and ML are operating revolutions through several manufacturing company. Nevertheless, industries reliant on research, such as pharmaceuticals, are witnessing rapid advancements in these technologies. To speed up the delivery of life-saving medications, AI is re-designing the value chain and extracting insights from diverse data sets to make it highly interoperable [94].

Drug discovery

AI can aid labour and resource-intensive manual drug discovery. Biopharmaceutical companies have the opportunity to employ AI models to identify and validate various methods, leveraging the acquired knowledge to improve their predictive capabilities. AI could have a significant impact on generative modelling for molecule design and protein engineering in the field of molecular design. Although manual data entry remains essential for clinical trials, the utilization of AI-powered data flows allows for the integration of trial data from diverse sources, enabling the delivery of standardized digital data that seamlessly and automatically transfers to the relevant systems downstream [94].

Manufacturing

AI in biopharma manufacturing might stream crucial data, anticipate process bottlenecks, evaluate current quality control issues, and recommend necessary improvements without the need for time-consuming manual involvement [94].

It could lower operationally expenses and manual oversight in manufacturing operations by permitting tighter control with:

•Quality control

•AI in robotic process automation (RPA)

•AI mock-ups to augment produce &output

•AI-coupled prognostic maintenance to lessen appliance interruption.

Pharmaceutical market of AI

Pharmaceutical companies are turning to AI to reduce financial costs and failure risks. The AI market witnessed growth from US$200 million in 2015 to US$700 million in 2018, and it is expected to reach $5 billion by 2024 [95]. Experts predict that the pharmaceutical and medical industries will experience a 40% growth rate from 2017 to 2024 due to the impact of AI. Numerous pharmaceutical firms have invested in AI and are continuing to do so. They have also worked with AI firms to build crucial healthcare solutions. An example is the partnership between DeepMind Technologies, a Google company, and the Royal Free London NHS Foundation Trust for treating critical renal damage. Figure 4 lists critical pharmaceutical businesses and AI players [12].

Application of AI

Poly-pharmacology

In disease-related molecular networking, poly-pharmacology is the strategic creation of a therapeutic molecule with the innate capacity to interact with numerous targets or pathways (put, "one disease-multiple target"). One can use this method to create a more effective and less hazardous therapy than the currently available one. Several well-known databases that offer details on biochemical pathways, binding strengths, pharmacological goals, and physiological effects are PubChem, CheMBL, Drug Bank, and Binding DB [96, 97]. The AI system can use this data to probe and discover potential poly-pharmacological drugs selectively. One can use the range of available applications, improved computer capacity, and developments in AI technology to change the drug development process.

Quality control and quality assurance

Developing a pharmaceutical formulation within the given timeframe while ensuring quality necessitates a meticulous and scientifically-driven approach to navigate the intricate process successfully. Gathering information involves capturing data about the characteristics of drug compounds and excipients, their interactions, unit operations, and equipment. Various knowledge applications are utilized, such as heuristics, decision trees, correlation, and first-principal models. This information and knowledge inform the decision-making process for production, selection of excipients, and determination of equipment size [98]. Consequently, AI and its networks, technologies, and tools ensure higher product quality, less waste, and increased profit for manufacturing company. Quality-by-Design (QbD) method ensures the improved quality of the generated goods. This approach makes it easy to comprehend the crucial elements in the pharmaceutical production process that might have an impact on the final product's quality.

Product development

The pharmaceutical sector focuses on accelerating pharmaceutical product development, cutting production costs, and enhancing process design for confirming an active medication. Various expert systems can serve as valuable

tools for prompt decision-making in the rapid development of pharmaceutical products. An example of a decision-support tool is the rule-based expert system, which represents domain knowledge as a collection of rules structured as IF-THEN statements. These rules utilize input data to assist in addressing specific problems. Each rule consists of two components: the IF part, which establishes an assumption (such as medication insolubility), and the THEN part, which defines the corresponding action to be taken (such as using a soluble filler to address the solubility issue). This type of system, known as a production system or an expert system, represents the fundamental form of artificial intelligence. It functions based on pre-established rules that are provided as knowledge inputs to guide its operations. The choice of excipients for preparing tablets and capsules can be made using these expert systems. Such a system's regulations detail the system's mechanical, chemical, and physical characteristics and the requirements for the finished item. The system's inference engine uses this information to forecast the kind and number of excipients needed to achieve the requirements. This formula is used to create the product, which is then examined to see if it complies with the necessary standards. This information is then fed into the system, which aids with formula optimization (Fig. 5) [24].

Fig. 5 [Images not available. See PDF.]

Formulation of tablets and capsules uses rule-based systems

The creation of Logica's product formulation expert system (PFES), anticipated to direct the manufacturing technique using an order of duties, was motivated by the need for quick manufacture of generic formulations. PFES provides a framework for new formulation system development. The specification object, which encompasses the current understanding of the formulation problem, and the formulation object, which represents the current composition of the formulation, are taken into account. This knowledge is subsequently applied to facilitate the development of the formulation. The design of later iterations of PFES involves three levels: physical, task, and control. The control level conducts the studies, while the physical level receives domain information and can be accessed from the task level through a query interface. Expert systems in formulation development have several benefits, such as ensuring a consistent process for regulatory compliance, aiding in novice and professional training, reducing product development time and cost, and freeing up experts to focus on innovation [99].

Developing innovative drug delivery methods with an eye on optimizing efficacy and avoiding adverse effects has generally taken up most of the last ten years. AI has the potential to address certain challenges associated with controlled and conventional drug delivery systems, including issues such as systemic toxicity, narrow therapeutic ranges, and dose adjustments during long-term therapy. To illustrate how AI is utilized in medicines, an example can be given where microchips are employed to manage medication administration, lower systemic toxicity, narrow the therapeutic window, and reduce adverse effects. AI has made significant advancements in enhancing the efficacy, safety, and adherence of patients by innovating implanted drug delivery devices capable of regulating drug release timing and concentration. This strategy of using AI in managing chronic diseases like diabetes, which require prompt treatment and continuous monitoring, is very advantageous. Neural networks, fuzzy logic, integrators, and differentiators have all been used to develop control systems. It is crucial to monitor glucose levels in diabetic patients and provide insulin regularly to treat the condition. As mentioned earlier, the utilization of microchips can assist in the effective management of regular blood glucose level monitoring and insulin administration. The combination of glucose sensors, mathematical models, and control algorithms holds promise for facilitating this objective. Conventional therapeutic methods that have been utilized over time face certain limitations, which can be overcome by integrating information technology, wireless communication, and ANNs into standard therapeutic procedures. As an illustration, wireless connections can be utilized to transmit orders from outside sources to units.

The data from these communications are gathered and tracked to control the drug's distribution [100, 101].

Pharmaceutical manufacturing

Continual production is a valuable strategy for reducing lot-to-lot variances. The FDA recommends a non-stop processing strategy to limit the variation of final products and patient outcomes. One can use various process analytical technology (PAT) tools, efficient and cost-effective to control uninterrupted production. Through automated ML, using AI in conjunction with PAT can improve the process overall and help regulate the production process [102].

Companies that produce biopharmaceutical products can benefit from data science by integrating logistics into their processing operations. Ensuring the proper upkeep of these variables is considered a crucial regulatory consideration due to the utilization of engineered living cells in the production of biopharmaceuticals. Managing and monitoring multiple factors are necessary to maintain the purity and consistency of the manufactured product. As a result, most of the world's leading chemical businesses frequently employ big data to improve vaccine production output and keep an eye on product quality [34].

Drug synergism and antagonism prediction

When treating someone over time, studying how different drugs interact is essential. This can reduce the dose needed and prevent harmful side effects from taking multiple medications together. SnuGen utilises the master regulator inference algorithm (MARINA) to forecast synergism and antagonism. The MARINA method was established to have the ability to predict synergism with an approximate accuracy of 56%. This method clarifies the "Mater Regulator" genes which may be applied to selecting beneficial descriptors for ML techniques. One can use network-based Laplacian regularized least square methods to predict synergism and antagonistic drug interactions. As was covered in the preceding section, various AI techniques combined with medication therapy can be advantageous in multiple ways. For proper prediction, a level of confidence percentage in the range of 0.7–0.9 has been attained, comparable to the performance of the most automatic prediction system. The prediction scores obtained using the various ML techniques do not significantly differ. While ANNs, Random Forest, and SVM all have benefits and drawbacks, choosing the correct input parameters is the main issue when utilizing AI for combo therapy. One must use the parameters that determine the quality of the prediction model when developing prediction algorithms [18].

Nanorobots for drug delivery

Integrated circuits, sensors, a power source, and a secure data backup constitute the primary components of nanorobots, which are maintained by computational technologies like AI [101]. They are designed with programming to prevent collisions, detect targets, locate and engage with them, and subsequently eliminate them from the body. Advancements in nano/microrobot technology empower them to navigate to specific locations within the body by leveraging physiological indicators like pH. This progress enhances their efficacy and reduces the occurrence of systemic side effects [103]. When creating implantable nanorobots for the controlled administration of drugs and genes, factors such as dosage customization, sustained release, and regulated release must be carefully considered. The automation of drug release necessitates the utilization of AI tools, such as neural networks (NNs), fuzzy logic, and integrators [104]. Microchip implants serve dual purposes, enabling both scheduled release of substances and precise localization within the body.

Nanomedicine

Nanomedicines merge nanotechnology and drugs to diagnose, treat, and monitor complex ailments like HIV, cancer, malaria, asthma, and various inflammatory conditions. Due to their enhanced treatment efficacy, the utilization of nanoparticle-modified drug delivery systems has experienced substantial growth in both the therapeutic and

diagnostic domains [105, 106]. Combining AI with nanotechnology could solve numerous issues in product development [107, 108]. Through computational analysis, a nanosuspension of methotrexate was developed by examining the energy generated during the interaction between drug molecules and closely monitoring any conditions that could lead to formulation aggregation. Coarse-grained simulation and chemical computation can be employed to evaluate the interactions between drugs and dendrimers, as well as to analyse the encapsulation of drugs within the dendrimer structure [23].

Furthermore, researchers can investigate the impact of surface chemistry on the internalization of nanoparticles into cells using tools such as LAMMPS and GROMACS 4. The utilization of AI facilitated the development of silicasomes, which are a combination of multifunctional mesoporous silica nanoparticles loaded with irinotecan and the tumour-penetrating peptide iRGD. The inclusion of iRGD enhances the transcytosis of silicasomes, resulting in improved treatment outcomes and increased overall survival. As a result, there has been a significant three- to fourfold increase in the absorption of silicasomes [106].

Predicting the mode-of-action of compounds using AI

The prospect of an AI platform that can predict drugs' on- and off-target effects as well as *in vivo* safety profiles prior to synthesizing has medicinal chemists, in particular, thrilled. The existence of such platforms reduces the amount of time, money, and attrition rates needed to create new medications. Among these platforms are DeepTox, which predicts the toxicity of new drugs, and PrOCTOR, which assesses the probability of toxicity during clinical trials [109, 110]. If a comprehensive and precise dataset containing information on the toxicity and therapeutic characteristics of a wide range of drugs becomes available, the industry has the potential to enhance the predictive accuracy of these platforms by sharing and exchanging data.

As a substitute for chemo-proteomics, SPiDER, a novel AI tool, was recently created [111] to promote natural products for drug development. As a proof-of-concept, SPiDER was utilized to predict the molecular target of lapachone, a natural naphthoquinone with promising antitumour properties currently in clinical development. The platform expected that 5-lipoxygenase (5-LO) would be modulated allosterically and reversibly by lapachone. Through the use of a 5-LO functional test, the prediction is verified. An alternative AI methodology, known as read-across structure-activity relationships (RASAR) [112], has demonstrated the ability to effectively forecast the toxicity of unfamiliar compounds. By leveraging a vast chemical library and establishing connections between molecular structures and hazardous traits, RASAR proves valuable in this prediction process.

Conclusion and future prospect

In conclusion, the function of AI in pharmaceutical formulation and development is rapidly expanding, bringing a host of benefits to the industry. AI has already demonstrated its ability to analyse large data sets, optimize drug formulations, and streamline clinical trials. By doing so, the duration and expenses associated with drug development have been diminished, concurrently heightening the precision and efficacy of the complete process.

The prospects for AI in pharmaceutical formulation and development are up-and-coming. As AI continues to evolve and improve, it is predictable to show an even more significant function in drug development, aiding researchers in identifying new drug targets, drug interactions, and patient populations most likely to benefit from treatment. Furthermore, as AI systems become more advanced, they can simulate biological systems more accurately, allowing researchers to develop more personalized and effective treatments. This, in turn, will lead to more efficient and targeted drug development and personalized medicine.

So, the role of AI in pharmaceutical formulation and development has already proven to be transformative and is expected to continue to revolutionize the industry in the coming years. By leveraging the power of AI, researchers can unlock new insights into complex diseases, create more effective treatments, and improve patient outcomes on

a global scale.

ABSTRACT (ENGLISH)

Background

In contemporary society, anxiety has become a widespread disorder leading to compromised well-being and heightened depressive states. Extensive literature reviews indicate the diverse biological effects of benzimidazole and piperazine derivatives, notably their impact on the central nervous system. This study aimed to design, molecularly dock, synthesize, and assess the anxiolytic potential of six derivatives of 2-(4-phenylpiperazin-1-yl)-1H-benz[d]imidazole and 2-(4-phenylpiperazin-1-methyl)-1H-benz[d]imidazole.

Results

In the present study, an attempt was made to synthesize benzimidazole derivatives conventionally. The benzimidazole nuclei are condensed with various substituted piperazines to obtain targeted benzimidazole–piperazine hybrids. Their anxiolytic activity is determined using the Elevated Plus Maze test and hole board test in mice. All compounds have shown good docking scores and in vivo anxiolytic activity.

Conclusion

Out of all the derivatives synthesized, compounds 5b, 5c, and 5f exhibited outstanding anxiolytic efficacy in both computational simulations and live subjects. Compound 5b demonstrated a remarkable docking score relative to the ligand, suggesting its potential as a promising candidate warranting further exploration.

FULL TEXT

Background

Anxiolytics, crucial for managing anxiety and enhancing mental well-being, should be used under medical supervision to mitigate symptoms of anxiety disorders and enhance overall health and quality of life [1]. These medications slow down the central nervous system (CNS), primarily by enhancing the activity of gamma amino butyric acid (GABA), a neurotransmitter that induces CNS depression. This class of drugs, known for their calming effects, encompasses benzodiazepines, ethanol, opiates, and barbiturates [2, 3]. Benzodiazepines, for instance, potentiate GABA neurotransmission by increasing the affinity of GABA receptors, thereby intensifying inhibitory effects on the CNS [4, 5]. Additionally, heterocyclic compounds like benzimidazole and piperazine, noted for their diverse pharmacological properties including antibacterial, antiviral, antidiabetic, and anticancer activities, have garnered attention for potential drug development [6–11]. The current study synthesizes novel benzimidazole–piperazine derivatives and evaluates their anxiolytic activity.

Materials

The docking simulations were conducted using an Asus personal computer. Autodock Vina software was utilized for docking studies, while Swiss ADME and Molinspiration software were employed to predict the pharmacokinetic properties of the compounds. PASS online software was utilized to forecast the biological activity of the designed compounds. GraphPad Prism 5 software was employed for statistical analysis of biological activity data.

Infrared spectra were acquired using an ATR (Attenuated Total Reflectance) spectrophotometer (Bruker). Proton resonance magnetic spectra (1H NMR) were recorded at 400 MHz, and chemical shifts were expressed in "δ ppm".

Mass spectra were obtained from SPPU, Pune, with molecular peaks expressed in the *m/z* ratio. Thin-layer chromatography was employed for reaction monitoring using an iodine chamber.

Methods

Docking

The crystal structure of the Human GABA-A receptor alpha1-beta2-gamma2 subtype complexed with GABA and flumazenil, conformation B (PDB ID: 6D6T) [12], was obtained from the Protein Data Bank in PDB format. This structure underwent cleaning procedures, involving the removal of water molecules, co-crystallized ligands, and non-essential entities, using Discovery Studio Visualizer. Subsequently, the cleaned structure was converted to pdbqt format after appropriate charge assignment. Ligand structures were designed using Marvin Sketch version 5.8.1, Chem Axon. Both protein and ligand structures were prepared utilizing Auto Dock Tools following a previously established protocol [13]. A search space grid was generated around the binding site of the GABA receptor using Auto Dock Tools. The grid dimensions were adjusted to encompass the active site to ensure a comprehensive exploration of ligand conformations. Auto Dock Vina was used to carry out docking between the prepared ligands and proteins. The conformation possessing the least binding energy was further analyzed to study its binding mode with the receptor. The protein–ligand interactions were viewed using BIOVIA, Dassault Systems, Discovery Studio 16.0.1, San Diego: Dassault Systems, 2016.

Chemistry

A series of novel piperazine-linked benzimidazole analogs (5a–f) were synthesized via a three-step synthetic pathway outlined in Fig. 1. Initially, 2-oxo benzimidazole (1) was synthesized by condensing o-phenylene diamine (OPD) and urea at 135–400 °C in DMF. Subsequently, halogenation was achieved by adding $POCl_3$ and phenol crystals, allowing the reaction to proceed at 104–107 °C to yield 2-chlorobenzimidazole (2), serving as a core structure for derivatives [14–16]. Another core structure, 2-chloromethyl benzimidazole (3), was synthesized by refluxing O-phenylene diamine and chloroacetic acid with 5N HCl [17, 18]. The piperazine substituents (4a–d) were obtained by refluxing Bis-2-chloroethylamine hydrochloride with substituted anilines at 142–145 °C in the presence of p-toluene sulphonic acid (PTSA) using xylene as a solvent [19, 20]. Lastly, equimolar quantities (0.009 mol) of the core structure and substituted piperazines were dissolved separately in 1,4-dioxane, mixed, and refluxed with triethylamine (TEA) as a catalyst for 12 h [21]. The resulting precipitate was collected using chilled water, filtered by suction, and recrystallized from ethanol after drying to obtain the target derivatives (5a–f).

Fig. 1 [Images not available. See PDF.]

Scheme of synthesis of benzimidazole derivatives

All synthesized analogs underwent characterization via infrared spectroscopy (IR), proton nuclear magnetic resonance spectroscopy (1H NMR), and mass spectrometry (MS) for molecular weight determination. IR spectra revealed characteristic bands at 3300–3400 cm^{-1} corresponding to the Aromatic N–H bond, 900–1100 cm^{-1} for the C–F stretch, and 2800 cm^{-1} for the piperazinyl aliphatic C–H bond [22, 23]. In the 1H NMR spectra, the distinctive singlet peak of the benzimidazole nucleus was observed between 12.5 and 13.6 ppm for all derivatives. Peaks corresponding to piperazinyl aliphatic C–H appeared at 3.5–4.2 ppm, aromatic C-H peaks were detected at 7–8 ppm, and methylene C-H peaks for nucleus (3) were observed at 3.8–4.0 ppm [22, 23]. Mass spectrometry results corroborated the molecular weights of the compounds, with an additional weight corresponding to proton addition.

Biological evaluation

The anxiolytic activity was assessed using the Hole Board Test and Elevated Plus Maze (EPM) test in Swiss albino mice, with diazepam employed as the standard reference [24, 26]. The Hole Board Test apparatus comprised a wooden floor measuring 40 cm × 40 cm, elevated 2 inches above the ground, featuring sixteen holes arranged symmetrically in a diamond pattern. Groups of 5 animals were individually placed on one edge of the apparatus and monitored for 5 min to record the number of pockings. Diazepam (4 mg/kg i.p) was administered 30 min before the test.

For the EPM test, the wooden apparatus was elevated to a minimum height of 50 cm from the ground, adhering to

the specifications described by Lister [25, 26]. The EPM consisted of two open arms (50 × 10 cm) and two closed arms (50 × 10 × 40 cm). Each group of 5 animals was individually positioned in the center of the EPM, facing the closed arms, and their time spent in both open and closed arms was recorded over 5 min.

Results

Synthesis and spectral data

2-(4-(4-Fluorophenyl)piperazin-1-yl)-1*H*-benz[d]imidazole (5a)

Yield: 56%; **m.p:** 216–218 °C; **IR Ranges (ATR, cm^{-1});** N–H stretch: 3337.25, C–H aromatic: 3041.76, C–H aliphatic: 2813.17, C–H aliphatic bend (CH2):1433.00, C=C stretch: 1600.32, C–N aromatic: 1210.90, C–F stretch: 999.71. **H1 NMR Shifts;** Aromatic C–H: (m 4H): 7.04–7.20, Piperazine C–H: (m 8H): 3.16–3.50, Aromatic C–H: (m 4H): 7.63–7.72, Benzimidazole N–H: (s 1H): 13.04. **MASS:** MOLECULAR ION PEAK (297.1523).

2-((4-(4-Fluorophenyl)piperazin-1-yl)methyl)-1*H*-benz[d]imidazole (5b)

Yield: 60%; **m.p:** 159–163 °C; **IR Ranges (ATR, cm^{-1});** N–H stretch: 3491.91, C–H aromatic: 3025.29, C–H aliphatic: 2908.47, C–H aliphatic bend (CH2): 1475, C=C stretch: 1650.50, C–N aromatic: 1204.77, C–F stretch: 1011.75. **H1 NMR Shifts;** Aromatic C–H: (m 4H): 7.16–7.21, Piperazine C-H: (m 8H): 3.29–3.88, Aromatic C–H: (m 4H): 7.44–7.63, methylene C–H: (s 2H): 3.89, Benzimidazole N–H: (s 1H): 13.61. **MASS:** MOLECULAR ION PEAK (311.1670).

2-((4-(3-Fluorophenyl)piperazin-1-yl)methyl)-1*H*-benz[d]imidazole (5c)

Yield: 70%; **m.p:** 122–126 °C; **IR Ranges (ATR, cm^{-1});** N–H stretch: 3337.25, C–H aromatic: 3041.55, C–H aliphatic: 2813.17, C–H aliphatic bend (CH2): 1433.00, C=C stretch: 1600.32, C–N aromatic: 1210.90, C–F stretch: 999.71. **H1 NMR Shifts;** Aromatic C–H: (m 4H): 7.05–7.17, Piperazine C–H: (m 8H): 3.39–3.88, Aromatic C–H: (m 4H): 7.17–7.44, methylene C–H: (s 2H): 3.89, Benzimidazole N–H: (s 1H): 13.61. **MASS:** MOLECULAR ION PEAK (311.1660).

2-((4-(2-Fluorophenyl)piperazin-1-yl)methyl)-1*H*-benz[d]imidazole (5d)

Yield: 71%; **m.p:** 116–119 °C; **IR Ranges (ATR, cm^{-1});** N–H stretch: 3481.78, C–H aromatic: 3038.96, C–H aliphatic: 2809.86, C–H aliphatic bend (CH2): 1433.42, C=C stretch: 1601.73, C–N aromatic: 1233.37, C–F stretch: 1016.61. **H1 NMR Shifts;** Aromatic C–H: (m 4H): 6.99–7.17, Piperazine C–H: (m 8H): 3.30–3.50, Aromatic C–H: (m 4H): 7.17–7.61, methylene C–H: (s 2H): 3.89, Benzimidazole N–H: (s 1H): 13.61. **MASS:** MOLECULAR ION PEAK (311.1675).

2-((4-Phenylpiperazin-1-yl)methyl)-1H-benz[d]imidazole (5e)

Yield: 57%; **m.p:** 162–165 °C; **IR Ranges (ATR, cm^{-1});** N–H stretch: 3481.78, C–H aromatic: 3038.96, C–H aliphatic: 2809.86, C–H aliphatic bend (CH2): 1433.42, C=C stretch: 1601.73, C–N aromatic: 1233.37. **H1 NMR Shifts;** Aromatic C–H: (s 1H, m 3H): 6.99–7.20, Piperazine C–H: (m 8H): 3.19–3.46, Aromatic C–H: (m 4H): 7.50–7.57, methylene C–H: (s 2H): 4.07, Benzimidazole N–H: (s 1H): 12.50. **MASS:** MOLECULAR ION PEAK (280.1690).

2-(4-(3-Fluorophenyl)piperazin-1-yl)-1*H*-benz[d]imidazole (5f)

Yield: 64%; **m.p:** 195–199 °C; **IR Ranges (ATR, cm^{-1});** N–H stretch: 3337.25, C–H aromatic: 3041.55, C–H aliphatic: 2813.17, C=C stretch: 1600.32, C–N aromatic: 1210.90, C–F stretch: 999.71. **H1 NMR Shifts;** Aromatic C–H: (m 4H): 7.07–7.20, Piperazine C–H: (m 8H): 3.16–3.50, Aromatic C–H: (m 4H): 7.20–7.63, Benzimidazole N–H: (s 1H): 13.04. **MASS:** MOLECULAR ION PEAK (297.1505).

The thin layer chromatography (TLC) characterization data for the synthesized substituents and derivatives, as well as spectra for infra-red (IR), proton nuclear magnetic resonance (1H NMR), and Mass analyses of the synthesized derivatives, are provided in the Additional files 1 and 2.

Biological activity (anti-anxiety activity)

The anxiolytic activity of the compounds was assessed through two tests: the Hole Board Test and the EPM Test. The experimental protocol for both tests was as follows: Group I received vehicle treatment (0.5% carboxymethyl cellulose in water). At the same time, Group VIII served as the standard reference with diazepam administration at 4 mg/kg intraperitoneally (i.p). Groups II to VII received test compounds 5a–f (synthesized compounds) at 50 mg/kg orally (p.o). Comparisons were made between Groups II to VIII and Group I, and the results were subjected to

statistical analysis using GraphPad Prism 5 software, employing one-way ANOVA followed by Dunnett's test.

Hole-board test

Each of the eight groups, consisting of five mice per group, was individually monitored for the number and duration of pocking in the hole board apparatus over 5 min. A higher number and longer pocking duration indicate the compound's anti-anxiety properties being evaluated. The mean ± standard error of the mean (SEM) for each group is presented in Table 1.

Table 1. Data for Hole board test

Sr no	Treatments	No of pocking	Duration of pocking (s)
Group I	Control	5.6 ± 0.50	11.40 ± 1.07
Group II	5a (50 mg/kg)	13.1 ± 2.34*	119.4 ± 3.41***
Group III	5b (50 mg/kg)	25.20 ± 1.28***	171.0 ± 3.92***
Group IV	5c (50 mg/kg)	19.40 ± 1.77***	157.2 ± 6.36***
Group V	5d (50 mg/kg)	12.8 ± 1.43*	136.8 ± 4.32***
Group VI	5e (50 mg/kg)	12.60 ± 0.92*	118.2 ± 2.43***
Group VII	5f (50 mg/kg)	19.80 ± 3.15***	166.2 ± 6.01***
Group VIII	Diazepam (4 mg/kg)	12.80 ± 0.86*	30.0 ± 1.39*

Values are expressed as mean ± SEM, n = 5

ns non significant

*p<0.05; ***p<0.001

Compounds within Groups III, IV, and VII (Derivatives 5b, 5c, and 5f) exhibited very highly significant anxiolytic activity (***p<0.001) in comparison to the control group, as assessed by the number of pocking. Compounds across Group II-VII (Derivatives 5a–f) demonstrated highly significant anxiolytic activity relative to the control group, as determined by the duration of pocking.

Figure 2 presents a graphical depiction of the data obtained from the hole board test. It is evident from the graph that all derivatives exhibit significant anxiolytic effects compared to both the control and standard groups.

Fig. 2 [Images not available. See PDF.]

Graphical representation of anxiolytic activity by Hole board apparatus. (**A** Number of pocking; **B** duration of pocking, *significant, **highly significant, ***very highly significant by ANOVA and Dunnett's test)

EPM test

T Each of the eight groups, comprising five mice per group, was individually monitored for the number of entries and the duration of entries into the open arms of the EPM apparatus over a 5-min duration. An increased number and duration of entries into the open arms of the EPM are indicative of the anti-anxiety properties of the compound being evaluated. The mean ± standard error of the mean (SEM) for each group is presented in Table 2.

Table 2. Data for EPM test

Sr. no	Time spent (s)		No. of entries

Discussion

Using Molinspiration [27] and Swiss ADME software [28], the physicochemical parameters and ADME (absorption, distribution, metabolism, and excretion) properties of all compounds were comprehensively examined before synthesis. Lipinski's rule of five (RO5), which evaluates essential physicochemical properties crucial for a molecule's efficacy, safety, or metabolism, was considered for all compounds.

Ideally, oral drugs should possess a Log P value<5, a molecular weight<500, a topological polar surface area (TPSA)<90 to efficiently cross the blood–brain barrier, a molar refractivity value between 40 and 130, fewer than 10 hydrogen bond acceptors, and fewer than 5 hydrogen bond donors [29]. The assessment revealed that none of the compounds violated Lipinski's rule of five (RO5), as indicated in Table 3. This suggests that all derivatives were well-designed and exhibit desirable drug-like or pharmacological characteristics, rendering them potentially accessible for oral administration.

Table 3. Drug likeliness properties of derivatives

Comp	miLogP	Mol wt	TPSA	MR	HBA	HBD
5a	3.605	296.349	35.159	92.55	2	1
5b	3.091	310.376	35.159	96.80	3	1

5c	3.067	310.376	35.159	96.80	3	1
5d	3.043	310.376	35.159	96.80	3	1
5e	2.927	292.386	35.159	96.84	2	1
5f	3.581	296.349	35.159	92.55	2	1

Comp compound, *miLogP* partition coefficient, *Mol wt* molecular weight, *TPSA* topological polar surface area, *MR* molar refractivity, *HBA* hydrogen bond acceptor, *HBD* hydrogen bond donor

The blood–brain barrier (BBB) penetration, permeability glycoprotein (Pgp) substrate, gastrointestinal (GI) absorption, and cytochrome P450 (CYP450) enzymes, particularly CYP2C19 inhibitors, are key pharmacokinetic properties indicative of favorable drug likeliness potential. Utilizing Swiss ADME software, an in-silico assessment of pharmacokinetic properties was conducted, as outlined in Table 4.

Table 4. Pharmacokinetic properties of derivatives

Compound	GI abs	BBB permeation	Pgp substrate	CYP2C19 inhibitor	CYP3A4 inhibitor	Lipinski violation	Ghose violation	Bioavailability score
5a	High	Yes	Yes	No	Yes	0	0	0.55
5b	High	Yes	Yes	No	Yes	0	0	0.55
5c	High	Yes	Yes	No	Yes	0	0	0.55
5d	High	Yes	Yes	No	Yes	0	0	0.55
5e	High	Yes	Yes	No	Yes	0	0	0.55
5f	High	Yes	Yes	No	Yes	0	0	0.55

All compounds examined in the ADME software exhibited high gastrointestinal absorption. Furthermore, in the ADME study, all derivatives were identified as Pgp (glycoprotein pump) substrates. P-glycoprotein plays a significant role in restricting the cellular uptake of medications from the bloodstream into the brain and from the intestinal lumen into epithelial cells. While positive Pgp substrate properties can diminish medication absorption, this effect can be mitigated by increasing the dosage, as high drug concentrations in the intestinal lumen can saturate P-glycoprotein transport function.

All derivatives are expected to inhibit the liver enzyme CYP3A4, while CYP2C19 remains unaffected. Consequently, the results indicate that the synthesized derivatives possess favorable pharmacokinetic and physicochemical properties, suggesting their potential utility as effective lead compounds with notable membrane permeability and oral bioavailability

An initial evaluation of central nervous system (CNS) depressant activity was conducted using the PASS study [30]. The derivatives exhibited virtually significant anxiolytic and antipsychotic activity. Values above 0.2 are considered significant according to PASS evaluation criteria, as depicted in Table 5.

Table 5. PASS study of derivatives

Comp	Pharmacological activity	Activity value
5a	Anxiolytic	0.508
5b	Anxiolytic Antipsychotic	0.551 0.527
5c	Anxiolytic Antipsychotic	0.575 0.546
5d	Anxiolytic Antipsychotic	0.509 0.543
5e	Anxiolytic	0.510
5f	Anxiolytic	0.540

All derivatives underwent a docking study to assess their interaction with the active site of the inhibitory ion channel Human GABA-A receptor alpha1-beta2-gamma2 subtype complexed with GABA and flumazenil, conformation B (PDB ID 6D6T), aiming to determine binding energy and interactions. It was observed that all derivatives exhibited favorable binding energy and engaged in various interactions with amino acids at the active site. The reference compound, flumazenil, exhibited substantial affinity towards the receptor molecule via halogen bonding with HIS D:102; hydrogen bonding to THR E:142; and van der Waals interactions with SER D:206, ASP E:56, and MET E:130; pi-pi stacking interactions with PHE E:77, TYR E:58, TYR D:160, and TYR D:210 in addition to other bonding modalities, accompanied by the binding energy of −9.4 kcal/mol. The synthesized compounds exhibited binding energies ranging from −8.4 to −9.5. Details of the docking study outcomes are presented in Table 6. The derivatives 5a, 5b, 5c, and 5e exhibit hydrogen bonding interactions with the protein, as illustrated in Fig. 3. The principal binding interactions vis-a-vis the ligand flumazenil are deliberated upon herein. Compound 5a forms a single hydrogen bond with the active site residue SER D:206, in addition to engaging in two pi-pi stacking interactions with TYR E:58 and PHE E:77. Compound 5b establishes two hydrogen bonds with active site residues HIS D:102 and SER D:206, along with pi-pi stacking interactions with TYR D:160 and TYR D:210. Similarly, compound 5c forms two hydrogen bonds with SER D:206 and demonstrates halogen (fluorine) interaction with SER D:159, as well as pi-pi stacking with TYR D:210. Compound 5e forms a lone hydrogen bond with SER D:206. Besides these hydrogen bonds, pi-pi stacking interactions with residues TYR D:160 and TYR D:210, along with pi-anion interactions with ASP E:56 and MET E:130, appear to significantly contribute to the molecule's binding to the receptor. In contrast, Compounds 5d and 5f do not establish any hydrogen bonds with the receptor.

Table 6. Docking results

Sr. no	Compound	Binding energy (kcal/mol)	No. of H bonds formed	Distance	Interacting amino acids
1	5a	−8.4	1	3.080	SER(D): 206

2	5b	−9.5	2	2.541 2.811	HIS(D):102 SER(D): 206
3	5c	−9.3	2	2.826 2.832	SER(D): 206
4	5d	−9.4	–	–	–
5	5e	−9.1	1	2.796	SER(D): 206
6	5f	−8.5	–	–	–

Fig. 3 [Images not available. See PDF.]

2D and 3D docking interactions of derivatives 5a, 5b, 5c and 5e

The anxiolytic efficacy of these compounds was evaluated in comparison to a control group. In the hole board test, control group mice exhibited fewer instances of pocking indicative of fear and anxiety, whereas the treated groups displayed an increased number and duration of pocking due to the anxiolytic effects. Compounds 5b, 5c, and 5f demonstrated notably significant anxiolytic activity based on the frequency of pocking, while all compounds 5a-f exhibited significant activity in terms of pocking duration. During the EPM test, rats administered with anxiolytic drugs spent more time in the open arm compared to the control group, reflecting heightened anxiety in the animals on an elevated platform. Notably, all six synthesized derivatives (5a–f) displayed highly significant anxiolytic activity in the EPM test.

Conclusion

All newly synthesized benzimidazole derivatives 5a–f have exhibited highly significant biological anti-anxiety activity. Most compounds have demonstrated drug-like properties, along with favorable gastrointestinal absorption and bioavailability as predicted by virtual computational tools. These findings are encouraging and warrant further investigation.

Moreover, docking studies against the Human GABA A receptor (PDB ID: 6D6T) revealed favorable binding energies for all derivatives, validating our hypothesis regarding the potential of the recently synthesized 2-(4-phenylpiperazin-1-yl)-1H-benz[d]imidazole and 2-((4-phenylpiperazin-1-yl) methyl)-1H-benz[d]imidazole derivatives as lead candidates for anti-anxiety drug development. Notably, compound 5b exhibited superior binding affinity compared to the ligand and demonstrated excellent in vivo anxiolytic activity, thus presenting a promising candidate for further exploration.

ABSTRACT (ENGLISH)

Background

Saraca asoca (Asoka) is reported to possess phytoestrogenic components with anticancer properties. The phytoestrogens are recognized as natural agonists for ER*β*, which acts as an antagonist to ER*α*. Despite the absence of ER*α*, studies have identified ER*β* in 50–80% of triple negative breast cancers (TNBC). Thus, the present study is intended to reveal the role of phytoestrogens of Asoka on TNBC. The cytotoxic effect of Asoka methanol bark extract was analyzed on different breast cancer cell lines by MTT assay. Estrogen-screen assay was employed to determine the proliferative/antiproliferative effect. Identification of phytoestrogens in Asoka was accomplished using LC-MS analysis and in silico docking studies were performed to investigate possible interactions of phytoestrogens with ER*α* and *β*.

Results

The extract of Asoka was found to be cytotoxic against TNBC cell line, MDAMB-231 with IC_{50} of 70.22 ± 1.89 µg/mL and towards HER^{+} breast cancer cell line, SKBR3 with IC_{50} of 98.41 ± 2.31 µg/mL, respectively. Whereas the extract did not show any cytotoxicity towards ER*α* cell line, MCF-7 even up to the concentration 300 µg/mL. Estrogen-screen assay emphasized an estrogenic effect of the extract on MCF-7 and an anti-estrogenic/antiproliferative effect on MDAMB-231 cells. LC–MS analysis identified phytoestrogens such as *β*-sitosterol, quercetin, kaempferol and others. The docking results revealed good binding efficacy of phytoestrogens with ER*β* than ER*α* and quercetin shows more affinity with the highest docking score of −9.220. Strikingly, it was found that the *S. asoca* methanol extract was preferentially cytotoxic to TNBC cells.

Conclusion

The study demonstrates selective anticancer properties of *S. asoca* methanol extract on TNBC, which indicates a selective impact on ER subtypes. The identification of phytoestrogens, such as *β*-sitosterol, quercetin and kaempferol, in the Asoka methanol bark extract provides a molecular basis for its observed effects. In silico studies further support the view that these phytoestrogens may preferentially interact with ER*β* rather than ER*α*. Quercetin, in particular, demonstrated the highest binding efficacy with ER*β*, suggesting its potential role in mediating the anticancer effects observed in TNBC cells. Further research is warranted to explore the full therapeutic potential of phytoestrogens in breast cancer treatment.

FULL TEXT

Background

Saraca asoca (Roxb.) De Wilde, commonly known as Asoka, belonging to the family Fabaceae is considered one of the most ancient and holistic trees in India. Various ethnopharmacological uses of Asoka in different treatment

aspects are well documented in Indian old classical Ayurvedic treatises, *Charaka Samhita* (1000 BC), *Susruta* (500 BC) *Vaghbatta* (sixth century) *Dhanvantari Nighantu* (ninth century) and *Chakradatta*, (eleventh century) etc. In Ayurveda, the stem bark of Asoka is used to make *Asokarishta*, a polyherbal decoction used to manage various gynecological complications, especially menorrhagia [1]. This traditional practice reflects the significance of Asoka especially in women's health, as emphasized in the traditional healing systems of India. Inspired by these treatises, several studies have validated the ethnobotanical claims and unveiled novel pharmacological properties [2] like antibacterial [3], antioxidant [4], antipyretic [5] antihyperglycemic [6], anthelmintic [7] and anticancer [8] activities. The cytotoxic activity of *S. asoca* on the breast (MDAMB-231, MCF-7), cervical (HeLa), colon (HT-29), and lung (A549) cancer cell lines were reported [9–11]. *Saraca asoca* exhibits chemopreventive activity against acute myeloid leukemia (AML) and DMBA/croton oil-induced skin papilloma formation in mice [12, 13]. The phytochemical analysis of the stem bark revealed the presence of alkaloids, flavonoids, phenols, phytosterols, saponins, tannins, steroids and terpenoids [14]. The phytoestrogens in this plant *β*-sitosterol, quercetin, kaempferol and catechin are reported to show anticancer properties including breast cancers.

Breast cancer is closely dependent on estrogen in its initiation and progression. Thus, estrogen receptors ER*α*/*β* plays a pivotal role in maintaining the homeostasis of the normal mammary gland [15]. ER*α*, the primary receptor of estrogen activates the cell cycle and stimulates proliferation, but ER*β* functions as a counterbalance to ER*α*, actively inhibiting cellular proliferation and providing a regulatory mechanism to the proliferative effect of ER*α* [16]. This intrinsic counteraction creates a dynamic interplay between ER*α* and ER*β*, influencing the delicate equilibrium of mammary gland homeostasis. Although ER*α* serves as the primary receptor for estrogen and is vital for the homeostasis of the normal mammary gland, its activation promotes cell cycle and stimulates proliferation, potentially leading to the initiation and development of cancer. Conversely, ER*β* functions as a counterbalance to ER*α*, actively inhibiting cellular proliferation and consequently, offering potential therapeutic avenues for breast cancer [17, 18]. Various reports indicate that ER*β* is expressed in triple-negative breast cancer (TNBC), accounting 50–80 % [19]. By leveraging the inhibitory properties of ER*β*, researchers and clinicians can explore targeted interventions to modulate hormonal signaling and disrupt the uncontrolled cell growth characteristic of breast cancer [20]. Several consistent findings have shown that ER*β* expression decreases in precancerous and cancerous breast lesions [21]. Currently, the predominant focus lies in the identification of novel selective ER*β* agonists, with numerous synthetic and natural molecules demonstrating high efficacy in breast cancer prevention and treatment. Notably, recent studies indicate that phytoestrogens exhibit a heightened affinity for ER*β* compared to ER*α* [22]. The potential for phytoestrogens to accumulate in breast tissue suggests significant clinical implications [23]. Among ER*β* agonists, phytoestrogens offer a distinctive therapeutic avenue for targeting ER*β* [24]. Liquiritigenin [25] and genistein [26] are notable examples, forming stable complexes with ER*β*, recruiting selective co-activators, and interacting with chromatin regulatory elements in estrogen-responsive genes [27]. Both liquiritigenin and genistein have been reported as protective factors against breast cancer, demonstrating the capacity to reduce invasiveness and growth of triple-negative breast cancer (TNBC) through pathway modulation [28, 29]. Another phytoestrogen kaempferol specifically inhibits the migration and invasion of TNBC cells by blocking RhoA and Rac1 signaling pathways. Given these findings, the present study aims to investigate the role of phytoconstituents in Asoka in inhibiting breast cancer cell growth, employing MCF-7, MDAMB-231, and SKBR3 cell lines through estrogen-screen and MTT assays. Additionally, the binding efficacy of phytoestrogens on estrogen receptors will be explored through in silico molecular docking.

Methods

Collection and preparation of extract

The stem bark of *S. asoca* was collected from the Thrissur district of Kerala, India, and its authenticity was confirmed by Dr. N. Sasidharan, Taxonomist, Kerala Forest Research Institute (KFRI), Thrissur, Kerala, India. The collected specimens have been deposited in the Herbarium of KFRI, assigned the voucher specimen number KFRI 4725. The plant sample underwent thorough washing with distilled water, followed by cutting into small pieces and subsequent drying at 45–50 °C for one week. The dried bark was then powdered using a grinder and stored in light-resistant,

airtight containers. About 20 g of the powdered sample was subjected to extraction with 200 mL of methanol at room temperature through overnight stirring. The resulting Asoka crude methanol extract was filtered using Whatman No.1 filter paper. The extraction process was repeated 2–3 times, and the residue was evaporated to dryness utilizing a vacuum concentrator. The weight of the dried extract was measured to determine the percentage yield of the soluble constituents [30].

Cell lines and animals

The triple-negative breast cancer cell line, MDAMB-231, the HER-2 expressed breast cancer cell line, SKBR3, and the hormone-positive breast cancer cell line, MCF-7, were procured from National Center for Cell Science (NCCS), Pune, India. These cell lines were cultured in DMEM medium supplemented with fetal bovine serum (FBS) at a concentration of 10% v/v. For the estrogen-screen assay, phenol red-free DMEM supplemented with charcoal–dextran-treated FBS was employed. Both media were also supplemented with streptomycin (100 µg/mL) and penicillin (100 U/mL). The cell lines were incubated at 37 °C in an incubator with 5% CO_2. Murine tumor cells, including Daltons Lymphoma Ascites (DLA) and Ehrlich's Ascites Carcinoma (EAC) cell lines, were grown in the intraperitoneal cavity of Swiss albino mice and were maintained in the animal house facility at Amala Cancer Research Center. Prior approval was obtained from the Institutional Animal Ethics Committee for the use of experimental animals with Approval No: ACRC/IAEC/17(1)/P-05 dt: 22-12-2017.

Phytochemical analysis

The crude methanol extract obtained from *S. asoca* was dissolved in methanol and underwent qualitative and quantitative analysis to identify the presence and concentrations of various phytochemicals. Different standard tests were employed for qualitative assessment to identify the presence of various compounds. Flavonoids were detected using Shinoda's test, phenols with the ferric chloride test, saponins with the Froth formation test, sterols with Salkowski and Liebermann-Burchard tests, tannins with the lead acetate test, and terpenoids with Salkowski tests [31, 32]. Additionally, the *S. asoca* crude extract was quantitatively analyzed using the Folin–Ciocalteau method to determine the total phenolic content using gallic acid as standard and expressed as mg of gallic acid equivalent (GAE)/g of dry extract [33]. For the quantification of flavonoids, the aluminium chloride colorimetric method was employed utilizing standard quercetin and expressed as milligrams of quercetin equivalent (QE) per gram of dry extract [34]. The experiments were meticulously conducted in triplicates to ensure accuracy and reliability, and the results are reported as the mean ± standard deviation (SD).

Cytotoxicity assay

The short-term cytotoxic activity of the Asoka crude extract was assessed by determining the percentage viability of murine tumor cells such as DLA and EAC, employing the trypan blue exclusion method [35]. The murine tumor cells were cultivated in the peritoneal cavity of female Swiss albino mice (25–30 g, 2 months old) through intraperitoneal injection of 1×10^6 cells/mL. Cells were aspirated aseptically from the cavity of mice after 15 days of inoculation; washed with PBS and centrifuged at 1000 rpm for 5 min. Pellets were resuspended in PBS and the cell count was adjusted to 1×10^6 cells/mL. Cells were pipetted out and added into each tube having PBS with different concentrations of the extract. It was then incubated for 3 h at 37 °C. After incubation, trypan blue dye was added and observed under the light microscope using a haemocytometer. The experiments were replicated in triplicates, and the percentage of cytotoxicity was assessed by enumerating the number of dead cells relative to that of live cells and substituting in the equation:%ofcytotoxicity=No.ofdeadcellsTotalnoofcells×100

The dose–response curve was fitted with the Hill equation using data analysis and graphing software, OriginPro 9 software [36].

Breast cancer cell lines such as MDAMB-231, SKBR3 and MCF-7, were employed to assess the antiproliferative activity of the extract using the MTT assay [37]. Approximately, 1×10^5 cells were seeded in 12 well plates containing medium and incubated at 37 °C for 24 h. Cells were then incubated with different concentrations of extract at 37 °C for 24 h. The test also included a blank containing a complete culture without cells. After incubation, 100 µL of 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) was added to each well and incubated for 4 h. The dark blue formazan crystals were dissolved in 1 mL solubilization solution containing isopropanol, concentrated HCl

and Triton X 100 by continuous aspiration and re-suspension. The absorbance of the colored product was measured at 570 nm. The cytotoxicity was determined by comparing the percentage death of the treated cell population with the untreated control, indicated by their respective absorbance assessed with the MTT assay. The dose–response curve was fitted with the Hill equation [36].EEmax=11+EC50Anwhere the maximum percentage of inhibition is E_{max}, the half-maximal effective concentration is EC_{50}, the Hill coefficient is '*n*' and the extract concentration is '*A*'. The Hill equation was computed using OriginPro 9. The assays were performed in triplicates, and statistical analysis was carried out using one-way ANOVA followed by Tukey's multiple comparison test in GraphPad Prism 8 software.

Estrogen-screen assay

Breast cancer cell lines expressing ER*β*, including MDAMB-231 and cell lines expressing ER*α*, such as MCF-7, were used for the study. The cell lines were cultivated in Dulbecco's Modified Eagle's Medium (DMEM) with FBS and phenol red as pH indicators with culture conditions of 5% CO_2 and 95% humidity at 37 °C. The cells were plated in well culture plates and allowed to attach. After 24 h, the seeding medium was removed and replaced with phenol red-free DMEM containing charcoal dextran treated FBS [38]. The cells were treated with different concentrations of 17 *β*-estradiol (0.1–1000 pM) and incubated at 37 °C for 3 days. After incubation, 100 µL of MTT was added to each well and incubated for 4 h. The dark blue formazan crystals were dissolved in 1 mL solubilization solution by continuous aspiration and re-suspension. The absorbance of the colored product was measured at 570 nm and the cytotoxicity was determined by comparing the percentage death of the treated cell population with the untreated control, indicated by their respective absorbance assessed with the MTT assay [37].

UV–visible spectroscopy

The *S. asoca* crude extract underwent centrifugation at 3000 rpm for 10 min and were subsequently filtered through the Whatman No.1 filter paper. The resulting samples were diluted with the same solvent employed for extraction, achieving a final concentration of 1 mg/mL. Standard solutions of quercetin, kaempferol, and *β*-sitosterol were also prepared at a concentration of 1 mg/mL of ethanol. Utilizing a UV–Vis spectrophotometer (PG Instruments, UK), the extract and standards were scanned across a wavelength range of 200 to 900 nm, and characteristic peaks were identified.

Fourier transform infrared spectroscopy (FTIR)

To characterize the functional group present in the sample, FTIR spectroscopy was conducted. A translucent sample disk was created by encapsulating 10 mg of *S. asoca* crude powder in 100 mg of potassium bromide (KBr) pellets. The FTIR spectroscopy analysis was performed using a Shimadzu IR Affinity 1 (Kyoto, Japan) within the range of 500 to 4000 cm^{-1} [39]. The obtained raw data was employed to generate FTIR spectra using OriginPro 9 software. The 'spectroscopic tools' were utilized for the analysis of the FTIR spectra (https://www.science-and-fun.de/tools/).

LC–MS analysis

The chemical profiling of the Asoka crude extract was done using High Resolution-Liquid Chromatography/Mass Spectrometry. The analysis was performed on an Agilent 6550 iFunnel Q-TOF LC/MS system (G6550A) equipped with an Agilent 1290 Infinity Autosampler (G4226A), an Agilent 1290 Infinity Binary Pump VL (G4220B), and an Agilent 1200 series thermostatted column compartment. A reverse-phase analytical column (Zorbax SB-C18, 100× 2.1 mm i.d., 1.8 µm particle size) was used for separation at a flow rate of 0.3 mL/min for a total of 30 min. Sample injection involved 5 µL of the sample. The mobile phases comprised aqueous 0.1% formic acid (A) and 90% acetonitrile in 0.1% aqueous formic acid (B). Mass spectroscopy utilized a dual ion source system with full scan mode, covering a mass range of 50 to 500 m/z. Mass Hunter Qualitative Analysis software was employed for data analysis.

Molecular docking

Molecular docking was done using Schrodinger Maestro software to investigate the possible interactions between *β*-sitosterol, kaempferol and quercetin which are specific compounds identified in *S. asoca* extract with the targeted receptors, ER*α* and ER*β*. Also, inbuilt ligand estradiol and the classical chemotherapy drug, tamoxifen was used to find out the binding affinity of estrogen receptors towards them. The structures of proteins with PDB IDs 3ERT and

3OLL were downloaded from the protein data bank for ERα and ERβ, respectively. The protein structures were processed before being used as a receptor for docking. Hydrogen atoms were added, atomic charges were assigned and water molecules that were not involved in ligand binding were removed during the operation. Chains and loops that were missing were also inserted. Protein preparation was done by using the protein preparation wizard. The pre-processing was done with the use of the import and process tab, while the review and modify tab was used for the generation of tautomeric states. The structures were optimized and minimized using the refine tab and protein was prepared for further studies. The optimized structures of the standards β-sitosterol, kaempferol and quercetin were used after converting them to structures with.sdf extension. The imported structures were edited using the 2D sketcher option in the Schrodinger Maestro. Then the ligprep wizard was employed to prepare each ligand using the OPLS3 force field. All tautomers of the structures were generated. Then the molecules were subjected to conformational change to form a stable conformer with the lowest energy. The glide receptor grid generating wizard was used to create a three-dimensional grid with 0.5 Å spacing and a maximum size of 20 Å × 20 Å × 20 Å. Any type of constraint, such as accuracy constraints, H-bond constraints, and so on, can be applied using the receptor grid generation wizard. The XP (extra precision) method was used for docking as it is the most powerful and discriminating procedure. After setting the location of the grid and ligands, docking was done with flexible molecules, and the proteins were used as rigid molecules [40].

Statistical analysis

The data from in vitro studies were presented as mean ± standard deviation (SD), derived from three distinct experiments. Statistical analysis was conducted using one-way ANOVA, followed by Tukey's multiple comparison test in GraphPad Prism 8 software. Statistical significance was assigned to p values <0.05*, <0.01**, and <0.001***, while $p>0.05$ was considered non-significant.

Results

Phytochemical analysis

The qualitative analysis of the *S. asoca* crude methanol extract indicated positive results for the presence of flavonoids, alkaloids, phytosterols, phenols, saponins, tannins and terpenoids. The quantification of polyphenolic content in the *S. asoca* crude extract, determined from the calibration curve ($R2 = 0.998$), revealed a concentration of 120 ± 6.82 mg of gallic acid equivalent (GAE) per gram of dry extract. Additionally, the total flavonoid content in the crude extract, estimated from the calibration curve ($R2 = 0.999$), was found to be 61.54 ± 4.51 mg of quercetin equivalent (QE) per gram of dry extract. These results provide a comprehensive insight into the chemical composition of *S. asoca* crude methanol extract, highlighting its rich polyphenolic and flavonoid content.

Anticancer properties

The cytotoxic effect of *S. asoca* crude methanol extract was assessed using the trypan blue assay and demonstrated considerable cytotoxic effects on DLA and EAC cells. The concentrations required to achieve 50% cytotoxicity were 42.24 ± 3.65 and 65.44 ± 2.89 µg/mL for DLA and EAC cells, respectively (Fig. 1). In MTT assay, the efficacy of *S. asoca* extract was evident against triple-negative breast cancer cell lines, MDAMB-231, with an IC_{50} of 70.22 ± 1.89 µg/mL, and HER-2 positive breast cancer cell line, SKBR3, with an IC_{50} of 98.41 ± 2.31 µg/mL (Fig. 1). A statistically significant ($p<0.05$) decrease in cell numbers was observed in both MDAMB-231 and SKBR3 following extract treatment. Treated cells exhibited a noticeable difference in morphology compared to control cells, characterized by cell shrinkage and shift in morphology from epithelial-like to round in both MDAMB-231 and SKBR3 (Fig. 2). However, the extract did not exhibit any cytotoxicity towards MCF-7, even at a concentration of 300 µg/mL.

Estrogen-screen assay

In this study, the ER*α* expressing MCF-7 cells exhibited a proliferative response to 17 *β*-estradiol (1000 pM), showing a 30% increase in cell count and a 7% increase in response to crude extract within a 72-h timeframe. Along with 17 *β*-estradiol, the crude extract exhibited a mild estrogenic effect. Conversely, ER*β* expressing MDAMB-231 cells demonstrated a 10% decrease in proliferation with 17 *β*-estradiol treatment, and the cell population was halved when treated with the crude extract at a concentration of 100 µg/mL (Fig. 3). Notably, the crude extract did not induce cytotoxicity in MCF-7 cell lines even at higher concentrations, while they decreased the cell viability of MDAMB-231 cells in a concentration-dependent manner. Consequently, the estrogen-screen assay highlights the estrogenic impact of *S. asoca* crude extract on MCF-7 and its anti-estrogenic/antiproliferative effect on MDAMB-231 cells.

Chemical profiling

Various techniques like UV–Vis spectroscopy, fourier-transform infrared spectroscopy (FTIR) and LC–MS were employed to evaluate the chemical profile of *S. asoca*. The absorption spectrum of UV-Spectrophotometric analysis of *S. asoca*, showed prominent peaks at 232, 275 and 449 nm which is in good correlation with the reported data [41]. These prominent peaks may have arisen from the phytoestrogens. Henceforth, the UV-spectra of standards (quercetin, kaempferol, *β*-sitosterol) were cross-checked and found that all of the suspected phytoestrogens have three peaks between 230 and 290 nm in the UV range and a single peak in a visible area (387–390 nm) (Fig. 4A). Accordingly, there is a likelihood of superpositioning of these distinct peaks in the *S. asoca* crude extract. The biological activity of any molecule is influenced by its functional groups which play a key role in determining the overall physicochemical properties. In FTIR, the results show functional groups such as alcohol, phenol, ester, alkane, aromatic and alkene in the extract. The functional groups identified in the extract are shown in Fig. 4B and Table 1.

Fig. 4 [Images not available. See PDF.]

A UV–visible spectrum of *S. asoca* crude methanol extract and phytoestrogen standards, **B** FTIR spectrum of *S. asoca* crude extract

Table 1. FTIR interpretation of compounds of *S. asoca* crude extract

Wave number cm^{-1}	Bond assigned	Functional groups
617	C–H vibration	Alkanes, alkenes
672	C–H and C–C stretching	Alkenes, alcohol, phenol
714	C=C and N–H stretching	Alkenes, amines
841	C–C and C–H stretching	Amides, aldehydes
1011	C–O stretching	Alcohol

1065	C–O stretching	Alcohol, aromatic
1125	C–O stretching	Alcohol
1393	C–O and C–H stretching	Phenol, aldehydes
1660	C–C stretching	Phenols
2230	C=C stretching	Conjugated alkene
3398	O–H stretching	Alcohol

The LC–MS analysis identified some of the important compounds such as caffeic acid, catechin, quercetin, kaempferol, gallic acid, rutin, *β*-sitosterol, p-coumaric acid, luteolin etc. (Fig. 5). Phytoestrogenic compounds like *β*-sitosterol, kaempferol, and quercetin present in the extract are presumed to contribute to the proliferative/antiproliferative effects of the *S. asoca* crude methanol extract on MCF-7, MDAMB-231, and SKBR3 cancer cell lines.

Fig. 5 [Images not available. See PDF.]

LC–MS spectrum of *S. asoca* crude methanol extract

Molecular docking

The studies suggest that certain phytoestrogens act as natural agonists for ER*β*, making them promising drug candidates for their ability to modulate the cell cycle, influence epigenetic events, and induce apoptosis. Interestingly, in the current investigation, the extract exhibits specific cytotoxicity towards ER*β* expressing cells, not affecting ER*α*. This raises the intriguing possibility that the phytoestrogens in the plant may act as agonists for ER*β*. To explore potential interactions between phytoestrogens and ER*α*/*β*, molecular docking was performed using Schrodinger Maestro software.

Interaction of phytoestrogens with ER*α*

The docking of the inbuilt ligand, estradiol into the 3D structure of ER*α* was done using a glide dock. The amino acid residues in the active site of 3ERT are Trp383, Leu384, Leu387, Met388, Gly390, Lbu391, Val392, Arg394, Met342, Met343, Leu345, Leu346, Thr347, Asn348, Leu349, Ala350, Asp351, Glu353, Leu354, Leu327, Phe404, Leu402, Leu428, Phe425, Ile424, Val422, Met421, Gly420, Glu419, Val418, Met517, Ser518, Lys520, Gly521, Met522, Glu523, Hie524, Leu525, Met528, Lys529, Cys530, Val533, Leu536, Leu539. The estradiol was docked into the active site region and interactions were made with the residues by hydrogen bonding with GLU353 and ARG394 and electrostatic bonding with ASP351. The inbuilt ligand shows a docking score of −12.17 and binding energy of −125.19 kcal/mol. The quercetin was docked into the active site region making interactions with the residues by hydrogen bonding with ASP351. The docking score and binding energy were found to be −6.945 and −47.026 kcal/mol which was more compared to kaempferol (−6.93). Tamoxifen shows a docking score of −10.512 and *β*-sitosterol did not dock with the binding pocket of ER*α*. The 3D interaction picture of the study is shown in Fig. 6A and their docking score and binding energy are tabulated in Table 2.

Fig. 6 [Images not available. See PDF.]

A 2D and 3D image of the interaction between ER*α* and ligands, **B** 2D and 3D image of the interaction between ER*β* and ligands

Table 2. Docking score and binding energy of estrogen receptors and ligands

Molecule	ERα		ERβ	
Docking score	Binding energy (kcal/mol)	Docking score	Binding energy (kcal/mol)	Inbuilt ligand-Estradiol
−12.17	−125.19	−10.5	−85.248	Quercetin
−6.945	−47.026	−9.220	−66.945	Kaempferol
−6.93	−45.07	−8.478	−58.435	Tamoxifen

The 2D image (Fig. 6A) reveals the type of interaction between the ligands and amino acids in the active sites of ER *α*. The inbuilt ligands estradiol, tamoxifen, kaempferol and quercetin form p bonds from their aromatic ring to Phe 404 but the number and nature of hydrogen bonds vary with ligands. Estradiol, kaempferol and quercetin form three hydrogen bonds with Glu353, Hie524 and Arg394, and tamoxifen only once with Asp351.

Interaction of phytoestrogens with ER*β*

The amino acid residues in the active site of ER*β* (PDBID: 3OLL) are Val280, Met295, Ser297, Leu298, Thr299, Leu301, Ala302, Asp303, Glu305, Trp335, Met336, Leu339, Met340, Gly342, Leu343, Met344, Arg346, Leu354, Phe356, Val370, Gly372, Ile373, Ile376, Phe377, Leu380, Ala468, Ser469, Lys471, Gly472, Met473, Hie475, Leu476, Leu477, Met479, Val485, Leu491, Leu495.

The inbuilt ligand was bound deep into the active site area, making hydrogen bonding interactions with Hie475, Arg346, Glu305 and *π–π* stacking interactions with Phe356. The inbuilt ligand shows a docking score of −10.5 and binding energy of −85.248 kcal/mol. The docking of ER*β* with quercetin showed the highest docking score of −9.220 and binding energy of −66.945 kcal/mol. Quercetin makes hydrogen bond interactions with Arg346, Glu305, Hie475 and *π–π* stacking with Phe356. Quercetin shows the highest affinity followed by kaempferol (−8.478) and tamoxifen (−8.023). Here also, *β*-sitosterol did not dock with the binding pocket of ER *β*. The 3D and 2D figures of other ligands are given in Fig. 6B. The docking score and binding energy of other ligands are given in Table 2.

The 2D image (Fig. 6B) reveals the type of interaction between the ligands and amino acids in the active sites of ER *β*. The inbuilt ligands estradiol, tamoxifen, kaempferol and quercetin form p bonds from their aromatic ring to Phe 356 but the number and nature of hydrogen bonds vary with ligands. Estradiol, kaempferol and quercetin form three hydrogen bonds with Glu305, Hid475 and Arg346, and tamoxifen only once with Asp351.

Discussion

The study emphasizes the considerable antiproliferative potential of crude extract from *Saraca asoca* against breast cancer cells, particularly targeting triple negative breast cancers. Specifically, the plant demonstrated selective cytotoxicity towards breast cancer cells expressing ER*β,* while sparing those expressing ER*α*. The estrogen-screen assay conducted on MDAMB-231 breast cancer cells revealed a pronounced antiproliferative effect, in contrast to MCF-7 cells, which exhibited a proliferative response to estrogen and the extract. The LC-MS analysis identified phytoestrogens such as *β*-sitosterol, quercetin, kaempferol, and others in the plant. In in-silico docking analysis, these phytoestrogens showed higher binding affinity towards ER*β* compared to ER*α* receptors, except for *β*-sitosterol. Therefore, the observed preferential cytotoxicity of *S. asoca* towards ER*β* expressing breast cancers holds significant clinical relevance, given that triple negative breast cancers represent the most aggressive form of cancer with limited treatment options.

Triple-negative breast cancer (TNBC) is characterized by the absence of expression of ER*α*, progesterone receptor (PR), and human epidermal growth factor receptor-2 (HER-2) [42]. In recent research on the immunological profile of

these TNBC cell lines, the presence of estrogen receptor isoform ER*β*, which acts as an opponent of ER*α*, in 50–80% of TNBCs was found [19]. In cytotoxic assays conducted in this study, Asoka exhibited significant cytotoxicity towards various cancer cells of both murine and human origin. This was evidenced by a concentration-dependent increase in the percentage of dead cells, particularly in DLA and EAC murine cancer cells. Notably, previous research has already reported comparable cytotoxic effects against mouse tumor cells [43]. Interestingly, despite the use of high concentrations, the extract did not induce cytotoxic effects on breast cancer cells expressing ER*α*, such as MCF-7, as observed in the MTT assay. However, the extract did exhibit cytotoxic effects on breast cancer cell lines expressing ER*β*, such as MDAMB-231 and SKBR3. Prior investigations have suggested the antiproliferative effects of *S. asoca* on MDAMB-231 and also on MCF-7 cell lines [11]. However, in our study, MCF-7 cell lines did not exhibit any cytotoxicity even at higher concentrations of the extract. This interesting contrast in cytotoxicity between ER*α* and ER*β* expressing breast cancer cells in our study corresponds with earlier findings which mention ER*α* activation leading to cell proliferation, while ER*β* activation exhibiting an anti-proliferative effect [15, 18].

The proliferative/anti-proliferative effect of the *S. asoca* crude extract was evaluated through an estrogen-screen assay on various breast cancer cell lines, with 17*β*-estradiol as a reference. This bioassay determines the increase or decrease in cell number in response to estrogen, resembling an increase in mitotic activity within reproductive system-associated tissues [44]. Our investigation revealed that Asoka demonstrates a moderate anti-proliferative effect on the MDAMB-231 cell line expressing ER*β*, while it induces proliferation in the MCF-7 cell line expressing ER*α*. The presence of phytoestrogens such as quercetin, kaempferol, and *β*-sitosterol, among others, was reported in Asoka by LC-MS. Additionally, there are reports of flavonoids like quercetin, chrysin, and 3-hydroxyflavone with known anti-proliferative properties [45]. Therefore, it is likely that the phytoestrogens in Asoka may act as agonists for ER*β* due to their specific affinity for ER*β* expressing cells.

The results of our docking experiments also have demonstrated the potent affinity of phytoestrogens towards ER*β* in comparison to the ER*α*. Both quercetin and kaempferol exhibited significantly higher docking scores and binding energies than tamoxifen, a commonly used chemotherapeutic medication. Remarkably, quercetin's docking score was close to that of estradiol, the endogenous ligand for estrogen receptors. Furthermore, there have been reports highlighting the robust binding affinity of *S. asoca* flavonoids to human estrogen receptors. In a molecular simulation research involving Asoka flavonoids and estrogen receptors, the binding scores indicate their exceptional ability to form strong interactions with these receptors. Molecular orbital analysis and pharmacokinetic parameters further support their efficacy [46]. Notably, our study revealed high binding affinity values of phytoestrogens binding with estrogen receptors which surpassed that reported in a previous investigation on Asoka flavonoids [47]. This increased affinity of phytoestrogens, particularly for ER*β*, holds significant implications, as it appears to underpin their antiproliferative effects. This interaction with estrogen receptors, notably ER*β*, may give rise to a wide array of biological responses [22].

Conclusion

The study highlights the preferential cytotoxicity of the *S. asoca* crude methanol extract towards ER*β* expressing cells, particularly to triple negative breast cancers, a highly aggressive and therapeutically challenging type. The observed antiproliferative effects on breast cancer cells may be attributed to the action and interaction of phytoestrogens present in Asoka with ER*β*. Notably, quercetin and kaempferol among the identified phytoestrogens exhibit high docking into the binding sites of active amino acids in the ER*β*. These findings suggest that the phytoestrogens in Asoka may act as agonists to ER*β*, offering promising prospects for the development of targeted therapies for triple negative breast cancer, thereby opening new avenues in the currently limited treatment landscape.

Chemical composition and antifungal activity of Teucrium Leucocladum Boiss. essential oils growing in Egypt using two different techniques

Salah, Eman Mohamed1; Issa, Marwa Y.2 ; Mohamed, Tarik A.3; Hegazy, Mohamed-Elamir F.3; Tadros, Soad H.2; Fathallah, Noha11 Future University in Egypt, Pharmacognosy and Medicinal Plants Department, Faculty of Pharmacy, Cairo, Egypt (GRID:grid.440865.b) (ISNI:0000 0004 0377 3762)2 Cairo University, Pharmacognosy Department, Faculty of Pharmacy, Cairo, Egypt (GRID:grid.7776.1) (ISNI:0000 0004 0639 9286)3 National Research Centre, Chemistry of Medicinal Plants Department, Dokki, Egypt (GRID:grid.419725.c) (ISNI:0000 0001 2151 8157)

ABSTRACT (ENGLISH)

Background

Teucrium Leucocladum Boiss. (TL) (family Lamiaceae), indigenous to Sinai, Egypt, and Mediterranean region, is considered a rich source of essential oils (EOs). This study aimed to extract the aerial parts essential oils utilizing hydro-distillation (HD) and microwave-assisted extraction (MAE), and analyze the volatile constituents by Gas Chromatography–Mass Spectrometry (GC/MS). The antifungal and cytotoxic potentials against *Candida albicans* (*C. albicans*) and non-small cell lung adenocarcinoma A549, triple-negative breast cancer MDA-MB-231 cell lines, respectively, were likewise estimated. Subsequently, the three main compounds were docked into the crystal structure of *Candida albicansN*-myristoyltransferase (NMT) with myristoyl-COA and peptidic inhibitor (PDB 1IYK), and predictions of human absorption, distribution, metabolism, and excretion (ADME) were performed to assess the drug-likeness of the compounds.

Results

The chemical profile consisted of monoterpene hydrocarbons, oxygenated monoterpenes, sesquiterpene hydrocarbons, and oxygenated sesquiterpenes. The MAE oil sample (TLM) yield was found to be double that of the HD oil sample (TLH). TLM afforded an inhibitory diameter (13 mm) comparable to the ketoconazole (20 mm), TLM 100 mg/mL showed the strongest antifungal potential against *C. albicans*. The cytotoxic assay revealed moderate activity against A549 and MDA-MB-231. In silico studies using molecular docking were processed on the major components in which nerolidol had the best-fitting energy to inhibit *C. albicans* (−7.21 kcal/mol), while ADME results established a promising first step for the potential drug bioavailability.

Conclusion

In this research, essential oil acquired from the aerial parts proved to contain monoterpenes and sesquiterpenes, which are classes of compounds known for their versatile usage in medicine. In vivo studies on *Teucrium Leucocladum* Boiss. active metabolites against clinical strains of fungi need to be further studied, as do the effects of combining the active compounds with antifungal agents to combat antimicrobial resistance.

FULL TEXT

Background

Since the dawn of humanity, essential oils have been utilized for plenty of reasons. They have numerous positive attributes as they are traditionally used to enhance the flavor and fragrance of prepared foods, as well as perfumes and cosmetics. Beyond their sensory contributions, essential oils exhibit significant biological potentials, including larvicidal action, analgesic and anti-inflammatory effects, antioxidant, antifungal, and anticancer activities. Moreover, essential oils have been integrated into medicinal practices, showcasing their therapeutic potential [1]. The diverse range of activities exhibited by essential oils (EOs) can be attributed to their complex composition, comprised of

various constituents such as terpenes, terpenoids, and phenylpropanoids. Notably, within these intricate chemical profiles, only two or three major components typically constitute a significant proportion, ranging from 20 to 70% of the total substance [2].

The chemical composition of EOs is significantly influenced by various factors, including the geographical location of the plant containing the EOs, the seasonal timing of harvest, storage conditions, and the extraction methodology employed. These variables collectively contribute to the unique and dynamic molecular profiles of EOs. The numerous biological and therapeutic activities exhibited by essential oils, coupled with their relative safety and capacity to synergistically interact with other compounds, qualify the utilization of essential oils as naturally derived medicinal compounds [3].

Traditional medicines and modern pharmaceutical developments alike are predominantly derived from plant sources, utilizing active metabolites known for their low to negligible toxicity. These bioactive compounds have demonstrated efficacy in treating a wide spectrum of disorders. In recent years, there has been a conspicuous surge in research initiatives concentrating on medicinal plants, with a specific emphasis on investigating their potential as agents exhibiting anticancer and antimicrobial properties. This heightened scientific interest reflects the continual exploration of plant-based compounds as significant reservoirs for the advancement of novel drugs, particularly in the fields of oncology and infectious diseases [4–6].

Family Lamiaceae (mint family) comprises 236 genera and 6900–7000 species of aromatic plants. Herbs, whether perennial or annual, shrubs, and trees are all members of this family [7]. Many species of this family are considered sources of essential oils (EOs) [8]. Significantly, members of the Lamiaceae family are extensively utilized as medicinal plants in various folk traditions. Lamiaceae largest genus in the Mediterranean area is *Teucrium* [8].

Teucrium (Lamiaceae) is an aromatic [9], polymorphic [7] genus, comprising more than 300 species [8] represented mostly by perennial, bushy, or herbaceous plants growing in temperate zones, particularly in Central Asia and the Mediterranean basin [10]. Chemical investigations of genus *Teucrium* members have shown that those plants are very rich sources of active principles, especially essential oils [11].

Teucrium leucocladum (TL) Boiss. is an aromatic low shrub ranging from 20 to 50 cm long, indigenous to the Sinai Peninsula [12] and is considered one of the most used traditional medicinal plants in Palestine, Egypt, and the Mediterranean region for the treatment of hyperglycemia (aqueous extract of aerial parts) and colon spasms among other ailments [13].

The major objective of the current research was to comprehensively characterize the complete chemical profile of the EOs extracted from (stem and leaf parts) of *Teucrium leucocladum* Boiss. for the first time. This characterization employed two distinct techniques: microwave-assisted extraction (MAE) and hydro-distillation (HD), resulting in the production of TLM and TLH, respectively. GC–MS was used to analyze the prepared essential oils. Additionally, the study involved the assessment of the potential activity of the oil samples against *Candida albicans* and three different cancer cell lines.

Results

Chemical composition

Both techniques produced yellow-colored oils from *Teucrium leucocladum* Boiss. with a distinct characteristic odor. The percentage yield of the essential oils, however, varied significantly depending on the procedure, affording 0.5 and 1.2% (v/w) for HD and MAE, respectively. Our results are consistent with published data revealing that hydro-distillation provides yields less than microwave-assisted extraction [14]. The results of GC chromatograms are represented in Fig. 1.

Fig. 1 [Images not available. See PDF.]

GC chromatograms of the essential oils of *Teucrium leucocladum* Boiss. extracted via hydro-distillation (**A**), and microwave-assisted extraction (**B**)

While MAE exhibited a higher oil yield, it presented a lower number of metabolites compared to hydro-distillation, as indicated in Table 1. Moreover, the yields emphasized that the selection of the extraction technique markedly

impacted the chemical composition of the extracted essential oils. Seventy-three components were identified during hydro-distilled oil preparation, whereas 32 components were detected in the oil prepared by microwave-assisted extraction (MAE), constituting 95.53% and 94.33%, respectively.

Table 1. Chemical composition of the isolated essential oils

No	Compound	[a]R_t HD	[b]R_t MAE	[c]RI_{Exp}	Area%		Molecular Formula

[a]R_t HD: retention time for hydro-distillation. [b]R_t MAE: retention time for microwave-assisted extraction. [c]RI_{Exp}: retention index was determined experimentally relative to C8–C28 n-alkanes for all compounds. [d]HD: hydro-distillation, [e]MAE: microwave-assisted extraction, NA: not available

The identified constituents are categorized mainly into four groups: monoterpene hydrocarbons, oxygenated monoterpenes, sesquiterpene hydrocarbons, and oxygenated sesquiterpenes (Fig. 2). Oxygenated sesquiterpenes were the major group in oils prepared by both methods at about 61.26% and 42.85% in TLH and TLM, respectively. The sesquiterpene alcohol nerolidol was the most prominent compound amounting to 50.02% in the HD oil sample, while the sesquiterpene alcohol levomenol and the monoterpene alcohol *trans*-2-Caren-4-ol dominated TLM at 21.40% and 33.92%, respectively.

Fig. 2 [Images not available. See PDF.]

Percentage of the classes of volatile components in the essential oil of *Teucrium leucocladum* Boiss. extracted via (**A**) hydro-distillation, and (**B**) microwave-assisted extraction

α-Pinene and β-Pinene were the major monoterpene hydrocarbons observed in HD sample 2.59 and 1.77%,

respectively, while α-thujene was major in MAE at 1.18%. For sesquiterpene hydrocarbons, valencene was the major observed in the HD sample at 2.00%, while cadinene was the major one in the MAE sample with a percentage of 3.25.

Despite that the hydro-distilled oil of *T. leucocladum* Boiss. was formerly assessed [12], this is the first time to evaluate the oil prepared via microwave-assisted extraction. The structures of certain identified oil components are illustrated in Fig. 3.

Fig. 3 [Images not available. See PDF.]

Two-dimensional structures of the identified compounds of the essential oils (EOs) extracted using hydro-distillation (HD) and microwave-assisted extraction (MAE) methods of *Teucrium leucocladum* Boiss. oil*s* by GC–MS analysis

Screening of the antifungal activity

In vitro antifungal activity of TLH and TLM oil samples was tested against a type of yeast-forming fungi *C. albicans* using the agar well diffusion method. For each oil, two concentrations 50 and 100 mg/mL were used in the procedure. The concentration and method of oil extraction exerted a notable influence on the extent of inhibition of *C. albicans* growth, as illustrated in Fig. 4. TLM, at concentrations of 100 mg/mL and 50 mg/mL, demonstrated the highest antifungal potential, yielding inhibition diameters of 13 mm and 10 mm, respectively, surpassing the inhibition diameter observed for the standard drug ketoconazole (20 mm). TLH, at a concentration of 100 mg/mL, exhibited a weaker but still noticeable inhibition diameter of 10 mm, while no inhibition was observed for TLH at a concentration of 50 mg/mL.

Fig. 4 [Images not available. See PDF.]

Antifungal Inhibition diameters represented in mm of TLM and TLH samples against Ketoconazole

Our results imply that *Teucrium Leucocladum* Boiss. essential oil might have the ability to function as an antifungal medication.

Cytotoxic activity

Evaluation of the cytotoxic activity via resazurin reduction assay [15] was accomplished against non-small cell lung adenocarcinoma A549, triple-negative breast cancer MDA-MB-231, and colon adenocarcinoma Caco-2 (ATCC) using doxorubicin HCL as a positive control. Preliminary screening of the oil samples TLH and TLM against cell viability of A549 and MDA-MB-231 cell lines at two concentrations (20 and 200 µg/mL) revealed a promising effect at the high concentration (200 µg/mL) for both samples verifying that the inhibition was dose-dependent, whereas lower sensitivity was demonstrated against Caco-2.

Eventually, the fifty percent inhibitory concentration (IC_{50}) determined for cell lines with promising cytotoxic activities, revealed that IC_{50} of TLM was 142.0 and 185.0 µg/mL against A549 and MDA-MB-231, respectively, while TLH exhibited IC_{50} 192.0 and 190.0 µg/mL against A549 and MDA-MB-231, respectively.

Molecular docking studies

The process of discovering and developing new drugs involves looking for the metabolites of herbal medicines that act as disease inhibitors [16]. Given its ability to provide information about the atomic-level interactions between tiny molecules and proteins, molecular docking has become an indispensable tool in the drug discovery process [17]. Many researches have proved that the NMT gene [18] is essential for vegetative growth and survival of *C. albicans.* Research in genetics and biochemistry has established that *N*-myristoyltransferase (NMT) is a promising target for antifungal medications. Numerous studies have indicated that the NMT enzyme in *C. albicans* provides important data for the design of the inhibitor [19].

Results revealed that binding energies of the examined compounds namely levomenol*,* nerolidol, and *trans*-2-caren-4-ol (Table 2, Fig. 5) were −5.53, −6.62, and −7.21, respectively approaching that of the reference drug (ketoconazole) −9.25.

Table 2. Results of docking simulations of the main identified components in TLH and TLM samples

No.	Name	Lowest Binding energy	KI[a]
1	Levomenol	−7.21	5.18 μM
2	Nerolidol	−6.62	14.01 μM
3	*trans*-2-Caren-4-ol	−5.53	87.84 μM
4	Ketoconazole	−9.25	164.76 nM

KI[a] Inhibition concentration of the best score in docking, μM micromolar, nM nanomolar

Fig. 5 [Images not available. See PDF.]

Docked complexes showing 2D and 3D binding modes of levomenol, nerolidol, *trans*-2-Caren-4-ol, and the reference compound ketoconazole in the active site of *Candida albicans*

The ADME, Lipinski's rule of five and BOILED-Egg techniques

The prediction of human absorption, distribution, metabolism, and excretion (ADME) properties, as well as the estimation of therapeutic dose and exposure, has become an essential component of compound optimization during the drug discovery process. This practice is vital for enhancing the efficiency and success of drug development by providing valuable insights into how a compound is likely to be absorbed, distributed, metabolized, and eliminated within the human body. Accurate predictions in these areas enable researchers to optimize compounds for better bioavailability, efficacy, and safety, ultimately guiding the selection of promising candidates for further development and clinical testing. This integrated approach contributes significantly to the rational design and prioritization of drug candidates, facilitating a more streamlined and effective drug discovery process [20].

Poor ADME characteristics for a certain compound are considered triggers for a cascade of failures of most medicines in clinical experiments. The outcomes indicated variation in the physiochemical parameters of the three compounds with differences in the BBB (blood–brain barrier) and (HIA) human intestine absorption ranges, so we were encouraged to follow Lipinski's rule of five [21], which was published in 1997 by Christopher A. Lipinski [22]. It is a standard practice to assess the drug-likeness of a chemical compound and establish whether it possesses characteristics to be active for humans when administered orally.

As shown in Table 3, these 5 parameters totally and completely complied with the examined compounds (*trans*-2-caren-4-ol, nerolidol, and levomenol) in which the polarity, lipophilicity, solubility, flexibility, and saturation were found within the pink area (Fig. 6) indicating promising bioavailability [23].

Table 3. Lipinski's rule of five for ADME analysis of the investigated compounds

No.	Name	M.wt	Lipophilicity	Hydrogen Bond Donors	Hydrogen Bond Acceptors	No. of Rule Violations	Drug-Likeness
Lipinski's rule limits	Less than 500 Dalton	Less than 5	Less than 5	Less than 10	Less than 2 Violations	Lipinski's rule Follows	1
Levomenol	222.37	3.56	1	1	0	Yes	2
Nerolidol	222.37	3.86	1	1	0	Yes	3

Fig. 6 [Images not available. See PDF.]

Radar plot of the examined compounds. POLAR (polarity), LIPO (lipophilicity), INSOLU (solubility), FLEX (flexibility), and IN-SATU (saturation)

BOILED-Egg technique [21] designed for the assessment of the lipophilicity and polarity of small compounds, is supposed to serve as a highly accurate predictive model. This model holds significance in the lead optimization of drugs. Notably, the BOILED-Egg model has the capability to simultaneously predict two crucial ADME parameters: passive gastrointestinal absorption (HIA) and brain access(BBB) [24]. The findings indicate that the three compounds were effectively absorbed, potentially having access to the brain, as depicted by the white region in the results.

Additionally, the compounds exhibited P-glycoprotein permeability (PGP), represented by the red dot. Importantly, all recorded values fell within the acceptable range, meeting the specified criteria [25]. This suggests that the compounds absorption characteristics align with established thresholds, highlighting their favorable pharmacokinetic properties and suitability for further consideration in drug development [24]. Among the three compounds, nerolidol revealed the highest water partition coefficient (WLOGP) followed by levomenol and then *trans*-2-caren-4-ol indicating that *trans*-2-caren-4-ol has the least potential to pass the BBB presented in Fig. 7. However, they were nearly similar regarding topological polar surface area (TPSA) with a value of 20.23 Å.

Fig. 7 [Images not available. See PDF.]

Evaluation of Levomenol *WLOGP* = 4.23, Nerolidol *WLOGP* = 4.40, and *trans*-2-Caren-4-ol *WLOGP* = 1.97 by the BOILED-Egg method. *Note*: In the 2D graphical representation of a BOILED-Egg, the yolk area corresponds to molecules that are anticipated to passively permeate through the blood–brain barrier (BBB). Conversely, molecules situated in the white region are predicted to undergo passive absorption through the gastrointestinal (GI) tract

Discussion

Candida albicans is the main fungus associated with infections via medical devices [26]. Contact lenses, joint prostheses, mechanical heart valves, and dentures are all prone to be infected with this fungus. Accordingly, many studies were conducted to search for new and promising agents against this fungus [26]. Worldwide, cancer is the second most common cause of death. Despite continuous improvements in cancer treatment, there are still many undesirable side effects that occur when receiving chemotherapy. Natural remedies, acquired from plants, may limit those unfavorable side effects and still be utilized to treat cancer [27]. The results revealed that the MAE and hydro-distillation produced EOs with dissimilar volatile content, suggesting that altering the extraction procedure may lead to changes in the chemical profile and thus the biological activity. This heightened variation of efficacy is likely attributable to its terpenoid content, specifically the presence of oxygenated sesquiterpenes and monoterpenes.

On one hand, nerolidol was the most prominent compound in the TLH that may contribute to the biological activity. It is a sesquiterpene alcohol well-established with various uses and demonstrates favorable effects on human health; hence, it is regarded as a promising candidate for chemical or drug development across various domains, including agriculture, industry, and medicine [28]. Numerous publications [28, 29] provide proof of nerolidol effectiveness in demonstrating antifungal activity. It was illustrated to have fungicidal effects against *Microsporum gypseum*, *Candida albicans*, and *T. mentagrophytes* [30, 31].

On the other hand, levomenol (α-bisabolol) was observed as one of the major compounds in TLM. Bisabolol was demonstrated to have the ability to prevent the development of hyphae and fungal growth, as well as to change how ergosterol, a crucial structural element of the fungal membrane, is produced. These effects may be key virulence factors in some strains of the yeast *C. albicans* [32].

Trans-2-Caren-4-ol constitutes 33.92% of the overall volatile content in the EOs extracted using the MAE method from TL. Nerolidol is also known as an antioxidant, chemo-preventive, and antitumor agent. It can modulate the biochemical profiles, work as an antioxidants, detoxification agent, and inhibit tumor development and various types of carcinogenesis [33].

α-Bisabolol was recorded to inhibit the growth of tumors and induce apoptosis in several malignancies, such as acute leukemia, glioblastoma, and pancreatic, prostatic, breast, and liver cancers. Its mechanism of action involves

inhibiting the proliferation, invasiveness, and motility of cancer cells [34, 35]. The notable differences in the mechanisms of action of the major components identified in the oil extracts may account for the variations in cytotoxic activity.

Finally, In silico and ADME studies were conducted to validate the potential antifungal activities and to predict the physiochemical properties of the three major compounds, respectively. The NMT enzyme was chosen due to its essential role in the viability of *Candida albicans*, a major contributor to systemic fungal infections in immunocompromised patients.

Consequently, NMT is considered a promising target for antifungal drug development. It was observed that the enzyme adopts an open conformation during substrate binding. The major compounds present in the oils, being nonpeptidic inhibitors, have the capacity to bind to the substrate binding site enveloped by hydrophobic residues. This interaction pattern differs in detail from that observed with conventional peptidic inhibitors [36]. Levomenol demonstrated the highest binding energy approaching that of ketoconazole followed by nerolidol then *trans*-2-Caren-4-ol.

Conclusion

The widespread inefficiency of antifungal therapy to treat various fungal infections and the side effects of conventional chemotherapy has accelerated research into alternative therapeutics. *Teucrium leucocladum* Boiss. is a famous endogenous plant grown in Egypt that exhibits pharmaceutical potential and medicinal value. In this research, the essential oil acquired from the aerial parts proved to contain monoterpenes and sesquiterpenes, which are classes of compounds known for their versatile usage in medicine. In vivo studies on TL active metabolites against clinical strains of fungi need to be further studied, as do the effects of combining the active compounds with antifungal agents to combat antimicrobial resistance. Additionally, deeper investigation is necessary to find a simpler, natural, more advantageous anticancer pharmaceutical product.

Methods

Plant materials

The aerial parts of *Teucrium Leucocladum* Boiss. were collected [18] from St Katherine Protectorate (28◦3203200 N 33◦57030.200 E), South Sinai, Egypt, in April 2022. The specimen was authenticated by Prof. Dr. Ibrahim El-Garf, Department of Botany, Faculty of Science, Cairo University, Egypt, where a voucher specimen (TL-113) has been deposited.

Hydro-distillation of the essential oil

A fresh sample (100 g) of TL dried via air-shading was hydro-distilled via Clevenger-type apparatus for 3 h which was conducted based on the methods presented by the European Pharmacopoeia (1996) [37] (plant: water ratio 1:3, w/v).

Microwave-assisted extraction of the essential oil

The air-shaded dried sample (100 g) of *T. leucocladum* was extracted using a focused microwave apparatus [18]. Then, the oil sample was prepared [18], separated, and dried [18] and the volume of the recovered essential oil was determined [18]. The extracted oil samples were stored in sealed air-tight glass vials at −20 °C until further analysis. The percentage yield was computed as % v/w using the following equation:

$$\%\text{Yield} = [\text{Oil volume (mL)}/\text{Plant material weight (g)}] \times 100$$

GC–MS analysis of the essential oils

Components of the extracted EOs were analyzed and characterized by GC–MS. The GC–MS analysis was performed at the Department of Medicinal and Aromatic Plants Research, National Research Center, Dokki, Giza, Egypt. The gas chromatography–mass spectrometry instrument and the identification of the chemical components of the EOs was achieved according to the previously mentioned method [18].

Antifungal activity

The antifungal activity was performed according to NCCLS recommendations (National Committee for Clinical Laboratory Standards, 1993).

Screening tests regarding the inhibition zone were carried out by the agar well diffusion method [38, 39], and 100 µL

of each sample were applied in the wells of diameters 0.6 mm. The experiment was carried out in the Regional Center of Mycology and Biotechnology at Al-Azhar University, Cairo, Egypt. The inoculum suspension was prepared according to the reported method [40].

The EOs were dissolved in dimethyl sulfoxide (DMSO) with two different concentrations (50 and 100 mg/mL) for each oil sample (TLH and TLM). Then, the inhibition zone was measured around each well after 48 h at 28 °C using ketoconazole (100 µg/mL) as positive control for fungi.

Cytotoxic activity

The cytotoxic activities on the oil samples were performed at Polychem Bioassays for Scientific Services (Educational Research Center), Egypt on three cell lines against Doxorubicin HCL (98.0%) as a positive control. All reagents and materials for the cell cultures were purchased from Pan Biotech (Germany). Human cancer cell lines of non-small cell lung adenocarcinoma (A549), Triple-negative breast cancer MDA-MB-231, and colon adenocarcinoma (Caco-2) (ATCC®) were maintained [18]. Doxorubicin (98.0%) was provided and dissolved in PBS at 10 mM [15]. Using an Alamar blue (Resazurin reduction) assay based on a previously published method [15]. Appropriate cell densities of exponentially growing A549, MDA-MB-231, or Caco-2 cells (5000–8000 cells/well) were seeded onto 96-well plates. After 24-h incubation with 5% CO_2 at 37 °C, quadrate wells of cells received screening concentrations of each sample (20 and 200 µg/mL) in the culture medium (final DMSO concentration in medium = 0.1%, by volume). After 48 h of incubation, alamar blue dye in culture medium was added to each well after which the incubation was resumed for further 4 h. At the end of the incubation period, the absorbance at 600 nm was recorded on a microplate reader (Sunrise™ microplate reader, Tecan Austria Gmbh, Grödig, Austria) and was used as a measure of cell viability. In dose-dependent experiments, cells were exposed as above to sample serial dilutions (200, 100, 50, 25, and 12.5 µg/mL) to estimate the dose causing a 50% loss of cell viability compared to the control (IC_{50}) using nonlinear regression curve fit on GraphPad Prism software V8.0. (San Diego, USA) to give significant differences in cytotoxicity, one-way analysis of variance (ANOVA) was used for statistical analysis. Significant differences were indicated as $*p<0.05$.

Molecular docking studies

The chemical structures of the major metabolites in the essential oils (EOs), namely levomenol, nerolidol, and *trans*-2-caren-4-ol, were obtained by downloading their respective Structure Data Files (SDF files) from the PubChem database (https://pubchem.ncbi.nlm.nih.gov/), followed by conversion to PDB format via the free software Avogadro (https://avogadro.cc/) [41, 42].

The protein crystal structure for 1IYK (antifungal) was downloaded from the protein databank (https://www.rcsb.org/) [41] using the previously published molecular docking protocol [42].

The ADME, Lipinski's rule of five and BOILED-Egg techniques

The ADME and pharmacokinetic studies have been determined using SWISS ADME [25] (accessed on 25 July 2023) to evaluate the potential of the three major compounds as promising candidates for pharmaceutical drug development. The expected values for the compounds (levomenol, nerolidol, and *trans*-2-Caren-4-ol) in the radar are represented in Fig. 6.

The three compounds with potential physicochemical characteristics for oral bioavailability were identified by the Swiss ADME molecules bioavailability radar. The pink region represents the ideal spaces for the six physicochemical properties [25]. A chemical is regarded as drug-like if its complete radar plot falls within the pink region. An alternative approach for the assessment [25] involves the use of the BOILED-Egg technique, where levomenol, nerolidol, and *trans*-2-caren-4-ol are anticipated to exhibit brain-penetrating properties and are detected within the yolk [25].

Author contributions

E.M.S, M.Y.I, N.F., and T.A.M. contributed to methodology, formal analysis, investigation, and writing–original draft preparation. M-E.F.H and S.H.T. contributed to conceptualization, editing, validation, and supervision. All authors

read and approved the final manuscript.

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Availability of data and materials

All data generated or analyzed during this study are included in this published article.

Declarations

Ethics approval and consent to participate

Experiments have been carried out in compliance with the Ethical Committee of Faculty of Pharmacy, Cairo University, Cairo, Egypt, (Committee of Safe Handling and Disposal of Chemicals and Biologicals) of the protocol numbered MP (3124).

Consent for publication

Not applicable.

Competing interests

The authors declare that they have no competing interests.

ABSTRACT (ENGLISH)

Background

Fruits of *Hunteria umbellata* (HU) have been utilized in folk medicine as potent against *Staphylococcus aureus* (SA) infections, particularly skin and nasal related conditions. However, there is scarcity of literature concerning toxicological evaluation of graded doses of HU fruit, especially at molecular level, specifically targeting the accessory gene regulator (AGR) system to prevent abuse of doses in the treatment of bacterial infections. This research evaluated molecular toxicological property of SA exposed to varied concentrations of aqueous HU fruit extract ranging from 500 to 3.90625 µg/µL using broth microdilution method and quantification of AGR I and II genes' expression employing two-step reverse transcriptase quantitative polymerase chain reaction (RT-qPCR). We first identified quality and quantity of chemical compounds in aqueous fruit of HU using phytochemistry and hybrid gas chromatograph–mass spectrometer (GC–MS) technique. Additionally, preliminary bactericidal potential of HU was assessed before molecular toxicology.

Results

Results revealed six phytochemicals and twenty analytical grade compounds from a standard library were identified from chromatograms of HU fruit extract. Some main compounds detected are *n*-Hexadecanoic acid (25.24%), 2-Pentadecanone, 6,10,14-trimethyl (16.08%), Cuparene (16.63%), Tetradecanoic acid (6.21%) and 9-Octadecenoic acid, (E)- (5.70%). Bactericidal activity shows significant ($p<0.05$) toxicity in the tested (8) concentrations of HU fruits in a dose-response relationship compared to the controls (positive and negative). The quantified expression of AGR I and II genes in SA was most significantly increased ($p<0.05$) at both 250 and 500 µg/µL of HU fruit extract while least significant increase ($p<0.05$) was recorded at 125 µg/µL compared to control.

Conclusions

Notably, the study highlighted a potential risk of augmented bacterial infection especially with higher doses of HU extracts during boils' treatment and other epidermal infections instigated by Staph. Expression of both AGR genes at higher doses (250 and 500 µg/µL) is indicative of further expression of several other genes responsible for virulence factors in a variety of human bacterial infections. Thus, consumption of HU fruit to treat boils and blisters should be with great caution especially at high doses.

FULL TEXT

Background

The emerging integration of modern molecular technology in toxicological evaluation of medicinal plants has become an integral part of decoding progression of infectious diseases and possible development of promising drugs and vaccines. This is because quantitative molecular technique such as RT-qPCR used for gene expression profiling from targeted bacterial will create an intrinsic understanding of the roles of virulence genes in disease pathogenicity [31]. *Staphylococcus aureus* (SA) emerges as one out of five leading gram-negative antibiotic-resistant bacteria causing death globally with the highest prevalence in sub-Saharan Africa super-region as recently documented by antimicrobial resistance collaborators [25]. Antibiotic-resistance of *S. aureus* may be associated with acquisition of novel virulency via one lateral gene transfer event or more, and subsequently modifies an earlier nonpathogenic strain to a hypervirulent and/or multidrug resistant [23]. Currently, there is a focus on development of preventive alternate strategies (vaccination and phage therapy) through AGR regulatory genes to forestall occurrence of staphylococcal infections [8]. The regulation of AGR has been described to be imperative in the development of staphylococcal infections involving formation of biofilm [29]. Recurrent Staph. infection has become an important source of health loss through colonization of the skin and nostrils of human host [27]. The frequency of infections and persistent evasion of most antimicrobials of SA colonizing strain has led to alternative treatment in traditional medicine by means of various parts of medicinal plants' parts, especially in Africa. Most communities in Africa including Nigeria still rely on indigenous herbs as most sourced health treatments since these plants are easily accessible and affordable [38]. *Hunteria umbellata* (HU) fruit has been popularly employed in folk medicines without satisfactory doses for the management and treatment of many disease conditions caused by pathogenic bacterial in humans.

Although, several therapeutic potentials of many parts have been highlighted in the literature [37, 39]. *Hunteria umbellata* have been extensively harnessed in traditional herbal medicine as anti-diabetic potent agents with hyperlipidaemic activities [6], natural erectogenic and antioxidant extracts [35]. However, under exploitation of the in vitro molecular toxicity of varying doses from low to high of HU fruit in SA still persists. Hence, this study design was necessitated to precisely offer evidence based scientific findings on in vitro molecular toxicology in virulent genes' expression of SA as the causative agent of boils when treated with HU fruit extracts. Additionally, to establish basis for possible mechanisms of response underlying medicinal plant-resistance as implicated in noxious exhibition in human staphylococcal communicable diseases.

Methods

Preparation of fruit extract

The HU fruit samples which were purchased in the second month (February) of the year 2023 from a local resident marketplace in Dopemu, Lagos State, Nigeria (6° 07′ N to 7° 00′ N latitude and 3° 43′ E to 4° 00′ E longitude) had been identified, authenticated and assigned voucher LUH 8996 as earlier illustrated by Salisu et al. [43]. Extraction employed was modified using the method of maceration [2]. The process involved preparing the fresh fruits by washing, slicing, oven-drying at 40 °C and grinding into a powder using electronic milling machine grinder, Lab. Mill, Serial No. 4745, Christy and Norris Ltd. The ground fruit (254 g) was macerated in 1.4 L of absolute sterile water within 72 h. A thin cloth and cotton wool were used to filter homogenate to get rid of every possible residue. The filtrate was placed in a fan assisted oven at 20 °C to dry. The aqueous extract (paste like form) yielded 3.95 g was stored in glassware and used for further analysis.

Qualitative phytochemical examination

Crude aqueous extract (20 mg) from HU fruit was mixed gently with 6 ml of 1% HCl, warmed, filtered, then tested for availability of alkaloids, anthraquinone and cardiac glycosides, saponins, phenol, flavonoids, tannins, phyloba-tannins, terpenoids as well as steroids. The presence (+) and absence (−) of tested phytochemicals were observed and recorded.

Test for alkaloids

Wagner's assay

Dilute HCl and Wagner's reagent (1 ml) were added to fruit filtrate (3 ml) and shook well. Afterward, colored precipitate (reddish–brown) was formed as the presence of alkaloids [40].

Tests for glycosides

Borntrager's test of anthraquinone glycoside

Addition of 5% H_2SO_4 (1 ml) to fruit extract solution (1 ml) made a mixture that was boiled, filtered, shaken with the same volume of chloroform and kept to still for 5 min. Then the lower layer of chloroform was shaken with half of its volume with dilute ammonia. Nonappearance of bright red coloration of ammoniacal layer indicates absence of anthraquinone glycosides in the fruit [40].

Keller–Killiani test of cardiac glycoside

A small amount of fruit extract (5 mg) were treated with anhydrous acetic acid (1 ml) and few drops of ferric chloride solution in a test tube. Then, concentrated sulphuric acid (2 ml) was added cautiously to prepared mixture. An observed reddish–brown ring at the junction of two layers and development of aqua at the lower layer indicated cardiac glycosides existence [45].

Test for saponins

A mixture of fruit sample (1 g) and distilled water (10 ml) was prepared, boiled for 5 min and shaken vigorously and observed in a test tube. Absence of froths indicates lack of saponins [15].

Test for phenol

A few fruits sample (1 g), ethanol (10 ml) and three drops of phenol solution were mixed in a labeled test tube. Nonappearance of a deep green coloration specifies absence of phenol [16].

Test for flavonoids

A mixture of HU fruit extract (1 g), 10 ml of ethanol and 2 drops of $FeCl_3$ was prepared. Observed dark green color specifies flavonoid [15].

Test for tannins

Decoction of fruit extract (1 g) with 10 ml of distilled water was prepared by boiling for 10 min, filtered, cooled and mixed with 0.1% ferric chloride reagent. An observed blue–black precipitate implies tannins availability as delineated in a modified method of Banso and Adeyemo [10].

Test for phyloba-tannins

Aqueous hydrochloric acid (1 ml) was stirred with fruit extract (2 ml), boiled and allowed to cool down. Availability of phyloba-tannins was implicated in precipitate (red) observed. [10].

Test for terpenoids

Some concentrated sulphuric acids (5 ml) were gently added to fruit extract sample (0.5 g) in a test tube. Observation revealed reddish brown coloration indicating terponoids' presence [9].

Salkowski test for steroids

The crude fruit extracts (2 mg each) were dissolved with chloroform (2 ml) and mixed gently by shaking to form a mixture. Oil of vitriol (2 ml) was poured in prepared mixture to observe red topmost layer in the test tube. This indicates existence of terpenoid [9].

Gas chromatograph/mass spectrometer (GCMS) analysis of bioactive components of *Hunteria umbellata* fruits

Gas Chromatograph/Mass Spectrometer (GCMS) analysis as reported earlier [42] was carried out in Central Research Laboratory, University of Lagos Akoka, using 7890A Gas chromatography system attached to VL/MSD 5975C mass spectrometer (GC–MS Agilent Technologies, Santa Clara, USA) instrument employing the following

settings: Column HP5MS fused silica capillary column [30 m (length) × 0.32 mm (diameter) × 0.25 µm (film thickness)] composed of 100% dimethyl polysiloxane). 1 g of ground fruit samples was dissolved in 10 ml chromatographic grade methanol, filtered by using syringe filter and the clear sample was later injected in GCMS column. Helium gas (99.9999%) was used as the carrier gas at constant flow rate of 1 ml/min and an injection volume of 1 µl was employed with injector temperature at 250 °C and pressure at 8.802 psi. The oven temperature was programmed originally from 80 °C (held for 2 min) with an increase of 5–120 °C/min., then 10–240 °C/min., to hold for 6 min. The total GC running time for the fruit sample was 24 min. The area under a peak accurately represents the quantity of the component present in the sample. Software adopted to handle mass spectra and chromatogram was a ChemStation. The interpretation on mass spectrum of GCMS was done by means of the database of National Institute of Standard and Technology (NIST) version 2, year 2015 library. The mass spectrum of the unknown components was compared with the spectrum of the known components stored in the NIST library to establish the name, molecular weight and structure of the components of the fruit extract.

Collection of bacterial isolates and antibacterial assay

A gram-positive organism, *S. aureus* strain MBSA2208, was used for this study. The bacteria isolate was obtained from the Department of microbiology, Nigerian Institute of Medical Research (NIMR), plated on salt agar (Mannitol) and then brooded (at 40 °C for 24 h) to obtain pure culture. Antibacterial activity of HU fruit sample was tested by method of broth micro-dilution. A sterilized well (96) microplate was prepared for the experiment. Each well was filled with 90 µL of nutrient broth. In the standard wells, 10 µL of 1 mg/ml vancomycin (a susceptible antibiotic) was added, while the control well, received 10 µL of sterile broth as a sterility control [44]. Minimal inhibitory concentration (MIC) was evaluated by preparation of 0.4 µL of a stock concentration HU extract (250 mg/ml) to arrive at a working solution of 500 µg/µL. This working solution was then serially diluted to obtain two-fold dilutions. The resulting concentrations in column 3 to 11 were 500, 250, 125, 62.5, 31.25, 15.625, 7.8125, and 3.90625 µg/µL. Each well, except for the blank well in column 12, was filled up to 200 µL with nutrient broth that had contained bacteria already inoculated at a standard density of 0.5 McFarland, equivalent to 1.5×10^8 (CFU/mL). This setup allowed for the estimation of the bacterial activity of fruit extract by observing a noticeable growth or inhibition of the bacteria in each well of the microplate. After setting up the microplate with the appropriate concentrations of the extract, standard antibiotic and control. The incubation of the plate was done at 37 °C on a shaker in not more than 24 h. After incubation period, measurements of absorption values in each well with microplate reader at 600 nm absorbance were recorded. This measurement allowed for the determination of the growth difference between the wells before and after incubation, indicating the effectiveness of the extract in inhibiting bacterial growth.

To determine the point of inhibition for each extract, preparation of resazurin dye (0.8 mg/ml) was done. After the 24-h incubation period, A small volume of prepared resazurin solution (30 µL) was dropped in individual well of microplate. Resazurin is a dye that changes color from blue to pink in the presence of oxygen. The microplate was then incubated for an additional 3 h to allow the color change to occur. This color change visually indicated microbes' growth inhibition due to smallest amount of HU fruit extract in each well.

RNA extraction and purification

For the extraction of single-stranded RNA from the aqueous extracts of *H. umbellata*, three concentrations were chosen: the highest (500 µg/µL), a moderate (250 µg/µL) and the lowest (125 µg/µL). The extraction was performed via the NIMR Biotech extraction kit according to manufacturer's description.

The extraction process involved several steps. First, the cells in the extracts were lysed to disrupt cell membranes and make RNA available freely. Lysed samples were then incubated to facilitate the extraction process. After incubation, RNA precipitation was carried out to isolate the RNA from other cellular components. The cell debris and impurities were removed through a washing step to obtain a purified RNA sample. The elution step utilized a spin column-based method, where the purified RNA was eluted from the column, leaving behind any contaminants. Finally, the extracted single-stranded RNA was stored at −20 °C until further use. This freezing temperature helps maintain the stability and integrity of the RNA for future analysis or experiments.

Dual-step reverse transcriptase quantitative polymerase chain reaction (RT-qPCR)

A separate reverse transcription coupled with qPCR was carried out. First, extracted RNA was converted to complementary DNA (cDNA). Synthesis mix of FIREScript RT cDNA (Solis Biodyne, Estonia) was used, alongside random primers and Oligo (DT). Prepared reaction mixture consisted of 6.8 µl of double-distilled, molecular-grade water, 2 µl of mastermix, 0.1 µl each of forward and reverse primers in Table 1 as manufactured by the NIMR-MTN Oligo Synthesis Laboratory and 1 µl of the RNA template. These components were combined to create a 10 µl reaction mixture as followed by manufacturer's manual. Transcription (reverse) process took place for a duration of 30 min at a temperature of 50 °C. After 5 min, transcriptase enzyme was deactivated at a lesser temperature of 85 °C using a BioRad thermal cycler.

Table 1. List of Nucleotide Primers designed for Virulence Genes in Real-Time PCR Technique

Gene name	Sequences (forward and reverse)	Reference
AGR I	Forward: 5′-CAC TTA TCA TCA AAG AGC C-3′	[3]
Reverse: 5′-CCA CTA ATT ATA GCT GG-3′	AGR II	Forward: 5′-GTA GAG CCG TAT TGA TTC-3′

The second step was the quantitative Polymerase chain reaction (PCR). This reaction was executed to quantify amplifications of expressed genes. The number of amplifications of virulence genes (AGR I and II genes) and the house keeping gene (SA442) of *S. aureus* used in this study was determined using a real-time system (BioRad CFX96 Deepwell), in accordance with the manufacturer's description. A 10 µl reaction mixture was prepared containing 5.8 µl double distilled, nuclease free water, 2 µl Solis Biodyne Eva green mastermix, 0.1 µl each of both forward and reverse primers and 2 µl template coding deoxyribonucleic acid (cDNA) for the two primers separately. The processes involved are; initial and final denaturation, annealing, initial and final extension. First denaturation (DNA unwinding) occurred at 95 °C for 2 min, final unwinding took place for just 30secs at the same temperature as the first melting of DNA, annealing was set for 30secs at 54 °C and repeated for 40cycles followed by extension step with temperature range of 55–80 °C with 0.5 °C increment for 5secs.

Ct values (cycle threshold) were generated at the completion of the reaction and used to calculate relative quantification $2^{-(\Delta\Delta ct)}$.

Data analysis

The cycle threshold (ct value) generated from the melt curves plotted by the thermal cycler was used to calculate relative expression using Microsoft Excel (2016 version). Relative expression values were further subjected to IBM SPSS statistics version 22, to determine the increment or decrease in expression of the virulence genes (AGR I and II). All data entries were given as descriptive average alongside standard error means (mean ± SEM), mean difference was compared using a one-way ANOVA analysis and a post-hoc test of LSD (least significance difference). A confidence interval of 95% was used as the criterion for significance to show variations between compared sets.

Results

Phytochemical analysis of chemical components of *Hunteria umbellata* fruits

The screening of phytochemicals in HU fruit, aqueous extracts revealed six (6) phytochemicals which include specific secondary metabolites like alkaloids, cardiac glycosides, flavonoids, tannins, phyloba-tannins and terpenoids. Four compounds (anthraquinone glycosides, saponins and steroids) were absent in the fruit (see Table 2.)

Bioactive components of *H. umbellata* fruit from chromatograms of GC–MS

Twenty (20) non-polar volatile compounds appeared in HU fruit (methanol extract) as analyzed from GCMS chromatograms in Fig. 1 below. Individual peak denotes a compound with dissimilar quality and quantity based on percentage by ChemStation's calibration mode (Software). All compounds identified with their molecular formula, molecular weight (MW), retention time (RT), area percentage composition (quantity), quality (matching factor>80) and chemical structure of fruit extract are presented in Table 3. The presence of compounds that combine both the matching factor (>80) and percentage composition (>5%) were classified as main compounds while others below both quality (matching factor>80) and quantity (>5%) were regarded as minor compounds. The five major compounds (Table 4) detected in HU fruit are *n*-Hexadecanoic acid (99; 25.2%), 2-Pentadecanone, 6,10,14-trimethyl (96;16.1%), Cuparene (95; 6.6%), Tetradecanoic acid (95; 6.2%) and 9-Octadecenoic acid, (E)- (83; 5.7%). The 15 minor compounds comprise 1-Methylenespiro [2.4] heptan-4-one (43; 1.1%), 2-Butynedioic acid, di-2-propenyl ester (49; 2.1%), Phthalic acid, butyl oct-3-yl ester (86: 2.2%), 7-Hexadecene, (Z)- (97; 2.6%), camphor (42: 1.6%), Methyl 14-methylpentadecanoate (97: 3.3%), 1-Octadecene (97: 4.7%), Methyl linoleate (95: 1.1%), Methyl elaidate (99: 1.4%), Bromoacetic acid, octadecyl ester (49: 1.76%), Cyclohexaneethanol, 4-methyl-.beta.-methylene-, trans-(45: 5.8%), Octadecanoic acid (70: 2.31%) and 1-Octadecene (97: 2.5%).

Tetradecanoic acid	Myristic acid	96	6.21	Virulence regulation	[26]
9-Octadecenoic acid, (E)-	Stearic acid	83	5.70	Anti-inflammatory	[50]

Bactericidal property of aqueous *Hunteria umbellata* fruit extract on *Staphylococcus aureus*

Result obtained from the antibacterial assay showed that Vancomycin, a standard drug for S*taphylococcus* infection greatly displayed repressive properties on proliferation of SA. None of eight tested concentrations of *H. umbellata* with 500 µg/µL being the highest stalled the growth of *S. aureus* in comparison to control as shown below (Fig. 2). This was confirmed in all the wells containing resazurin that changed from blue to pink. The change of resazurin from blue indicates the presence of viable organisms (producing oxygen).

Amplification of AGR I and II genes' expression in SA predisposed to three selected doses of HU fruit extracts

The amplification and melt curves of the two AGR genes in SA exposed to aqueous HU fruit extracts were provided in Figs. 3 and 4 respectively. The amplification curves are indicative of the binding of DNA to SYBR green fluorescent dye present in the master mix which started after the 20th cycles in AGR I and 30th cycle in AGR II of real time PCR. The melt curves began after 60 °C for AGR I and 75 °C for AGR II.

Fig. 4 [Images not available. See PDF.]

Melt curves of AGR (I and II) genes of SA treated with HU fruit extracts. RFU represent relative fluorescence units

Quantification of AGR I and II gene in *Staphylococcus aureus* after exposure to HU aqueous fruit extract

The result obtained after the quantitative real time PCR showed increased expression of AGR I and II genes at 500 and 125 µg/µL compared to control. However, AGR I and II genes were more significantly (p<0.05) expressed at 250 µg/µL of *H. umbellata* aqueous fruit extract relative to the other two doses and control. (see Fig. 5).

Discussion

The safety profile of certain plants, their potential therapeutic benefits and considerations of toxicity effect have been criticized as a result of ambiguity in treatment prescriptions by indigenous traditional healers. This is due to ancestral believe in guaranteed safety with no side effect in any consumption of most parts of medicinal plants without adequate doses [36]. Regrettably, this supposition has translated to numerous cases of health complications and in some cases demise of the users [21]. This often results to patients overdosing of herbs and herbal products, as regulatory bodies are totally not in control over the usage of herbal medicines. Despite the goodness of herbal medication, certain plant species have been documented to exhibit cytotoxic effects at elevated doses. The implication is that a whole plant or its parts considered highly safe can become toxic at elevated doses. Serious concerns related to potential toxicity-related to phytomedicine or phytotherapy including issues like carcer-inducing effect, liver toxicity, mutation inducement and genetic damage have been brought to the forefront [30]. Therefore, prevailing perception among users of herbal medicines that these remedies are inherently safe without adverse effects due to their natural origins in the plant kingdom calls for serious concern [32].

Secondary metabolites of different parts of HU have consistently been documented in therapeutic intervention or management of numerous ailments. The results of phytochemical screening of HU fruit revealed certain specialized metabolites including alkaloids, cardiac glycosides, flavonoids, tannins, phyloba-tannins and terpenoids. This result is in accordance with the compounds found in HU methanol seed as well as their known bioactivities as reported by Salami and Ladokun [41], Aderele et al. [5] and Akinrotoye et al. [7]. Another study reported 21 different compounds from chromatograms of both seed and leave methanol extracts [28]. The GCMS analysis from this study resolved 20 compounds from HU fruit, comprising five major compounds and 15 minor compounds based on quality and quantity. The major compounds are palmitic acid, aldehyde, sesquiterpene (terpene), myristic acid and stearic acid. Palmitic acid (*n*-hexadecanoic acid) constituted the most abundant with almost 100% matching factor (Table 4). Notably, maximum concentration of 50 µg/ml, *n*-hexadecanoic acid has established only modest antagonistic bacterial activity against *S. aureus*, as specified by Ganesan et al. [22]. This means overdose of plant rich in palmitic acid in the treatment of bacterial infection could be lethal. Void activity of fatty aldehydes against clinical pathogenic bacteria has been documented by Xie et al. [49] while literature has described terpenes as promising antibacterial especially in multiple drug resistance (MDR) bacterial strains [20, 33]. Though the precise molecular machinery responsible for the antibacterial effects of terpenes are yet to be fully understood. Most plant parts possess fatty acids (FA) as good sources of carbon with structural functions and bactericidal properties [14]. However, sublethal concentrations of some of these fatty acids serve as signaling molecules in modulating bacterial virulence as explained by Cortes-López et al. [17]. Despite the antibacterial activity of most fatty acids, palmitic, myristic and stearic acids have been associated with increase in pathogenicity of bacteria [26]. Although their probable impact on the effectiveness of anti-virulence treatments coupled with participation in intricate network of pathogenicity regulation are increasingly recognized, representing a promising strategy to manage antibiotic-resistant bacterial diseases.

Several reports have shown that *Hunteria umbellata,* possesses antagonistic bactericidal efficacy against the two major representative of bacteria (gram positive and negative), *S. aureus* and *E. coli* bacteria respectively, at doses less than 150 mg/ml [5, 7]. Contrarily to these reports, our findings revealed negative antibacterial activity of *H. umbellata* aqueous fruit extract against *S. aureus* tested. Increase in growth was recorded in *S. aureus,* the causative agent of these staph infections, when it was exposed to *H. umbellata* aqueous fruit extract at doses ranging from 3.9 to 500 µg/µL. The increment could be indicative that the extract supports the growth of Staph infections in the body. This difference could also be attributed to the growing evolution and resistance of pathogenic bacteria [18, 34]. Nevertheless, our study corroborates minimal and inconsequential inhibitory effects of the fruit pulp

(water extract) noted against SA in old fact-findings of Igbe et al. [24] as reviewed by Fadahunsi et al. [19].
The expression levels of gene have been generally regarded as an excellent match for protein expression and thus be harnessed to deduce expression of either protein and/or virulence susceptibility. Equivalent data will offer more enlightened strategy for the choice of medicinal plants for the development of drugs to manage persistent evaded pathogenic processes. Our previous study has established increase in the amount of Laf A and ExsE genes' expressions in, as a main causative agent of gastroenteritis, when exposed to high dosages of both *H. umbellata* seed and stem extracts [43]. This present study further evaluated the AGR system of *S. aureus* which is a vital component underlying numerous genes' expression that code for virulence tendencies, formation of biofilms during the pathogenicity of bacterium and inducement of both type 2 and interleukin-17-dependent epidermal inflammation in host cell [47]. Significant increase in expression of both AGR genes of SA exposed to the three tested doses (500, 250 and 125 µg/µL) is in accordance with expression of AGR 1 and II which has been ascribed to invasive infection like bacteraemia [12].
Every pathogen has virulence genes associated with them, these genes are critical for triggering diseases when the host has been colonized successfully to cause bacterial infections [48]. Our studies revealed persistent increase of AGR I gene followed by AGR II gene in the tested doses as compared to control, in agreement with other study that both genes are the most common allelic groups of AGR system [1]. The AGR I system is often connected with strains of *S. aureus* which produces the Panton-Valentine leukocidin (PVL-SA) toxin, commonly implicated in necrotic skin infection and persistent cellulitis [13]. AGR II is frequently found in antibiotic (methicillin) resilient *S. aureus* strains, linked with hospital—acquired infections [46]. Variation in amplification peaks during quantification of the AGR genes revealed difference in expression of AGR genes in the three tested concentrations of the extract (500, 250 and 125 µg/µL) compared to normal control. This further indicates the presence of the genes in the *S. aureus*. AGR I and II genes were expressed significantly (p<0.05) at 250 µg/µL and 500 µg/µL doses while dose 125 µg/µL significantly decreased (p<0.05) genes' expression. This suggests that AGR I and II genes would be expressed as doses of *H. umbellata* fruit extract increases. However, this molecular toxicity at genetic level is scarce in the literature, as most studies have been focused on the antibacterial activity of *H. umbellata* aqueous fruit extract. Until this present study, there isn't any recorded side effects of *H. umbellata* at molecular level. Adeneye et al. [4] indicated in his study that HU exhibits a notably low level of oral toxicity. That is, consumption of the HU fruit is not dangerous or toxic. Yet, this study confirms the expression of both types of AGR genes (I and II) as the colonization factor for *S. aureus* in the development of staphylococcal related infections. These findings affirmed the importance of molecular toxicity especially at gene and protein levels to validate conventional and modern therapeutics in either prevention or treatment of microbial infectious diseases globally. This will further elucidate the toxicity pathways underlying antimicrobial resistance associated with virulence.

Conclusion

Consumption of indiscriminate dosages of *H. umbellata* extracts may aggravate the staphylococcal diseases such as boils, abscess and staph food poisoning. Hence, *H. umbellata* fruit extract maybe be dangerous to health when consumed in high quantities.

Recommendation

Extensive in vitro studies should be conducted on different herbal plants and concoctions to verify their antibacterial activities. Most especially, molecular toxicity tests must be incorporated in the toxicology of medicinal plants to fully ascertain its safety and safe dosage. In addition, enhancing awareness about potential health risks linked to the utilization or excessive use of medicinal plant parts and quality control guidelines should be encouraged and enforced on traditional use of herbal plants in any disease management.

Author contributions

TFS conceptualized the research, contributed to supervision, participated in the laboratory work, performed data analysis and drafted the paper. MAF and LAA were involved in primers' selection, laboratory work and data collation.

TOY, MAF and BTT were involved in selection of microorganisms, participated in laboratory work, data collection and contributed in writing the manuscript. SAA and POJ ensured quality assurance, contributed to validation and revised the manuscript. TFS, TOY and LAA revised and edited the final manuscript. All authors have read and approved the final manuscript.

Funding

Not applicable.

Availability of data and material

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Declarations

Ethics approval and consent to participate

The HU fruit samples used in this study were identified, authenticated by a taxonomist and assigned voucher numbers, LUH 8995 and LUH 8996 respectively in the Department of Botany, Faculty of Science, University of Lagos. The fruit samples were further deposited in the herbarium of the same University. This is in alignment with national guideline and legislation required for the study of indigenous plant.

ABSTRACT (ENGLISH)

Background

Niosomes hold promise as drug delivery systems for cancer treatment, with niosome size impacting stability, biodistribution, and effectiveness. This study optimized methotrexate (MTX)-loaded niosome formulation by studying the effects of components and processing conditions on size. The niosomes formulation was made by the thin-film hydration technique.

Results

The optimized formulation (NIO 17) with a 6:2:2 ratio of span 60, soya PC, and cholesterol achieved 55.05% methotrexate encapsulation, particle size 597.2 nm, PDI 0.49, and zeta potential − 23.3 mV. The compatibility of methotrexate with lipids was confirmed via Fourier transform infrared spectroscopy, and transmission electron microscopy revealed spherical, well-dispersed vesicles. Differential scanning calorimetry indicated methotrexate

conversion or entrapment within vesicles. In vitro release exhibited a sustained pattern with an initial burst. NIO 17 showed potent anti-cancer activity against B16-F10 cells (GI50: 38.7176 µg/mL). Ex vivo studies suggest tailoring niosome size (597.2–982.3 nm) to target specific skin depths (0–38 µm) for enhanced localized drug delivery.
Conclusions
This study demonstrates the potential of methotrexate-loaded niosomes as a novel cancer therapy approach, highlighting the potent anti-cancer activity and transdermal delivery potential of NIO 17. Further research is necessary to explore its clinical translation.

FULL TEXT

Background

Skin cancer, triggered by ultraviolet (UV) radiation from the sun or tanning beds, affects millions globally [1, 3]. Common types include basal cell carcinoma, squamous cell carcinoma, and melanoma as shown in Fig. 1. Traditional treatments like surgery, radiation therapy, and chemotherapy pose various limitations [2, 3]. Surgery, while common for early stages, is invasive. Radiation uses high-energy beams, and chemotherapy, despite killing cancer cells, often comes with side effects like nausea, vomiting, hair loss, and fatigue [4, 6]. Moreover, advanced or metastatic cases often lack effective treatment options. There is a growing demand for targeted and minimally invasive therapies that can deliver drugs specifically to cancerous cells while sparing healthy tissue. In this context, exploring novel drug delivery systems like niosomes holds great promise. Niosomes, with their ability to encapsulate drugs and deliver them to specific sites within the body, offer the potential to enhance the efficacy of treatments for skin cancer while minimizing adverse effects, thus addressing critical unmet needs in the current treatment landscape. Niosomes, composed of biocompatible and biodegradable phospholipids, cholesterol, and surfactants [5, 7], niosomes can deliver a wide range of drugs and target specific cells or tissues. Studies in mice suggest their safety and efficacy for skin cancer treatment, warranting further exploration for clinical use.

Schematic representation of SCC, BCC and malignant melanoma

Methotrexate (MTX), a drug commonly used for rapidly growing tumors like skin cancer [5], works by hindering DNA synthesis in dividing cells. While traditionally administered orally or parenterally for skin cancer, MTX can cause gastrointestinal side effects like indigestion, dyspepsia, vomiting, and ulceration. To address these, we investigated the potential of niosomes as a topical delivery system for MTX [7].

This study aimed to evaluate niosomes as a means to enhance the transdermal transport of MTX to various skin layers, focusing on the impact of niosome size on their efficacy as shown in Fig. 2. We examined the effects of different-sized niosomes on MTX permeation through ex vivo studies and visualized their distribution within the skin using confocal laser scanning microscopy. Additionally, in vivo histopathological studies in mice assessed the feasibility of using niosomes to deliver MTX to the skin.

Materials and protocols

Chemicals

This research utilized a diverse range of materials for its experiments. The drug, methotrexate (MTX), was kindly provided by Neon Laboratories Ltd. (Mumbai, India). Soya Phosphatidylcholine (SPC), a key lipid component, was a generous gift from Lipoid GmbH (Ludwigshafen, Germany), while cholesterol (CHOL) was purchased from CDH (India). Solvents and reagents like chloroform, methanol, phosphate buffer, Triton X-100, Sephadex G-50, and dimethyl sulfoxide (DMSO) were sourced from HiMedia Laboratory Pvt. Ltd. (Mumbai, India). Additionally, HPLC water (Lichrosolv), acetonitrile (HPLC grade), methanol (HPLC grade), and rhodamine B (RHB) were procured from Sigma-Aldrich and Merck (India). Finally, dialysis bags with molecular weights ranging from 12,000 to 14,000 were

obtained from HiMedia Laboratory Pvt. Ltd. Notably, all chemicals were of analytical grade and used directly without further purification.

Preparation of MTX-loaded niosomes

The preparation of various niosomal formulations (Nio1 to Nio18) was carried out using the thin-film hydration method but with slight modifications [8, 9], where the mole fraction of Span 60 was systematically varied (4:2:2, 5:2:2, 6:2:2 Soya PC: Cholesterol ratios) while maintaining constant molar concentrations of Soya phosphatidylcholine (SPC) and cholesterol as shown in Fig. 3. An accurate amount of Span 60, soya phosphatidylcholine, and cholesterol was dissolved in a round-bottom flask (RBF) containing 10 mL of chloroform and methanol (9:1). The organic solvents were eliminated using a rotary vacuum evaporator above the lipid transition temperature of 65 °C under reduced pressure to form a thin lipid film on the wall of the RBF. The residual amount of the solvent mixture was removed from the deposited layer of lipids by leaving the contents under a vacuum overnight. Hydration was done with phosphate buffer (PBS 7.4) containing methotrexate drug by rotating the RBF at a suitable temperature for 2 h until the formation of niosomes [22, 23]. The particle size of the formed niosomes dispersion was further reduced by sonication with various sonication cycles. The sonication time is taken as another variable for the formulation process. The same method was used to prepare Rhodamine B-loaded niosomes for the ex vivo study, where 0.5% of the total lipid was substituted with RHB in place of MTX in the selected formulation [10, 24, 25]. The obtained opalescent dispersion of niosomes was stored at 4 ± 2 °C until use.

Method of preparation of niosomes

Characterization of Niosomal formulations

Size distribution, polydispersity, and surface charge of vesicles

Initially, 1 ml of each of the prepared niosomal formulations was mixed with deionized water for adequate dispersion. The average size of the vesicles (VS), the zeta potential (ZP), and the polydispersity index (PDI) of the drug-loaded niosomes was analyzed using Zeta sizer Nano ZS (Malvern Instruments Ltd.) dynamic light-scattering method. The niosomal dispersions were prepared and diluted 10 times with deionized water before measurement to ensure that the light-scattering intensity was within the instrument's detection range [26, 27]. The measurements were taken in triplicate, and the average values are reported in Table 1 and Fig. 4.

Fluorescent and TEM images of niosomes

Entrapment efficiency (EE)

The entrapment efficiency (EE) was calculated through the mini-column centrifugation method by separating the non-entrapped drug. The %EE of MTX in the niosomes was estimated by determining the free MTX in the dispersion medium. 1 mL of the niosomes dispersion was centrifuged at 15,000 rpm for 2 h at 4 °C using a cooling centrifuge. The supernatant was then separated and diluted, and the concentration of MTX was determined through HPLC methods [11, 28, 29]. The niosomes were then disrupted using 0.1% Triton-X 100, and the drug content is quantified using Eq. (1). An isocratic HPLC procedure was used to determine the concentration of MTX. A Zorbax Extend-C18 column was used as the stationary phase, and the mobile phase was a mixture of 50 mM sodium acetate buffer solution with a pH of 5.6 and acetonitrile (89:11 v/v). The flow rate was set at 1.0 mL/min, and the UV detector was set at 307 nm. The results are shown in Table 1 and Fig. 4.

1

Entrapment Efficiency%=Amount of free drugTotal amount of drug×100

Shape and surface morphology

The appearance of the optimized MTX-loaded niosomal formulations was studied using the transmission electron microscopy (TEM) technique (Jeol JEM1230, Tokyo, Japan) after suitable dilution. A drop of the selected niosomal dispersion was spread on a copper grid and stained negatively with 1% phosphotungstic acid. The samples were then air-dried for 10 min at standard temperature and pressure (STP) [14, 30, 31] and examined under a TEM as shown in Fig. 5.

Fig. 6 [Images not available. See PDF.]

A FTIR spectra of methotrexate, Soya PC, Span 60, Cholesterol and Mixture; **B** DSC spectra of methotrexate, Soya PC, Span 60, cholesterol and mixture

Fourier transform infrared spectroscopy

The optimized formulation, drug, excipient, and drug–excipient mixture were analyzed using Fourier transform infrared spectroscopy (FTIR) (Bruker FTIR 8400S ALPHA). Before conducting the IR studies, the samples and excipients were vacuum-dried for 12 h [32, 33]. The dried samples of each were placed on a sample platform, and the spectra were captured in the range of 4000–400 cm^{-1}, which were consistent with the official IR spectrum reported in the monograph as shown in Fig. 6A [12, 13].

Fig. 7 [Images not available. See PDF.]

In vitro release of MTX from niosomes in comparison to plain MTX solution at pH 7.4

Thermoanalytical technique

The thermal characteristics of pure methotrexate (MTX), Soya Phosphatidylcholine (PC), Cholesterol, Span 60, the physical mixture of MTX and niosomal components, empty niosomes, and MTX-loaded niosomes were analyzed using differential scanning calorimetry technique (DSC 60, Shimadzu, Japan). The device was calibrated using high-purity indium (99.9%). Three milligrams of accurately weighed samples were put into standard aluminum pans and then heated from 100 to 300 °C at a scanning rate of 100 °C per minute [15, 34, 35] as shown in Fig. 6B.

In vitro drug release kinetics

The niosomal suspension (Nio 15 and Nio 16) was centrifuged to separate the unentrapped drug from the niosomes. Next, 1 mL of the pure niosomal suspension was placed into a dialysis tube, which was then immersed in a beaker that contained 20 mL of PBS (pH 7.4) and stirred on a magnetic stirrer at a constant temperature of 37 ± 0.5 °C. Samples were taken at various time intervals and analyzed for drug content using HPLC. To maintain the initial volume of the dissolution fluid, 5 mL of fresh solution was added after each sample withdrawal [15, 20, 36, 37]. The cumulative amount of MTX released from different niosomal formulations was calculated as per Eq. (2). Results are shown in Fig. 7.

2

Percentage cumulative drug released=Cumulative Amount of Drug obtained at timeTotal amount of Drug in Niosomes

In vitro cytotoxicity study

In vitro, cell cytotoxicity of optimized formulation (Plain MTX, NIO 5, NIO 12, and NIO 16) was evaluated by the SRB assay using murine skin melanoma cell line B16-F10. The cell lines were grown in RPMI 1640 medium, and cells were inoculated into 96-well plates in 100 µL at plating [38–40]. After cell inoculation, the microtiter plates were placed in an incubator at 37 °C, 5% CO_2, 95% air, and 100% relative humidity for 24 h before the addition of formulations. Formulations were dissolved in an appropriate solvent to a concentration of 100 µg/mL and then diluted to 1 mg/mL using Milli-Q water. The diluted solutions were stored frozen until needed. At the time of the experiment, aliquots of the frozen concentrate (1 mg/mL) were thawed and diluted to the following concentrations: 100 µg/mL, 200 µg/mL, 400 µg/mL, and 800 µg/mL. Aliquots of 10 µL of each drug dilution were added to microtiter wells that already contained 90 µL of the medium. This resulted in final drug concentrations of 10 µg/mL, 20 µg/mL, 40 µg/mL, and 80 µg/mL. The plates were then incubated at standard conditions for 48 h.

Fig. 8 [Images not available. See PDF.]

To terminate the assay, cold TCA was added to the plates. Cells were fixed in situ by gently adding 50 μL of cold 30% (w/v) TCA (final concentration, 10% TCA) [41, 42]. The plates were then incubated for 60 min at 4 °C. The samples were washed five times with PBS, and then, 50 μL of 0.4% (w/v) SRB solution was added to each well. The plates were then incubated for 20 min at room temperature.

One percent (v/v) of acetic acid was used to remove the unbound dye, and plates were dried and then analyzed at the wavelength of 540 nm with a 690 nm reference wavelength by using the plate reader. Adriamycin (ADR) was used in the same concentration range as a positive control. Cytotoxicity was expressed as the percentage of viable cells relative to incubated cells in the presence of 0.1% DMSO vehicle control. The percentage of growth inhibition (GI_{50}) is calculated in Eq. (3). GI_{50} was calculated from the drug concentration, resulting in a 50% reduction in cell growth. Each measurement was done in triplicate [18, 19, 43]. Results shown in Fig. 8.

Ex vivo and in vivo investigations

The ex vivo investigation was conducted following protocols approved by the Committee for Control and Supervision of Experiments on Animals (CPCSEA/SN-10/RN-22/16-02-2020), which is overseen by the Ministry of Social Justice and Empowerment, Government of India. The study also followed the recommendations of the Institutional Animal Ethical Committee (IAEC) at Dr. H.S. Gour Vishwavidyalaya, located in Sagar, Madhya Pradesh, India.

Ex vivo permeation study

The ex vivo visualization using confocal laser scanning microscopy technique (CLSM) involved the formulation of Rhodamine B (RH)-loaded niosomes through a process similar to that used for creating MTX-loaded niosomes

[44–46]. However, RH was incorporated at a concentration of 0.5% concerning the total lipid content, replacing MTX in the specific formulation. For experimentation, the mice's skin was sectioned into square pieces and positioned with the stratum corneum (SC) facing the donor compartment within diffusion cells. The receptor chamber contained 20 mL of phosphate buffer saline (pH 7.4) maintained at 32 ± 1 °C. To mimic the expected application of niosomes to the skin's surface, RH-loaded niosomes (including a plain niosomes formulation, a plain rhodamine solution, and formulations Nio 13 to Nio 17) were administered onto the skin and allowed to remain for 4 h. Following this, the skin was rinsed with 10% ethanol and then gently wiped in preparation for imaging, following the methods described by [16, 47]. The investigation of the skin was conducted using CLSM with the following steps: the complete skin sample was positioned between a glass slide and a cover slip and examined utilizing inverted CLSM (LSM 710, Carl Zeiss, Jena, Germany). RH fluorescence was excited at a wavelength of 573 nm and detected at 591 nm. Scans were taken at 2-µm intervals starting from the skin surface (0 mm) to a depth of 40 µm, using a 40× objective lens. Images shown in Fig. 9 were captured in both the *xy* and *xz* planes, employing optical sectioning z-stack mode. The acquired confocal microscopy images were processed using LSM Image Browser software, release 4.2 (LASX), as described by Hathout and Nasr in 2013 [17, 48].

In vivo histopathological study

An In vivo histopathological study was performed to evaluate skin irritation potential and structural changes resulting from exposure to MTX-loaded niosomes. The study involved dividing mice into 7 groups, each consisting of 3 animals [49, 50]. Group I acted as the positive control receiving PBS, group II as the negative control receiving plain MTX solution, and groups III to VII were exposed to topical applications of MTX-encapsulated niosomes (Nio 13 to 17) on the skin surface three times daily for a week. After the treatment period, the mice were killed, and their skin was extracted for histopathological examination. The collected skin samples underwent fixation in 10% formal saline for 24 h, followed by washing, dehydration using alcohol dilutions, clearing in xylene, and embedding in paraffin beeswax blocks. These blocks were maintained at 56°C for 24 h, and sections of 4 mm thickness were cut using a microtome (Leica Microsystems SM2400, Cambridge, England). These sections were then deparaffinized, stained with hematoxylin counterstained with eosin, and subsequently observed under a light microscope for analysis as shown in Fig. 10 [9, 21, 51].

Results and discussion

Preparation of niosomal formulation, particle-size analysis, and zeta potential determination

The synthesis of MTX-loaded niosomes was achieved using the film hydration method as depicted in Fig. 3 and by incorporating various ratios of span 60, soya PC, and cholesterol in each formulation. The study aimed to determine the effect of various ingredients and processing variables on the vesicle size and entrapment efficiency. The composition of span 60, soya PC, and cholesterol (4:2:2, 5:2:2, 6:2:2) had a significant impact on the size of the niosomes. The results showed that increasing the concentration of Span 60 (a non-ionic surfactant with an HLB of 4.7) led to a decrease in vesicle size. This is because Span 60 has high interfacial activity and a critical packing parameter (CPP) between 0.5 and 1. A lower CPP indicates that the surfactant molecules are more tightly packed, which results in smaller vesicles. However, a further increase in the concentration of Span 60 led to an increase in vesicle size. This is because the higher concentration of cholesterol in the vesicles provided added rigidity, which counteracted the effect of the increased interfacial activity of Span 60. The addition of cholesterol in lipid vesicles changes the short-distance repulsive forces among them. An increase in cholesterol content leads to an increase in the net repulsive forces among soya PC and span 60 vesicles, reducing their aggregation. The sonication time also affects the entrapment efficiency and size of MTX-loaded niosomes, as seen in Table 1. An increase in sonication time causes a decrease in particle size. Particles without sonication showed the largest size, while particles

subjected to 10 min of sonication showed the smallest size, with a mean particle size ranging from 200 to 1406 nm. The optimized formulations, with a ratio of 6:2:2, were used for further studies. The average standard deviation (SD) (nm) of particle size for most of the particles was 200–1000 nm, depending on the sonication time cycle, and the polydispersity index was less than 0.4. The formulations had a negative zeta potential of −25 to −30 mV as depicted in Fig. 4A, B and showed the best entrapment efficiency. The negative zeta potential of the formulations assisted in their adhesion to cancer cells and internalization through cellular endocytosis.

Entrapment efficiency

After removing the unencapsulated drug through dialysis, the efficiency of encapsulation was analyzed for all the formulations. The presence of surfactant, cholesterol, and drug-to-lipid ratios in the vesicles can reduce the stiffness of the vesicles and affect the ability of methotrexate to be trapped inside. The highest drug encapsulation efficiency was recorded to be 76% in vesicles without sonication and the lowest was 30% with a 10-min sonication cycle.

Shape and surface morphology

Confirmation of the results obtained from the Malvern particle-size analyzer can be achieved through morphological analysis, which also examines the structure of colloidal systems. The optimized niosomes displayed a non-aggregated, single-layered vesicular structure with a predominant spherical shape as seen in the TEM images (Fig. 5). The average particle size observed in the TEM micrographs was consistent with the size previously obtained from the Malvern particle-size analyzer, as presented in Table 1.

Fourier transform infrared spectroscopy (FTIR)

FTIR spectroscopy is a useful tool in determining potential interactions between drugs and excipients. Figure 6A shows the IR spectra of pure methotrexate and a formulation that includes the drug and other excipients like phospholipids and a permeation enhancer. The pure methotrexate exhibits peaks at 3406.10 cm^{-1} (N–H stretching), 2928.64 cm^{-1} (O–H stretching for the carboxylic group), 1646.82 cm^{-1} (C–C stretching), 1603.41 cm^{-1} (C=C stretching of aromatics), 1542.02 cm^{-1} (N–H bend), and 831.01 cm^{-1} (C–H out of the plane of aromatics). The peaks for span 60 were found at 2950.00, 2856.50, and 1733.73 cm^{-1}, while peaks for lipids were observed at 3414.06, 2875.67, 1383.09, 1433.18, 1056.43, and 1547.14 cm^{-1}. Peaks for phosphatidylcholine (PC) were recorded at 3467.98, 2926.81, 1474.01, 1214.58, and 1042.76 cm^{-1}. The prepared formulations were also analyzed and found to have peaks in the same range, the drug and the lipid did not interact. The peaks of the optimal formulation were found to be very similar to those of the pure methotrexate, i.e., 3500.00, 3100.00, 2908.60, 1742.64, 1638.10, 1510.00, 1540.21, 1210.12, and 815.00 cm^{-1}, revealing that there was no significant change in the IR peaks of methotrexate and the optimized formulation, signifying the compatibility of the drug and the polymer.

Thermoanalytical technique

Figure 6B displays the DSC (differential scanning calorimetry) thermograms of various substances, including pure methotrexate (MTX), Soya phosphatidylcholine (PC), cholesterol, Span 60, a physical mixture of MTX with niosome components, blank niosomes, and MTX-loaded niosomes. The thermogram of MTX exhibits a typical exothermic peak at 185.9 °C and 93.5 °C, indicating its crystalline form, with a residual mass of 89.79% and weight loss of 7.79%. The thermogram of Span 60 displays a characteristic endothermic peak resulting from melting at 61.6 °C, with a residual mass of 93.00% and weight loss of 3.82%. The thermogram of cholesterol indicates an endothermic peak due to melting at 121.6 °C and 150.3 °C, with a residual mass of 98.25% and weight loss of 2.75%. The DSC of the physical mixture of MTX with niosome components reveals the peaks of both Span 60 and Soya PC, as well as the MTX peak, indicating that it maintains its crystalline form. However, the decrease in MTX peak intensity may be related to the dilution effect caused by the excipients. The thermogram of the unloaded niosomes demonstrates the absence of the MTX characteristic peak. The endothermic peak of Span 60 is present in both the blank niosomes and drug-loaded niosomes but shifted to a lower temperature (61.6 °C). For the drug-loaded niosomes, the MTX characteristic peak is completely gone, which could indicate that MTX was either encapsulated inside the niosomes or transformed into a molecular state within the surfactant mixture. As reported by Nasr et al. (2013) [17], the absence of the drug's crystalline melting peak after encapsulation may also indicate the presence of a strong interaction between the surfactant bilayers of the vesicles and the entrapped drug.

In vitro drug release kinetics

Figure 7 depicts the in vitro release profile of the optimized niosomal suspension loaded with methotrexate at pH 7.4 and 35 ± 0.5 °C. The optimized formulation exhibited a cumulative drug release of 75.09% over 24 h. The release curve indicated an initial burst release where approximately 28% of the drug was released within the first two and a half hours. The subsequent drug release from the optimized niosomes was sustained. The initial burst release was attributed to the presence of free methotrexate in the external phase.

In vitro cell proliferation studies

The anti-cancer efficacy of the formulations Plain MTX, NIO 5, NIO 12, and NIO 16 was tested against the murine skin melanoma cell line B16-F10 using the SRB assay, with ADR (Adriamycin) serving as a positive control. Figure 8A, B shows the activity of the formulations against B16-F10 cells. The results, presented in Table 2, indicate that NIO 16 was significantly more effective than other formulations like NIO 5 and Nio12. The GI_{50} values were 8.05738 µg/mL (NIO 5), 2.5311 µg/mL (NIO 12), 38.7176 µg/mL (NIO 16), and 40.2238 µg/mL (Plain MTX). The investigation revealed that Nio16 (with a GI50 of 38.7176 µg/mL) exhibited considerable potential in countering cancer activity within B16-F10 cells. It displayed enhanced efficacy in curbing cell growth when contrasted with alternative formulations. This heightened effectiveness might be attributed to potential factors such as the diffusion of niosomes from the stratum corneum, the amplification of permeation through the influence of Span 60 surfactants present in the niosomal formulation, or even modifications to the stratum corneum to augment the permeability of the intercellular lipid barrier. The drugs (MTX) can cross through the niosomes due to their interactions with aggregation, fusion, and adhesion, leading to a large thermodynamic gradient. Our research found that Nio16 had a potent cell inhibition capacity against B16-F10 cells, suggesting that the modified formulation would be beneficial in the treatment of cancer.

Table 2. Cytotoxic effects of formulations NIO 14 to NIO 17 on murine tumor cell line B16F10 cells

Treatment	% Growth inhibition at concentration (µg/mL)				GI_{50} (µg/mL)
10	20	40	80	NIO 14	9.1
9.9	6.7	6.9	2.5311	NIO 15	4.3
− 0.5	− 2.1	7.5	8.05738	NIO 16	1.7
− 0.8	6.7	14.1	40.2238	NIO 17	5.9
5.8	14.8	32.3	38.7176	ADR	− 70.5

Ex vivo and In vivo investigations

Ex vivo skin penetration study

The ex vivo drug permeation study was conducted to gain insights into the potential in vivo performance of RH-loaded niosomes as a transdermal drug delivery system. Employing CLSM, z-stack images were captured to depict optical sections of mice skin at 2 µm intervals, covering a depth span of 0 to 38 µm. Formulations utilizing PBS as a positive control did not exhibit any detectable particles. Likewise, formulations with Plain Rhodamine as a negative control also displayed no observable particles. The findings from this ex vivo skin permeation study, which identified specific depth ranges for particle presence in various niosome formulations, have significant implications for potential applications in skin cancer treatment. Notably, Nio13 (982.3 nm), with particles observed at a depth of 0–6 µm, suggests a potential for superficial skin cancers. Nio14 (783.9 nm), spanning from 4 to 18 µm, may have relevance in treating lesions at slightly greater depths. The formulation Nio15 (707.7 nm), demonstrating distinct

particles between 16 snf 22 μm, could be well-suited for targeting tumors residing slightly deeper within the skin. For more deeply seated skin cancers, Nio16 (671.5 nm), with particles at depths ranging from 24 to 32 μm, may offer a solution. Additionally, Nio17 (597.2 nm), with particles distributed within a broad range of 12 to 38 μm, could be instrumental in addressing skin cancers with varying depths or infiltrative characteristics. The particles of Nio 18 (205.0 nm) will go into systemic circulation. This study suggests that tailoring niosome size and properties to specific depth ranges has the potential to enhance localized drug delivery for skin cancer treatment, increasing the precision and effectiveness of therapeutic interventions. These findings offer valuable insights into the distribution patterns and potential penetration capabilities of the RH-loaded niosomes across different skin layers. CLSM has emerged as a valuable tool for studying the skin's permeation and nanocarrier distribution due to its real-time imaging, multi-depth capabilities, and noninvasive nature. In this study, Rhodamine B (RH) acted as a model lipid-soluble fluorophore, mimicking a hydrophilic drug in niosomes. Before imaging, untreated skin displayed no fluorescence within the fluorophore's detection range. The visualizations (Fig. 9) showcased the widespread distribution of fluorescence across skin layers following treatment with fluorolabeled niosomes. The interaction of proposed surfactant-containing niosomes with skin surface lipids might have facilitated intracellular drug penetration. This study's findings highlight the potential of MTX-loaded niosomes as effective transdermal drug carriers and underscore the utility of CLSM in comprehending their skin permeation behavior.

In vivo histopathological study

The in vivo histopathological examination provided valuable insights into the potential skin irritation of different treatment groups. The untreated control group (Group I) displayed a healthy and intact skin structure with well-defined layers, as seen in Fig. 10. This serves as a baseline for comparison. Skin treated with only the MTX solution (Group II) also showed an intact epidermis and dermis, despite minor congestion in deeper blood vessels. This suggests that the MTX itself might not be a significant skin irritant in this context. Skin sections from groups receiving niosomal formulations (Groups III–VII) revealed a key finding: no epidermal erosion. However, crucially, this erosion was not accompanied by any signs of inflammation, such as edema or erythema. This strongly suggests that the irritation was mild and manageable, likely influenced by the presence of penetration enhancers like Span 60 and Soya PC in the niosome formulations. Importantly, other skin layers remained intact, and no major disruptions were observed beyond the topmost keratinized stratum corneum. While the qualitative observations are valuable, adding a quantitative scoring system to assess the degree of epidermal erosion and congestion across groups could further strengthen the conclusions about niosomal safety. This would provide more objective and comparable data for future studies. These findings support the idea that MTX-loaded niosomes exhibit a relatively acceptable safety profile. The absence of significant inflammation despite mild erosion suggests that the potential for irritation in clinical settings is likely low. However, future studies implementing quantitative scoring would further bolster these conclusions and provide even more robust evidence for the safety of these niosomes as drug delivery systems.

Discussion

The discussion of the study's findings reveals important insights into the formulation and properties of MTX-loaded niosomes, as well as their potential for cancer treatment.

The study's investigation into the impact of formulation components, particularly the ratios of span 60, soya PC, and cholesterol, on niosome properties revealed a complex relationship between these components and vesicle size. The initial decrease in vesicle size with a higher span 60 concentration highlights the surfactant's interfacial activity, facilitating smaller vesicle formation. However, beyond a certain point, increased span 60 content coupled with higher cholesterol led to larger vesicle sizes due to increased rigidity. This observation underscores the delicate balance required between these components to achieve optimal vesicle properties. A possible solution lies in fine-tuning the component ratios to strike the right balance between interfacial activity and vesicle stability.

The study's findings on the encapsulation efficiency of MTX shed light on the influence of sonication time on drug loading. The variations in encapsulation efficiency can be attributed to the interplay of sonication energy, vesicle size, and drug solubility. To address this, a controlled and standardized sonication process should be established, accounting for both drug entrapment and vesicle size optimization.

The FTIR spectroscopy results confirm the compatibility of MTX with niosome components, supporting the formulation's potential for effective drug delivery. This is a significant assurance of the stability and efficacy of the loaded drug within the vesicles.

The DSC thermograms' insights into the thermal behavior of components, including the disappearance of the drug's crystalline peak after encapsulation, suggest a change in the drug state or its encapsulation within the vesicles. While this finding holds promise for sustained drug release, further investigations are warranted to understand the exact mechanism of drug encapsulation and release from the vesicles.

The study's anti-cancer efficacy evaluation revealed the superior activity of the Nio17 formulation against B16-F10 cells, attributed to the presence of span 60 as a permeation enhancer. This underscores the potential of niosomes as effective carriers for anti-cancer agents, particularly when incorporating permeation enhancers.

The ex vivo drug permeation study provided visual evidence of the penetration of RH-loaded niosomes into different skin layers, showcasing their potential for transdermal drug delivery. This underscores the practical relevance of the formulation's structure and composition in facilitating drug penetration through the skin. The presence of particles was observed in Nio13 (without sonication), with an average size of 982.3 nm (nm) visible within 0 to 6 μm (μm). This suggests that sonication may be beneficial for enhancing skin penetration. The formulations with sonication durations of 2, 4, 6, and 8 min (Nio14, Nio15, Nio16, and Nio17, respectively) produced progressively smaller particles at increasing depths. The particle sizes ranged from 783.9 nm (4–18 μm), 707.7 nm (16–22 μm), 671.5 nm (24–32 μm), to 597.2 nm (12–38 μm), indicating improved permeation. The positive results of Nio17, revealing the presence of particles within skin layers rather than in the bloodstream, underscore its potential as a promising candidate for effective drug delivery.

The in vivo histopathological examination indicated no epidermal erosion or inflammation, supporting the formulation's potential for transdermal delivery in skin cancer therapy. However, the absence of severe inflammation suggests the formulation's acceptability for clinical use. This observation highlights the importance of considering local skin effects in the development of transdermal drug delivery systems.

This study offers valuable insights into the formulation and properties of MTX-loaded niosomes, demonstrating their potential as effective transdermal drug carriers for cancer treatment. The findings underscore the need for careful optimization of formulation components and process parameters to achieve desired vesicle characteristics, encapsulation efficiency, and drug release profiles.

Conclusion

This study comprehensively investigated the formulation, properties, and potential of MTX-loaded niosomes for transdermal cancer therapy. The complex interplay of formulation components, particularly span 60, soya PC, and cholesterol, on vesicle size and encapsulation efficiency necessitates fine-tuning to achieve optimal properties. Compatibility between MTX and niosomes was confirmed by FTIR, while DSC hinted at a possible sustained release mechanism. Notably, Nio16 demonstrated superior anti-cancer activity against B16-F10 cells, highlighting the benefits of permeation enhancers. Ex vivo studies visually confirmed niosome penetration into skin layers, with smaller particles achieving deeper penetration. While mild epidermal erosion was observed in vivo, the absence of severe inflammation suggests acceptable safety. This study establishes the promising potential of MTX-loaded niosomes for transdermal cancer treatment, emphasizing the importance of optimizing formulation parameters and exploring complementary techniques like CLSM for further validation. This research lays the groundwork for developing innovative and effective transdermal drug delivery systems for cancer therapy.

In the future, our study will be advanced by comparing niosomes with market-available formulations for skin diseases and other nanovesicles under research. Physicochemical properties of our niosomes will be compared with liposomes, polymeric nanoparticles, and other nanocarriers using standardized in vitro assays, focusing on size, stability, and drug loading capacity. In vitro drug release profiles will be analyzed to understand potential differences in release kinetics and therapeutic effects. Additionally, comparative in vivo studies in relevant animal models will evaluate biodistribution, pharmacokinetics, and efficacy of our niosomes compared to other nanocarriers, considering factors like targeted delivery, systemic exposure, and potential side effects.

ABSTRACT (ENGLISH)

Background

Streptozotocin (STZ) is a glucose analogue commonly used for inducing diabetes in experimental animals. This study is intended to investigate the ability of captopril (Cap) pretreatment to augment STZ-induced diabetogenic effect in an experimental rat model. If this hypothesis were proven, Cap administration to rats could reduce the dosage of STZ by augmenting its effect and resulting in a subsequent reduction in STZ cost. Forty-two adult male Wistar rats were randomly divided into seven groups: a control group that fed a normal diet, whereas the other six experimental groups were fed a high-fat diet (HFD). The six groups were then divided into STZ-30, STZ-30-Cap, STZ-40, STZ-40-Cap, STZ-50, and STZ-50-Cap. All Cap-received groups were supplemented with 50 mg/kg Cap orally one hour just before intraperitoneal (I.P.) injection of STZ. 30-STZ, 40-STZ, and 50-STZ-treated groups were injected once with STZ I.P. at doses of 30, 40, and 50 mg/kg, respectively. An intraperitoneal glucose tolerance test (IPGTT) was done. Pancreatic tissue was obtained to measure Tumor necrosis factor alpha (TNF-α), interleukin one beta (IL-1β), and nitric oxide (NO) by enzyme-linked immunosorbent assay (ELISA) and glucose transporter 2 (GLUT2) gene expression by reverse transcription polymerase chain reaction (RT-PCR). Pancreatic sections were examined by hematoxylin and eosin (H&E) stain, and immunohistochemical staining by anti-insulin and anti-TNF-α antibodies.

Results

Results indicated that administration of Cap before STZ in different doses significantly augmented the hyperglycemic state that was evident by intraperitoneal glucose tolerance test, and markedly increased pancreatic pro-inflammatory markers. Histological analysis of islets of Langerhans indicated degeneration with extensive vacuolations associated with a significant decrease in mean area % of insulin immunoreactivity and an increase in optical density of TNF-α immunoreactivity.

Conclusion

These findings pointed to the ability of captopril pretreatment to augment the hyperglycemic state and the diabetogenic response that was induced secondary to STZ injection in an experimental rat model.

FULL TEXT

Introduction

The animal models played a crucial role in studying how disease pathogenesis develops and evaluating novel therapeutic agents. Diabetes mellitus (DM) was one of the disorders that necessitated ongoing creative therapy approaches [1]. DM refers to a set of metabolic illnesses that result in high blood glucose levels and a state of chronic hyperglycemia. In this context, the two most prevalent types of diabetes mellitus are type-1 diabetes and type-2 [2].

Type-1 diabetes is classified as an autoimmune disease due to the attack and destruction of insulin-producing pancreatic β-cells [3], while type-2 diabetes is accompanied by insulin resistance and insufficient insulin secretion due to a lack of appropriate compensation by the beta-cells. Consequently, the selection of appropriate animal models for diabetes research should be contingent upon the specific aspects of the disease under investigation [4]. To induce DM. in animal models, the traditional toxic chemicals that selectively target pancreatic β-cells have been used by many researchers. For instance, alloxan has been utilized to induce β-cell destruction through the production of free radicals. However, alloxan demonstrated several prominent drawbacks, including high animal mortality, the generation of animal ketosis due to the formation of free fatty acids, reversible diabetic states, species-specific resistance to its diabetogenic effects as in guinea pigs, and renal toxicity within a narrow effective dose range [5]. As a result, streptozotocin (STZ) has emerged as a substitute for alloxan due to its more favorable characteristics for diabetes induction [6]. STZ can be used to induce animal models of both type-1 and type-2 diabetes by applying either high or low doses [7]. High doses of STZ can severely impair insulin release resembling what happened in type-1 diabetes and can also lead to the formation of ketone bodies, a feature of uncontrolled type-1 diabetes. In contrast, low doses of STZ can cause mild impairment in insulin secretion that mimics type-2 diabetes. However, the low-dose STZ-induced animal model does not address insulin resistance which is in general

a feature of type-2 diabetes [8].

A model, that combines a high-fat diet (HFD) followed by a low STZ dose to induce peripheral insulin resistance, would closely resemble human type-2 diabetes [9]. Although there are several experimental models of DM reported to date, the HFD-STZ-type-2 diabetes model is still considered the preferable one [10, 11]. The STZ dose-dependent direct and indirect toxicity is still the main significant drawback. Studies reported that some albino rats developed stomach ulcers, decreased bone volume and muscle mass, reproductive problems, hepatotoxicity, and nephrotoxicity at a dose of 65 mg/kg and 100% mortality in Wistar rats due to the lethal end-point at a dose≥ 70 mg/kg [11].

Even while it appears to be easy to induce diabetes in many different animal species with STZ, it is difficult because of factors like unpredictability, high cost, and high mortality rates. Based on their particular experiences, the investigators employ different techniques when implementing this paradigm. The STZ dosage, the way it is administered, the animal species, the gender, and the body weight are all subject to variation. The investigators have made numerous attempts aiming to create more stable and consistent hyperglycemia [12].

The local renin–angiotensin system (RAS) has been discovered to play a crucial role in pancreatic physiology and is involved in pancreatic function. Angiotensin II receptors include two types 1 and 2 (AT1R and AT2R), they have been demonstrated to be present in pancreatic islets, whereas the function of AT2R is still controversial and not fully understood [13, 14].

Recent evidence revealed that RAS could regulate the endocrine and exocrine function of the pancreas and short-term Angiotensin II (Ag II) infusion changes the intra-islet blood flow while the chronic exposure effects are still unknown [15]. Another study found that Ang II has a significant vasoconstrictive effect on islet vasculature and reduces islet blood flow. In contrast, the angiotensin receptor blockers vasodilate islet arterioles and stimulates insulin secretion in response to high glucose levels [16, 17].

Captopril (Cap), an angiotensin-converting enzyme (ACE) inhibitor medication, is used in controlling hypertension, management of left ventricular dysfunction after myocardial infarction, and diabetic nephropathy. Many researchers discovered its role in increased glucose uptake by pancreatic tissues, the exact mechanism is unclear, but a vasodilation effect may be incorporated [18].

This study aimed to investigate the possibility of developing a modified experimental model of diabetes mellitus by estimating the adding effect of captopril on different low doses of STZ in HFD adult Wistar rats. The authors compared the changes in serum glucose levels in response to the intraperitoneal glucose tolerance test (IPGTT), and local pro-inflammatory markers in pancreatic tissues secondary to injecting different doses of STZ that were given either alone or in combination with captopril for inducing animal model diabetes.

Material and methods

Experimental animal &grouping

Forty-two adult male Wistar rats (8–10 weeks in age and 180–200 g weight) were purchased from and housed in the Animal House of the Faculty of Medicine, Cairo University. Animals were left for seven days to acclimate to ordinary environmental living conditions regarding humidity, temperature, and dark/light cycles. Rats had free access to food and water to ensure normal growth and behavior; they were kept in wire mesh cages (three rats in each) before starting the experimental procedures. All animal procedures were done in accordance with the highest International Criteria for Animal Experimentation of Helsinki. The Faculty of Medicine, Cairo University Ethical Approval No is; CU/III/F/38/22.

Drugs and chemicals

STZ was purchased from Sigma-Aldrich, MO, USA, and was given at doses of (30, 40 &50 mg/kg). STZ was dissolved in freshly prepared 0.1 M citrate buffer (pH 4.5; Talpate, Bhosale, Zambare, &Somani). Captopril purchased from Sigma-Aldrich, MO, USA, as a powder, was dissolved in sterile distilled water and was given at 50 mg/kg orally. All other chemicals and reagents were of high analytical grade.

Investigation protocols

Rats were randomly divided into seven groups (six rats each), **Group I**; control normal rats (fed a normal rat chow

(12% fat, 60% carbohydrate, and 28% protein), and the other six main experimental groups were maintained on a HFD; 41% fat, 41% carbohydrate, and 18% protein) for 2 weeks. Then, the overnight-fasted rats in the experimental groups were injected with STZ. The rats were allocated to: **Group II (STZ-30);** the rats in this group received STZ at a dose of 30 mg/kg (I.P.) [19], **Group III (STZ-30-Cap)**; the rats were subjected to the intake of captopril (50 mg/kg orally) [20, 21] one hour just before injecting STZ at a dose of 30 mg/kg, **group IV (STZ-40)**; the rats in this group were subjected to STZ injection at a dose of 40 mg/kg I.P.), **group V (STZ-40-Cap)**: the rats were subjected to oral administration of captopril at the same of group III one hour just before injecting 40 mg/kg of STZ, **group VI (STZ-50)** ; the rats were subjected to STZ injection at a dose of 50 mg/kg (I.P.), and **group VII (STZ-50-Cap)**; the rats were subjected to oral administration of captopril (at the same of group III, and V one hour just before injecting 50 mg/kg of STZ.

At the end of the study, after 28 days (one week allowed for acclimatization of the experimental rats, followed by a two-week span during which the rats were maintained on a HFD). The final week was dedicated to the implementation of the treatment protocol and served as the end-point of the study, the blood pressure of each rat was measured using the tail-cuff method. The animals were fasted overnight for about 12 h, and then the blood samples were obtained from the femoral vein under ketamine/xylazine (60/7.5 mg/kg, i.p) [22] anesthesia using non-heparinized capillary tubes for separation of sera. Samples were kept immediately in ice-chilled, siliconized disposable glass tubes. The serum samples were obtained by centrifuging blood samples at 4,000 g for 15 min at 4 °C and kept at − 80 °C until further analysis. After that, the rats were sacrificed by cervical dislocation under anesthesia, and the pancreatic tissues were excised and fixed in a 10% buffered formalin solution for histopathologic analysis. More treatment protocol clarification is shown in Fig. 1.

Noninvasive blood pressure measurement

The noninvasive rat tail systolic arterial blood pressure was recorded at the end of the study using a noninvasive blood pressure meter (LE 5002, Harvard Apparatus). The rat is placed in a restrainer and warmed. A pneumatic pulse sensor is attached to its tail. A cuff is placed around the tail, and slowly inflated above the systolic pressure until it causes pulsations to cease, measured by the piezo-electric pulse sensor. The cuff pressure at which pulsations cease is taken to be the SBP in the tail.

Verification of diabetes

Intraperitoneal glucose tolerance test (IPGTT)

All rats were subjected to IPGTT [23, 24]. Male rats were fasted overnight and injected with glucose at a dose of 2 g/kg (I.P.). Blood glucose levels were measured at times of fasting (time zero), 30, 60, and 120 min with a glucometer (GlucoDrTM, All Medicus Co. Ltd, Gyeonggi, Korea) [25].

Biochemical measurement

TNF-α in pancreatic tissue by ELISA

TNF-α in pancreatic tissue protein was assessed by ELISA technique according to kit instructions; Rat TNF-α ELISA Kit, Catalog No: MBS2507393. MyBioSource, Inc. San Diego, CA 92195–3308, USA.

IL-1β in pancreatic tissue by ELISA

IL-1β in pancreatic tissue protein was assessed by ELISA technique according to kit instructions; Rat IL-1β ELISA Kit. Catalog No: MBS824956.MyBioSource, Inc. San Diego, CA 92195–3308.

NO level in pancreatic tissue

NO level in pancreatic tissue was assessed according to kit instruction; Nitric Oxide Assay Kit (Colorimetric). Catalog No: ab65328, Abcam, Waltham, USA.

GLTU2 gene expression in pancreatic tissue by RT-PCR

The pancreatic tissues from all studied groups were homogenized and total RNA was isolated with Gene JET Kit

(Thermo Fisher Scientific Inc., Germany, #K0732). A one-step qRT-PCR reaction was done; for reverse transcription; about 5 µl from the total RNA from each sample (once for the GLUT2 gene and once for ß actin gene) was used with subsequent amplification with Bioline, A median Life Science company, UK (SensiFASTTM SYBR R Hi-ROX) One-step Kit (catalog number PI-50217 V) in a 48-well plate using the Step-one instrument (Applied Biosystems, USA). Thermal profile was as follows: 45 °C for 15 min in one cycle (for cDNA synthesis), 10 min at 95 °C for reverse transcriptase enzyme inactivation, followed by 40 cycles of PCR amplification. 10 s at 95 °C, 30 s at 60 °C, and 30 s at 72 °C were adjusted for each cycle.

RNA quantitation assessment was carried out using a spectrophotometer the Nano Drop® (ND)-1000 (Nano Drop Technologies, Inc.) by measuring the absorbance at 260 nm.

RNA purity was assessed by comparing the absorbance ratio using a spectrophotometer the Nano Drop® (ND)-1000 (Nano Drop Technologies, Inc.) as we measured the absorbance at 280 to exclude contamination with protein and reagent that absorbed near 280, the 260/280 ratio was 2, also the absorbance at 230 was measured to exclude contamination with another compound as carbohydrate and phenol that absorb near 230, the 260/230 ratio was 2.1

From the expression of the studied genes, genes were normalized relative to the mean critical threshold (CT) values of ß actin as the housekeeping gene by the Ct method. Primers' sequences for studied genes are listed in Table 1.

Table 1. Primer sequence for a studied gene

Gene	Primer sequence from 5′- 3′
GLTU2	Forward: GCACACTCTTGGCCCGG Reverse: GCCTGGGAAGAAGAGACT
ß actin	Forward: GCA CCA CAC CTT CTA CAA TG Reverse: TGC TTG CTG ATC CAC ATC TG

Pancreatic tissues histological study

The Pancreas was dissected, fixed in 10% formaldehyde solution, and processed into paraffin blocks. Five-micron sections were cut and mounted on glass slides for hematoxylin and eosin (H&E) staining to examine structural changes in islets of Langerhans in the pancreas.

Immunohistochemical staining of the pancreatic tissues

Pancreatic sections were de-paraffinized, hydrated with descending grades of alcohol, and treated with citrate buffer pH 6 in the microwave for antigen retrieval, then incubated overnight with: 1-anti-insulin antibody (ab63820; rabbit polyclonal antibody, dilution (1:100), Abcam, Cambridge, UK). 2-anti-TNF-α receptor (ab220210; mouse monoclonal antibody, dilution (1:100), Abcam, Cambridge, UK). Two drops of biotinylated secondary antibody were applied for 20 min and then two drops of streptavidin peroxidase for 10 min. The reaction was visualized with diaminobenzidine (DAB) as a chromogen and Mayer's hematoxylin as a counter-stain. The primary antibodies were replaced in negative control serial sections with PBS.

Morphometric assessment

The "Leica Qwin 500 C" image analyzer computer system Ltd. (Cambridge, UK) was used to collect the data. The image analyzer was made up of an Olympus color video camera, a colored monitor, and an IBM hard drive that was attached to a light microscope and ran "Leica Qwin 500 C" software. To automatically translate the measurement units (pixels) generated by the image analyzer program into actual micrometer units, the image analyzer was first calibrated.

The mean diameter of the islet of Langerhans, area % of anti-insulin immunoreactivity, and optical density of TNF-α immunoreactivity were assessed in 10 non-overlapping randomly selected high-power fields (×400).

Statistical analysis

The results were obtained as mean ± standard deviation (SD). Statistical analysis for parametric measures was done via one-way analysis of variance (ANOVA) version 25, followed by the Tukey–Kramer multiple comparisons test as a post hoc test. A comparison of glucose levels in each group with time was done using repeated measure ANOVA. Statistical significance was considered when $P<0.05$. Statistical analysis will be carried out using IBM SPSS Statistics for Windows, version 25 (IBM Corp., Armonk, N.Y., USA).

Results

The intraperitoneal glucose tolerance test (IPGTT) and the systolic and diastolic blood pressure result in all studied groups

The blood pressure was recorded both before and after the administration of STZ and Cap to confirm any changes in blood pressure. The findings showed that there were no significant differences in the reading among all studied groups.

As shown in Table 2, all treated groups showed a significant increase in fasting, and estimated blood glucose was measured after 30, 60, and 120 min following I.P. injection of glucose compared to the control group. Moreover, receiving captopril before injecting STZ at 30 mg/kg and 40 mg/kg was able to significantly increase the levels of blood glucose measured at different times compared to STZ-40 and STZ-50, respectively. Additionally, the maximum results of estimated blood glucose were obtained STZ-50-Cap group at different times compared to other groups.

Captopril administration was able to enhance the expression of GLUT2 and increased nitric oxide levels in pancreatic tissues in the studied groups

The expression levels of GLUT2 were estimated in all studied groups and the pre-intake of captopril before the administration of STZ was able to enhance its expression levels that were documented by PCR. Our data documented enhanced expression levels in the STZ-30-Cap compared to STZ-30, and a significant increase in the same parameter in the STZ-40-Cap compared to its corresponding values in the STZ-40 group, additionally significant increase in GLUT2 expression was recorded in the STZ-50-Cap compared to its corresponding values in

the STZ-50 group, without recording any significant difference between STZ-30-Cap, STZ-40-Cap, STZ-50-Cap groups (Table 3). Additionally, the levels of nitric oxide were significantly increased in all STZ-treated groups compared to the control group, and captopril administration before STZ injection was able to significantly increase the levels of NO in these groups compared to the corresponding values of the STZ-treated groups (Table 3).

Effect of STZ and captopril pre-intake on pancreatic tissue degeneration

As shown in Fig. 3, the histological examination using H&E staining of the pancreatic tissues demonstrated that the control group showed normal architecture of the pancreas with the islet of Langerhans surrounded by pancreatic acini. The experimental groups, STZ-30; STZ-30-Cap; and STZ-40, exhibited a degenerated islet of Langerhans. However, STZ-40-Cap; STZ-50; and STZ-50-Cap groups revealed massive degeneration of islets of Langerhans with large areas of vacuolations and numerous depleted β-cells.

Fig. 3 [Images not available. See PDF.]

Representative histological photomicrographs of H&E-stained rat pancreatic Sects. (400x). **A** The control group shows a pale-stained islet of Langerhans surrounded by a darkly stained closely packed pancreatic acini. The acini are formed of pyramidal cells displaying apical acidophilia and basal basophilia with vesicular nuclei and prominent nucleoli. **B** &**C** Groups STZ-30 and STZ-30-Cap illustrate degenerated islets of Langerhans with vacuolations

(arrows) and a few depleted β-cells that display darkly stained nuclei (arrow heads). **D** &**E** Group STZ-40 illustrates a degenerated islet of Langerhans with few vacuolations (arrows) and few depleted β-cells that display darkly stained nuclei (arrow heads). Group STZ-40-Cap exhibits more vacuolations (arrows) in islets of Langerhans and more depleted B-cells with darkly stained nuclei (arrow heads). **F** &**G.** Group STZ-50 displays marked degeneration of islets of Langerhans with vacuolations (arrows) and many depleted β-cells. Group STZ-50-Cap shows massive degeneration with vacuolations (arrows) and most of the cells are depleted (arrow heads). **H.** Histogram representing mean area % Islet of Langerhans size; *denotes significant difference compared to control, # denotes significant difference compared to STZ-30, $ denotes significant difference compared to STZ-30-Cap, € denotes significant difference compared to STZ-40, ¥ denotes significant difference compared to STZ-40-Cap, and @ denotes significant difference compared to STZ-50. *STZ* Streptozotocin, *Cap* Captopril

Immunohistochemical assessment of the pancreas stained with anti-insulin

As shown in Fig. 4; the control group revealed strong widespread insulin immunostaining in the islet of Langerhans. All STZ-treated groups exhibited a significant decrease in the mean area % of insulin immunoreactivity in comparison with the control group. β-cells in experimental groups, STZ-30; STZ-30-Cap; and STZ-40, demonstrated moderate heterogeneous insulin immunostaining. STZ-40-Cap group showed weak insulin immunostaining. Moreover, STZ-50 and STZ-50-Cap groups exhibited faint heterogeneous insulin immunostaining in β-cells, revealing a significant decrease in mean area % of insulin immunoreactivity when compared to groups STZ-30; STZ-30-Cap; and STZ-40. Furthermore, the STZ-50-Cap group demonstrated a significant decrease in mean area % in comparison with all experimental groups. A significant difference was recorded between STZ-30 and STZ-30-Cap groups as well as between STZ-40 and STZ-40-Cap groups in addition between STZ-50 and STZ-50-Cap groups.

Mean area % of insulin antibody immunoreactivity result

In addition, STZ-30-Cap, STZ-40-Cap, and STZ-50-Cap revealed a significant decrease when compared to group STZ-30, STZ-40, and STZ-50, respectively (Fig. 4).

Optical density of TNF-α antibody immunoreactivity result

The optical density of TNF-α immunoreactivity in all experimental groups revealed a significant increase when compared to the control group. Groups STZ-30-Cap, STZ-40-Cap, and STZ-50-Cap exhibited a significant increase in comparison with groups STZ-30, STZ-40, and STZ-50, respectively (Fig. 5).

Discussion

To our knowledge, this study is the first to investigate the possibility of developing a modified experimental model of DM by estimating the adding effect of captopril on different low doses of STZ in HFD adult Wistar rats. Our goal was to reduce the high doses of STZ and to reduce the cost of the experimental protocols.

The components of RAS have been proven to be expressed locally in rodent and human pancreatic islets a long time ago. Twenty years ago, researchers [26] discovered the intrinsic angiotensin system in dog exocrine pancreas, and numerous data support the idea of an intrinsic RAS in the rat pancreas indicating its role in pancreatic function regulation and insulin secretion [27].

In this study, we tried to explore a new modified experimental model for the induction of DM in which we investigated the effect of the addition of ACE inhibitor, captopril, to different doses (30, 40, &50 mg/kg) of STZ aiming to augment the diabetic response caused by low doses of STZ by combining it with captopril. This approach assists in achieving a more efficient model of diabetes while reducing the hazards associated with giving high doses of STZ; which can sometimes be lethal to the animals.

Our results were consistent with our working hypothesis as the administration of 50 mg/kg of captopril just an hour before the I.P. injection of 30 mg/kg STZ to the HFD rats resulted in a significant increase in both fasting and postprandial glucose levels more than in groups that were injected with STZ alone and all animals were still alive till the end of the experiment. However, there is some mortality at the other two higher doses (40 &50 mg/kg) in STZ combined with captopril. Captopril is a medication used as an antihypertensive drug that prevents the conversion of angiotensin I to the potent vasoconstrictor angiotensin II [28]. However, its precise mechanism in producing hyperglycemia is not evident but a long time ago, several studies have suggested the relationship between RAS and both pancreatic and islet blood flow.

Studies revealed that islet RAS exhibits a significant role in regulating islet glucose-stimulated insulin release and the locally produced Ang II markedly impair islet blood flow and blocks glucose-induced insulin secretion. RAS antagonists, such as enalaprilat and irbesartan (an AT1 receptor antagonist), can selectively augment pancreatic islet blood flow and improve glucose-stimulated insulin release [29].

A study was done by Olsson et al. [30] to investigate the effect of Ang II on revascularization and local blood flow regulation in transplanted rat pancreatic islets and they concluded that Ang II decreased the vascular conductance of the islet grafts in both nondiabetic and diabetic animals. Carlsson et al. [29] suggested that RAS has marked impacts on the growth, differentiation, secretion, and insulin sensitivity of pancreatic islets, which in turn affect glucose uptake, metabolism, and pathogenesis of DM. Campbell and his colleague [31] 1986 have reported that mRNA encoding angiotensinogen, renin, and Ang II have been discovered in the pancreas of various species. This Ang II can adversely influence pancreatic and islet blood flow through the vasoconstrictive mechanism. A further study was conducted by Lau et al. [32], which used a double immunostaining technique to detect high-affinity binding sites for Ang. Results showed that Ang II was specifically located in islet beta-cells, and it was found to block

glucose-induced insulin release either directly by inhibiting β-cell insulin exocytosis or indirectly through suppressing islet blood perfusion. This effect was fully reversed by losartan indicating a potential role of locally produced pancreatic Ang II in glucose homeostasis. Based on these earlier studies, RAS inhibitors may have a promising role in increasing local pancreatic and islet blood flow which may increase glucose and glucose analog (STZ) uptake through the GLUT2 mechanism. According to these prior studies, the authors of the current study found that the biochemical and both histological and immunohistochemical findings support this theory.

In the present study, the histological examination of pancreatic sections revealed degeneration of islets of Langerhans with β-cell necrosis after STZ administration which is augmented with captopril intake. These results agree with Raza and John [33], stating that administration of STZ at low doses results in β-cell dysfunction and apoptosis while at higher doses leads to β-cell necrosis. Various data explained that STZ induces diabetes in experimental animals through different pathways, The first mechanism involves DNA fragmentation due to the STZ nitrosourea moiety, the second is releasing nitric oxide (NO), the third is creating reactive oxygen species (ROS) and inducing oxidative stress, the fourth mechanism is inhibiting the activity of the glycoside hydrolase O-GlcNAcase enzyme in the β-cell, which is responsible for removing O-GlcNA from proteins. This produces irreversible O-glycosylation of intracellular proteins causing β-cell apoptosis [34].

In addition, STZ contains deoxyglucose molecules that are very reactive and can produce direct cytotoxic damage on pancreatic β-cells. It targets the GLUT2 receptor, which is copious on β-cells plasma membranes making them its primary target [35]. Hence the STZ mechanism begins with GLUT2, a transmembrane carrier protein found in β-cells of the pancreas, the absorptive epithelial cells of the intestinal mucosa, liver, and renal cells [36]. The current results showed that the administration of captopril before STZ exposure resulted in more damage of β-cells, this may be due to enhanced expression of GLUT2 in pancreatic tissues of all groups regardless of the dosage compared to the groups that only received STZ.

Furthermore, this could be attributed to the fact that pancreatic β-cells selectively accumulate STZ via GLUT2 and STZ damage to the β-cells is dependent on GLUT2 expression [37].

The contribution of NO and oxidative stress is a crucial aspect of STZ toxicity [38]. Since β-cells have lower levels of enzymes that scavenge NO and free radicals, they are particularly vulnerable to damage caused by NO and free radicals [39]. In our study, we found that NO levels in pancreatic tissues were increased significantly in all groups that administered STZ. This increase was particularly significant in the STZ-Cap groups, and this may be related to the marked uptake of STZ by captopril. Results were supported by the work done by Eleazu et al. [40] who explained the mechanism of increased NO as the nitrosamine group found in STZ serves as an intracellular donor of NO in pancreatic β-cells, and the amount of NO released locally in pancreatic tissues increased with a high level of STZ. When released in excessive amounts NO hinders the action DNA enzyme, aconitase, which ultimately leads to alkylation and damage of DNA. Aconitase is an enzyme that safeguards mitochondrial DNA from degradation. This enzyme can be inhibited by various ROS as well as reactive nitrogen species [41].

Selective and progressive destruction of insulin-secreting β-cells secondary to the diabetogenic action of STZ can enhance local pancreatic infiltration with inflammatory cells and cytokines, such as TNF-α, IL-1β, and interferon-γ (IFN-γ). Furthermore, IFN-γ and TNF-α, either alone or in combination, produce high levels of NO in pancreatic cells [42, 43].

The current results reported a significant increase in pancreatic TNF-α and IL-1β levels in STZ and STZ-Cap-treated groups which reflect the inflammatory state of the pancreatic tissues. Moreover, the captopril intake before STZ administration was able to augment the production of both TNF-α and IL-1β in STZ-Cap which might be due to increased STZ uptake. Also, histopathological findings of the pancreas showed a significant degeneration of islets of Langerhans and an increase in the optical density of TNF-α immunoreactivity at the doses 30 mg/kg in both STZ and STZ-Cap and the degree of degeneration increased by increase STZ-Cap doses. Also, the mean area % of anti-insulin immunoreactivity had a significant decrease in all groups STZ and STZ-Cap. This decrease ranges from moderate heterogeneous insulin immunostaining in β-cells to faint immunostaining according to STZ doses. Our results are consistent with Akash et al. [44] who denoted that the first pro-inflammatory cytokine that was recognized

due to its involvement in insulin resistance pathogenesis and T2DM was TNF-α and the release of other cytokines like IL-6 and IL-1β is enhanced by the pro-inflammatory TNF-α. During acute inflammation, the elevation in both TNF-α and IL-1β impairs β-cell activity and disrupts the insulin signaling pathway.

In conclusion, our study suggests that captopril may be a crucial regulator of glucose analog uptake (STZ) by β-cell. We found that the prior administration of captopril significantly enhanced the effect of low-dose STZ, helped the induction of diabetes, and decreased the mortality rate that occurred at the other higher doses this could make it a potential novel modified experimental model for the induction of diabetes in experimental animals.

Limitation and future recommendations

Future work is highly recommended to elucidate the long-term effect of coadministration of captopril and STZ regarding the state of hyperglycemia. We combined captopril with different doses of STZ, and we found that the intake of STZ at a dose of 40 mg/kg produced the same results of 50 mg/kg. By introducing the appropriate dose and route of administration for STZ and Alloxan chemical compounds, it could be possible to produce an optimal experimental model for type II DM with a low dose of STZ in rats. However, the long-term effect on plasma glucose and insulin levels, and islet morphology was not investigated.

In addition, it is highly recommended to investigate the effect of the combined treatment protocol versus STZ on the liver and kidney.

Author contributions

The authors declare that all data were generated in-house and that no paper mill was used. All authors contributed to the study conception and design. Material preparation, data collection, and analysis were performed by Ateyya Hayam; Harb Inas; ShamsEldeen Asmaa; Adel Sara; Samir Samaa; Rashed Laila; Mostafa Abeer. HI., AH., and S A. conceived and designed research. AH, HI, and HS conducted experiments. RL, SA, and KS contributed new reagents or analytical tools. AH, HI, AM, and AH analyzed data. AH and SA wrote the manuscript. All authors read and approved the manuscript.

Funding

The authors declare that no funds, grants, or other support were received during the preparation of this manuscript.

Availability of data and materials

The data that support the findings of this study are available from the authors upon reasonable request.

Declarations

Ethics approval and consent to participate

The study was done in accordance with the highest International Criteria of Animal Experimentation of Helsinki and was approved by the animal house of the faculty of medicine, Cairo University, approval No; CU/III/F/38/22. The authors confirm that neither the manuscript nor any parts of its content are currently under consideration or published in another journal.

Consent for publication

Not applicable.

Competing interests

We would like to declare that there were no conflicts of interest in conducting this research.

ABSTRACT (ENGLISH)

Background

Researchers, prompted by the toxicity and side effects associated with cisplatin, are exploring alternative approaches for developing transition metal-based anticancer agents. Employing a green biochemical approach, we transformed Nickel pyridine dicarboxylic acid compounds into the nanoscale using the aqueous extract of Macrotyloma uniflorum (horse gram).

Results

Characterization of the biosynthesized nanoparticles involved electronic and IR spectroscopy. A scanning electron microscope revealed a predominant spherical shape for most Nickel nanoparticles (Ni-NPs), with XRD patterns

indicating particle sizes ranging from approximately 30–150 nm. The nanoparticles were evaluated for their free radical scavenging efficiency and in vitro anti-malignant properties against HeLa and A549 cancer cell lines. Numerical optimization of the DPPH and MTT assays was conducted using response surface methodology (RSM), focusing on the effects of 3,4-pyridine dicarboxylic acid (ML_1), 2,4-pyridine dicarboxylic acid (ML_2), nickel nanoparticles concentration, and temperature. In this investigation, the incorporation of Horse Gram seed extract (Macrotyloma uniflorum) has unveiled its abundance in phenolic and flavonoid compounds, widely acknowledged for their robust antioxidant activity in the existing literature.

Conclusion

The present study highlights the potential for refining the bio-toxicity and biochemical attributes of Ni-NPs to pave the way for a new generation of versatile anticancer agents with clinically established efficacy. Notably, the anticipated data closely corresponds with experimental outcomes, reinforcing the trustworthiness and validity of the RSM model for examining anticancer and antioxidant properties in this context. ML_2 exhibited heightened antioxidant and anticancer activities in comparison to ML_1 nanoparticles.

FULL TEXT

Background

Nanoparticles derived from metals exhibit a range of advantageous properties, including excellent conductivity, a significant surface-to-volume ratio, and notable nano-plasmonic characteristics [1]. The extensive study of metal nanoparticles is driven by their potential applications in sensor devices, bio-devices, data storage, catalytic processes, and spectrophotometric techniques [2]. Biogenic nano-sized particles obtained from plant-based materials offer a straightforward and time-efficient synthesis method, with plant extracts proving more conducive to size reduction compared to microbiological cultures [3]. Literature supports the efficacy of botanical extracts in treating skin diseases, outperforming results obtained from various microbes [4].

In this research, the focus is on exploring different ligands for the creation of Ni-nanoparticles. Two isomers of pyridine dicarboxylic acid, namely pyridine-2, 4-dicarboxylic acid (Lutidinic acid) and pyridine-3,4-dicarboxylic acid (Cinchomeronic acid), have been selected as ligands for the study in conjunction with Nickel metal. Lutidinic Acid, recognized as a corrosion inhibitor [5], is also noted for its cytotoxic nature [6]. The objective is to examine the outcomes of these ligands in the synthesis of Ni nanoparticles.

The rationale behind selecting the organic moiety pyridine-2, 4-dicarboxylic acid and its derivatives for the study is clear. These compounds have demonstrated significant effects on physiological activity, acting as immuno-suppressants [7] and fibrous-repressive drugs crucial for the initiation and growth of certain plant families [8]. Additionally, they play a protective role by preserving specific enzymes in the cells of Bacillus subtilis species under temperature reduction conditions [9]. Notably, the pyridine compound with 2,4-dicarboxylic acid features structure identical to 2-oxoglutarate, a well-known inhibitor of 2-oxoglutarate-dependent dioxygenases. This inhibition, as observed in the growth of tomato seedlings exposed to various concentrations of pyridine dicarboxylic acid, resulted in diminished root size and smaller epicotyl [10].

Bio-nanotechnology involves the synthesis of nanoparticles through the utilization of organic biomolecules, encompassing living organisms such as fungi, bacteria, herb, yeast, as well as various naturally occurring moieties like proteins, peptides, sugar and vitamins [11, 12].

The integration of physical and chemical methodologies with fundamental standards, such as redox reactions, in the presence of biological adjuvants or natural phytonutrients, results in the production of nanoparticles with specific functions [13]. The biological synthesis of nanoparticles offers an environmentally friendly, uncomplicated, and cost-effective approach for researchers. This method also possesses the advantage of stabilizing nanoparticles through the utilization of plant secondary metabolites, serve equally reducing and capping molecules. Notably, nanoparticles produced using green technology exhibit minimal toxicity compared to chemically prepared counterparts, making them efficient carriers for drug delivery systems in in vivo applications [14].

Nickel nanoparticles, for instance, show promising applications in various fields including magnetism [15], microelectronics, power skills [16], and biomedical applications [17]. Due to their rapid reactivity, ease of operation,

and environmentally friendly properties, nanoparticles play a pivotal role in accelerating various organic reactions. These include oxidative coupling of thiols with multiple reaction pathways [18], reduction of aldehydes and ketones [19], hydrogenation of olefins [20], preparation of stilbenes through alcohol by Wittig-olefination [21], and α-alkylation of ketones [22]. Furthermore, they serve as catalysts for the decomposition of ammonia and its products [23]. A cutting-edge application of nanoparticles involves the fabrication of nanotubes, particularly carbon nanotubes (CNTs) [24].

The literature extensively covers the biological synthesis, characteristics, and applications of both Ni and Ni-oxide nanoparticles, with numerous articles and reviews focusing on environmentally friendly approaches for their preparation [25]. Nasseri et al. presented a method for synthesizing NiO nanoparticles using an aqueous extract of Tamarix serotina, showcasing their catalytic properties and confirming the nanoparticles' size to be in the range of 10–15 nm with a cuboid shape [26].

Presently, various plants segments, including leaves, flowers, seeds, fruits, barks, and peels, are employed for distillation to produce nanoparticles [27]. The plant distillate, rich in phytonutrients, antioxidants, and essential organic compounds, holds potential therapeutic significance [28, 29]. Over the past decade, the preparation and fabrication of nickel oxide nanoparticles have been continuously advancing, exploring their applications in various natural biological systems [30].

A strong statistical technique for experiment design and parameter optimisation is response surface methodology (RSM). Using process parameters, this can be utilized to create an accurate model for the response function in the optimal area [31]. Minimum quantity of research has been documented using RSM to optimize different ligands as parameters.

Our summary encompasses the accomplishments in the eco-friendly biotechnical preparation of Nickel nanoparticles and explores the influence of organic moieties to the physical characteristics of newly synthesized Ni-nanoparticles. Additionally, we present findings on the relative influence of various ligands using RSM, examining their structural effects and the biological properties of organically synthesized Nickel nanoparticles.

Methods

Chemical procurements

Chemicals are sourced from Sigma-Aldrich and employed in chemical reactions, with all solvents subjected to drying and additional purification through standard methods.

Synthesis of Ni complex

The compounds used in this study were obtained from the Department of Chemistry at the University of Rajasthan. The template condensation process was applied to produce Nickel (II) macrocyclic complexes, specifically utilizing benzyl dihydrazone with 3,4-pyridine dicarboxylic acid (ML_1) and 2,4-pyridine dicarboxylic acid (ML_2) in the presence of metal chloride. The synthesis followed established protocols as described in the literature. Subsequently, these complexes were further converted into nano-sized structures within our laboratory for their several applications. The illustrated macrocyclic structures are depicted in Fig. 1.

Fig. 1 [Images not available. See PDF.]

Structures of the macro cyclic complexes

Preparation of plant extract

Macrotyloma uniflorum is acquired from the supermarket, cleaned with deionized H_2O, and drenched in distilled H_2O at 40 °C for 12 h. Subsequently, it undergoes a germination process for 48 h at 30 °C, with regular moistening using deionized H_2O every half day. The sprouts are then crushed to form a dense paste by incorporating phosphate buffer solutions (pH 8). The resultant blend is strained through a twin layer of whatman No.1 filter paper, and the filtrate was centrifuged at 12,000 rotations per minute for 8 min below 40 °C. The weightless floating liquid is collected, and the extract solution is employed for the reduction of compounds into nanoform (Fig. 2).

Fig. 2 [Images not available. See PDF.]

Synthesis of extract of *Macrotyloma uniflorum*

Synthesis of Ni nanoparticles

The synthesis of Ni nanoparticles through a green route involves mixing the seed extract with the specific quantity of aqueous solution of nickel compounds, followed by allowing mixture to remain undisturbed until a noticeable colour change indicates nanoparticle formation. This process occurs either at room temperature or at 60–70 °C, depending on specific requirements.

For the microwave-assisted synthesis, a reduced amount of extraction solvent and a shorter reaction time yield efficient results. The reaction mixture is heated in a microwave at a power of 100–150 W for about 1–2 min. Later the extract undergoes centrifugation to room temperature, and the resulting precipitate is dried to obtain the desired metal nanoparticles. Notably, the percentage yield of nanoparticles from both synthesis methods was found to be nearly identical.

Utilizing an aqueous solution comprising plant material and Ni metal complexes in a 10:1 ratio, nanoparticles were synthesized following literature guidelines [32]. The mixture underwent incubation over a water bath, with careful pH control using 1 Normal H_3PO_4. Within 2–3 h, a distinct colour transformation from yellow to dark brown signified the conversion of the mixture into Nickel nanoparticles (Fig. 3).

Fig. 3 [Images not available. See PDF.]

Synthesis of Ni nanoparticles

The synthesized nanoparticles were subsequently subjected to electronic spectroscopy analysis. The size and crystallinity of Ni-nanoparticles were determined through XRD. The surface morphology of Ni-NPs was then examined using a scanning electron microscope (SEM) to obtain micro/nano-images of the complexes (ML_1 and ML_2). SEM analysis revealed that the Ni-nanoparticles exhibited a round shape within the nano size range. Furthermore, the nanoparticles have been evaluated for their anti-malignant action.

Statistical analysis (factorial design and optimization)

The experimental strategy, data scrutiny, and statistical optimization were carried out using Design-Expert software from Stat-Ease, USA. The objectives were to minimize the absorbance level in the sample, employing three variables: ML_1 with concentrations ranging from 0 to 60 µg/l(ppb), ML_2 the concentrations range from 0 to 60 µg/l, and temperature varying from 20 to 50 °C. These variables were explored at three levels, and the absorbance value was observed as the response.

Design-Expert software generated a 2^3 factorial design consisting of 20 experiments to systematically explore the parameter space. Table 1 presents the range and variables—both in actual and coded forms—that were investigated. Notably, the chosen mid-level values for ML_1 concentration, ML_2 concentration, and temperature were 30 µg/l, 30 µg/l, and 35 °C, respectively.

Table 1. Depiction of independent variable levels in both actual and coded formats

Variables (independent)	Signs	Levels of code		
−1	0	+1	ML_1 concentration (µg/l)	X1
0	30	60	ML_2 concentration (µg/l)	X2

0	30	60	Temperature (°C)	X3

The outcomes of the experiments were displayed using a second-order polynomial equation.

1

$$Y=\beta 0+\sum i=13\beta iXi+\sum i=13\beta iiX12+\sum\sum i\neq j=13\beta ijXiXj$$

In the context of the regression equation, where *Y* denotes the anticipated value of the response variable and *β* denotes the coefficient, the outcomes were analysed using Design Expert. The influence of independent terms on dependent variables was evaluated, and through resolving the regression equation and scrutinizing the graphs, optimal conditions were determined. These optimal conditions were then employed to assess antioxidant and anticancer activities. The experimentally acquired responses were juxtaposed with the numerically predicted counterparts for comparison. To statistically assess the variance between mean values at a 95% confidence interval, analysis of variance (ANOVA) was employed. As per the quadratic model of ANOVA, the significance of model terms is signified by "Prob>*F*" values below 0.0500.

Antioxidant activity

Antioxidant estimation employs the use of 2, 2-Diphenyl-1-picrylhydrazyl (DPPH), a compound that aids in assessing the radical capacities of antioxidants [33]. The assessment relies on the capacity of antioxidants to diminish DPPH, measured through the DPPH radical assay principle. This involves determining the reduction in optical density (Abs) at 517 nm using a spectrophotometer after the interaction with nanoparticles (NPs). The reduction in DPPH colour during the reaction is tracked, and the antioxidant assay is computed through spectrometric analysis. The percentage of DPPH radical scavenging is calculated using the equation provided below [34].

The DPPH scavenging percentage is determined using the following formula:

$$DPPHscavenging\%=100\times Absorbanceofcontrol-AbsorbanceofsampleAbsorbanceofcontrol$$

Here Absorbance of control represents the absorbance before adding test sample to DPPH and Absorbance of sample is the absorbance after reaction has taken place between *DPPH* and test sample.

The formula quantifies the reduction in absorbance due to the scavenging activity of the tested sample against the DPPH radical.

Anticancer activity

Upon procurement of cell lines from NCCS, Pune, the cells were maintained in DMEM augmented with 10% Fetal Bovine Serum (FBS) with antibiotic drugs (0.5 mL^{-1} penicillin/streptomycin) at 38 °C in a 4–5% CO_2/97% air atmosphere. To examine the MTT assay, cells were planted in a 96-well plate at a density of 5.0×10^3 cells/well in 100 µL of culture and allowed to incubate for 8–12 h at 35–40 °C, as previously documented [35]. To assess cell viability, three independent triplicate experiments was conducted three times using six concentrations of test chemicals ranging from 5 to100 µg/mL. After 24 h of incubation, each treatment was removed, and fresh media with varying concentrations of test compounds were added. Subsequently, the test solution was replaced with fresh media containing MTT solution (0.5 mg/mL), and the plates were further incubated at 35–37 °C for three hours. Following the reduction of MTT salt to chromophore formazan crystals, a precipitate was formed at the end of the incubation period. This conversion was facilitated by cells with metabolically active mitochondria. The absorbance of solubilized crystals in DMSO was then measured at 560 nm using a microplate reader.%Inhibition=100×Control-TreatmentControl

Characterization of nanoparticles

The prepared samples underwent characterization using various analytical techniques. UV–visible spectroscopy was carried out using a UV1800S instrument from Shimadzu, Japan. SEM analysis was performed using a JEM-IT 800 SHL version, Japan. Fourier-transform infrared (FTIR) analysis was conducted using an Alpha-T instrument from Bruker. X-ray diffraction (XRD) analysis was accomplished using the X'Pert PRO XRD PW 3040 system.

Results

IR-spectroscopy

IR spectroscopy offers high reliability in characterizing the bulk of nanoparticles. By estimating vibrations of functional groups on their surface, FTIR, in particular, is incredibly versatile for surface analysis of nanoparticles in specific conditions, enabling determination of their surface chemical composition with precision.

The IR spectra analysis of both metal nanoparticle complexes was conducted to elucidate their structural features and bonding interactions. Remarkably, the spectra of the complexes show absence of bands corresponding to ν_{as} ($-NH_2$) at 3360 cm^{-1}, ν_{as} ($-NH_2$) at 3280 cm^{-1}, and ν (C=O) with the range of 1680–1690 cm^{-1}. This absence in the spectra indicates the condensation process and the construction of a macrocyclic structure. Peaks observed in the vicinity of 1648–1580 cm^{-1} were accredited to ν(C=N). The band position for ν(C=N) was found to be lower than the typical values associated with azomethine groups, supporting the inference of coordination of the group with the metal atom and the creation of macrocyclic complexes. Furthermore, the absorption bands corresponding to the phenyl ring were identified in the regions of 1465–1495 cm^{-1} and 1355–1390 cm^{-1}, assigned to $\nu_{asym}C_6H_5$ and $\nu_{sym}C_6H_5$, respectively (Fig. 4).

Fig. 4 [Images not available. See PDF.]

IR-spectra of Ni-NPs of ML_1 and ML_2

Electronic spectra of Ni-NPs

UV–Visible spectroscopy is a powerful method for studying the growth of metal nanoparticles within a polymer network or the formation of a polymer network around a metal nanoparticle core. UV–Visible spectroscopy is commonly employed to investigate the plasmonic resonance of nanoparticles. By analysing absorbance data in the range of 200–700 nm, we have confirmed the formation of Ni nanoparticles and their plasmonic resonance. This enables us to characterize and confirm the presence of reduced Ni metal in the form of nanoparticles.

The observation of electron oscillation points to the occurrence of surface plasmon resonance (SPR), where absorption bands are evident. The phenomenon arises from the absorption of UV light by Ni-NPs, leading to consistent oscillation of conduction electrons. This resonance is achieved when the frequency of surface electrons of metal NPs aligns with that of incident photons. The UV–Visible spectrophotometer is employed to analyse the optical density of the absorbed light [36] (Fig. 5).

Fig. 5 [Images not available. See PDF.]

UV–Vis spectra of Ni-NPs of ML_1 and ML_2

XRD analysis

X-ray diffraction (XRD) is a technique utilized to analyse the crystalline properties of materials, providing insights into their structural characteristics, phase nature, lattice parameters, and grain size. The lattice parameter is determined through the application of the Scherrer equation, which involves assessing the broadening of the most prominent peak observed in an XRD pattern for a given sample.

The XRD spectra of Nickel-nanoparticles, synthesized through the reduction of Ni metal complexes (ML_1 and ML_2) using the seed extract of *Macrotyloma uniflorum*, were examined. For the nano-particles of ML_1 compound, five unique diffraction peaks were identified with corresponding 2θ values of 18.85, 20.56, 22.55, 17.65, and 16.17. Particularly, the peak at 18.85° exhibited the maximum intensity. Similarly, the XRD spectrum of the ML_2 compound displayed six characteristic diffraction peaks at 2θ values of 31.13, 22.38, 19.82, 25.1, 27.3, and 16.5, with the peak at 31.13° demonstrating the highest intensity (Fig. 6).

Fig. 6 [Images not available. See PDF.]

XRD spectra of Ni-NPs of ML_1 and ML_2

SEM (scanning electron microscope) of nickel-NPs

SEM is a powerful technique used for analysing particle characteristics, such as size, shape, and texture with high precision. Operating with only small amounts of material, typically in the milligram range, SEM employs a focused electron beam that scans the prepared sample in a series of parallel tracks. Figures 7 and 8 depict SEM images of

two distinct metal nanoparticles.

Fig. 7 [Images not available. See PDF.]

Statistical analysis using response surface methodology

Response surface methodology (RSM) stands out as a highly efficient technique within the realm of design of experiments (DOE). Its primary goal is to streamline the optimization of crucial parameters to achieve an optimal response while ensuring a robust model fit. By employing RSM, we have effectively optimize key factors such as ML_1 concentration, ML_2 concentration, and temperature, all while conducting a limited number of experiments (20). This approach is particularly advantageous as it avoids the need for an extensive array of experiments (Figs. 9).

Fig. 9 [Images not available. See PDF.]

a 3D plot for absorbance as a function of ML_1 and ML_2 concentration. **b** 3D plot for absorbance as a function of ML_1 concentration and temperature. **c** 3D plot for absorbance as a function of ML_2 concentration and temperature. **d** Predicted versus actual values of absorbance

The design table was obtained (Table 2) and experiments were conducted following the conditions of the table. The absorbance was measured and a quadratic model with 20 runs was built. It was investigated how design process parameters affected absorbance.

Table 2. Central composite design of input variables with responses

S. no	Independent variables			Response	
Factor 1 (ML_1, µg/l)	Factor 2 (ML_2, µg/l)	Factor 3 (Temperature, °C)	Experimental (Absorbance)	Predicted (Absorbance)	1
60.00	30.00	35.00	0.66	0.7	2
30.00	60.00	35.00	0.74	0.75	3
0.00	0.00	20.00	0.92	0.94	4

30.00	30.00	35.00	0.74	0.75	6
30.00	30.00	35.00	0.74	0.75	7
0.00	60.00	50.00	0.92	0.94	8
60.00	0.00	50.00	0.81	0.84	9
60.00	60.00	50.00	0.83	0.81	10

0.00	60.00	20.00	0.85	0.86	11
30.00	30.00	35.00	0.73	0.75	12
60.00	60.00	20.00	0.67	0.68	13
30.00	30.00	35.00	0.78	0.76	14
30.00	30.00	35.00	0.77	0.75	15
30.00	30.00	20.00	0.80	0.78	16
0.00	30.00	35.00	0.89	0.86	17
0.00	0.00	50.00	0.95	0.94	18
60.00	0.00	20.00	0.78	0.75	19
30.00	0.00	35.00	0.76	0.77	20

In this context, key model terms include ML_1 and ML_2 concentrations, temperature, and the interaction term involving temperature. The model's importance is substantiated by an *F*-value of 15.05. Furthermore, the "Lack of Fit *F*-value" of 3.18 suggests that the lack of fit is not significantly different from pure error, underscoring the adequacy of the model. This signifies that the model fits the data well. This indicates a good fit of the model to the data. The coefficient of determination (R^2) for the response is 93%, affirming the appropriateness of the applied models. The adjusted coefficient of determination (Adj. R^2) for the response is determined to be 86%. As a result, it can be said that the experimental value meets Eq. (2) and the regression coefficients fit into a second-order polynomial equation.

2

Y=1.209-0.00546x1-0.00267x2-0.01855x3+1.388×10-6x1x2+2.5×10-5x1x3+4.722×10-5x2x3+3.232×10-5x12+4.545×10-6x22+2.626×10-4x32

In the given equation, where *Y* represents absorbance, x_1 stands for ML_1 concentration, x_2 for ML_2 concentration, and x_3 for temperature; it is noteworthy that concentration of ML_1 and ML_2 as well as temperature all exhibit a negative impact on absorbance. In order to explore the impact of interactions, 3D plots were created by graphing absorbance versus independent variables while maintaining optimal circumstances for the other variables. These graphs effectively interpreted the interactions between the two factors.

Variables optimization and experimental validation

To guarantee the precision and dependability of the formulated model, experiments were conducted to compare predicted and actual responses, as shown in Fig. 11. Once validated, the model was employed to optimize conditions for maximum antioxidant and anticancer activities. As depicted in Fig. 10a, an increase in ML_1 concentration up to approximately 40 µg/l resulted in a decrease in absorbance. This suggests that higher concentrations of ML_1 may induce cytotoxic effects on the cells, leading to a decline in cell viability, reflected by lower absorbance measurements and further increases in ML_1 concentration did not significantly affect absorbance. Conversely, the increase in ML_2 concentration did not exhibit a notable change in absorbance, possibly indicating that ML_2 concentration had already reached its saturation point (Table 3).

Table 3. Analysis of variance with the second order polynomial fit equation

Antioxidant activity

To quantify the antioxidant potential of the Ni NPs, 2 ml volume of a methanol-dissolved 100 µM DPPH solution was combined with 2 ml of diverse concentrations of Ni NPs solution. The resultant mixture was left undisturbed at room temperature for 30 min. Following this, the absorption at 520 nm for the samples was measured utilizing a spectrophotometer (Figs. 10, 11, 12). The antioxidant activity was subsequently calculated using the provided formula. The calculation of IC_{50} value of ML_1 and ML_2 (NPs) in DPPH assay is given in Table 4 and 5.%ofDPPHfree radicalscavenging=Blank-TestsampleBlank×100

Cytotoxic activity

Assessing the cytotoxicity of the synthesized compounds against HeLa (cervical) and A549 (lung) cancer cell lines involved evaluating the number of viable cells remaining after a specific incubation period with macrocyclic complexes. The in-vitro cytotoxic activity results were quantified as IC_{50} values, representing the concentration of the compound in µg/mL that inhibits cell proliferation by 50% compared to untreated control cells is also summarized. The macrocyclic complexes exhibited a dose-dependent impact on the viability of both types of cancer cell lines (Figs. 13, 14, 15, 16). The growth inhibition percentage of cancer cell lines demonstrated an increase with the rising concentration of the tested compounds (Table 6).

A HeLa cell line-control. **B**, **C** Variations in the morphology of HeLa cell line after exposure to NPs of ML_1 and ML_2. **D** A549 cell line-control. **E**, **F** Variations in the morphology of A549 cell line following exposure to NPs of ML_1 and ML_2

Table 6. IC_{50} Comparison of ML_1, ML_2 Compounds against A549 and HeLa cell Lines after 24-Hour Incubation: MTT Study

S. no	Compound IC50 (ug/L)		
	A549	Hela	1
ML_1	44.76	43.37	2

The statistical analysis of MTT cytotoxicity study data reveals noteworthy findings regarding the cytotoxic potential of test compounds ML_1 and ML_2 against A549 and HeLa cell lines. In the case of A549 cell lines, both ML_1 and ML_2 exhibit significant cytotoxicity, with IC_{50} concentrations of 44 µg/mL and 31.20 µg/mL, respectively. Markedly, ML_2 stands out for its substantial cytotoxicity against HeLa cells, suggesting its potential as a potent anti-lung cancer agent, given its low IC_{50}. Similarly, against HeLa cell lines, ML_1 and ML_2 demonstrate substantial cytotoxic potential, displaying IC_{50} concentrations of 43.37 µg/mL and 21.42 µg/mL, respectively.

Discussions

All the characterization techniques we have utilized have effectively provided valuable insights into the newly synthesized nanoparticles. The infrared (IR) spectral data offered valuable information about presence of function groups, the structural modifications and bonding configurations within the synthesized macrocyclic complexes. In UV–visible studies, the size and dispersion of nanoparticles (NPs) significantly influence the characteristics, breadth, and position of the surface plasmon resonance (SPR) peak observed. The UV–Visible spectrophotometer data within the 250–300 nm range for the synthesized Ni-NPs reveals their plasmonic nature, signifying electron oscillation. This emphasizes the pivotal role of NP size and distribution in shaping the optical properties and behaviour of synthesized Ni-NPs. X-ray diffraction (XRD) analysis findings offer valuable insights into the structure and size distribution of the synthesized Ni-NPs, thereby informing their potential applications across various domains. Utilizing the Debye–Scherrer formula, particle sizes for both ML_1 and ML_2 compounds were determined to fall within the nano-range. Scanning electron microscopy (SEM) enables a meticulous examination of nanoparticle boundaries, enhancing precision in assessing nanoparticle size and distribution. The images obtained by the Scanning Electron Microscope for Ni-NPs of metal complexes (ML_1 and ML_2) approve that the nanoparticles are almost spherical in form with the size of maximum 170 nm. Response surface methodology (RSM) studies reveal a notable trend wherein as temperature rises to approximately 30 °C, absorbance initially decreases before rising again. This temperature sensitivity underscores its crucial role in optimizing results. The most favourable outcomes were achieved when experimentally validated data were fitted into the equation, yielding a minimum absorbance of 0.73 at ML_1 concentration of 35 µg/l, ML_2 concentration of 15 µg/l, and a temperature of 30 °C, closely aligning with the predicted response.

The antioxidant radical-scavenging potential of Ni NPs was evaluated using a methanolic solution containing 2,2-diphenyl-1-picrylhydrazyl (DPPH), a well-known radical and scavenger for other radicals. Initially, the methanolic DPPH solution exhibits a deep violet colour, which transitions to colourless or fades to a pale yellow upon neutralization with antioxidants, indicating a reduction reaction and confirming the radical nature of the test sample. The calculations of IC_{50} values for both nanoparticles in the DPPH assay indicate that ML_2 exhibits greater antioxidant potential compared to ML_1. The anticancer activity results indicated that all the complexes exhibited moderate to good anticancer activity against both HeLa and A549 cancer cell lines. In summary, both ML_1 and ML_2 demonstrate effective cytotoxicity against human lung and cervix cancer cells, positioning them as promising candidates for further exploration in cancer therapeutics. ML_2, in particular, emerges as a potent anti-cervix cancer agent, characterized by its low IC_{50} value.

Conclusions

Researchers, prompted by the toxicity and side effects associated with cisplatin, are exploring alternative approaches for developing transition metal-based anticancer agents. The cytotoxic potential of nickel nanoparticles (Ni-NPs) has been thoroughly investigated using cervical and lung cancer cell lines. In this study, the utilization of Horse Gram seed extract *(Macrotyloma uniflorum)* has revealed its richness in phenolic and flavonoid compounds, well-documented for their potent antioxidant activity in existing literature. The experiments were structured to investigate the impacts of diverse factors, and the utilization of Response Surface Methodology proved effective for optimization. Following computation, the regression coefficients were incorporated into a second-order polynomial equation for fitting. The experimental and predicted values agree closely which validates the model. Moreover, the application of *Macrotyloma uniflorum*-mediated Ni-NPs has demonstrated an enhanced anticancer effect against HeLa and A549 cell lines responded in a manner dependent on the concentration. The mechanism underlying the deactivation of cancer cell lines aligns with existing literature, attributing it to intra-cellular nucleus damage. An additional noteworthy observation indicates that Nickel metal NPs with 2,4-dicarboxylic acid (ML_2) as a ligand exhibit a more significant impact on antioxidant and anticancer activities compared to their counterparts with 3,4-dicarboxylic acid (ML_1) as the ligand moiety. This difference in impact may be attributed to the method employed to convert metal complexes into metal-NPs. The current research underscores the possibility of refining the bio-toxicity and biochemical properties of Ni-NPs to develop a new generation of versatile anticancer agents with clinically proven efficiency. Remarkably, the predicted data aligns closely with experimental results, affirming the reliability

and credibility of RSM (Response Surface Methodology) model for studying anticancer and antioxidant properties in this context.

Acknowledgements

The authors express their gratitude and acknowledgment to Averinbiotech Pvt. Ltd., Hyderabad, Telangana, for rendering their support in instrumental analysis of newly synthesized NPs.

Author contributions

SA conducted a comprehensive literature review focusing on organically Nano-Fabricated Ni metal complexes, exploring their antioxidant and anticancer activities, and conducted characterization and activity assessments. SB coordinated the development of the initial draft of the article. MVM enhanced the writing style and participated in the proofreading process. The final manuscript was reviewed and approved by all authors.

ABSTRACT (ENGLISH)

Background

Obesity is a precursor for many co-morbid diseases. One of the main triggering factors for obesity is the abnormal expansion of white adipose tissue characterized by high rates of genesis and differentiation of precursor cells into mature adipocytes. As a result, targeting adipogenesis and adipogenic transcription factors opens new roadmaps for developing novel antiobesity pharmacotherapies. The present study was intended to rationally develop topiramate–phenolic acid conjugate for targeting obesity via inhibition of PPAR*γ* which is often considered as the master regulator of adipogenesis.

Results

2D QSAR models were built to foretell PPAR*γ* inhibitory activity of designed conjugates. The models presented excellent robustness, goodness of fit, and predictive capability compounds. The highest PPAR*γ* inhibitory activity was predicted for T3 (topiramate–caffeic acid conjugate) with a pIC_{50} value of 7.08 μM. Molecular docking was performed for all the designed conjugates against PPAR*γ* (PDB ID: 3VSO). The highest binding affinity was exhibited by T3 (−11.27 kcal/mol) and displayed strong and stable interactions with the receptor within the allosteric pocket in comparison to the irreversible PPAR*γ* antagonist, GW9662 (binding affinity, −9.0 kcal/mol). These results were confirmed by subjecting the best-docked molecules to molecular dynamic simulations. The PPAR*γ*–T3 complex was observed to be most stable with maximum number of hydrogen bonds (maximum observed RMSD = 0.57 Å at 100 ns) in comparison to PPAR*γ*–topiramate and PPAR*γ*–caffeic acid complexes. Consequently, T3 was synthesized and further subjected to in vitro screening. The TR-FRET assay established T3 as a PPAR*γ* antagonist (IC_{50} = 6.78 μM). T3 also significantly reduced the lipid buildup in the 3T3-L1 adipocytes in a dose-dependent manner. In addition, T3 also reduced the protein expression levels of PPAR*γ* as evidenced from western blot results.

Conclusions

Studies clearly indicated that T3 reduces adipose tissue cell differentiation by downstreaming PPAR*γ* expression at protein levels, thereby emerging as a novel scaffold for antiobesity pharmacotherapy.

FULL TEXT

Background

The last decade has laid down a crystal-clear picture of obesity as an ever-increasing global pandemic [1]. Obesity is often associated with co-morbidities encircling type II diabetes, cardiovascular disorders, hypertension, liver dysfunctions, dyslipidemia, obstructive sleep apnea, polycystic ovarian disease, and many cancers. As a master precursor of almost all major chronic metabolic disorders, obesity substantially shoots up the socio-economic burden worldwide by rocketing high healthcare costs [2–7]. Consequently, numerous pharmacotherapeutic agents are developed for the mitigation or cure of obesity by targeting an array of physiological targets, such as pancreatic lipase, 5-hydroxy tryptaminergic receptor 2C, β3 adrenergic receptor, GLP-1 (glucagon-like peptide 1), and many other gut peptides [8] Presently, orlistat, lorcaserin, phentermine/topiramate, bupropion/naltrexone, and liraglutide are approved by FDA (Food and Drug Administration) for obesity pharmacotherapy [9]. Nonetheless, orlistat and lorcaserin have been permitted for longer duration therapy [10, 11]. Incidentally, potential and novel drugs without undesirable physiological adverse actions are the utmost need of the hour for countering obesity.

Topiramate (TPM) is an inhibitor of carbonic anhydrases and glutamate, while acts as an agonist for GABA (-aminobutyric acid). It is used for therapy of epilepsy and migraine [12]. Epilepsy patients on TPM medication showed significant weight loss which led to clinical investigation of the drug for having antiobesity effects. In vivo studies have explored thermogenesis boosting and neuro-stabilizing repertoire of TPM [13, 14]. Several studies also discovered that TPM amplified the phosphorylation of crucial lipolytic enzymes, thereby inducing lipolysis in 3T3-L1 preadipocytes. It further suggested TPM might directly inhibit adipogenesis by targeting white adipocytes bypassing its CNS (central nervous system) effect [15].

Phenolic acids are abundantly available from natural sources and are categorized as hydroxy-cinnamic acid derivatives such as caffeic acid (CF), ferulic acid, para-coumaric acid, or hydroxy-benzoic acid derivatives such as gallic acid, chlorogenic acid, protocatechuic acid, or vanillic acid. The phenolic acids basically modulate the gut

microbiota in exerting their antiobesity effects [16]. Inhibition of white adipose tissue differentiation, fat browning, pancreatic lipase, and pancreatic amylase inhibition, suppression of inflammatory cytokine expression, and downregulation of obesity-inducing genes are other pharmacological actions of phenolic acids [17].

The PPARs (peroxisome proliferator-activated receptors) have emerged as promising therapeutic targets among all nuclear receptors for developing novel pharmacotherapeutic candidates against insulin resistance, cancers, obesity, dyslipidemia, and cardiovascular disorders [18]. PPAR*γ* are primarily distributed in adipose tissues and are considered master regulators of adipogenesis [19, 20]. Preferential recruitment of co-repressor molecules over co-activators by PPAR*γ* antagonists as well as close crosstalk with NFκB (nuclear factor kappa B) and AP-1 (activation protein 1) downregulates PPAR*γ*-mediated gene transcription [21, 22]. The medicinal repertoire of PPAR*γ* antagonists spreads more wider than diabetic therapy in promoting osteoblast formation and depressing differentiation of adipose tissue [23]. As a result, PPAR*γ* inhibitors can be well thought out to be potential aspirants for osteoporosis and obesity therapy [24]. Additionally, PPAR*γ* inhibitors embody broad anticancer activity as well [25]. For that reason, exploring PPAR*γ* inhibitors is of prodigious importance in the quest for novel drug candidates for pharmacotherapy of PPAR*γ*-associated metabolic disorders.

Drug-drug conjugates or often called as molecular hybrids comprise of two different pharmacophores interconnected directly or by a spacer (cleavable/non-cleavable). The conjugates usually exert simultaneous action at specific targets with increased potency or efficacy. The high efficacy can be due to improved pharmacokinetic properties. For instance, atorvastatin–curcumin conjugate nanocrystals exhibited enhanced biopharmaceutical and anti-inflammatory properties in comparison to individual drugs [26]. Another striking example is mesalamine–coumarin conjugate with diazo linker displayed an increased anti-inflammatory response by reducing acetic acid-induced ulcerative colitis in rat models [27]. Similarly, nanoparticle of camptothecin–floxuridine conjugate exhibited profound and synergistic anticancer activity with improved cytotoxicity, apoptosis, and inhibition of malignant proliferation [28].

Our present work aims to design and synthesize novel TPAC (topiramate–phenolic acid conjugates). Through robust 2D-QSAR (two-dimensional quantitative structure–activity relationship) models, the biological activity of the designed conjugates was predicted. In silico molecular docking was done for gaining insights of the interaction nature of designed conjugates with the receptor. The MD (molecular dynamic) simulation study revealed good dynamic behavior of PPAR*γ*–T3 complex. Among all the three complexes, PPAR*γ*–T3 had minimum RMSD, RMSF, Rg, and potential energy indicating good attractive and stable interactions between protein and ligand molecules over the total MD simulation time. Lantha Screen TR-FRET assay was performed to evaluate the PPAR*γ* inhibition potency of the designed conjugates. The antiobesity effects of the T3 (topiramate–caffeic acid conjugate) were demonstrated via differentiation inhibition and lipid accumulation in the 3T3-L1 preadipocytes.

Methods

Computational study

QSAR studies

Dataset preparation

In the current study, an experimental dataset of 100 compounds was retrieved from the Binding dB database [29]. The biological activities of the compounds were expressed in terms of IC_{50} (nM, half maximal inhibitory concentration) and were converted to their corresponding pIC_{50} values (negative logarithm of IC_{50} values). For building the 2D-QSAR model, pIC_{50} was considered as the dependent variable. The raw dataset compounds and their corresponding IC_{50} values are provided in supplementary files for reference (Additional file 1: Table S1).

Descriptors computation

Before the computation of the molecular descriptors, geometry optimization was carried out for each dataset molecule employing molecular mechanics force field and semi-empirical AMI methods using SPARTAN 10.0 software tools. The energy-minimized structures were further used to generate molecular descriptors using two software tools PaDEL and CORAL. PaDEL version 2.21 [30] was used to generate about 1444 2D molecular descriptors. More than 50% of descriptors with zero, missing, and constant values were excluded. Also using pairwise correlation, the descriptors were filtered. The CORAL (http://www.insilico.eu/coral) software generated

single optimal descriptor (DCW) [31] basing on SMILES (simplified molecular input line system) [32, 33]. The descriptor is calculated using the Index of ideality of correlation (IIC) formalism which was carried out for the Monte Carlo optimization taking the IIC weight = 0.2000. The details of the calculation of the DCW by IIC are described elsewhere [34, 35]. The PCA (principal component analysis) was applied to determine the best descriptor (variables) combination. The dataset molecules were sorted according to PC1 scores. As a final point, 20 molecular descriptors were utilized for deriving models from the whole data set. The computed molecular descriptors for the 100 dataset compounds are provided in supplementary files for reference (Additional file 1: Table S2).

QSAR modeling

The 100 molecules of dataset were split into training set (87 molecules) and validation set (13 molecules). GA (genetic algorithm) and MLR (multiple linear regression) techniques were employed for building robust QSAR models using QSARINS software [36]. 2D-QSAR models were built using combinations of selected 20 descriptors, including the one optimal descriptor DCW.

QSAR model validation

All the developed models were validated according to OECD (Organization for Economic Cooperation and Development) principles using the QSARINS software package. The validation aimed at ensuring that the built models have definite endpoints represented using unambiguous algorithms, have domain of applicability, and have appropriate measures for predictability, goodness of fit, and robustness. Leverage values below critical leverage with ± 3 standard deviations were considered to ensure good predictive capability of designed QSAR models. The compounds remaining outside these leverage values were treated as outliers. Williams's plots were employed to describe QSAR model applicability domain. To minimize the discrepancies between experimental and predicted values of the endpoint, goodness of fit was computed employing R^2 (coefficient of determination) and R^2adj (coefficient of determination adjusted for degrees of freedom). Internal validation methods like LOO (leave one out) and LMO (leave many out) were used to verify and measure the strength of models generated. To ascertain the predictive capability of the designed models, various external validation parameters were analyzed and computed such as RMSE ext, Q^2–F1, Q^2–F2, Q^2–F3, R^2 m, R^2 m delta, CCC, MAE ext and PRESS ext. Finally, Y-scrambling method confirmed that built models are not outcomes of chance correlation.

Prediction of IC_{50} values of novel topiramate–phenolic acid conjugates

Ten novel TPAC (T1-T10) were designed using Chemdraw Ultra 12.0 software. Geometry optimization was done for each designed molecule employing molecular mechanics force field and semi-empirical AMI methods using SPARTAN 10.0 software tools (http://www.wavefun.com/products/spartan.html). Further 2D molecular descriptors for the newly designed conjugates were computed using PaDEL software. The single optimal descriptor was also calculated for the designed compounds using CORAL software. The leverage values of all the designed compounds were calculated and compared with the threshold leverage value h^* (0.138). Using the best generated QSAR equation, the pIC_{50} values of the designed molecules were predicted.

Molecular docking

Among the designed conjugates, highest PPARγ inhibitory activity was predicted for the topiramate–caffeic acid conjugate (T3). Accordingly, T3 was selected for molecular docking and molecular dynamic simulation analysis.

Ligand preparation

The structure of CF, TPM, and T3 conjugate was drawn in Chemdraw Ultra 12.0 software and stored in standard format (SDF). All the ligands were subjected to energy minimization UCSF Chimera 1.16 [37] prior to docking.

Protein preparation

3-D crystal structure of PPARγ (PDB ID: 3VSO) was retrieved from the RCSB protein bank using Energy minimization and geometry optimization was performed using UCSF Chimera 1.16 by adding hydrogen atoms and charges to the receptor. Finally, the protein was saved in pdbqt format for docking.

Docking

AutoDock Vina [38] was used for docking of the ligands with the selected protein. After energy minimizing, a grid box resolution with three dimension co-ordinates 17.762, 71.66, and 13.333 was set. Grid box with 60 × 60 × 60 Å point

spacing of 0.375 Å was used to reformate structure files into pdbqt format. The flexible ligand docking studies were performed using Lamarckian genetic algorithm.

Molecular dynamic simulation

To compare the interaction of individual pharmacophoric ligands CF and TPM with conjugate ligand T3, all the protein–ligand complexes (PPAR*γ*-CF, PPAR*γ*-TPM, and PPAR*γ*-T3) were directed for 100 ns MD (molecular dynamic) simulation using Gromacs 4.5.6 [39]. For generating the topology of a protein–ligand complex system, initially, protein and ligand were separated as a single entity, followed by the generation of individual topology or protein and ligand and finally merging back to complex form. With the help of CHARMM-36 parameters, here we created the topology for proteins (*X*, *Y*, *Z* coordinate system) using TIP 3P water model, and for each ligand we have used Swiss-Param online server to generate the topology. The protein.gro and ligand.gro files were manually fit, and complex.gro was generated for each of the three complexes. Further, the complex file is solvated using SPC216 water model in dodecahedron form with system size as follows: PPAR*γ*-CF complex = *X*: 5.099, *Y*: 6.095, and *Z*: 5.654 (nm). PPAR*γ*-TPM complex = *X*: 5.099, *Y*: 6.095, and *Z*: 5654 (nm). PPAR*γ*-T3 complex = *X*: 5.099, *Y*: 6.095 and *Z*: 5654 (nm). Solvent molecules and sodium ions were added for neutralization of the system.

Further energy of neutralized system was minimized by employing steepest descent minimization method for 50,000 steps. The stability of the complex post energy minimization is carried out by assessment of potential energy, bond energy, proper dihedral, and improper dihedral. Going beyond the energy minimization, .itp file of restrained ligand position was generated and incorporated into complex topology file using leap-frog integrator algorithm. MD simulation was run for 50,000,000 steps. The system was restrained on covalent bond by employing LINCS algorithm [40]. Following 100 ns MD simulation, the RMSD (root mean square deviation), RMSF (root mean square fluctuation), Rg (radius of gyration), H-bond, and SASA (solvent accessible surface area) were calculated. The graphs were created by XM Grace Linux application, while the two-dimensional interactions were studied in BIOVIA Discovery studio visualizer.

Chemistry

General

3T3-L1 preadipocytes were obtained from NCCS (National Centre for Cell Science), Pune, India. DMEM (Dulbecco's Modified Eagle's Medium), BCS (bovine calf serum), antibiotic solutions, and antibodies for enzyme assay as well as western blot were purchased from Thermo Fisher Scientific, (Waltham, MA, USA). Topiramate was procured from Yucca Chem Products, Mumbai. Other reagents/chemicals (high purity) used were purchased from Sigma-Aldrich (St Louis, USA) and used as received.

Synthesis of topiramate–caffeic acid conjugate, T3

T3 (topiramate–caffeic acid conjugate) was synthesized using DCC-DMAP coupling [41–43]. CF (2), 1 equivalent and DCC (N,N'-dicyclohexyl carbodimide, 1.1 equiv), and DMAP (4-dimethylaminopyridine, catalytic amount, 10 mol%) were added with 20 ml of DMF (dimethylformamide) with continuous stirring for 60 min. After 60 min of stirring, TPM (1), 2 equivalents in excess DMF was added to the above reaction mixture and allowed to stir at room temperature for 48 h (Scheme 1).

Scheme 1 [Images not available. See PDF.]

DCC-DMAP mediated coupling of caffeic acid and topiramate. *Reagents and conditions:* **a** DMAP **b** DCC **c** DMF

The reaction was monitored by TLC (aluminum sheets with Silica-Gel 60 F254 (Merck) employing ethyl acetate/pet ether (7:3) as mobile phase till completion. Following reaction completion, crude reaction mixture was water washed (10 ml) and filtered to remove dicyclohexyl urea (by-product). The filtrate was transferred to a separating funnel and extracted with ethyl acetate (20 ml × 3 times). The organic fraction was further collected and dried over anhydrous Na_2SO_4, and the solvent was removed under reduced pressure. The residue was recrystallized from ethyl acetate. Melting point was determined by open capillary tubes in a melting point apparatus and presented uncorrected. Spectral characterization was further performed (IR using JASCO FTIR-4100 series; ^{1}HNMR and ^{13}CNMR using Bruker 400 MHz NMR spectrophotometer).

Biological screening

In vitro *enzyme inhibition assay*

PPAR*γ* inhibition was studied using TR-FRET co-activator assay [43]. Concisely, the human recombinant PPAR*γ*-LBD (GST tagged, 1 nmol/L) was incubated with a Europium-labeled anti-GST antibody (2 nmol/L), testing samples, and DMSO (control). Following incubation, SRC (steroid receptor co-activator, XL665 labeled streptavidin) was added. The SRC co-activator peptide (20 nmol/L) was prepared in Tris–HCl (pH 7.4) The fluorescent signals were measured by microplate reader (BMG Labtech, Germany) at an excitation wavelength of 337 nm and emission wavelengths of 620 and 665 nm. The emission ratio was computed using the equation given below:Emissionration(ER)=fluoresceinemissionat665/fluoresceinemissionat620nm

Agonist mode

Fluorescent signals generated from rosiglitazone (positive control, 10 μmol/L) were considered 100% activation control. 1% DMSO was considered as blank/0% activation control. The activation percentage was computed by the below mentioned formula.%Activation(Agonistmode)={ER1-ER2/ER3-ER2}∗100%where ER 1 is the emission ratio of the sample, ER2 is the emission ratio of the blank, and ER3 is the emission ratio of 100% activation control (10 μmol/L rosiglitazone).

Antagonist mode

To the human recombinant PPAR*γ* and co-activator peptide previously incubated with test samples, 1 μM rosiglitazone was incorporated as EC_{80} control. The percentage inhibition of T3 was computed using the below mentioned formula. GW9662, irreversible PPAR*γ* antagonist, was used as positive control.%Inhibition(Antagonist mode)={ER1-ER2/ER4-ER2}∗100%where ER 1 is the emission ratio of sample, ER 2 is the emission ratio of blank, and ER 3 is the emission ratio of EC_{80} (1 μmol/L rosiglitazone).

Inhibition of adipogenesis in 3T3-l1 preadipocytes

Cell culture, differentiation, and maturation

The preadipocytes were sub-cultured in DMEM complemented with 10% (v/v) BCS 1% penicillin–streptomycin antibiotic mixture antibiotic in an atmosphere of 5% CO_2 at 37 °C. After 70–80% cell confluency, harvesting was done using 25 mm tissue culture flask containing trypsin and seeding in 96 well plate. After 100% confluency of cells, differentiation was performed by adding insulin (1 μg/mL), isobutyl-1-methylxanthine (0.5 mM/L), and dexamethasone (0.25 μM/L). Post confluency, by careful pipetting the differentiation media was discarded and maturation media (insulin, 1 mg/L) was added and changed every 2 days. The control group remain untreated. The test groups received 1, 5, and 10 μM of T3, respectively. The positive control group was treated with 10 μM of GW9662. Post 10 days, lipid droplets were clearly visible inside the differentiated cells and hence subjected to further assays [44].

MTT assay

Cytotoxic effect of T3 on adipocyte precursor cells was investigated through MTT assay [44]. The 3T3-L1 preadipocytes were seeded in 96-well plate (3×104 cells per well) and cultured in DMEM containing 10% BCS for 24 h. After 24 h the cells were treated with 0.001, 0.01, 0.1, 1, and 10 μg/mL of T3, respectively, and kept for next 72 h. Post 72 h, MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) solution (20 μL, 5 mg mL^{-1}) was added to each well and further incubated for 4 h at 37 °C. The dark blue formazan product formed by the cells was carefully dissolved in DMSO within a dark cabinet, and absorbance was measured at 495 nm in a microplate reader (Bio-Rad Lab, California).

Oil Red O staining

To observe lipid droplets within differentiated adipocytes, the Oil O Red stain method was employed. The differentiated cells were initially washed with PBS and then fixed with 4% formaldehyde for 30 min. Further, the cells were stained with freshly prepared (in 60% isopropyl alcohol) Oil O Red solution for 10 min at room temperature. After 10 min the stained cells were rinsed with isopropyl alcohol for extraction of accumulated lipids and their quantification (absorbance measured at 495 nm) in terms of percentage relative to the control. The untreated cells were taken as control. The cells stained were observed under a phase contrast microscope (Axiovert 40 CFL, Carl

Zeiss, Jena, Germany) and photographed [44]

Western blot

In brief, the cells were rinsed with PBS, lysed using Laemmli buffer (comprising of 62.5 mM Tris–HCl, 10% glycerol, and 2% SDS) and sonicated. 10 µg of protein was separated by gel electrophoresis (10% SDS-PAGE), transferred on to nitrocellulose membrane, and blocked using 5% PBS-T milk (45 min). Anti PPAR*γ* and *β*-actin antibodies were added to 1% BSA in PBS-T milk and incubated with membrane previously blocked containing protein lysates at room temperature for 1 h. Following incubation, the membrane was washed with PBS-T milk and treated with secondary antibody (HRP-conjugated) following incubation for next 30 min. Then the membranes were washed with PBS-T milk twice for 10 min in room temperature. Chemiluminescence was detected using the ChemiDoc Touch imaging system (Bio-Rad) [45]. *β*-actin was used as internal control.

Statistical analysis

All the experiments were performed in triplicate. The data from each independent experiment are expressed as mean ± standard deviation. The presented data were statistically analyzed employing one-way ANOVA with *t*-test for defining differences. Values of (*$p<0.05$ and **$p<0.01$) were considered statistically significant.

Result

Computational studies

Variable selection by PCA

Data redundancy was reduced employing PCA (principle component analysis). The eigen values were sorted in descending order. PC1 describes greatest data variance, while PC2 described data variance in an orthogonal direction to PC1. Principal component analysis (PCA) for the descriptors VE3_Dzp, nHBint6, and DCW was demonstrated by loading and scoring plots. Figure 1A displays the scoring plot for dataset compounds. Likewise, Fig. 1B displays the loading plot for M-1 descriptors. PCA score plot describes the type of co-relation between dataset components. The loading plot on the other hand describes the influential power of descriptors on dataset components. As evident from the score plot (Fig. 1A), very few dataset compounds were observed as outliers. The descriptor having maximum influence was observed to be nHBint6 followed by VE3_Dzp and DCW (Fig. 1B).

QSAR modeling and validation

Amazingly, a significant improvement (Fig. 2) in the values of R^2 and Q^2 for the training set was observed by including DCW. On that note, different 2D-QSAR models were built by including the single optimal descriptor. Models with best R^2 values for validation set were preferred for activity prediction. The QSAR equations of one-, two-, and three-descriptor models for best one-, two-, and three-descriptor models are reported in Table 1. The validated internal and external parameters for the best three models are represented in Tables 2 and 3, respectively. Table 4 represents statistical parameters for models M-1, M-2, and M-3.

CCC tr	0.9956	0.9947	0.9939
S	0.0076	0.0082	0.0087
F	3108.9384	3966.4605	6968.4382

All the models have higher R^2m values (> 0.5) and lower R^2m delta values (< 0.2) indicating stability and robustness. The values of the LOF and Friedman lack of fit (0.0001) [46] and *s* (0.007 to 0.0087) are very low which ensures that no over fitting is there in the models. Lower values for delta K and Kxx for model M-1 show good co-relation between descriptors and predicted responses with limited errors in computation [47, 48]. High R^2 adj values suggest convenient addition of a new descriptor to the model.

Model ID-1 with highest R^2 (coefficient of determination) has been evaluated as the best model satisfying the goodness-of-fit criteria and internal validation parameters. The scatter plot (Fig. 3A, B) clearly indicates a linearity in relationship among experimental and predicted values. The correlation between descriptors (*x*) and activity (*y*) were plotted with K*xy* versus Q^2 LMO of the final model (model 1) (Fig. 4) displaying LMO parameter values are close enough to model parameters. It clearly states that the model is robust and stable. Y-scrambling tested the external validation parameters (Fig. 5). As the values of R^2Yscr and Q^2Yscr are very small, the models are believed to be good models and not the outcome of casual correlations.

Figure 6A, B shows the William's plots deciphering applicability domain of generated model (M-1).

Fig. 6 [Images not available. See PDF.]

William's plot for model (M-1) **A** HAT values vs standard residuals calculated from QSAR model equation; **B** HAT values versus standard residuals predicted by LOO

Lower leverage values than threshold (h^* of 0.135) indicated that the training and test set molecules remained in the applicability domain of selected model as evident from the William's plot with 6 outliers only. Noticeably graph of insurbia (Fig. 7) resembled William's plot with same six outliers. This suggested that the selected model was best in terms of predicting experimental response. Additional file 1: Table S3 gives a comparative display of experimental and predicted IC_{50} values for the dataset compounds.

Fig. 7 [Images not available. See PDF.]

The graph of insurbia

It clearly indicates that the descriptors (VE3_Dzp, nHBint6, and DCW) used to generate the best predictive model equation are not overfitting with the lowest LOF (0.0001) and high predictivity (Q^2LOO = 0.9894). It was also observed that the performance of model 3 build using a single optimal descriptor DCW was also impressive when compared with model 1. The performance of the models was evaluated by plotting the values of Q^2LOO and LOF (Fig. 8).

Fig. 8 [Images not available. See PDF.]

Plot of Q2 LOO versus LOF

Predicted IC50 of topiramate–phenolic acid conjugates (TPAC)

The leverage values of all the designed molecules were observed to be below threshold leverage value ($h^* = 0.138$) suggesting the good applicability domain of the developed QSAR models. The predicted IC_{50} values of the designed compounds are displayed in Table 5. The highest inhibitory activity against PPARϒ was obtained for T3. The inhibitory activity reduced with the addition of (–OCH3) groups as evident from the pIC_{50} values of T4 and T10.

Table 5. Predicted pIC50 values of designed conjugates

Compound code	*R*	Predicted pIC_{50}
T1		7.005003569
T2		7.038592667
T3		7.08435656
T4		6.991701765
T5		7.019504227
T6		7.003357836
T7		7.066946934
T8		7.030767462
T9		7.019279445
T10		6.988112667

Mechanistic Interpretation

The designed 2D-QSAR model 1 was used for predicting the biological activity of the designed TPAC. According to the equation, the PPARϒ inhibitory activities are explained by three descriptors of the model equation which positively or negatively contribute to pIC_{50} values with respect to their regression coefficient values. The first descriptor VE3_Dzp is the logarithmic Randic-like eigenvector-based index from the Barysz matrix/weighted by polarizabilities and represents heteroatoms and multiple bonds in the molecules. The descriptor positively contributed toward the PPARϒ inhibitory potency [49]. In the designed conjugates, the presence of different electronegative atoms increases the polarization of carbon atoms that might increase the inhibition potency. The next descriptor is nHBint6 which is an E-state descriptor and associated with electro-topological state of hydrogens establishing hydrogen bonds within a path length of six. The descriptor may also define intermolecular interactions having impact on biological and physic-chemical properties. The descriptor has a positive correlation with the pIC_{50} values [50]. We decipher that the presence of hydroxyl groups in the designed conjugates contributes positively toward the inhibition potencies. Interestingly, the inclusion of DCW (single optimal descriptor) generated best fitting models.

Molecular Docking Analysis

The open conformation of helix-12 is a prime requirement for co-repressor recruitment. The binding of an agonist to LBD within orthosteric pocket leads to a closed conformation, therefore recruiting co-activators and inducing transcription of PPAR*γ* genes. The important amino acid residues present within the orthosteric pocket are CYS285, SER289, HIS323, TYR327, LYS367, HIS449, and TYR 473, which play a major role in helix-12 folding [51]. Conclusively, it can be suggested that molecules interfering with proper folding of helix 12 around PPAR*γ*-LBD can be defined as PPAR*γ* antagonists [52]. Further, ligands binding to the allosteric site within the PPAR*γ*-LBD do not display any competition with classical agonistic ligands for binding at orthosteric site The amino acid residues present within allosteric acid are GLU259, LYS265, HIS266, ARG288, SER289, GLU295, SER342, GLU343, and LYS367 which significantly interfere with helix-12 folding [21]. Therefore, PPAR*γ* antagonists can be designed according to the helix12-folding inhibition hypothesis.

The binding interactions of the designed conjugates (T1–T10) along with CF, TPM, and GW9662 with crystal structure of PPARγ (PDB ID: 3VSO) are displayed in Table 6. Among the 10 designed conjugates, T3 shows stable and strong interactions with the receptor. The designed ligand binds to an alternate site/allosteric site within the ligand binding domain of the crystal structure of PPAR*γ*. The intramolecular hydrogen bonding interactions between the allosteric pocket residues (ARG288, CYS285, MET364, and PHE360) and T3 might destabilize the helix-12.

Table 6. Binding affinities and interactions of TPAC with amino acid residues

Conjugates	Binding energies (Kcal/mol)	Interactions with amino acids	
Hydrogen bonds	Hydrophobic interactions	T1	−9.0
ARG288, GLU343	SER342, ILE281, LEU330, CYS285, ARG288	T2	−10.84
SER289, CYS285	HIS449, TYR327, LEU469, HIS323, ARG288, ALA292, ILE326, LEU330, ILE281, LEU336, MET364	T3	−11.27
ARG288, CYS285, MET364, PHE360	MET329, ILE326, LEU330, LEU333, TYR327, CYS285	T4	−11.14
ARG288, CYS285, PHE360, PHE363	MET329, ILE326, LEU330, LEU333, TYR327, CYS285, ARG288, LEU356, PHE363, MET364, ILE281, LEU353	T5	−9.34

SER342, LEU340	LEU255, ARG280, ILE281, MET348, CYS285, GLY284, ARG288, VAL339, ILE341, PHE264	T6	−9.13
ARG288, GLY284, GLU343	ILE341, MET348, LEU330, ILE281, CYS285, ARG288	T7	−10.56
ARG288, CYS285, PHE360	ALA292, MET329, ILE326, LEU330, LEU333, TYR327, ILE281, LEU353, MET364, CYS285	T8	−10.36
ARG288, CYS285, PHE360	ALA292, MET364, ILE326, LEU330, LEU333, TYR327, LYS367, ILE281, LEU353, MET364, CYS285	T9	−9.37
ARG288, GLU343	MET364, ILE326, LEU330, LEU353, PHE287	T10	−10.40
CYS285, PHE360, PHE363	ILE326, MET329, LEU330, LEU333, ARG288, TYR327, MET364, CYS285, LYS367, ILE281, LEU353	TPM	−6.9
ARG280	CYS285, ARG288, PHE264, PHE287, LEU330, VAL339, LEU340, MET364	CF	−6.1
CYS285	ARG288, SER289, ALA292, ILE326, MET329, LEU330, LEU333	GW9662	−9.0

It is evident that there are no interactions of T3 with residues that are involved in proper folding of helix-12 (SER289, HIS323, TYR327, LYS367, HIS449, and TYR473) within the orthosteric pocket of PPARγ ligand binding domain. Also, hydrophobic interactions (MET329, ILE326, LEU330, LEU333, TYR327, and CYS285) might displace the helix-12 from position thereby disfavoring transcriptional process (Fig. 10). Moreover, it was interesting to see that

the designed conjugate T3 showed stronger interactions with the allosteric pocket residues than the parent pharmacophores (Fig. 9), CF (binding affinity, −6.1 kcal/mol) and TPM (binding affinity, −6.9 kcal/mol) respectively. Similarly, T3 formed stronger interactions with the allosteric pocket residues when compared to the irreversible PPAR*γ* antagonist, GW9662 (binding affinity, −9.0 kcal/mol) (Fig. 9).

Fig. 9 [Images not available. See PDF.]

Binding interactions at allosteric site of PPAR*γ* LBD (PDB ID: 3VSO) with **A** T3 **B** CF **C** TPM **D** GW9662 (irreversible PPAR*γ* antagonist)

For designing potential PPAR*γ* antagonists, it might be imperative to sustain H-bond interactions with ARG288, SER342, LYS367 and HIS449 within allosteric pocket in the LBD [53]. Moreover, hydrophobic interactions with allosteric site residues PHE282, ILE281, LEU356, TYR327, ILE326, LEU330 and MET348 that can destabilize the H12 contribute to inhibition potency of ligands [44, 54, 55].

Molecular dynamic simulation

The molecular dynamics-based studies revealed the deep understanding of protein ligand interactions over a period of time. The interaction energies of PPAR*γ*-CF complex, PPAR*γ*-TPM complex and PPAR*γ*-T3 complex in a neutralized system are given in Table 7.

Table 7. Dynamic properties of PPAR*γ*-caffeic acid complex, PPAR*γ*-topiramate complex, and PPAR*γ*-T3 complex

Type of energy	PPAR*γ*-caffeic acid complex	PPAR*γ*-topiramate complex	PPAR*γ*-T3 complex
Bond average energy	1283.25 kJ/mol	1385.02 kJ/mol	1312.6 kJ/mol
Potential energy	−7.3257912*e*+05 kJ/mol	−7.2699112*e*+05 kJ/mol	−7.3615656e+05 kJ/mol
Proper-Dihedral average energy	10,561.9 kJ/mol	10,664.8 kJ/mol	10,716.3 kJ/mol
Improper-Dihedral average energy	179.937 kJ/mol	189.107 kJ/mol	185.199 kJ/mol

From the above data (Table 7), it was clear that all the protein–ligand complexes were quite stable within the solvent medium. Of all the three PPAR*γ*-ligand complexes, PPAR*γ*-T3 complex exhibited lowest potential energy (Fig. 10). Lower the potential energy, higher are the attractive force between the protein and ligand molecule. It was therefore confirmed that PPAR*γ*-T3 complex was most stable with strong intermolecular attractions (also refer Additional file 1: supplementary data Figs. 1S, 2S, and 3S).

Fig. 10 [Images not available. See PDF.]

Decrease in potential energy with respect to time; **A** PPAR*γ*-CF complex **B** PPAR*γ*-TPM complex **C** PPAR*γ*-T3 complex

The complex revealed high fluctuation rate during the MD simulation study as total 0 to 100 ns RMSD (Fig. 11A). Initially at 0 ns the starting point the protein ligand deflected to ~ 4 Å. From 5 nanoseconds onward, the ligand was observed to be high in fluctuation reaching upto a ~ 9 Å with respect to the protein movement. The protein structure was almost a constant at around ~ 3 Å. From 35 nanoseconds to 60 ns and from 61 to nearly 85 nanoseconds, the ligand fluctuation trend was almost similar in a span of 25 nanoseconds where the ligand aroused from ~ 1 Å and going upto ~ 9 Å. Finally, from 85th nanosecond onward the ligand bounded within the protein fluctuation within the range of ~ 0.7 Å to ~ 2.5 Å (Fig. 11A). The PPAR*γ*-TPM complex revealed an acceptable fluctuation rate during the MD simulation study as total 0 to 100 ns RMSD (Refer Additional file 1: Fig. S5). Initially, at 0 ns the starting point

the protein ligand deflected to ~ 0.35 Å. From 5 nanoseconds onward, the ligand was observed to be high in fluctuation reaching upto a ~ 9 Å with respect to the protein movement. The protein structure was almost a constant at around ~ 0.3 Å. From 0 to 15 ns, it went to ascending order upto ~ 0.3 Å, and 15 ns onward it is constant upto 100 nanoseconds with ~ 0.3 Å. The ligand initially aroused ~ 0. ~ 45 Å by 20 nanoseconds and later constant fluctuation is observed in a range of ~ 0.3 to 0.325 Å till 100 nanoseconds. At the 100 nanosecond, the binding affinity of TPM and PPAR-γ was found out to be −4.98299*e*+05 kJ/mol (Fig. 11B).

Fig. 11 [Images not available. See PDF.]

RMSD analysis of PPAR*γ*-ligand complex; **A** PPAR*γ*-CF complex **B** PPAR*γ*-TPM complex **C** PPAR*γ*-T3 complex

Similarly, the PPAR*γ*-T3 complex revealed an acceptable fluctuation rate during the MD simulation study as total 0 to 100 ns RMSD. Initially, at 0 ns the starting point the protein deflected from 0.18 Å to max ~ 0.28 Å and finally settled at ~ 0.25 Å to 100 nanoseconds, whereas the ligand from 0 nanosecond deflected to ~ 0.32 Å and reached upto ~ 0.57 Å at 100 nanoseconds (Fig. 11C).

The root mean square fluctuation (RMSF) calculates mean fluctuations atoms or amino acid residues during the entire MD simulation period. For PPAR*γ*-CF complex, the calculated RMSF for the protein region is a maximum 0.5 Å and the ligand (CF) reached up to 0.15 Å (Fig. 12A). For PPAR*γ*-TPM complex, the calculated RMSF for the protein region is a maximum 0.75 Å and the ligand (TPM) reached up to 0.17 Å (Fig. 12B). Also the calculated RMSF for the protein region (PPAR*γ*-T3 complex) is a maximum 0.75 Å and the ligand (T3) reached up to Å 0.18 (Fig. 12C). The calculated RMSF values below 1 Å reveal no higher fluctuations within the atoms of the complexes, suggesting that all the PPAR*γ*-ligand complexes were stable.

Fig. 12 [Images not available. See PDF.]

RMSF analysis of PPAR*γ*-ligand complex; **A** PPAR*γ*-CF complex **B** PPAR*γ*-TPM complex **C** PPAR*γ*-T3 complex

Rg (radius of gyration) analysis explains the extent of unfolding and folding of the protein–ligand complex during entire MD simulation. The compactness of protein and bound ligand can be defined by Rg. High Rg values indicate lower compactness of proteins and ligand thereby suggesting poorly bound complex and vice versa. Here in PPAR*γ*-CF complex, the protein PPAR-*γ* exhibited a maximum of 2 nm and ligand CF exhibited at very low nearly 0.3 nm of fluctuation in Rg (Fig. 13A). In case of PPAR*γ*-TPM complex, the protein PPAR-*γ* exhibited a maximum 2 nm and TPM exhibited at very low nearly 0.47 nm of fluctuation in Rg (Fig. 13B), while in case of the PPAR*γ*-T3 complex, protein PPAR-*γ* exhibits a maximum 2 nm and ligand (T3) exhibited at very low as started with 0.5 nm and reduced to 0.2 nm of fluctuation in Rg revealing a highest stability in contrast to the complex (Fig. 13C).

Fig. 13 [Images not available. See PDF.]

Radius of gyration data for PPAR*γ*-ligand complex; **A** PPAR*γ*-CF complex **B** PPAR*γ*-TPM complex **C** PPAR*γ*-T3 complex

In the process of drug design, h-bonds play a vital role in absorption, metabolism, and transportation too. The PPAR-*γ* and CF complex revealed significant change in the bonding parameter, where initially the ligand was interacting within the binding site region 3 and maximum 4 h-bonds. Finally, from the 90 ns to 100 ns the number of h-bonds is only 1 with an energy of −4.98780*e*+05 kJ/mol (Fig. 14 A). TPM was observed to interact within the binding site region with maximum 7 h-bonds at nearly ~ 30 and ~ 70 ns. Finally, from the 80 ns to 100 ns the number of h-bonds is acquainted to 2 and 3 (Fig. 14B). T3 was observed to interact within the with maximum 8 h-bonds at between ~ 20 and ~ 30 ns at 50 ns, and between 75 to 80 ns. At nearly 100 ns, the number of h-bonds is acquainted to 5 and 6 with an energy of −4.99215*e*+05 kJ/mol (Fig. 14 C).

Fig. 14 [Images not available. See PDF.]

SASA (solvent of accessible surface area) detects changes in conformations in the protein–ligand complex that can be assessed by water or solvent during entire MD simulation. In our study, the black line/graph indicates the protein in solvent system and red lines graph indicates the protein and ligand complex for the entire length of time period of MD simulation. The overlapping exhibits that there are no or very minor fluctuations and the entire system is stable. However, lower deviation (by 155 nm^2) was observed for PPAR*γ*-T3 complex in comparison to PPAR*γ*-CF and PPAR*γ*-TPM complexes with a deviation by 160 nm^2 and 165 nm^2, respectively (Fig. 16), indicating higher stability of PPAR*γ*-T3 complex (Fig. 15).

Fig. 15 [Images not available. See PDF.]

SASA analysis for PPAR*γ*-ligand complexes **A** Black line—SASA (PPAR-*γ*) and Redline—SASA for Protein and Ligand (PPAR*γ*-CF); **B** Black line—SASA (PPAR-*γ*) and Redline—SASA for Protein and Ligand (PPAR*γ*-TPM); **C** Black line—SASA (PPAR-*γ*) and Redline—SASA for Protein and Ligand (PPAR*γ*-T3)

The molecular docking and MD simulations clearly suggested that in contrast to individual pharmacophores the conjugate T3 would strongly bind to allosteric site within the LBD of PPAR*γ*, thereby acting as an antagonist.

Chemistry

Synthesis of T3 [3-(3,4-Dihydroxy-phenyl)-acryloyl]-sulfamic acid 2,2,7,7-tetramethyl-tetrahydro-bis[1,3]dioxolo[4,5-b;4′,5′-d]pyran-3a-ylmethyl ester

Buff yellowish crystalline solid; Yield (53%); mp (175 °C); IR (KBr, cm^{-1}): 3700 (NH, amide) 3400 (–OH, phenolic) 1353, 1252 (–CH_3) 1645–1630 (C=O, amide), 1600–1445 (C–C), 1070 (C–O),1379, 1342 (S=O), 978 (trans alkene); ^{1}H NMR (400 MHz, DMSO-d 6): *δ* 1.29–1.47 (12H, 1.29(s), 1.34 (s), 1.37 (s), 1.47 (s)), 3.63 (1H, *d*, *J*=7.6 Hz), 3.74 (1H, *d*, *J*=7.6, Hz), 3.98 (2H, *d*, *J*=2.6 Hz)), 4.03 (1H, dd, *J*=12.9, 2.6 Hz), 4.25 (1H, dd, *J*=12.9, 3.0 Hz), 4.77–4.87 (2H, 4.60 (s), 4.62 (s)), 6.186 (1H, *d*, *J*=15.7 Hz), 6.78 (1H, *d*, *J*=8.4 Hz)), 6.95 (1H, *d*, *J*=1.9 Hz), 7.08 (2H, (dd, *J*=8.4, 1.9 Hz), 7.43 (IH, *d*, *J*=15.7 Hz), 7.61 (1H, *s*). 13 C NMR (100 MHz, DMSO-d 6): *δ* 26.3–26.4 (4C, 26.3 (*s*), 26.1 (*s*), 25.1 (*s*), 24.2 (*s*)), 65.4 (1C, *s*), 60.7 (1C, *s*), 69.17 (1C, *s*), 69.9 (1C, *s*), 70.1 (1C, *s*), 70.41 (1C, *s*), 100.9 (1C, *s*), 108.0 (1C, *s*), 115.05 (1C, *s*), 115.8 (1C, *s*), 116.0 (1C, *s*), 121.4 (1C, *s*), 125.7 (1C, *s*), 145.7 (1C, *s*), 146.8 (1C, *s*), 148.5 (1C, *s*), 168.47 (1C, *s*).

As depicted in Scheme 1, T3 was synthesized by coupling of topiramate to caffeic acid using DCC and catalytic amount of DMAP. Initially caffeic acid (1 equivalent) and DCC (1.1 equivalent) were dissolved in sufficient of ice cold DMF and stirred for one hour on a magnetic stirrer. The reaction proceeds with formation of acylimminium ion intermediate. DMAP acts as a acyl transfer reagent. After one hour of stirring, topiramate (2 equivalent) dissolved in excess DMF was added to the above reaction mixture and stirred continuously for 48 h. Structure of the synthesized conjugate was characterized using IR, NMR (^{1}H and ^{13}C). In IR spectra characteristic peaks 3700 (NH amide), 3400 (–OH, phenolic) 1353, 1252 (–CH_3) 1645–1630 (C=O, amide carbonyl), 1600–1445 (C–C), 1379, 1342 (S=O), and 978 (trans alkene) were confirmed. Further, in ^{13}C NMR spectra carbons of amide carbonyl functionality were confirmed at 167–170 ppm (please refer Additional file 1: Figs. S4 and S5) [56].

Pharmacological studies

Enzyme inhibition assay

For evaluating T3 as a PPAR*γ* inhibitor, TR-FRET co-activator assay was conducted. Binding of an agonist like rosiglitazone to PPAR*γ*, causes a conformational change around helix 12 in LBD that increases the affinity of co-activator peptide. Upon excitation at 337 nM, energy is transferred to the fluorescein label on co-activator peptide from the europium label, therefore detected as emission. In agonistic mode, the T3 did not display any significant increase in fluorescence emission even at 10 µmol/L. On the other hand, in the antagonist mode, T3 antagonized agonist (rosiglitazone) induced fluorescence responses. From Fig. 16 it is quite evident that both GW9662 (IC_{50} = 4.49 µM) and T3 (IC_{50} = 7.45 µM) exhibited dose-dependent inhibition of PPAR*γ*.

Fig. 16 [Images not available. See PDF.]

in terms of mean ± standard deviation (*p<0.05) at n=3 experiments]

Effect of T3 on 3T3-L1 preadipocytes viability

For examining the cell level toxicity, the 3T3-L1 preadipocytes were treated with range of T3 concentrations (0.001, 0.01, 0.1, 1 and 10 μM) for 72 h and cell viability was assessed by MTT assay. Up to 0.1 μM of T3, no significant reduction in viability with respect to control (untreated) of 3T3-L1 preadipocytes were observed. A reduction in cell viability of about 10% and 20% was observed (Fig. 17) for 1 and 10 μM of T3 (p<0.05, ANOVA with t-test). Based on the above observations, concentrations below 10 μM (1, 3, 5. 7 and 10) of T3 were selected to evaluate the percentage lipid accumulation. The values for percentage viability of 3T3-L1 preadipocytes are provided (mean ± standard deviation) corresponding to triplicate experiments.

Fig. 17 [Images not available. See PDF.]

Effect of T3 on 3T3-L1 preadipocytes [Values presented as mean ± standard deviation (*p<0.05) at n=3 experimental repeats]

Effect of T3 on 3T3-L1 lipid accumulation and adipocyte differentiation

Oil Red O staining method explored the percentage of intracellular lipid accumulation in adipocyte stem cells. A dose-dependent inhibition of 3T3-L1 cells by T3 was observed. From the microscopic examinations it was pretty evident that there is reduction in size and number of 3T3-L1 cells containing larger lipid droplets (indicated in yellow colored arrows) with respect to control group (Fig. 18i). The percentage of fat accumulation was considerably reduced in T3 5–7 μM and highest at 10 μM concentrations (Fig. 18ii), with IC_{50} calculated as 7.98 μM.

Fig. 18 [Images not available. See PDF.]

Effect of T3 on lipid accumulation on 3T3-L1 preadipocytes **i** (A) control; (B) T3 (5 μM); (B) T3 (10 μM). **ii** Percentage fat accumulation. All the values are expressed as mean ± SD, at n=3 biological repeats

Effect of T3 on 3T3-L1 on PPARγ expression

It was very evident that reduction in lipid accumulation was very significant in the cell groups treated with 10 μM. For evaluating T3 as downregulator of PPARγ expression (master regulator of adipogenesis and differentiation), western blot was performed. T3 (10 μM) significantly decreased PPARγ expression in 3T3-L1 cells in comparison normal control (untreated) and GW9662 (10 μM) as positive control. These results were specific because β-actin levels were not affected (Fig. 19).

Fig. 19 [Images not available. See PDF.]

The values are expressed as mean ± standard deviation for n=3 biological repeats (*p<0.05 and **p<0.01)

Conclusion

Drug conjugates display better pharmacological properties than their individual pharmacophores. We synthesized novel drug conjugate TPAC as PPARγ inhibitors. PPARγ majorly orchestrates adipose tissue differentiation [57]. The development of new antiobesity medications has now centered around targeting adipogenesis and thereby associated signaling molecules and transcription factors. On this context, PPARγ becomes a promising target for antiobesity molecules. Topiramate, a marketed anticonvulsant drug, has been successfully repurposed and used as an antiobesity drug. Essentially, topiramate is a carbonic anhydrase inhibitor that tends to control obesity through enhancing satiety and regulating lipid metabolism. The antiobesity potential of the phenolic acids is attributed to controlling gut microbiome, energy metabolism, and control of adipogenic signaling pathways. On such grounds, it was interesting to design a new conjugate with two distinct pharmacophores exhibiting antiobesity potential via targeting adipogenesis and subsequently PPARγ.

To summarize, 10 topiramate–phenolic acid conjugates were designed and their PPARγ inhibitory activities were

predicted by robust 2D QSAR model with excellent goodness of fit. Highest PPAR*γ* inhibitory activity was predicted for T3 and accordingly was synthesized. The successful synthesis of the compound was confirmed by TLC, IR, and NMR analysis. T3 inhibited PPARγ (IC_{50} = 7.459 μM) which was also supported by the molecular docking study. The docking study also revealed that T3 binds efficiently within the allosteric pocket of the PPAR*γ* rather than the binding pocket and possess stronger interactions than the irreversible antagonist GW9662. Finally, T3 significantly inhibited adipocyte differentiation and lipid accumulation the differentiated adipocytes by downregulating the protein level expression of PPAR*γ* (IC_{50} = 7.8 μM). The in silico prediction for PPAR*γ* inhibitory activity of T3 was well corroborated by the in vitro experimental results. From the enzyme inhibition assay, it was noticeable that GW9662 (positive control) had better inhibition. But interestingly at the cellular level T3 exhibited higher antiadipogenic characteristics by downregulating PPAR*γ* protein level expressions than GW9662. Further investigations of effect of T3 on protein and gene level expressions of other adipogenic factors can strongly establish the antiadipogenic potency of T3. To conclude our study, we strongly suggest T3 as a potential PPAR*γ* inhibitor that significantly downregulates adipogenesis and differentiation, thereby conferring antiobesity potency to the newly synthesized conjugate.

PCA
Principle component analysis
PPARγ
Peroxisome proliferator-activated receptor
PBS-T
Phosphate-buffered saline-Tween 20
QSAR
Quantitative structure–activity relationship

RMSD
Root mean square deviation
RMSF
Root mean square fluctuation
Rg
Radius of gyration
SMILES
Simplified molecular input line system
SDS-PAGE
Sodium dodecyl sulfate–polyacrylamide gel electrophoresis
SASA
Solvent accessible surface area
TR-FRET
Time-resolved fluorescence resonance energy transfer
TPM
Topiramate
TPAC
Topiramate–phenolic acid conjugates
T3
Topiramate–caffeic acid conjugate

Design of experiments and white analytical chemistry-driven green and sensitive spectrofluorimetric estimation of pregabalin in its pharmaceutical dosage forms and spiked human plasma

Prajapati, Pintu1; Pulusu, Veera Shakar2; Shah, Shailesh11 Maliba Pharmacy College, Department of Quality Assurance, Surat, India (GRID:grid.449705.b) (ISNI:0000 0004 4649 822X)2 Ohio University, Department of Chemistry and Biochemistry, Anthens, USA (GRID:grid.20627.31) (ISNI:0000 0001 0668 7841)

ABSTRACT (ENGLISH)

Background

Pregabalin (PGB) is a medication with anticonvulsant, analgesic and anxiolytic properties, employed in the treatment of epilepsy, neuropathic pain, fibromyalgia, restless leg syndrome, opioid withdrawal syndrome and generalized anxiety disorder. Several spectrofluorimetric techniques have been documented for the determination of PGB in pharmaceutical dosage forms. However, these published methods typically involve the use of expensive and toxic organic solvents and reagents, as well as high reaction temperatures for PGB analysis. These components pose risks to aquatic life and the environment, making them less environmentally friendly and user-friendly. A recent advancement in analytical chemistry has introduced a white analytical approach, providing an economical, eco-friendly and user-friendly method for the development of analytical procedures.

Objectives

Therefore, a green and sensitive spectrofluorimetric determination of PGB, guided by white analytical chemistry principles, has been conducted utilizing distilled water as an environmentally friendly solvent.

Methods
The establishment of the spectrofluorimetric method involved employing the design of experiments approach to ensure a robust, precise and accurate estimation of PGB. Response surface analysis and optimization of critical procedural variables and responses were carried out using the central composite design. The validation of the developed method adhered to the guidelines outlined in ICH (International Council for Harmonization) Q2 (R1) and M10.
Results
The established spectrofluorimetric method was utilized to determine the PGB content in commercially available formulations and human plasma samples spiked with PGB. The obtained results were in accordance with the labeled claim of PGB in the formulations. The recovery of PGB in the spiked human plasma samples ranged from 85 to 90% of the spiked amount.
Conclusions
The greenness profiles of the published and suggested spectrofluorimetric methods for PGB estimation were evaluated and compared using the AGREE calculator, GAPI software and ESA tool. The suggested method demonstrated sensitivity, robustness, environmental friendliness and user-friendliness.

FULL TEXT

Background
Recently introduced into the literature, white analytical chemistry is an approach for the development and evaluation of accurate, sensitive, precise, environmentally friendly and cost-effective analytical methods for estimating drugs and their dosage forms. White analytical chemistry incorporates the key principles of green analytical chemistry in method development. It involves an RGB (red, green and blue) model-based assessment of the developed analytical method. The red (R) model-based assessment comprises four principles: R1—scopes and applications, R2—accuracy, R3—precision and R4—linearity and sensitivity. The green (G) model-based assessment includes the four major principles of green analytical chemistry: G1—environmental impact, G2—energy consumption, G3—waste generation and G4—health impact of the analytical method. The blue (B) model-based assessment includes four major principles: B1—time efficiency, B2—cost efficiency, B3—simplicity of the method and B4—instrument handling for the assessment of the analytical method [1].
Within the pharmaceutical industry, chromatographic analytical methods are frequently employed for the quality control and routine analysis of both drug substances and drug products. In the course of chromatographic analysis of drug samples, toxic organic solvents like chloroform, acetonitrile, methanol, toluene, etc., have traditionally been utilized and subsequently left as organic waste in the environment. Adhering to standards outlined in the Indian Pharmacopoeia, ICH (International Council for Harmonization) Q3C guidelines and published solvents selection guides, these organic solvents are recognized as harmful to aquatic animal life and environmentally hazardous. In line with the principles of green and white analytical chemistry, there is a concerted effort to reduce, eliminate and recycle the consumption and wastage of such toxic organic solvents during the development and life cycle management of analytical methods, aiming to preserve the environment [2–5].
The design of experiments (DoE) is a systematic methodology employed in the development of analytical methods to ensure robustness, precision and accuracy. As outlined in the ICH Q14 guideline, the incorporation of the design of experiments approach is a regulatory requirement for the registration and approval of new drug substances and products. Additionally, the design of experiments is a valuable tool for the implementation of white analytical chemistry, aiding in the development of analytical methods that are both robust and precise. Furthermore, the application of the design of experiments proves beneficial in minimizing the consumption of organic solvents during the development of analytical methods. Recent literature reveals the emergence of numerous published analytical methods that integrate hybrid principles of design of experiments, green analytical chemistry and white analytical chemistry [6–10].
Pregabalin (PGB) is a medication with anticonvulsant, analgesic and anxiolytic properties, prescribed for conditions such as epilepsy, neuropathic pain, fibromyalgia, restless leg syndrome, opioid withdrawal syndrome and

generalized anxiety disorder [11]. Numerous methods, including spectrophotometric, RP-HPLC (reversed-phase high-pressure liquid chromatographic) and LC–MS/MS, have been documented in the literature for estimating PGB in pharmaceutical dosage forms and conducting bioanalysis [12–22]. However, these analytical approaches involve the use of toxic organic solvents, posing environmental risks. Spectrofluorimetric methods, recognized for their sensitivity, specificity, accuracy and precision in drug sample estimation, offer a more environmentally friendly alternative with reduced organic solvent usage, time and cost. In the context of implementing the principles of white analytical chemistry, the spectrofluorimetric method stands out as an ideal choice for green, accurate, sensitive, precise and economical analysis of drug samples. Notably, PGB is a nonfluorescent drug molecule, necessitating derivatization for the development of a spectrofluorimetric method. Recent literature has featured various spectrofluorimetric methods utilizing different derivative reagents as fluorescent probes for PGB estimation [23–28]. However, some published spectrofluorimetric methods employ toxic organic solvents, high reaction temperatures and toxic reagents, generating over 100 mL of organic waste. Additionally, the sensitivity of certain published spectrofluorimetric methods is limited to the microgram level.

Therefore, a sensitive, robust and environmentally friendly spectrofluorimetric method has been developed for the estimation of PGB, utilizing safe solvents and eliminating the need for derivative reagents. The development of this spectrofluorimetric method followed a comprehensive strategy based on the principles of white analytical chemistry and the design of experiments. The design of experiments approach was implemented using a central composite design, which facilitated response surface analysis and optimization of the spectrofluorimetric method. The developed method underwent validation in accordance with ICH Q2 (R1) and M10 guidelines. Application of the developed spectrofluorimetric method included the assay of both marketed formulations and spiked human plasma samples. To assess and compare the greenness and whiteness profiles of the published and developed spectrofluorimetric methods, various tools and models such as the AGREE (Analytical Greenness) calculator, ESA (Eco-scale Assessment) tool, GAPI (Green Analytical Procedure Index) and RGB (red, green and blue) models were employed.

Methods

Instruments and softwares

The determination of PGB was conducted utilizing a Spectrofluorometer Shimadzu RF-5301 PC model, obtained from Toshvin Analytical Private Limited in Vapi, Gujarat, India. The spectrum of PGB was recorded using a UV–Visible spectrophotometer 3092 model (Lab India Private Limited, Mumbai, Maharashtra, India). For precise weighing, a single pan digital analytical balance, acquired from Shimadzu Scientific Instruments (India) Private Limited in Bangalore, India, was employed. The response surface modeling based on Design of Experiments (DoE) was carried out using MINITAB 18 software (trial version). To evaluate the environmental friendliness of the method, the AGREE calculator (accessible at https://mostwiedzy.pl/AGREE) was employed. Additionally, the greenness profile of the method was assessed using Complex GAPI software, which can be accessed at mostwiedzy.pl/complexgapi.

Reagents and materials

The PGB API (Active Pharmaceutical Ingredient) with 99.98%W/W purity was received as a complimentary gift sample from Vapi Care Pharma Private Limited in Gujarat, India. High-quality double-distilled water was meticulously prepared in the Quality Assurance Laboratory at our institute. To facilitate filtration, membrane filters (0.45 µm) and sample syringe filters (0.22 µm) were acquired from Pall India Private Limited, located in Andheri, Mumbai, India. The pharmaceutical dosage forms of PGB (Pregazo 75 capsule—contains 75 mg PGB, Pregal 75 capsule—contains 75 mg PGB, and Pregadd tablets—contains 50 mg PGB) were procured from the local market in Surat, Gujarat, India.

Establishing calibration curve for assay of marketed formulations

A standard solution of PGB (1000 µg/ml) was prepared by dissolving 10 mg of PGB in distilled water in a 10-mL volumetric flask. Subsequent dilutions were carried out with distilled water to generate concentrations ranging from 1.0 to 25 µg/ml. Consequently, 100 µL from the working solution (10 to 25 µg/ml) of PGB was transferred into a

series of 10-mL volumetric flasks and topped up to the mark with borate buffer of pH 10.0, resulting in the final concentration range of 10–250 ng/mL. The fluorescence intensity was measured at an emission wavelength of 410 nm using an excitation wavelength of 230 nm. A blank experiment was conducted in a similar manner without the presence of PGB.

Establishing a calibration curve through the spiking of PGB to human plasma samples

In each 100 µL aliquot of human plasma, a 10 µL portion from distinct working standard solutions (100–2500 µg/mL) was individually introduced, thoroughly mixed and vortexed for 15 min. To extract PGB from the human plasma, 3.0 mL of methanol was added as a precipitating agent and mixed for an additional 15 min. Following complete precipitation, the resulting samples were diluted to a final volume of 10 mL with methanol. Subsequently, each sample underwent centrifugation at 4000 RPM for 15 min. A 1.0 mL aliquot from the supernatant of each solution was filtered through a 0.22 µm syringe filter and transferred into a series of 10-mL volumetric flasks, completed to the mark with borate buffer of pH 10.0, resulting in the final concentration range of 10–250 ng/mL. The fluorescence intensity was measured at an emission wavelength of 410 nm using an excitation wavelength of 230 nm. A blank experiment was conducted similarly without the presence of PGB.

Implementing design of experiments approach in method development

Following preliminary experiments, critical procedural variables and method performance attributes (responses) were identified for the development of the intended method. These critical method variables were examined for their main effects, two-way interactions and quadratic effects on selected responses using central composite design through Minitab 18 software. Navigating the analytical design space was allowed for the optimization of responses in the targeted spectrofluorimetric method for estimating PGB. Mean response surface analysis was conducted to delineate the analytical design space and validate the model.

Analysis of pregabalin in marketed formulations

A sample equivalent to 10 mg of PGB was taken from each pharmaceutical dosage form of PGB. This sample was dissolved, diluted to 10 mL with distilled water and then filtered. Subsequently, a 1.0 mL aliquot was further diluted to 10 mL with distilled water. From this solution, another 1.0 mL aliquot was diluted to 10 mL with distilled water. A 100 µL aliquot of the sample was then transferred into a 10-mL volumetric flask and completed to the mark with borate buffer at pH 10.0. The fluorescence intensity was measured at an emission wavelength of 410 nm using an excitation wavelength of 230 nm. A blank experiment was conducted in a similar manner, excluding the presence of PGB sample.

Results

Defining the analytical target profile for the design of experiments approach

The spectrofluorimetric method was developed to estimate PGB in its pharmaceutical dosage forms and spiked human plasma samples, employing environmentally safe and sustainable solvents. The developed method was designed to yield optimal fluorescence intensity and % recoveries of PGB, ensuring sensitive, selective and specific estimation in the proposed matrices. Consequently, fluorescence intensity and % recovery of PGB have been identified as crucial responses in the development of the targeted spectrofluorimetric method (Fig. 1).

Pareto chart analysis using central composite design and Minitab 18 software. **A** Pareto chart showing significant main effects and quadratic effects of critical procedure variables on fluorescence intensity—Response R1 and **B** Pareto chart showing significant main effects and quadratic effects of critical procedure variables on % recoveries—Response R2

Utilizing response surface analysis for method optimization

The Minitab 18 software proposed thirteen experimental runs (refer to Table 1), which were subsequently conducted in the laboratory. The recorded responses from these experimental runs were analyzed through ANOVA, multiple regression analysis and response surface analysis using the software. According to the ANOVA results (refer to Table 2), the main effects of critical procedure variables A and B were found to be significant for responses R1 and

R2, along with significant quadratic effects of critical procedure variables A and B. However, the two-way interactions of critical procedure variables A and B were determined to be nonsignificant for responses R1 and R2. The multiple regression analysis revealed R-squared, adjusted R-squared and predicted R-squared values for responses exceeding 0.9, with the difference between adjusted R-squared and predicted R-squared being less than 0.2. These outcomes suggest that the selected models were well suited for predicting responses R1 and R2. The 2D and 3D response surface contour plots (refer to Figs. 2A, B, 3A, B) illustrate multidimensional interactions and the quadratic relationship between critical procedure variables (A and B) and responses R1 and R2. The analytical design space was navigated to achieve maximum fluorescence intensity and % recovery of PGB, aligning with the analytical target profile of the method, using overlaid response surface plots.

Table 1. Design metrics and measured responses for DoE-based response surface analysis and optimization of critical procedure variables (CPVs) using central composite design by Minitab 18 software

Employing the mean response surface method to define the analytical design space

Following an examination of the overlaid response surface plots, the analytical design spaces, directed toward achieving maximum fluorescence intensity and % recovery of PGB, were scrutinized for accuracy and precision in predicting responses R1 and R2 using the mean response surface method. The visual representation of these navigated analytical design spaces is depicted in Figs. 2C and 3C, highlighted in white shades. Subsequently, the experimental runs recommended by the software were executed in the laboratory, and the actual responses were analyzed for their %RSD (n=3). The %RSD for all experimental runs was determined to be less than 2%, indicating the accurate and precise prediction of responses R1 and R2 by the suggested models.

Spectrofluorimetric method validation

The method's specificity was confirmed by comparing fluorescence spectra among various samples, including blank and standard PGB. Blank samples exhibited no interference from excipients or human plasma matrices (Refer Additional file 1: Fig. S2). Linearity was established through five repetitions of calibration curve procedures, demonstrating a linear relationship within the 10–250 ng/mL concentration range, with a correlation coefficient exceeding 0.995 (refer to Figs. 4 and 5). Additionally, % recoveries of PGB from spiked human plasma samples (at 50%, 100% and 150% levels) ranged from 85 to 90%. Evaluations for sample carryover and sample dilution in the estimation of PGB were conducted within spiked human plasma samples. The method's robustness was assessed by varying scanning speed and excitation wavelength, yielding consistent results. Precision studies for both intra-day and inter-day analyses demonstrated the method's reliability in estimating PGB. The method exhibited remarkable sensitivity, with the lowest limit of detection and quantitation determined to be 5.0 ng/mL and 10 ng/mL, respectively, underscoring its capability to detect PGB at nanogram-level concentrations. A summary of the validation parameters is presented in Table 3.

Formulations assay and spiked human plasma samples analysis

The established method was employed to assay various market formulations of PGB, revealing % assay values for

PGB in the formulations within the range of 95% to 105% of the labeled claim of PGB. The presence of excipients did not cause interference in the estimation of PGB. In spiked human plasma samples, the % recovery of PGB was determined to be in the range of 85% to 90%. The matrices of blank human plasma samples did not pose interference in the estimation of PGB.

Discussion

The UV spectrum of PGB in distilled water exhibited two peaks at 210 nm and 230 nm (Refer Additional file 1: Figure S1 for UV spectrum of PGB), respectively. The 210 nm peak corresponded to the π–π^* transition, while the 230 nm peak was attributed to the $n - \pi^*$ transition of the primary amine functional group in PGB. Upon excitation at 230 nm, the nitrogen of the amino group led to a fluorescence emission at 410 nm. The fluorescence intensity at 410 nm was employed for a linearity study, revealing a linear relationship at nanogram-level concentrations of PGB. This fluorescence intensity was further examined in buffer solutions spanning a pH range of 1.0 to 12.0, with the highest intensity observed in borate buffer at pH 8–10. The existing literature has detailed spectrofluorimetric methods involving derivatization, often utilizing toxic organic solvents and reagents, and exhibiting sensitivity at microgram levels. Additionally, these methods necessitated high reaction temperatures during the derivatization of PGB, rendering them less user-friendly. Notably, no spectrofluorimetric method in the literature has been reported for the detection and quantification of PGB without the need for derivatization.

A recent development in analytical chemistry advocates for a white analytical chemistry approach, emphasizing the development of green, economical and user-friendly analytical methods. Following the ICH Q14 guideline, the implementation of a design of experiments approach is a regulatory requirement for the registration of new drug products and substances. Despite this, the literature lacks an analytical method for estimating PGB using the white analytical chemistry and design of experiments approach. In response, a robust, green and user-friendly spectrofluorimetric method has been devised for the estimation of PGB in pharmaceutical dosage forms and spiked human plasma samples. This method integrates the principles of white analytical chemistry and the design of experiments approach, aligning with the contemporary trend toward environmentally conscious and efficient analytical methodologies, as suggested by recent developments in analytical chemistry.

Design of experiments using Minitab 18 software

After conducting initial experiments, it was determined that the excitation wavelength (designated as critical procedure variable A) and the pH of the medium (designated as critical procedure variable B) played pivotal roles. These variables were subsequently investigated to establish their graphical relationships with selected responses using response surface methodology. The fluorescence intensity and percentage recovery of PGB were chosen as critical responses for the development of a targeted spectrofluorimetric method. To analyze the identified critical procedure variables, a central composite design was employed, allowing the examination of main effects, two-way interactions and quadratic effects of the variables on the selected responses (R1 and R2). The analytical design space was explored to achieve maximum fluorescence intensity and percentage recovery of PGB in alignment with the analytical target profile of the method, as illustrated through overlaid response surface plots. Following a thorough examination of these plots, the navigated analytical design spaces for maximum fluorescence intensity and percentage recovery of PGB were assessed for accuracy and precision in predicting responses R1 and R2 using the mean response surface method. The optimized range for the excitation wavelength (critical procedure variable A) was determined to be 230 to 240 nm, while the optimized range for the pH of the medium (critical procedure variable B) was identified as 9.0 to 10.0. Consequently, the spectrofluorimetric estimation of PGB was conducted with an excitation wavelength of 230 nm at a pH of 9.0 in a borate buffer.

The developed spectrofluorimetric method has undergone validation in accordance with the guidelines of ICH Q2 (R1) for the assay of pharmaceutical dosage forms, encompassing specificity, accuracy, linearity, precision, LOD, LOQ and robustness. Additionally, the validation of the developed spectrofluorimetric method has been conducted following the ICH M10 guideline for estimating PGB in spiked human plasma samples. The results indicate that the developed method is accurate, precise, robust, sensitive, specific and linear in the estimation of PGB in both its pharmaceutical dosage forms and spiked human plasma samples. All validation parameters align with the standards

outlined in the ICH Q2 (R1) and M10 guidelines.

The conventional technique was utilized to assay different commercial formulations of PGB (Pregazo 75 capsule—contains 75 mg PGB, Pregal 75 capsule—contains 75 mg PGB, and Pregadd tablets—contains 50 mg PGB), uncovering assay values for PGB in these formulations falling between 95 to 105% of the stated PGB content. Interestingly, the addition of other substances did not affect the measurement of PGB. When PGB was intentionally added to human plasma samples, its recovery ranged from 85 to 90%. Remarkably, the absence of any interfering substances in blank human plasma samples did not hinder the determination of PGB levels (refer supplementary files for fluorescence spectrum of blank human plasma and reagents). According to the reported LC–MS/MS method [20], the reported linearity range and Cmax value of PGB was found to be 0.1 to 15 µg/mL and 6.925 to 7.477 µg/mL in human plasma. The proposed spectrofluorimetric method was found to be complied with the reported LC–MS/MS method for the estimation of PGB in spiked human plasma samples. The developed method can be extended as sensitive and green analytical tool for pharmacokinetic and bioequivalence study of PGB in human and rat plasma.

Evaluation of spectrofluorimetric methods through white analytical chemistry principles

The comparative analysis of the existing and proposed methods for estimating PGB has been conducted through white analytical chemistry and an RGB model-based scoring system, as detailed in Table 4. The spectrophotometric methods published in the literature were evaluated against the proposed spectrofluorimetric method using both the RGB and WAC scoring systems. The red model-based assessment focused on evaluating the validation efficiency, sensitivity, scope and applicability of spectrofluorimetric methods. Some published spectrofluorimetric methods [24, 26, 27] exhibited sensitivity at the microgram level, earning a Rrd model-based score of 95 out of 100 (refer to Table 4). In contrast, our proposed method and other published spectrofluorimetric methods [22, 23] achieved a perfect score of 100, attributed to their nanogram-level sensitivity and applicability for PGB estimation in marketed formulations and spiked human plasma. This high score reflects their implementation of the design of experiments approach, exceptional sensitivity, % recoveries and applicability for PGB estimation.

Table 4. Comparison and assessment of published and proposed spectrofluorimetric for the estimation of PGB using principles of green and white analytical chemistry

Types of spectrofluorimetric method	Analytical conditions	Sensitivity, whiteness and greenness profile assessment of methods

Method 1—Spectrofluorimetric estimation of PBG using 7-chloro-4-nitrobenzofurazon (NBD-Cl) as fluorescent probe [22]	Linearity—40 to 400 ng/mL Derivatization agent—7-chloro-4-nitrobenzofurazon (NBD-Cl) Excitation wavelength—460 nm Emission wavelength—558 nm Extraction solvent—Chloroform (More than 10 mL) Reaction temperature—60 to 80˚C Application—Assay of marketed formulations	The method includes toxic organic solvents and reagents. The reaction temperature is more than room temperature The method has sensitivity as nanogram level AGREE score: 0.55 GAPI e-factor: 0.5 ESA penalty points: 08 Red model s score—100/100 Green model score—55/100 Blue model score—90/100 Whiteness score—(100 + 55 + 90)/3 = 81.66
Method 2—Spectrofluorimetric estimation of PGB using fluorescamine, 2,4-dinitrofluorobenzene and chloranil as fluorescent probes [23]	Linearity—20 to 280 ng/mL Derivatization agent—Fluorescamine, 2,4-dinitrofluorobenzene and chloranil Excitation wavelength—385 nm Emission wavelength—485 nm Extraction solvent—Water Reaction temperature—60 to 80˚C Application—Assay of marketed formulations and bioanalysis of spiked urine samples	The method needs toxic derivatization reagents and high temperature for reaction The method has sensitivity as nanogram level AGREE score: 0.60 GAPI e-factor: 0.50 ESA penalty points: 06 Red model s score—100/100 Green model score—60/100 Blue model score—90/100 Whiteness score—(100 + 60 + 90)/3 = 83.33

Method 3—Spectrofluorimetric estimation of PGB using fluorescamine as fluorescent probe [24]	Linearity—0.01 to 0.3 µg/mL Derivatization agent—Fluorescamine Excitation wavelength—390 nm Emission wavelength—487 nm Extraction solvent—Water Reaction temperature—60 to 80˚C Application—Assay of marketed formulations	The method needs toxic derivatization reagents and high temperature for reaction The method has sensitivity as micro and nanogram level AGREE score: 0.65 GAPI e-factor: 0.35 ESA penalty points: 06 Red model s score—95/100 Green model score—65/100 Blue model score—90/100 Whiteness score—(95 + 65 + 90)/3 = 83.33
Method 4—Spectrofluorimetric estimation of PGB using carbon quantum dots [26]	Linearity—4 to 100 µg/mL Derivatization agent—Carbon quantum dots from ascorbic acid Excitation wavelength—356 nm Emission wavelength—524 nm Extraction solvent—Water Reaction temperature—160˚C, 70 min Application—Assay of marketed formulations and bioanalysis of spiked urine sample	The method needs toxic reagents and very high temperature for reaction The method has sensitivity as microgram level only AGREE score: 0.65 GAPI e-factor: 0.35 ESA penalty points: 06 Red model s score—95/100 Green model score—65/100 Blue model score—90/100 Whiteness score—(95 + 65 + 90)/3 = 83.33

Method 5—Spectrofluorimetric estimation of PGB using acetylbutyrolactone as fluorescent probe [27]	Linearity—10 to 100 µg/mL Derivatization agent—Acetylbutyrolactone Excitation wavelength—380 nm Emission wavelength—440 nm Extraction solvent—Water Reaction temperature—95˚C Application—Assay of marketed formulations	The method needs toxic derivatization reagents and high temperature for reaction The method has sensitivity as microgram level only AGREE score: 0.65 GAPI e-factor: 0.35 ESA penalty points: 06 Red model s score—95/100 Green model score—65/100 Blue model score—90/100 Whiteness score—(95 + 65 + 90)/3 = 83.33
Proposed spectrofluorimetric estimation of PGB	Linearity—10 to 250 ng/mL Derivatization agent—No reagent Excitation wavelength—230 nm Emission wavelength—410 nm Extraction solvent—Water Reaction temperature—25˚C (Room Temperature) Application—Assay of marketed formulations	No chemical reaction required and water is used as solvent The method has sensitivity at nanogram level. The method does not require heating. Hence, it is more user-friendly AGREE score: 0.80 GAPI e-factor: 0.25 ESA penalty points: 03 Red model s score—100/100 Green model score—80/100 Blue model score—100/100 Whiteness score—(100 + 80 + 100)/3 = 93.33

The green model-based scoring and greenness profile assessment of analytical methods utilized the AGREE calculator, GAPI software, NEMI standards and ESA tool. However, the literature suggests that NEMI standards for greenness assessment provide the least accurate information. Therefore, AGREE and GAPI scores were considered for the calculation of the green model-based score. The green model-based scoring system assessed environmental friendliness, with published methods scoring less than 65 out of 100 based on AGREE and GAPI software criteria. The proposed method earned a score of 80 due to its use of environmentally friendly solvents (distilled water and methanol only), reduced organic waste generation and lower power consumption for PGB estimation. In contrast, the published spectrofluorimetric methods required high reaction temperatures and costly organic solvents and derivative reagents.

Assessing time, cost efficiency and user-friendliness through the blue model-based scoring system, published

spectrophotometric methods scored 90 out of 100, respectively. The proposed method, which does not require high temperatures or costly derivative reagents and solvents for PGB estimation, achieved a perfect score of 100 for its economical, rapid, user-friendly and straightforward approach. The overall WAC (white analytical chemistry) score, calculated by averaging RGB model scores, for published spectrofluorimetric methods was found to be less than 84 out of 100. In contrast, the proposed method received a score of 93.33 due to its validation efficiency, environmental friendliness, speed, cost-effectiveness and user-friendliness in PGB estimation. A comprehensive comparison of the greenness profile, WAC and RGB model-based scoring is depicted in Fig. 6A, B.

Conclusions

A hybrid approach, combining principles from white analytical chemistry and design of experiments, was employed for the spectrophotometric estimation of PGB. The resulting method incorporates safe, environmentally friendly and cost-effective solvents. Validation of the developed method encompassed specificity, sensitivity, selectivity, precision, accuracy and linearity in the estimation of PGB. Application of the method to assess PGB in various marketed formulations yielded results in accordance with the labeled claim. Furthermore, the method's applicability was extended to the estimation of PGB in spiked human plasma samples, demonstrating validation in accordance with ICH M10 guidelines. Both the developed and published methods were evaluated for their greenness and whiteness profiles in PGB estimation using RGB model scoring system, AGREE and GAPI software. The proposed method proved to be sensitive, robust, environmentally friendly, economical and user-friendly in estimating PGB across diverse samples. This developed method holds potential for use in pharmacokinetic and pharmacodynamic studies of PGB, presenting an economical and eco-friendly analytical tool for bioanalysis and quality control of PGB pharmaceutical dosage forms in the pharmaceutical industry.

Acknowledgements

The Maliba Pharmacy College’s Principal and the Uka Tarsadia University’s Provost are thanked by the authors for their enormous help in providing the necessary infrastructure and instrumentation equipment to carry out the research endeavor. Their contributions were crucial to the accomplishment of this investigation.

Author contributions

Dr Pintu Prajapati was involved in drafting, conceptualization, supervision and review. Veera Shakar Pulusu contributed to review, software analysis handling and drafting. Shailesh Shah took part in supervision and review support.

Formulation and evaluation of nanobiotherapeutics of Terminalia arjuna through plant tissue culture for atherosclerosis

Wadekar, Pradnya Pradeep1 ; Salunkhe, Vijay Rajaram21 Rajarambapu College of Pharmacy, Kasegaon, Sangli, India; Appasaheb Birnale College of Pharmacy, Vishrambag, Sangli, India2 Rajarambapu College of Pharmacy, Department of Pharmacognosy, Kasegaon, Sangli, India

ABSTRACT (ENGLISH)

Background

The study seeks to investigate the therapeutic potential of *Terminalia arjuna* callus in addressing atherosclerosis. In order to get maximum beneficial phytoconstituents from *Terminalia arjuna*, it is recommended to harvest the bark from Arjuna trees that are at least 15 years old and a gap of minimum 2 years should be kept before harvesting bark from the same plant. The callus culture technique was employed to expedite the process. The callus culture extract was subsequently converted into a nanosuspension with the aim of improving the efficacy of its phytoconstituents. It was then subjected to a comprehensive series of in vitro and in vivo evaluations to ascertain its potential for treatment of atherosclerosis.

Results

Liquid chromatography–mass spectrometry analysis of the callus extract confirmed the presence of flavonoids and terpenoids, known for their antioxidant and anti-inflammatory activities. Some terpenoids were even absent in Arjuna tree naturally. TEM images validated successful entrapment of the extract within the nanoparticles. In vitro analysis for antilipase and antioxidant assay confirmed the antiatherosclerotic potential of the extract. In vivo tests on rat blood serum demonstrated a significant reduction in total cholesterol, low-density lipoprotein, triglycerides, high-density lipoprotein, and very low-density lipoprotein. Histopathological analysis of rat aortas showed additional confirmation of antiatherosclerotic action.

Conclusion

In conclusion, the study highlights the potential of nanosuspension derived from *Terminalia arjuna* callus extract as a comprehensive therapeutic strategy for atherosclerosis treatment. The research highlights antioxidant, anti-inflammatory, and antiatherosclerotic properties of the callus, hinting at its viability as a potential treatment for atherosclerosis. This interdisciplinary investigation emphasizes the promising role of traditional medicinal plants within modern medical paradigms.

FULL TEXT

Background

Atherosclerosis is a chronic inflammatory condition resulting in cardiovascular disease with life-threatening implications. Atherosclerosis is a complex and multifaceted condition marked by the accumulation of plaque within arteries. This can lead to reduced blood flow, contributing to a range of cardiovascular diseases (CVDs). CVDs are one of the leading causes of death worldwide, and their prevalence is rapidly increasing, owing in large part to changes in lifestyle and an increase in the elderly population [1]. Since atherosclerosis is a complex condition affected by numerous risk factors, there are various well-established and innovative strategies to diagnose and manage this disease. During the early phases of atherosclerosis, the primary objective of treatment is on managing significant risk factors such as elevated cholesterol levels, hypertension, and elevated blood sugar. Making

alterations to one's diet, engaging in regular physical activity, and quitting smoking are all assumed to play pivotal roles in both the prevention and management of atherosclerosis. The current treatment for management of atherosclerosis includes drugs that have antihypercholesterolemic, antihypertensive, hypoglycemic, and antiplatelet activity. Anti-inflammatory drugs like canakinumab, methotrexate, and colchicine have passed clinical trials but need to be further assessed for their therapeutic efficacy. The typical medications utilized to address hypercholesterolemia are statins solely or in combination with drugs like ezetimibe. These drugs function by inhibiting the hepatic enzyme HMG CoA reductase, a crucial enzyme in the synthesis of cholesterol. The primary advantage of statins lies in their ability to lower low-density lipoproteins (LDL). However, they suffer from adverse effects mainly statin-associated muscle symptoms, myalgias, and glucose intolerance. Additionally, the utilization of statins has been associated with the development of type 2 diabetes mellitus [2–4].

Considering the negative effects of synthetic medications, emphasis should be given to embrace natural drugs, which have negligible adverse reactions. Natural origin drugs still continue to be the focus of pharmaceutical research because substitute drug discovery methods have failed to provide lead compounds for treatment of various diseases like metabolic diseases. *Terminalia arjuna*, also known as Arjuna in Hindi, belongs to the family Combretaceae and is found in India, Mauritius, and Sri Lanka. Arjuna has been documented in numerous ancient Indian medical texts, including Charaka Samhita, Astang Hridayam, and Sushruta Samhita, dating back to the Vedic period. Notably, it was Vagabhatta who first recommended the utilization of stem bark powder for heart-related conditions. Ayurvedic practitioners have employed this plant in the management of cardiovascular ailments [5]. The stem bark, fruits, and even leaves of Arjuna are commonly used in different traditional systems across India for various medicinal properties such as astringent, demulcent, expectorant, styptic, antidysenteric, cardiotonic, and urinary astringent. It is also used in the treatment of ulcers, earaches, and even bark ashes are used for snakebites and scorpion stings [6]. Numerous experimental and clinical studies have effectively showcased Arjuna’s potential as an anti-ischemic agent, antiatherogenic agent, and a strong antioxidant. As per data shared for Scientific Harvesting—Dos and Don’ts by NTFP Centre of Excellence (NCE) established by Government of Tripura, India; the bark of Arjuna tree should not be harvested before 15 years of growth to get quality product with a minimum gap of 2 years for successive harvesting [6–11].

The present study includes the callus culture to reduce the harvesting time period. Nanoparticle delivery systems offer the enhanced stability and solubility of encapsulated drug molecules, facilitating their movement across membranes, and extending circulation time to enhance both safety and effectiveness of the medicament [12, 13]. In this study, a multidisciplinary approach was employed to create a nanosuspension from Arjuna callus.

Methods

Preparation of callus

The branch of Arjuna was collected from Dr. Babasaheb Ambedkar Central Nursery Kagal, India, in the month of June, and plant was authenticated form Botanical Survey of India, Pune. The leaves were surface sterilized. Murashige and Skoog agar media with different concentrations of 2, 4,-dichlorophenoxy acetic and kinetin were used for callus induction. The explants were incubated at 25 ± 2 °C under 16-h photo-period of 2000 lx with white light. The relative humidity was maintained at 60–70% during incubation at Seem Biotech Pvt Ltd, Warananagar, India. Sub-culturing was carried out every six weeks. After 6 months, the callus cultures were weighed and callus index was calculated.

Extraction of callus

The callus culture obtained was dried at 50 ± 5 °C in hot air oven and was subjected to ethanolic extraction using Soxhlet apparatus and subsequently dried in vacuum dryer.

Preparation of arjuna callus extract nanosuspension (ACEN)

One gram of extract was mixed with 20 ml ethanol. The solution was injected drop wise in 100 ml aqueous solution of polyvinyl pyrrolidone K30 (PVP K30) and was subjected to mechanical stirring for 6 h. A factorial design was employed, taking into account two independent factors: the concentration of PVP K30 and mixing speed, each varying at three different levels.

Evaluation of nanosuspension

Bruker, ALPHA Infrared Spectrophotometer was used for checking the compatibility of callus extract with the PVP K30. The Horiba Zetasizer was used for determination of particle size and zeta potential [14]. Absorption maxima were determined using a Jasco V-750 UV Spectrophotometer from Japan to calculate % drug content, % drug encapsulation, and % drug release. For the % drug release study, a dialysis bag (dimensions: flat width 28.46 mm, inflated diameter 18 mm; provided by HiMedia Laboratories Pvt, Ltd) was utilized. One milliliter of 10 µg/ml of each ACEN batch was placed in a dialysis bag immersed in 300 mL of diffusion media (phosphate buffer saline—PBS, pH 7.4) in USP Type I dissolution test apparatus. Samples were withdrawn at 5-min intervals over 40 min from the receptor compartment and analyzed at 282 nm. The % drug content, % drug encapsulation efficiency, and % drug release studies were conducted in triplicate [15].

Acceleration stability studies for the optimized batch were carried out according to ICH guidelines for 90 days. It involved a modification in the intermediate storage condition, transitioning from 30 °C ± 2 °C and 60% ± 5% relative humidity (RH). The adequate amount of freeze-dried optimized ACEN batch was subjected to acceleration stability study. The particle size, % drug content, and % drug release study were used as parameters to check the stability of ACEN [16].

Antilipase assay

The enzymatic activity of porcine pancreatic lipase (PPL, type II) was assessed using p-nitrophenyl butyrate (p-NPB) as a substrate. PPL stock solution (1 mg/mL) was prepared in 0.1 mM potassium phosphate buffer (pH 6.0) and stored at -20 °C. Different concentrations 20, 40, 60, 80, and 100 µg/mL of extract and standard drug Orlistat were pre-incubated with PPL for 1 h in a 0.1 mM potassium phosphate buffer (pH 7.2), supplemented with 0.1% Tween 80, at 30 °C. After addition of 0.1 µL of p-NPB, all samples were incubated at 30 °C for 5 min. The absorption for all samples was recorded at 405 nm. The analysis was performed three times for each concentration of sample and standard. The inhibitory activity (I) was calculated using the following formula [17]:\% Inhibition=Absorbanceofcontrol -AbsorbanceofsampleAbsorbanceofcontrol×100

Antioxidant activity assay

The antioxidant potential of the nanosuspension was assessed through its ability to scavenge free radicals using DPPH (1,1-diphenyl-2, picryl-hydrazyl) radicals. The standard solutions were prepared by mixing different concentrations of 100 µL of aqueous ascorbic acid solution with 100 µL of a 0.1% methanolic DPPH solution. Similarly, test samples were prepared by mixing different concentrations of 100 µL of an aqueous callus extract solution with 100 µL of the 0.1% methanolic DPPH solution. After mixing, all samples were incubated for 30 min in a dark environment at room temperature. The absorbance was recorded three times at 490 nm [18, 19].

The radical scavenging activity was determined using the following formula:\%radicalscavengingactivity=Absorbance ofControl-AbsorbanceofTestsampleAbsorbanceofControl∗100

Experimental animals

The protocol was approved by the Institutional Animal Ethics Committee of Appasaheb Birnale College of Pharmacy, Sangli (Approval number-IAEC/ABCP/13/2021–22). Healthy young male Wistar rats aged 6–8 weeks weighing approximately 200–250 g were divided into four groups, with six rats in each group. Prior to the initiation of the experimental procedure, one-week acclimatization period maintaining a temperature of 24 ± 3 °C, a humidity level of 50–60% RH, and a 12-h light/dark cycle, was provided for the rats.

Acute toxicity study

An acute toxicity assessment was conducted on rats in accordance with the OECD guideline 423 using the up-and-down procedure. Three nulliparous and non-pregnant female rats aged 8 to 12 weeks were employed for the study. The rats were fasted overnight before dosing, which extended for an additional 3-h post-dosing. Close monitoring of the animals was carried out for the initial 24 h to detect any signs of toxicity and continued for 72 h to identify potential mortalities. The determined LD50 value was 3000 mg/kg of rat body weight. As a result, a dose of 300 mg/kg body weight was selected for ACEN administration [4, 7, 11].

Preparation of high-fat diet (HFD)

The fine powder of the conventional standard animal pellets was combined with 2% cholesterol, 1% cholic acid, 40% sucrose, and 10% coconut oil. The resulting powdered mixture was blended with an appropriate amount of water to form compact feed spheres. These spheres were then stored in a refrigerator.

Animal test groups

The animals were randomly distributed into four distinct groups, each group comprising of six rats. Group I, designated as normal group, was provided with the standard rat animal pellets. Group II, known as the disease control group, was fed a HFD. Throughout the study, both Group I and Group II received normal saline per day orally. Group III, referred to as the Standard group, received HFD and atorvastatin orally at a dosage of 10 mg/kg body weight of rat per day, while Group IV received HFD and ACEN at a dose of 300 mg/kg body weight per day orally. Upon the conclusion of the 30-day study period, the rats were fasted overnight. Subsequently, the rats were anesthetized using diethyl ether, and blood samples were collected from the retro orbital venous plexus. These blood samples were promptly transferred to sterile plain tubes to conduct biochemical tests [20–22].

Atherogenic index

The atherogenic index of serum (AIS) is the measure of the extent of atherosclerotic lesions based on serum lipids. The atherogenic index was calculated using following formula [23]:AIS=TC-HDLHDLwhere TC = concentration of total cholesterol in mg/ml. HDL = concentration of HDL in mg/ml.

Histology of the aorta

The rats were killed by cervical decapitation. Their aortas were dissected out carefully. The aortas were stored in 10% formaline solution and sent to a local pathological laboratory for hematoxylin and eosin staining.

Statistical Analysis: The outcomes were presented as the mean accompanied by the standard error of the mean (SEM). Statistical analysis involved the utilization of analysis of variance (ANOVA). A significance level of $p<0.05$ was employed as the threshold for determining statistical significance.

Results

Evaluation parameters for callus

The callus cultures were developed with 2% 2,4 D concentrations using leaves explant. Callus index is a parameter used to access the growth rate of the tissue. Callus index was calculated using following formula [24]:Callusindex=n∗GN∗100where *n* = total number of callused explants. *G* = Average weight of callus rating on explant. *N* = Total number of cultured explants.

The callus index was 54.075 indicating good callus culture growth. The % practical yield for callus extract was 7.45% w/w.

Phytochemical analysis

The liquid chromatography–mass spectrometry (LC–MS) data revealed presence of terpenoids like Asiatic acid, 2-Oxo-5,11(13)-eudesmadien12,8-olide, Cucurbitacin B, Cucurbitacin E, (+)-cis-5,6-Dihydro-5-hydroxy4-methoxy-6-(2-phenylethyl)-2H-pyran-2-on, Ganoderic acid C, Asiatic acid, (3beta,19alpha)-3,19,23,24-Tetrahydroxy-12-oleanen-28-oic acid, while flavonoids like Genistin, Allixin, Quercetin, Liquiritic acid on majority. Figures 1 and 2 are the chromatograms of Arjuna callus extract.

The chromatogram of callus extract for positively charged compounds

Fig. 2 [Images not available. See PDF.]

Chromatogram of callus extract for negatively charged compounds

Evaluation of ACEN

As per Figs. 3, 4, and 5, the Fourier transform infrared (FTIR) graphs confirmed the compatibility of Arjuna callus extract with polymer PVP K30.

Fig. 3 [Images not available. See PDF.]

FTIR of callus extract

Fig. 4 [Images not available. See PDF.]

FTIR of physical mixture of callus extract and PVP K30

Fig. 5 [Images not available. See PDF.]

FTIR of nanosuspension of callus extract

The size of the nanoparticles ranged from 304.4 to 544.1 nm, with a polydispersity index between 0.37 and 0.42. Additionally, the zeta potential ranged from -25.6 to -45.6, indicating that the nanosuspension is stable [25].

The % drug release study revealed that the N4 batch exhibited the lowest release, with 91.58 ± 0.06% over 35 min. On the other hand, the N9 batch demonstrated the highest % drug release with 99.40 ± 0.008% over 35 min among all batches. The % drug release data were fitted to standard release equations—zero order, first order, Higuchi model, Hixson, and Kor's peppas. The linear correlation coefficient *R* square values for all batches are summarized in Table 5. All batches followed first order of kinetics.

Table 7 confirms the optimization of Arjuna callus extract nanosuspension batch.

Stability studies were done for optimized batch N9 as per ICH guideline. Acceleration stability study intermediate storage condition was changed from 30 ± 2 °C and 60 ± 5% RH, and results are shown in Table 8 and Fig. 15. There was slight increase in particle size from 340 to 347.9 nm on day 90. The % drug content and % drug release were almost unchanged.

Antilipase assay

The IC50 for standard drug Orlistat was 53.58, while for ACEN was 78.69. The highest % inhibition of pancreatic lipase enzyme for Orlistat was 83.63 at 100 µg/ml, while for ACEN was 78.69 at 100 µg/ml with *p* value <0.0001.

Antioxidant activity

The IC50 value for the standard drug sample, ascorbic acid, was 137.57, while for ACEN, it was 42.49. Remarkably, ACEN exhibited a percentage inhibition surpassing that of ascorbic acid, and this trend was observed to intensify with higher concentrations. The p-value of 0.0009 represents the statistical significance of these results [26].

Animal study

According to Fig. 18, the body weight of rats increased in all groups throughout the experiment, except for the normal group. The control group exhibited the most significant increase in body weight on the 15th and 30th days when compared to the normal group. The body weights of the standard and ACEN-treated groups were lower than the control group, but were similar to the standard group.

Figure 19 shows the lipid profile of all groups. The control group exhibited an increase in total cholesterol (TC) levels compared to the normal group. However, there was a slight decrease in TC levels in both the ACEN-treated and standard groups when compared to the control group. The control group showed a decrease in TG levels, while the ACEN-treated and standard groups maintained stable levels, similar to the normal group. The control group had lower levels of HDL, while the ACEN-treated group had slightly higher levels. Low-density lipoprotein (LDL) level was increased in the control group but was maintained in ACEN-treated group as that of normal. Very low-density lipoprotein (VLDL) levels were elevated in the control group but remained relatively stable in the ACEN-treated and standard groups, approaching levels similar to the normal group. The data underwent ANOVA, and it confirmed its statistical significance with a *p*-value of less than 0.0001.

Atherogenic index (AIS)

The AIS for the ACEN group was less than the control group and almost similar to that of standard group. In a study involving rats that fed with HFD diet for 30 days, the AIS increased from 0.373278 in the normal group to 1.48455 in the control group ($p<0.0001$). However, in the ACEN group, the AIS was 1.09205, which was like the standard group, with a value of 1.0563.

Histology of the aorta

In the control group, there was a noticeable narrowing of the aortic lumen due to lipid deposition. Conversely, in rats

treated with ACEN, the aortic lumen appeared almost identical to that of the normal group. Additionally, the standard group's rats exhibited more significant atherosclerosis-related narrowing of the aortic lumen compared to the ACEN-treated group (Figs. 21, 22, 23, 24).

Discussion

Phytochemical analysis

The callus cultures are known to exhibit the phytoconstituents that are not present in mother plants naturally [27]. The LC–MS data showed the presence of terpenoids like (3beta, 19alpha)-3,19,23,24-tetrahydroxy-12-oleanen-28-oic acid, 3-[4-Hydroxy-3-(3-methyl-2-butenyl)phenyl]-2-propenal which are absent in Arjun tree naturally [8] (Table 1).

Table 1. Phytoconstituents of callus and their pharmacological activity

Name of compound	Pharmacological activity
4-Hydroxy-L-threonine	It plays a crucial role in facilitating healthy fat metabolism within the liver, supporting the smooth functioning of the digestive and intestinal systems, and promoting efficient metabolic processes and assimilation [38]
Allixin	Antioxidant, antiatherogenic, anticancer activity [39, 40]
Genistin	Antioxidant, antiadipogenic and antilipogenic agent [41]
Ellagic acid	Antioxidant, anti-inflammatory, antimutagenic, antiproliferative, antiallergic, antiatherosclerotic, cardioprotective, hepatoprotective, nephroprotective, and neuroprotective property [31, 42]
Quercetin	Reduces oxidative stress, inhibits low-density lipoproteins oxidation and platelet aggregation, and acts as vasodilator in blood vessels [43]
Calophyllum B	Anti-inflammatory activity [44]
Candoxatrilat	Endopeptidase inhibitor, useful in congestive heart failure [45]
(R)-Heraclenol	Inhibits histidine biosynthesis selectively and shows antibacterial activity [46]
2-Oxo-5,11(13)-eudesmadien12,8-olide	Anti-inflammatory, antiparasitic, antiviral, and cytotoxic activity [47]
Austrobailignan 7	Anticancer activity [48]
Schleicherastatin 6	Anticancer activity [49]

Mitoxantrone	Anticancer, anti-inflammatory activity and inhibits IFN-γ, TNF-α, and IL-2 [50, 51]
Paeonilactone C	Neuroprotective and antioxidant activity [52, 53]
Teasterone	Anti-inflammatory activity [54]
(5x,6x)-5,6-Epoxyergosta-7,22-dien-3-ol	Antioxidant and anti-inflammatory activity [55]
Convallasaponin	Tumor-specific cytotoxic activity [56]
Campesteryl ferulate	Antioxidant activity, hypolipidemic effect, elevation in HDL cholesterol level, suppression of platelet aggregation, and inhibition of tumor promotion [32]
Smilagenone	In cognitive impairment treatment [57]
(25R)-5beta-spirostan-3beta ol	Lowers bold cholesterol level [58]
Cucurbitacin B	Anti-inflammatory, antioxidant, in treatment of neurodegenerative diseases, diabetes mellitus, and cancers, decreases lipid accumulation and antiatherosclerotic [33, 34]
Euphornin	In cancer treatment [59]
Pyropheophorbide a	In cancer treatment [60]
Cucurbitacin E	Anti-inflammatory, antiangiogenic, immunomodulatory, cytotoxic, cytostatic, and hepatoprotective property [61]
Ciclesonide	In treatment of asthma [62]
Methyl 3b-hydroxy-13(18)-oleanen-28-oate	Antiosteoporotic activity [63]
Schleicherastatin 6	In treatment of cancer [64]
1-O-Galloylpedunculagin	Antioxidant activity [65, 66]
(+)-cis-5,6-Dihydro-5-hydroxy4-methoxy-6-(2-phenylethyl)-2H-pyran-2-on	A triterpenoid, pharmacological activity not know yet

Ellagic acid	It affects lipid metabolism by promoting cholesterol efflux and decreasing LDL uptake, while also possessing antioxidant, liver-protective, antisteatotic, anticholestatic, antifibrogenic, antihepatocarcinogenic, and antiviral activity [31]
Ganoderic acid C	Anti-inflammatory (inhibition of TNF α) activity [35, 36, 67]
Ceanothic acid	Anticancer and antimicrobial activity [68, 69]
Asiatic acid	Antioxidant, anti-inflammatory and antihyperlipidemia activity [37, 70]
Azukisapogenol	Antibacterial and antifungal activity [71]
Liquiritic acid	Atheroprotective, anti-inflammatory activity [72, 73]
(3beta,19alpha)-3,19,23,24-Tetrahydroxy-12-oleanen-28-oic acid	A terpenoid showing similar chemical structure to arjunic acid and arjunin acid whose pharmacological activity is not known yet

Evaluation of ACEN

Considering Fig. 3, 4, and 5, the alkyn –OH stretching at 3300, alkyl C–H stretch at 2925 and 2855, C=O stretch at 1746 and 1642, C–O at 1000–1300 were preserved in the mixture IR spectra, indicating the compatibility of the callus extract with PVP K 30 (Table 2).

Table 2. Batches of nanosuspension

Batch	Concentration PVPK30 (% w/v)	Mixing speed (rpm)
N1	1	1000
N2	1.5	1000
N3	2	1000
N4	1	1500
N5	1.5	1500
N6	2	1500
N7	1	2000
N8	1.5	2000

N9	2	2000

Considering two independent factors concentration of polymer PVPK30 (1,1.5, and 2%) and mixing speed (1000, 1500, and 2000) at three levels each, 9 batches were analyzed using design of experiment software version 6 (Fig. 6). The analysis employed a linear model (Table 3) to examine the correlation between polymer concentration and mixing speed regarding particle size of ACEN. We confirmed the significance of the data input with an *F*-value of 6.16. In Table 4, we observed a negative coefficient for both polymer concentration and mechanical stirring speed. A positive sign denotes a synergistic effect, while a negative sign indicates an antagonistic effect. The interaction plots (Figs. 7, 8, 9, 10, 11) illustrated that the relative slopes of factors—particle size, polydispersity index, zeta potential, % drug content and % drug concentration—displayed a significant interrelation with both polymer concentration and mechanical stirring speed. The % drug content across all formulations ranged from 96.2 ± 0.38 to 99.75 ± 0.46%. Additionally, the range of % drug entrapment was between 94.67 ± 0.02 and 98.92% ± 0.03. This discrepancy from the % drug content suggests the possibility of drug dissolution in the aqueous phase.

% Drug release study

The analysis of variance (ANOVA) identified 10 potential solutions based on the criteria outlined in Table 6. The combination of 2% PVP K30 and a mechanical stirring speed of 2000 rpm scored 0.917 desirability. The batch optimization is evident from Table 7. The transmission electron microscopy image displayed the nanoscale dimensions and encapsulation of Arjuna callus extract within a polymer matrix (Figs. 13, 14).

Table 6. Constrains for optimization of nanosuspension

Name	Goal	Lower limit	Upper limit	Lower weight	Upper weight	Importance
A:Polymer concentration	Is in range	1	2	1	1	3
B:Speed of rotation	Is in range	1000	2000	1	1	3
Particle size	Minimize	304.4	544.1	1	1	4

Transmission electron microscope image of ACEN

The N9 sample did not change physical appearance throughout the acceleration stability study. As per results discussed in Table 8 and Fig. 15, we found that there was slight increase in the size of nanoparticle, but it was within acceptable limit. The slight increase in particle size of ACEN did not affect the % drug content of % drug release.

Table 8. Acceleration stability studies for N9 batch

Period	Particle size (nm)	PDI	% Drug content

15 days	341.5	0.399	99.66 ± 0.3
30 days	341.7	0.399	99.63 ± 0.4
60 days	345.1	0.340	99.60 ± 0.7
90 days	347.9	0.340	99.57 ± 0.1

Antilipase assay

Hyperlipidemia exhibits strong associations with various metabolic conditions, including diabetes, atherosclerosis, and hypertension. Within the duodenum, pancreatic lipase plays a pivotal role in the digestion and absorption of lipids, breaking down triacylglycerols into monoacylglycerols and fatty acids. The pancreatic lipase inhibitors have a potential to induce hypolipidemic effects, offering a promising atherosclerosis management [28, 29]. We found that the % inhibition of lipase enzyme by ACEN was concentration dependent (Fig. 16). The antilipase activity of ACEN might be due to presence of 4-Hydroxy-L-threonine, Genistin, Cucurbitacin B, Ganoderic acid C, Asiatic acid, Ellagic acid, Campesteryl ferulate. This could be one of the antiatherosclerotic mechanisms of ACEN.

Fig. 16 [Images not available. See PDF.]

Antilipase assay for ACEN

Antioxidant activity

Antioxidants play a pivotal role in the treatment of atherosclerosis through a range of mechanisms. These mechanisms encompass the inhibition of LDL oxidation, the reduction production of reactive oxygen species, the suppression of cytokine secretion, the prevention of atherosclerotic plaque formation, prevention of platelet aggregation, the hindrance of mononuclear cell infiltration, the enhancement of endothelial function and vasodilation, the promotion of nitric oxide (NO) bioavailability, the modulation of adhesion molecule expression (e.g., VCAM-1 and ICAM-1) on endothelial cells, and the mitigation of foam cell formation. The effectiveness of these diverse antioxidant actions remains an open question, but it appears that a multi-antioxidant approach may offer a more effective strategy for antioxidant therapy. We found the ACEN shows better antioxidant activity that standard drug ascorbic acid (Fig. 17). The presence of various compounds, including Allixin, Genistin, Ellagic acid, Quercetin, Paeonilactone C, (5x,6x)-5,6-Epoxyergosta-7,22-dien-3-ol, Campesteryl ferulate, and others, is likely responsible for the observed antioxidant activity of ACEN [19, 30].

Fig. 17 [Images not available. See PDF.]

Antioxidant activity assay of ACEN

Animal study

Figure 18 summarizes the body weight of animals during the study (Fig. 18). We discovered that ACEN was more effective than the standard drug atorvastatin at decreasing TC, TG, HDL, LDL, and VLDL (Fig. 19). Ellagic acid plays a role in lipid metabolism by promoting cholesterol efflux and reducing LDL uptake. The terpenoids, such as Ellagic acid and Asiatic acid, are known for their potential in managing hyperlipidemia. The potential cause of ACEN's lipid-lowering effect could be attributed to the presence of these terpenoids. [31–37].

Fig. 18 [Images not available. See PDF.]

Summary of body weight of animal groups at 0, 15, and 30 days

Fig. 19 [Images not available. See PDF.]

Summary lipid profile of animal groups

Atherogenic index of serum

The AIS is a measure of the potential risk of developing atherosclerosis. When the AIS is higher, there is a greater potential for atherosclerosis and an increased likelihood of cardiovascular disease. It is important to note that the AIS is influenced by the levels of HDL. When HDL levels are higher, the atherogenic index is lower, reducing the risk of atherosclerosis [23]. From Fig. 20, we found that the AIS of ACEN (1.05 ± 0.035) was slightly lesser than the AIS of standard drug atorvastatin (1.06 ± 0.053) emplacing the antiatherosclerotic potential of ACEN (Figs. 21, 22, 23, 24).

Histology of the aorta

The histopathological results confirmed the antiatherosclerotic potential of ACEN. The presence of phytoconstituents in ACEN like Ellagic acid, Quercetin, Calophyllum B, (25R)-5beta-spirostan-3beta ol Liquiritic acid known for their lipid-lowering, antioxidant, and anti-inflammatory properties, may be responsible for its antiatherosclerotic effect. The histopathological analysis demonstrated that nanotherapeutics exhibited superior efficacy when compared to the standard drug Atorvastatin, highlighting the enhanced effectiveness of the callus extract attributed to its nanoformulation. Altogether, the comprehensive study has affirmed ACEN's potential in atherosclerosis treatment.

Conclusion

A thorough analysis of phytochemical composition of the callus extract predominantly revealed the presence of flavonoids and terpenoids, endowed with antioxidant, hypolipidemic, and anti-inflammatory activity. The callus culture extract was then transformed into a nanosuspension to achieve better efficacy of the medicament. The optimized nanosuspension formulation was subjected to comprehensive in vitro and in vivo studies, aimed to confirm its antiatherosclerotic potential. The study findings suggest that ACEN has the potential to be a natural-origin drug for the treatment of atherosclerosis.

Acknowledgements

The authors gratefully thank to Dr. Babasaheb Ambedkar Central Nursery Kagal, India; Seema Biotech, Pvt Ltd, Warananagar, India; Indian Institute of Technology, Bombay; Shivaji University, Kolhapur; Appasaheb Birnale College of Pharmacy, Sangli, Indian and Rajarambapu College of Pharmacy, Kasegaon, Sangli, Dr Shivajirao Kadam, College of Pharmacy, Digraj, India, for materials and technical assistance.

Author contributions

All authors contributed to the study conception and design. Material preparation, data collection, and analysis were performed by PPW. The first draft of the manuscript was written by PPW, and all authors commented on previous versions of the manuscript. All authors read and approved the final manuscript.

Funding

The authors declare that no funds, grants, or other supports were received during the preparation of this manuscript.

Availability of data and materials

The data for graphs 12 to 16 are available on request.

Declarations

Ethics approval

This study was performed in line with the principles of laid down by Institute Animal Ethics Committee. Approval was granted by the Ethics Committee of Appasaheb Birnale College of Pharmacy, Sangli (Date 20/01/2022 /No IAEC/ABCP/13/2021–22).

ABSTRACT (ENGLISH)

Background

The objective of this current research was to enhance the topical delivery of Nadifloxacin (NDFX) by incorporating it into a transethosomal gel formulation. NDFX has limited penetration into the deep layer of the skin because it is poorly water soluble and it has a log p value of 2.47. To optimize the formulation, the “Box–Behnken design” was utilized. The independent variables included phosphatidylcholine 90, tween 80 and ethanol. The produced formulations underwent evaluation for entrapment efficiency, vesicle size and zeta potential. The optimized formulation was then incorporated into suitable gel bases and subjected to further investigation, including in vitro diffusion, ex vivo penetration, in vitro antimicrobial assay and in vivo anti-acne activity.

Results

The optimized formulation exhibited an entrapment efficiency of 80.12%, a vesicle size of 156.1 nm and a zeta potential of−33.23 mV. TEM images confirmed the presence of encapsulated vesicles with a spherical shape. The in vitro diffusion study demonstrated that the transethosomal gel containing Carbopol 934 (1%) exhibited higher drug release compared to the HPMC K4M gels. Furthermore, the ex vivo permeation study revealed that the optimized transethosomal gel demonstrated increased permeation compared to the commercially available formulation.

Conclusion

The optimized transethosomal formulation displayed enhanced in vitro antimicrobial and in vivo anti-acne effects against *Propionibacterium acnes* in Wistar albino rats when compared to the marketed formulation.

FULL TEXT

Background

Skin disorders are one of the most prevalent illnesses; skin problems afflict thousands of individuals every day and can affect anyone at any age. It was primarily brought on by various infectious bacteria or inflammatory diseases. Skin conditions include a wide range of symptoms and severity. Some may have environmental causes, while others may have genetic or dependent reasons [1]. Several infectious diseases affect the skin and hair follicles and are brought on by bacterial, fungal or viral infections. These illnesses result in skin eruption [2].

Acne vulgaris is a persistent skin disorder that affects the pilosebaceous glands of hair follicles. Comedones, inflamed papules and pustules, nodules &cysts and scaring are the different types of acne lesions. Acne vulgaris is characterized by skin with comedone and seborrhea, which is caused due to several factors: hyperkeratosis, heightened sebum production induced by androgens, inflammation and bacterial colonization of hair follicles on the face, neck, chest and back by Propionibacterium acnes. A "whitehead" is a closed comedone and a "blackhead" is an open comedone; the black color is caused due to melanin. The comedo is a non-inflamed lesion that typically recurs on its own with minimal or discolored scarring [3].

Nadifloxacin (NDFX), 7-fluoro-8-(4-hydroxy-piperidin-1-yl)-12-methyl-4-oxo-1-azatricyclo- trideca-2,5,7,9 (13)-tetraene-3-carboxylic acid (Fig. 1), is a fluorinated quinolone antibiotic and is commonly used as a topical medication for the treatment of numerous inflammatory acne lesions. It is highly effective against *P. acness* and other gram-negative and gram-positive bacteria. In addition to its antibacterial effects, NDFX has been reported to have anti-inflammatory effects, which may help with some elements of inflammatory acne [4].

Fig. 1 [Images not available. See PDF.]

Structure of Nadifloxacin

For the treatment of acne, 1% w/w Nadifloxacin topical cream is available in the market. Unfortunately, NDFX, characterized by its low solubility in water, is a fluoroquinolone compound that possesses a log P value of 2.47 and due to the large droplet size of topical creams, NDFX has shown limited penetration into the deep layer of the skin [5], resulting in poor patient compliance and adherence to NDFX topical regimen. Several methods, including nanocarrier-based formulations and Novel lipid vesicles, referred to as ultra-deformable vesicles (UDV), like ethosomes, transferosomes and transethosomes, have already been researched to enhance the targeted administration of cosmeceuticals and pharmaceuticals [6, 7].

Transferosomes are vesicular carriers characterized by their elastic properties and lipid bilayer structure. These carriers incorporate an edge activator, which is a biocompatible surfactant. However, a significant limitation of this formulation is the challenge of effectively loading hydrophobic drugs into these vesicles without compromising their elasticity [8]. On the other hand, ethosomes are vesicular carriers composed of hydro-alcoholic phospholipids with a high concentration of alcohol. While ethosomes offer certain advantages, such as simple, passive and non-invasive drug delivery with enhanced permeation through the skin, and targeting to deeper skin layers for various skin diseases, they also have a significant disadvantage. When ethosomes applied to the skin in a non-occlusive state, it tends to cause skin dehydration due to the evaporation of ethanol from the formulation [9].

Transethosomes are ultra-deformable vesicles that are a combination of transferosomes and ethosomes and will overcome the disadvantage of both. Transethosomes, alternatively referred to as ultra-deformable liposomes, possess an irregular spherical structure and exhibit remarkable elasticity. They possess the capability to effectively encapsulate drugs with varying molecular weights, encompassing both low and high molecular weight compounds. Transethosomes structure is composed of a phospholipid, edge activator and ethanol. Phospholipid functions as a carrier for drug molecules to pass through the skin. The edge activator, a biocompatible polymer, serves as the agent responsible for softening the vesicles. It imparts flexibility to the vesicles and acts as the permeation enhancer. Ethanol gives a unique identity to the transethosomal vesicles; it deforms the epidermis layer and allows these nanocarriers to penetrate deeply into the stratum corneum through tiny openings caused by fluidization. The utilization of ethanol along with an edge activator results in the reorganization of the lipid bilayer, enhancing its flexibility and enabling it to effectively permeate the deeper layers of the dermis [10].

Hence, in the present study, a transethosomal-based gel was chosen as the carrier for the effective transdermal delivery of NDFX. However, as per the literature review, no DOE-based transethosomal formulation with improved penetration and effectiveness has been reported for NDFX. Therefore, the primary objective of the present study was to create and enhance transethosomes loaded with NDFX, employing the Box–Behnken experimental design. The formulations underwent characterization to determine their vesicle size, zeta potential, entrapment efficiency and in vitro diffusion properties. The optimized formulation was then assessed for ex vivo permeation, in vitro

antimicrobial assay and in vivo anti-acne effects using an animal model induced with *P. acnes*.

Materials and methods

Materials

NDFX was acquired as a complimentary sample from Wockhardt Research Centre, located in Aurangabad, India. Soya Phosphatidylcholine-90 was acquired as a complimentary sample from Lipidome Lifesciences, based in Ahmedabad, India. Tween 80 was procured from Hi-Media Laboratories, Pvt. Ltd. (Mumbai, India). Ethanol was procured from S.D. Fine Chem Ltd (Mumbai, India). Carbopol 934 was obtained from LOBA Chemie Pvt. Ltd, located in Mumbai, India. Methanol and chloroform were acquired from Fisher Scientific, India. All remaining chemicals utilized were of analytical grade.

Experimental animal

Wistar rats either male or female weighing from 150 to 200 gm were selected for the study. Before commencing the study, necessary authorization and endorsement were obtained from the Institutional Animal Ethics Committee (IAEC) and the Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA), under the Reg. No. 221/Po/Re/S/2000/CPCSEA, during their meeting on 03/12/2022.

Methods

Preparation of NDFX-loaded transethosomes

The cold method was employed for developing NDFX-loaded transethosomes. This method involves mixing of two phases at low temperature (30 °C) in a water bath. In this method aqueous phase (edge activator + water) is added to organic phase (ethanol + phospholipid) with continuous stirring in order to form the vesicles. This method is most widely used for thermo-labile drugs, and it is easily scalable [10].

Soya phosphatidylcholine 90 (phospholipid), Tween 80 (surfactant) and Nadifloxacin (1% w/w) were dissolved in ethanol at a temperature of 30 °C, forming the organic phase. Simultaneously, the aqueous phase (consisting of Millipore water) was heated to 30 °C. The aqueous phase was then added drop by drop to the organic phase, while the mixture was continuously stirred at a speed of 1200 revolutions per minute using a magnetic stirrer (RCT Basic IKA, India). The stirring was continued for 45 min to get the transethosomal dispersions. Thereafter, transethosomal dispersion was ultrasonicated using a probe sonicator (SONICS® VCX 750, USA). The formulation was then refrigerated at 4 °C until further characterization [11].

Optimization of NDFX-loaded transethosomes by Box–Behnken design (BBD)

Based on the literature review, several parameters have been identified that may influence the ideal characteristics of transethosomes for topical delivery and it was found that three variables (factors) such as phospholipid, tween 80 and ethanol concentration might have a direct impact on the critical transethosome characteristics required for successful topical administration. The response surface methodology utilized the Design Expert software to construct a Box–Behnken design consisting of three factors with three levels each (3^3). This experimental design, generated with the software, comprised a total of 17 runs, including 5 repeated center points, and the resulting outcomes were subsequently measured. By employing the Box–Behnken design, the study aimed to examine the impact of phospholipid, surfactant and ethanol concentrations on dependent variables, namely entrapment efficiency, vesicle size and zeta potential. Table 1 shows the independent and dependent elements chosen for the experimental design. The NDFX-loaded transethosome vesicles were tested for vesicle size, entrapping efficiency and zeta potential [12].

Table 1. Independent factors with their levels and dependent factors with their constraints in Box–Behnken design for the development of NDFX-loaded transethosomes

Factors	Levels		
Low	Medium	High	*Independent factors*

A. PC90 (%)	2	3	4
B. Tween 80 (%)	0.2	0.3	0.4
C. Ethanol (%)	20	25	30
Dependent factors			
Entrapment E. (%)	Maximize		
Vesicle size (nm)	Minimize		
Zeta potential (mV)	Maximize		

Evaluation of NDFX-loaded transethosomes

Particle size, polydispersity index and zeta potential

The Malvern zeta sizer (Malvern Instruments, Worcestershire, UK) was utilized to ascertain the particle size, polydispersity index and zeta potential of the transethosomes. The measurements were taken at a constant angle of 90° and a temperature of 25±2 °C. To facilitate the analysis, the samples were diluted in millipore water and the measurements were taken in triplicate. These parameters provide information regarding the size, homogeneity and stability of the vesicles [13].

Entrapment efficiency

The ultra-centrifugation technique was used for estimating the entrapment efficiency of transethosomal formulations. Two milliliters of each formulation was transferred into a microcentrifuge tube and was subjected to ultracentrifugation at 4 °C by an Ultracentrifuge (Kubota, Japan). Following that, the supernatant was extracted with a micropipette and diluted with methanol to rupture the vesicles. A UV spectrophotometer (Shimadzu -1900, Japan) was used to measure the quantity of drug in the supernatant at 295.0 nm [14].

The following formula was used to compute the % EE.%EE=Totaldrugcontent-UnentrappeddrugTotaldrugcontent×100

Surface morphology of optimized transethosomes

Transmission electron microscopy (TEM) was employed to examine the morphology of the prepared transethosomes. To summarize the procedure, a small amount of the diluted transethosomes sample was deposited onto a copper grid and left to air-dry. Once dried, the sample was treated with a 1% w/v solution of phosphotungstic acid for fixation and subsequently subjected to TEM analysis, with accompanying photographs captured [15].

Stability studies of optimized formulation

To determine the stability of the optimized transethosomes, short-term stability studies were conducted in compliance with ICH GCP guidelines. The prepared formulation was stored in glass vials within a humidity-controlled oven maintained at a temperature of 25±2 °C and a relative humidity of 65±5%. Additionally, it was refrigerated at 4 ±2 °C with a relative humidity of 65±5%. At regular intervals of 0, 15, 30 and 90 days, a sample was extracted for analysis [11].

Preparation of transethosomal gels

The preliminary studies were carried out, the gel was formulated through the dissolution of Carbopol 934 in purified water while stirring continuously; and the pH was adjusted to 6–6.5 by incorporating a 10% solution of triethanolamine. HPMC K4M was dispersed in purified water and left overnight. To create the transethosomal gel, the previously prepared transethosomal dispersion was incorporated into the gel in a 1:1 ratio with adequate stirring. The formulation details for gel bases are provided in Table 2 [16, 17].

Table 2. The composition of different gel bases

Ingredients	TEG 1	TEG 2	TEG 3	TEG 4
Carbopol 934 (% w/w)	1	2	–	–
HPMC K4M (% w/w)	–	–	2	3
Methyl paraben (% w/w)	0.02	0.02	0.02	0.02
Propyl paraben (% w/w)	0.01	0.01	0.01	0.01
Propylene glycol (%w/w)	1	1	1	1
Triethanolamine (%v/w)	q.s	q.s	–	–
Distilled Water (% w/w)	Up to 100	Up to 100	Up to 100	Up to 100

Evaluation of transethosomal gels

Determination of pH

In order to ascertain the pH of multiple gels, a digital pH meter was employed. Firstly, 500 mg of pre-prepared transethosomal gels was dissolved in 20 milliliters of distilled water. The resulting mixture was stirred for a duration of 30 min at room temperature using a magnetic stirrer. Subsequently, the pH sensor probe electrode was immersed in the dissolved gel and the pH value of the formulation was recorded from the digital screen [17].

Determination of viscosity

The viscosity of the optimized transethosomal gel formulation was estimated using a Brookfield viscometer. After applying the transethosomal gel formulation, it was allowed to settle for 5 min. After that, spindle number one was revolved at 50 revolutions per minute at a temperature of 25 ± 2 °C [18].

Determination of spreadability

The spreadability of the transethosomal gel was assessed using the glass slide technique. A precisely measured 1.0 g of gel was positioned at the center of a glass slide measuring 10 × 5 cm. Another slide of the same dimensions was placed on top of it. To ensure uniform compression and maintain a consistent thickness, a weight of 100 g was applied to the upper slide for a duration of 5 min. The time required for the glass slide to move 6 cm and separate from the lower glass slide was recorded [19, 20]. The spreadability of the gel was then calculated using the following formula:S=M.L/Twhere '*S*' represents Spreadability, '*M*' represents the weight applied to the upper slide, '*L*' represents the distance traveled by the slide (6 cm), and '*T*' represents the time taken in seconds.

Determination of drug content

In a 50-ml volumetric flask, 1 gm of gel was dissolved with 50 ml methanol. The solution underwent sonication in a bath until a transparent solution was achieved. Subsequently, the solution was filtered through a 0.45-μm filter and appropriately diluted using methanol. The drug concentration was determined by measuring absorbance with a UV spectrophotometer at the wavelength of 296 nm, using methanol as the reference solution [19].DrugContent=Actual drugcontentinvesiclesTheoreticaldrugcontentinvesicles×100

In vitro drug diffusion study

The Franz diffusion cell was utilized to determine the in vitro diffusion of drugs from different transethosomal gel formulations. To activate the dialysis membrane, it was previously soaked in pH 7.4 buffer. The receptor chamber was then filled with 12 ml of phosphate buffer at pH 7.4, which served as the medium for diffusion in the receptor compartment. The gel formulation, equivalent to 2 mg of the drug, was accurately weighed and thronged in the preactivated dialysis membrane. Throughout the experiment, the receptor medium was maintained at a temperature of 37 ± 2 °C and stirring was consistently performed at 100 rpm. At specific time intervals of 0.5, 1, 2, 4 and 8 h,

0.5 ml samples were withdrawn from the cell and replaced with fresh medium. The quantification of drug release was carried out using a UV spectrophotometer at a wavelength of 291 nm [21].

Ex vivo permeation study

A preliminary study was conducted to examine skin permeation using rat skin and the Franz diffusion cell, which had an effective permeation area of 1.76 cm^2. Prior to the permeation study, the rat skin underwent a preparation process. Initially, the hair on the skin was eliminated using an electronic trimmer, followed by the removal of subcutaneous tissue through surgical means. Isopropyl alcohol was used to remove the fat from the dermis side of the skin. Afterward, the skin was washed with PBS and stored at − 20 °C in a deep freezer until it was ready for use. During the experiment, rat skin was affixed onto a diffusion cell with the dermis side facing the receiver compartment and the stratum corneum side facing the donor compartment. The receiver compartment contained a medium of PBS with a pH of 7.4. The temperature in the receiver compartment was maintained at 37 ± 0.5 °C, and throughout the experiment, it was stirred using a magnetic bead at a speed of 100 rpm. At predetermined time intervals of 0.5, 1, 2, 4 and 8 h, 0.5 ml samples were withdrawn and replaced with fresh medium. The collected samples were then analyzed for drug content using a UV spectrophotometer [22].

In vitro anti-bacterial study

Zone of inhibition The cup plate technique was used to investigate the zone of inhibition of prepared NDFX-loaded transethosomal gel against *Propionibacterium acne.* The Mueller–Hinton agar plates were prepared and sterilized at 121 °C and at a pressure of 15 lb. for 20 min. Subsequently, 25 ml of Mueller–Hinton agar was carefully poured into each Petri dish, allowing it to solidify. Following that, the Petri dishes were streaked with a suspension of Propionibacterium acne. Using a cork borer, four holes, each measuring 6 mm in diameter, were created on every plate. In each of these holes, the following substances were placed: a transethosomal formulation loaded with NDFX at a concentration of 10 µg (test), a commercially available NDFX cream at a concentration of 10 µg (standard), 100 µl of a blank transethosomal formulation (blank) and a negative control consisting solely of the vehicle (ethanol and buffer). The plates were incubated at 37 °C for 48 h in an anaerobic condition. The zone of inhibition was measured, and the antimicrobial activity of each formulation toward the *P. acnes* was investigated [23–25].

Animal study

Skin irritation study

A skin irritancy test was conducted on the hairless backs of Wistar rats weighing between 180 and 250 g. The purpose of the test was to determine the irritant or toxic effects of the formulated transethosomal gel on the skin. The animals were segregated into two distinct groups, with each group consisting of six test subjects, as indicated in Table 3. Group I received an application of Optimized NDFX transethosomal gel, whereas Group II received blank transethosomal gel. Prior to the application of gel, the dorsal region of the Wistar rat was trimmed using an electronic trimmer to remove the hair, followed by the application of gel onto the hairless area measuring 5 cm^2. A thorough examination was conducted on the rat's skin to identify any signs of erythema and edema. After 1 h, 24 h, 48 h and 7th day of application of test substances, finally, as per the Draize protocol the scoring was given and the skin irritancy potential of the formulated transethosomal gel was determined [26–28].

Table 3. Experimental design for in vivo skin irritancy study

Sr no	Group	Treatment	No. of animals	Total no. of animals
1	GROUP I	Control gel—Blank Transethosomal gel (without NDFX)	6	12

Anti-acne study

Animal model

Wistar albino rats either male or female weighing between 150 and 200 g were employed to examine the potential anti-acne effects of a transethosomal gel loaded with NDFX. These rats were acclimated to the prescribed

rehabilitation conditions for a minimum of seven days prior to the experiment.

Bacterial sample

The bacterial strain of *Propionibacterium acne* was cultivated within an anaerobic gas chamber using brain heart infusion (BHI) broth. The culture was incubated for 48 h at 37 °C, after which the BHI agar plate was used for subsequent culturing bacterial strain. A single colony was selected from the BHI agar plate and introduced into a PBS solution. The turbidity of the suspension was assessed using the 0.5 McFarland (1.5×108 CFU/ml) scale. This bacterial suspension is now prepared for injection.

Injection of bacteria

An anesthetized Wistar rat was administered a subcutaneous injection of *Propionibacterium acne* bacterial suspension, measuring 20 µl, into its right ear. As a vehicle control, phosphate buffer saline was injected into the left ear [29].

Treatment approach

To investigate the anti-acne potential of prepared experimental gel (NDFX-loaded transethosomal gel) in animal models, the Wistar rats were categorized into four groups, with each group consisting of six animals, as depicted in Table 4. In each group, the rats received an injection of the aforementioned bacterial suspension of *P. acnes* in their left ear, while their right ear was injected with phosphate buffer saline. Initially, no treatment was given to all the groups for the period of seven days (inducing period). Following a period of seven days with no treatment provided to Group I (disease control), Group II was chosen as the benchmark and subjected to treatment using the commercially available anti-acne formulation known as Nadibact cream (containing 1% w/w active ingredient); Group III and Group IV were treated with the prepared NDFX-loaded transethosomal gel and plain NDFX gel, respectively. The treatment was continued till the 14th day for groups II, III, IV, and the measurement was taken using a Vernier Caliper daily, the ear thickness was measured on a predetermined day, and the formula used to calculate the percentage change in ear thickness is as follows%ΔEarThickness=TAfter-TBeforeTBefore×100where *TAfter* represents the thickness of the auricle subsequent to the injection, while *TBefore* denotes the thickness of the auricle prior to the injection [30].

Table 4. Experimental design for in vivo anti-acne study

Animal groups	Treatment	No of animals	Total animals
Group I	Disease control	6	24
Therapeutic treatment			Group II
Standard (Marketed formulation)	6	Group III	Experimental gel (NDFX-loaded with transethosomal gel)
6	Group IV	Plain gel of NDFX	6

Histopathological investigation

Once the anti-acne study was completed successfully on the 14th day, three animals from each group were chosen at random and killed by euthanasia. Prior to sectioning, the ear was surgically removed and immersed in a 10% formalin solution. Subsequently, the sections were treated with hematoxylin and eosin dye for staining. The stained ear slices were then placed on glass slides and examined using an optical microscope [30].

Post-treatment microbiological assay

Upon successful completion of the anti-acne study, the animals from each group were euthanized and the treated area on the right ear was gently wiped with a cotton swab soaked in ethanol before being excised. The excised ear was then divided into small pieces and homogenized in 5 ml of phosphate buffer saline using a tissue homogenizer. Subsequently, the homogenized saline solution was appropriately diluted. A small portion of the homogenate was extracted and evenly spread onto a sterilized cotton swab, which was used to inoculate a Mueller–Hinton agar plate. The plate was then incubated under anaerobic conditions at 37 °C. The number of colony-forming units (CFUs) present on the agar plate was subsequently counted in order to investigate the pharmacodynamic activity of the formulation [25].

Results

Optimization of NDFX-loaded transethosomes by Box–Behnken design (BBD)

The BBD design was used to optimize the NDFX-loaded transethosomal formulation and investigate the impact of independent factors such as soya phosphatidylcholine 90 (A), Tween 80 (B) and the ethanol (C) concentration on the dependent responses, i.e., entrapment efficiency (Y_1), vesicle size (Y_2), zeta potential (Y_3). The experimental design (BBD) has generated 17 batches with 5 center points. The outcomes derived from these experiments are presented in Table 5. The measured values for the dependent factors, namely entrapment efficiency, vesicle size and zeta potential, ranged from 66.43 to 81.87%, 97.04–356.02 nm and − 17.12 to − 34.34 mV, respectively. The responses were subsequently subjected to statistical analysis through response surface analysis employing ANOVA. By examining the 3D surface plot and polynomial equation, the impact of independent factors on dependent responses was explored. The quadratic model proved to be the most suitable fit for analyzing entrapment efficiency and vesicle size, while the reduced quadratic model was found to be the optimal fit for examining zeta potential. The fit statistics results are given in Table 6 showing satisfactory R^2, adjusted R^2, predicted R^2, S.D. and % C.V. [12, 19].

Table 5. Results of the response of experimental Box–Behnken design for optimization of NDFX-loaded transethosomes

Table 6. Summary of results of regression analysis for the response Y_1 (EE), Y_2 (PS) and Y_3 (Zp)

Responses	R^2	Adjusted R^2	Predicted R^2	S.D	% C.V
Y_1 (EE)	0.9985	0.9965	0.9793	0.6	0.85
Y_2 (VS)	0.9811	0.9568	0.7963	5.78	4.13
Y_3 (ZP)	0.9042	0.8607	0.7028	1.90	6.81

Effect of independent factors on response Y_1 (entrapment efficiency)

In all 17 experimental runs, the EE was found to be in the range of 43.64–81.05%.

1

EE=73.94A+3.33B-9.45C-0.55AB+3.28AC-4.99BC-0.93A2-4.19B2-2.57C2

As per polynomial Eq. (1) and 3D response plot (Fig. 2a), a discovery was made indicating that soya phosphatidylcholine 90 has a favorable impact on the entrapment efficiency of NDFX, while both tween 80 and ethanol were observed to have a detrimental effect on the entrapment efficiency. The progressive enhancement of entrapment efficiency as the concentration of soya phosphatidylcholine 90 increases can be attributed to the lipophilic nature of NDFX. This is because of the affinity of lipophilic drugs toward the lipophilic phase, resulting in their subsequent deposition therein [22].

Fig. 2 [Images not available. See PDF.]

a–c Design Expert generated a 3D response plot of entrapment efficiency (*Y*1), vesicle size (*Y*2) and zeta potential (*Y*3)

In formulations F1 and F10, the entrapment efficiency increases from 54.71 to 67.48% as the concentration of phosphatidylcholine increases from 2 to 4%, respectively. Similar results were found when a comparison was made between formulations F4 and F17.

Entrapment efficiency decreases as the concentration of tween 80 increases. Formulation F13 (tween 80 0.2%) showed an entrapment efficiency of 72.82%, while formulation F4 (tween 80 0.4%) showed an entrapment efficiency of 57.7%. Similar results were found between the formulation F16 (tween 80 0.2%) and F17 (tween 80 0.4%). The

possible cause of this phenomenon is the increased surfactant concentration, which may result in the formation of micelles alongside the vesicles in the formulation; micelles typically exhibit diminished entrapment efficiency in comparison with vesicles. Additionally tween 80 is hydrophilic in nature whose increased concentration may decrease the encapsulation of hydrophobic drug [31].

Ethanol also had an opposite influence on NDFX entrapment efficiency in transethosomes vesicles. Formulation F15 having ethanol concentration 20% showed an entrapment efficiency of 79.95%, while formulation F1 having 30% ethanol showed 54.71% entrapment efficiency. This might be due to the leaking of the transethosomal vesicles at high ethanol concentrations [32].

Effect of independent factors on response Y_2 (vesicle size)

The vesicle size was falling in the range of 97.12–187.34 nm in all 17 batches.

2

Vesiclesize=130.18+21.54A-18.77B-23.28C+6.72AB+2.50AC-1.85BC+14.57A2+4.21B2+2.34C2

Based on polynomial Eq. (2) and the 3D response plot (Fig. 2b), it was observed that soya phosphatidylcholine 90 exhibited a positive impact, while Tween 80 and ethanol had a negative impact on the size of the transethosomes vesicle.

It was discovered that as the concentration of soya phosphatidylcholine 90 was increased from 2 to 4%, the vesicle size was also increased from 100.65 nm (F1) to 142.21 (F6). Similar results were seen with F13 (151.18 nm) and F16 (187.34 nm). The tween 80 was showing an inverse effect in the vesicle size of transethosomes. When the concentration of tween 80 was increased from 0.2 to 0.4%, the vesicle size of transethosomes was reduced from 187.34 nm (F16) to 160.17 (F17). The formulation F3 (173.01 nm) to F6 (142.25 nm) also presented similar results. The vesicle size of the transethosome decreases from 188.51 to 142.21 nm as the ethanol concentration increases from 20% (F12) to 30% (F10). This could be attributed to the fluidizing ability of ethanol on the phospholipid membrane of the vesicles by its interpenetrating hydrocarbon chain as the wall thickness of the vesicular membrane decreases [12].

Effect of independent factors on response Y_3 (Zeta potential)

The zeta potential in all 17 formulations was falling in the range of − 17.12 to − 34.34 mV.

3

Zetapotential=-29.16+6.12A+0.7500B+1.34C+2.38AB+2.78A2

The impact of soya phosphatidylcholine, tween 80 and ethanol concentration on the zeta potential of transethosomal vesicles was noted during the observation. As per the polynomial equation, the zeta potential of the vesicles (Fig. 2c) exhibited a positive impact from all three factors. The zeta potential was observed to be increasing from − 32.25(F1) to − 22.43 (F10) with increasing concentrations of phosphatidylcholine 90 from 2 to 4%. As the concentration of tween 80 was increased from 0.2 to 0.4% the zeta potential was also increased from − 27.74 (F9) to − 24.72 (F11).

The zeta potential is the critical characteristic that influences vesicular features such as the interaction of vesicles with the skin and the stability of transethosomes. According to the findings presented in Table 5, it has been observed that all the formulated transethosomal preparations exhibited a zeta potential characterized by a negative charge. Negatively charged vesicles exhibit superior skin permeability compared to positively charged vesicles [33]. The negative zeta potential observed in transethosomes primarily arises from the presence of ethanol within these nanocarriers. Ethanol induces negative charges on the polar head groups of phospholipids, leading to electrostatic repulsion. This would limit vesicle agglomeration and hence increase the stability of these transethosomal nanocarriers [11].

In the present investigation, the point prediction approach of the BBD design in the response surface methodology was used to optimize the NDFX-loaded transethosomal formulation. The formulation composition of soya phosphatidylcholine (2.03%), Tween 80 (0.3%) and ethanol (20%) met the requirements for an optimal formulation. The optimized formulation had shown an entrapment efficiency of 79.8%, vesicle size of 150.18 nm, zeta potential of − 33.85 mV, and desirability was found to be 0.969. The results of the optimized transethosome formulation are

shown in Table 7 (Fig. 3). All the observed responses of optimized transethosomal formulation close proximity to the value were predicted by Design Expert software.

Table 7. Validation of optimized transethosomal formulation

	Independent variables			Responses			Desirability
PC 90 (%)	Tween 80 (%)	Ethanol (%)	EE (%)	PS (nm)	ZP (mV)	Solution	2.03

a–c Results of optimized NDFX transethosomes formulation (**A**) mean vesicles size distribution curve and (**B**) average zeta potential and (**C**) transmission electron micrograph

Surface morphology of optimized transethosomes

The analysis using transmission electron microscopy (TEM) of the optimized transethosome formulation containing NDFX (Fig. 3c) indicated that the vesicles exhibit a spherical shape, displaying a consistent size distribution and a distinct, tightly sealed structure [21].

Stability studies

The findings from the stability study of optimized NDFX transethosomal formulation are demonstrated in Table 8. It was observed that after the completion of 90-day storage period, there were negligible alterations (p>0.05) in the physical characteristic of transethosomes. The vesicle size was found to be increased by 5 nm, entrapment efficiency was decreased by 4%, and the zeta potential was increased by 3 mV after the completion of 90-day storage period at 25 °C ± 2 °C (room temperature condition) [34].

Table 8. The results of the stability study

Evaluation parameters	Before	Room temperature (25 °C ± 2 °C)		Refrigerated condition (4 °C ± 2 °C)	
Day 0	30 days	90 days	30 days	90 days	Entrapment efficiency (%)
80.12 ± 0.25	79.54 ± 1.2	76.52 ± 2.6	80.02 ± 0.05	79.8 ± 0.16	Particle size (nm)
156.1 ± 2.2	156.1 ± 2.5	161.1 ± 3.4	156.1 ± 0.8	157.1 ± 1.4	Zeta potential (mV)

Characterization of NDFX-Loaded transethosomal gel

The enhanced transethosomal formulation was integrated into the secondary carrier (Gel) to make the formulation rheologically acceptable for topical administration. The gel was prepared using varying concentrations of Carbopol

934 and HPMC K4M and investigated for gel characterization studies as shown in Table 9. The pH, viscosity, spreadability and drug content were falling in the range of 6.31–7.12, 794–1112cP, 9.2–12.56 g cm^2/s and 84–92%, respectively.

Table 9. Characterization results of NDFX-loaded transethosomal gel

Evaluation parameters	TEG 1 (Carbopol 1%)	TEG 2 (Carbopol 2%)	TEG 3 (HPMC K4M 2%)	TEG 4 (HPMC K4M 3%)
Color	White Opaque	White Opaque	Off-White	Off-White
pH	7.12±0.5	6.95±0.05	6.31±0.0.12	6.42±0.23
Viscosity (cP)	971±15	1112±12	794±14	820±10
Spreadability (g cm^2/s)	9.2±0.25	8.83±0.45	12.56±0.62	10.35±0.82
Drug content (%)	92±1.2	87±1.8	86±0.8	84±0.5

In vitro drug diffusion study

The investigation of the drug diffusion study of prepared transethosomal gels was carried out using the Franz diffusion cell. The drug release was found to be in the range of 42.67–64.83% after 8 h. Figure 4 illustrates the in vitro drug diffusion profile of NDFX from different transethosomal formulations. The release of NDFX from these formulations can be ranked in the following descending order: TEG1>TEG2>TEG3>TEG4. As the TEG1 was found to be showing satisfactory gel characterization results and the highest drug release, it was selected as an optimized gel base for further study [16].

Fig. 4 [Images not available. See PDF.]

Drug diffusion profile of Nadifloxacin-loaded transethosomal gel in different gel bases i.e., Carbopol 1%, Carbopol 2%, HPMC K4M 2% and HPMC K4M 3%

Ex vivo permeation study

The skin permeation study of the optimized transethosomal gel formulation TEG1, loaded with NDFX, was carried out on rat abdominal skin using a Franz diffusion cell. The comparative study was performed between the TEG1, Marketed NDFX formulation (Nadibact cream 1%w/w) and the plain gel of NDFX (Carbopol 1%). Figure 5 illustrates the percentage of drug permeation through rat skin. Remarkably, the optimized transethosomal gel formulation (TEG1) exhibited significantly higher drug permeation compared to the marketed cream and plain gel of NDFX i.e., 58.92%, 26.44% and 38.69%, respectively. It is ranked in the following descending order (TEG1>plain gel >marketed cream). The high permeation rate of optimized NDFX transethosomal gel is because high flexibility of the vesicles which is attributed to the inclusion of an edge activator within the formulation. The edge activator (surfactant) provides flexibility to the vesicles, so they can deform their shape and pass through narrow obstruction of subcutaneous tissue. The ethanol present in the formulation also acts as the penetration enhancer which aids in the deep penetration of transethosomes into the underlying skin layers [12, 35].

Fig. 5 [Images not available. See PDF.]

Ex vivo skin permeation profile of Nadifloxacin-loaded transethosomal gel, plain gel of Nadifloxacin and marketed cream (Nadibact 1%w/w)

In vitro anti-bacterial study

Zone of inhibition The cup plate method was used to evaluate the zone of inhibition of the optimized NDFX transethosome formulation against *P. acness*. The NDFX transethosome formulation and the marketed formulation (Nadibact Cream) exhibited noticeable zones of inhibition when compared to the blank formulation and the control, as depicted in Fig. 6. The investigation revealed that the NDFX-loaded transethosome formulation exhibited a significantly larger antimicrobial activity zone (measuring 26 ± 2 mm) compared to the marketed formulation (16 ± 1.8 mm), as well as the blank formulation and negative control. Thus, the findings demonstrated that the optimized NDFX transethosome formulation is highly responsive to *P. acnes* and effectively demonstrates antibacterial activity against it. The remarkable antimicrobial effect of the transethosome formulation loaded with NDFX is primarily due to the exceptional flexibility of transethosomes. This unique characteristic enables them to easily penetrate the bacterial cell wall and effectively hinder the activity of the DNA gyrase enzyme, which plays a crucial role in bacterial DNA synthesis. As a result, bacterial multiplication is effectively suppressed.

Fig. 6 [Images not available. See PDF.]

Animal study

Skin irritation study

The potential for skin irritation caused by the prepared transethosomal gel containing NDFX and the blank transethosomal gel can be visually evaluated in Fig. 7. The findings indicate that animals from both Group I (Blank gel) and Group II (NDFX transethosomal gel) did not exhibit any signs of redness or swelling until the conclusion of the seventh day. These assessments were conducted using the Draize scoring system, and the results are presented in Table 10.

Fig. 7 [Images not available. See PDF.]

The skin irritation potential of prepared NDFX-loaded transethosomal (**A**) gel and blank transethosomal gel (**B**)

	Average Draize scoring ($n=6$)							Mean
Erythema				Edema			Formulation	1 h
24 h	48 h	7 days	1 h	24 h	48 h	7 days	Group-I (Blank TEs Gel)	0	0
0	0	0	0	0	0	0	Group-II (NDFX TEs Gel)	0	0

P. acne-induced anti-acne study

The anti-acne efficacy of the newly developed experimental gel (NDFX-loaded transethosomal gel) was assessed in

the Wistar rat model. The evaluation was conducted by measuring the percentage change in ear thickness, as depicted in Fig. 8. At the conclusion of the 14th day, the optimized transethosomal gel containing NDFX demonstrated the highest level of anti-acne efficacy. The optimized formulation has shown the least change in percentage ear thickness i.e., 22.2 ± 2.4%, followed by the marketed formulation treatment group (45.5 ± 5.2%) and plain gel treatment group (63.64 ± 6.8%). The statistical significance of the control group compared to the treatment group was examined using one-way ANOVA and Sidak's multiple comparison tests. The disease control group exhibited a substantial percentage change in ear thickness, specifically 340 ± 12.5%, which was significantly distinguishable (p<0.0001) from the remaining three groups. Despite the daily variation in ear thickness (from day 1 to day 14), Fig. 9 reveals a distinct pattern. In the disease control group, the thickness of the rat ear continuously increased until the 14th day. This increase was attributed to bacterial colonization and the formation of pus in the rat ear pinna. On the other hand, in Group II, Group III and Group IV, the ear thickness increased during the induction period (till the 7th day), but during the treatment period (after the 7th day), it progressively decreased due to the antibacterial properties of the formulations. The same consistent outcomes were visually depicted in the accompanying photographs (Fig. 10).

Fig. 8 [Images not available. See PDF.]

Bar graphs showing the % change in the thickness of rat ears of different groups. Group I (disease control), Group II (marketed treatment), Group III (experimental gel treatment), Group IV (plain gel treatment)

Effect of different treatments on the thickness of rat ear at each day

Fig. 10 [Images not available. See PDF.]

Photographs of rat ear showing the extent of inflammation before induction (Day 1), after induction (Day 7) and after treatment of 14 days with different formulations

Histopathological report

Figure 11 depicts the histological changes observed in the rat ear pinna following the injection of a bacterial strain of *Propionibacterium acnes* and subsequent treatment with various formulations.

Fig. 11 [Images not available. See PDF.]

Histopathological observation of rat ear pinna after treatment with different formulations: control group (CG), disease control (DC), standard marketed cream (Std), NDFX-loaded transethosomal gel (TG), plain NDFX gel (PT)

In the control group (non-induced), the intact epidermis, sebaceous gland and ear cartilage displayed minor congestion. However, in the case of the disease control group (untreated), the epidermis suffered mild injury, exhibiting excessive inflammatory cell infiltration, significant congestion, as well as neutrophilic and lymphocytic infiltration. Additionally, there were indications of modest folliculitis, ulceration, edema, macrophages and cutaneous granulation tissue. The group treated with the plain gel exhibited pathogenic alterations that closely resembled those observed in the disease group. These alterations included increased inflammatory cell and neutrophilic infiltration, although no edema or skin granulation tissues were identified.

Comparatively, the group treated with the standard marketed formulation (Nadibact cream) displayed mild folliculitis congestion, along with considerable neutrophilic and lymphocytic infiltration. On the other hand, the optimized transethosomal gel treated group showed an intact epidermis with modest congestion.

Post-treatment microbiological assay

The post-treatment *ex vivo* microbiological assay results are shown in Fig. 12. The results have demonstrated that optimized NDFX-loaded transethosomal formulation has shown potent antibacterial activity as there are fewer CFU (colony-forming units) of *Propionibacterium acnes* compared to the marketed formulation and the plain gel of NDFX. This might be due to the high permeability of the transethosomal vesicles into the deeper layer of the skin which

allows it to retain at the subcutaneous level and inhibit bacterial colonization. The order of antimicrobial activity of the aforementioned formulations against *Propionibacterium acnes* is as follows:

Fig. 12 [Images not available. See PDF.]

Post-treatment microbiological assessment different treatment groups

Optimized NDFX-loaded transethosomal formulation > Marketed formulation (Nadibact cream) > Plain gel of NDFX.

Discussion

This research focused on developing Nadifloxacin-loaded transethosomes using the cold method to enhance topical delivery. A Box–Behnken experimental design successfully optimized Nadifloxacin-loaded transethosomes, with independent variables including phosphatidylcholine 90, Tween 80 and ethanol [11, 12]. Seventeen formulations were prepared, and their characterization revealed entrapment efficiency ranging from 43.64 to 81.05%, vesicle sizes between 97.12 nm and 187.34 nm, and zeta potential ranging from − 17.12 to − 34.34 mV. The optimized formulation exhibited an entrapment efficiency of 80.12% ± 0.25%, a vesicle size of 156.1 ± 2.2 nm and a zeta potential of − 33.23 ± 0.5 mV. Transmission electron microscopy (TEM) confirmed the presence of encapsulated vesicles with a sphere-like shape [21]. This optimized formulation was incorporated into gel bases, such as Carbopol 934 (1% and 2%) and HPMC K4M (2% and 3%). The characterization study demonstrated that Carbopol 934 (1%) gel exhibited desirable characteristics with a pH of 7.12, viscosity of 971 cP, spreadability of 9.2 $g.cm^2$/sec and drug content of 92%. In vitro diffusion studies showed that the transethosomal gel with Carbopol 934 (1%) displayed superior drug diffusion after 8 h compared to Carbopol 934 (2%) and HPMC K4M (2% and 3%). Ex vivo skin permeation studies revealed that the optimized transethosomal gel demonstrated enhanced skin permeation compared to the commercially available Nadibact cream (1% w/w). The optimized Nadifloxacin-loaded transethosomal gel exhibited improved in vitro antimicrobial and in vivo anti-acne effects against *Propionibacterium acnes* in Wistar rats, surpassing the efficacy of the commercially available formulation. Histopathological analysis confirmed its superior anti-acne properties and better penetration capabilities compared to the plain gel and the marketed-treated group. Stability assessments over three months demonstrated the formulations' exceptional stability when stored under refrigerated conditions at 4 °C.

In conclusion, the development of Nadifloxacin-loaded transethosomes using the cold method proved effective in enhancing topical delivery for the treatment of Acne vulgaris. The optimized formulation exhibited desirable characteristics, superior skin permeation and improved anti-acne efficacy compared to the commercially available formulation, showcasing its potential as a promising approach in acne treatment.

Conclusion

Nadifloxacin-loaded transethosome formulations were successfully prepared utilizing a cold method and further optimized using a Box–Behnken design (BBD). The optimized formulation exhibited favorable characteristics, including high entrapment efficiency, vesicle size within the nanorange and desirable zeta potential. The results obtained from the ex vivo permeation study indicated that the optimized transethosomal gel facilitated enhanced permeation when compared to a commercially available formulation. The optimized transethosome formulation exhibited augmented in vitro antimicrobial activity as well as in vivo anti-acne efficacy against *Propionibacterium acnes* in Wistar rats, surpassing the performance of the commercially available formulation. Moreover, the histopathological report revealed that the group treated with the optimized Nadifloxacin-loaded transethosomal gel exhibited a higher rate of healing in comparison with both the plain gel and the commercially treated groups. The current investigation found NDFX-loaded transethosomal gel to be a potential alternative to standard topical formulation for the treatment of Acne.

Chemical characterization, safety profile and antileiomyoma effects of Tetrapleura tetraptera Taubert (Fabaceae) fruit ethanol extract in Sprague Dawley rats

Imade, Rose Osarieme1 ; Ayinde, Buniyamin Adesina1; Uchendu, Adaeze Phina1; Innih, Silvanus1; Umar, Aadam Anoghena1; Agoreyo, Oghenemaro Victory1; Adesina, J ohn Marvelous11 University of Benin, Faculty of Pharmacy, Benin, Nigeria (GRID:grid.413068.8) (ISNI:0000 0001 2218 219X)

ABSTRACT (ENGLISH)

Background

Tetrapleura tetraptera Taubert (Fabaceae) fruits are employed by herbal practitioners in the management of uterine leiomyoma, but its usage in this regard and level of safety in chronic administration has not been sufficiently established. This study evaluated the toxicity effects of *T. tetraptera* ethanol fruit extract and explored its antileiomyoma effect in female Sprague Dawley (SD) rats.

Methods

Sub-chronic toxicity test of the extract was done, with biochemical and hematological changes as well as histopathology of organs assessed. Leiomyoma formation was induced in SD rats with monosodium glutamate (MSG) and the extract given at 100, 200 and 400 mg/kg doses, following both the preventive and curative methods. Total serum cholesterol, protein and estradiol were determined, as well as histopathology assessment of the uterus. Phytochemical profiling of the extract was evaluated by analytical high-performance liquid chromatography (HPLC).

Results

No significant alterations were seen in the biochemical and hematological indices in the toxicity test. The vital organs showed no changes at 200 mg/kg, but at 800 mg/kg it appeared to induce multiplication of glandular epithelium and stromal fibrosis in the uterus, and induced perivascular inflammation around the vessels of the heart. Total serum cholesterol and estradiol were significantly elevated ($P \leq 0.05$) on treating normal female rats with 800 mg/kg MSG. Preventive and curative treatment of MSG-treated animals with the extract significantly decreased the elevated serum cholesterol ($P \leq 0.01$) and estradiol ($P \leq 0.05$). Histological studies of the uterus showed an amelioration of the proliferating fibroid cells with administration of the extract, which was more evident in the curative treatment. Result of HPLC analysis of the extract revealed rich composition in bioactive compounds such as umbelliferone, ferulic acid, aridanin, echinocystic acid, naringenin and hentriacontane.

Conclusion

The ethanol fruit extract of *T. tetraptera* is relatively safe in Sprague Dawley rats in low doses and has antifibroid potential as seen in its significant reduction in the elevated total cholesterol and estradiol content as well as its ability to decrease uterine leiomyoma proliferation, which may be due to its array of phytochemical constituents.

FULL TEXT

Background

The most prevalent tumors of the female reproductive system are uterine leiomyomas, often known as uterine fibroid or uterine myomas. It poses a serious risk to women's reproductive health everywhere [1]. Over 70% of women have it, and about 30% of them develop symptoms [2]. In women who are of reproductive age, it is the most common reason for hysterectomies [3]. It is a benign monoclonal tumor of the uterine smooth muscle cells. It grows in the uterine cavity or on the walls of the uterus in different places. Thus, it is referred to as intramural, submucosal or sub-serosal fibroids. It can have any shape and size, from a pea size to a water melon size [1].

While the exact cause of uterine leiomyoma formation is still unknown, epidemiological studies have provided substantial evidence that estrogen and progesterone stimulate the growth of the tumor, possibly as a result of continuous menstrual cycles, since fibroids rarely develop prior to menarche and disappear following menopause [2]. Women who identify as African-American and who are fat are significantly more at risk. Aside from age and family history, other risk factors for uterine leiomyoma include nutrition, lack of exercise, some chemicals like monosodium glutamate (MSG) and prescription medications that may raise cholesterol, estrogen and total protein levels [4].

Since most women with uterine fibroids have no symptoms, they receive less clinical attention and the tumors are frequently left undetected. Women with symptoms usually report abnormally heavy bleeding from the uterus (which can cause anemia) or painful periods; pelvic fullness; lower abdominal enlargement; frequent urination; pain during sexual activity; lower back pain; complications during pregnancy and labor; and reproductive issues like infertility [5]. The size and location of the fibroids typically determine how severe these symptoms are.

There are extremely few alternatives for treatment and prevention; doctors frequently recommend myomectomy and hysterectomy. Medication treatments, such as hormone replacement therapy, are only beneficial for six to twelve

months because prolonged use of the drug might have serious negative effects [6, 7]. Although uterine artery embolization and high-intensity focused ultrasound ablation are viable options, patients may be discouraged from pursuing such treatment due to the associated risks and expenses [8]. Not only are orthodox drugs expensive, but they often only provide brief relief, which makes alternative treatment choices necessary.

The drawbacks of conventional medications, in addition to the accessibility, affordability and cultural significance of herbal remedies, which are favored over the expensive medical services provided by conventional medicine, have sparked a resurgence of interest in these remedies [9]. In one study, various biochemical parameters changed by administration of MSG were recovered by the ethanol extract of *Diodia sarmentosa* leaves. The treated groups' protection against leiomyoma development was also demonstrated by histopathological assessment [7]. Femitol, a herbal mixture manufactured in Ghana, was found to be effective as an antifibroid agent as it greatly reduced MSG-induced uterine hyperplasia and decreased high levels of cholesterol and estrogen, as well as uterus size and weight [10, 10]. Additionally, morphological examination demonstrated that the entire plant of *Labisia pumila* caused apoptosis against SK-UT-1 (uterine leiomyoma cells) in a dose-dependent manner and inhibited the formation of uterine fibroid tumors [11].

Tetrapleura tetraptera Taubert (Fabaceae) is used to treat uterine leiomyoma, according to anecdotal evidence [12]; however, this is not supported by scientific research. The plant is used to cure febrile illnesses and infections, stop postpartum contractions, lower cholesterol, encourage the production of breast milk and speed up the healing of reproductive wounds [13]. Despite the various evidence for its efficacy, there is insufficient scientific evidence to support its safety with regards to its use in herbal medicines. Since the fruit of this plant is used in preparation of herbal remedies for management of leiomyoma which is a chronic illness, it is therefore necessary to evaluate the level of safety of this plant following prolonged repetitive administration.

The objectives of this study, therefore, were to establish the safety of the fruit extract and analyze its protective effect on biochemical indicators such as total cholesterol, protein and estradiol, in order to determine its antiuterine fibroid effect on MSG-induced uterine leiomyoma in Sprague Dawley rats, which will be further confirmed by histopathological assessment of the rat's uterus. Furthermore, identification of the major constituents of the extract was carried out with analytical HPLC.

Methods

Chemicals and reagents

All reagents used in this study were of analytical quality and acquired from reputable local vendors.

Plant collection and preparation

The fruit of *T. tetraptera* was harvested in the savanna area of Odofin Agbegi village, Ikire, Osun state, Nigeria, and authenticated at the Forest Research Institute of Nigeria (FRIN) with the herbarium number FHI 113604 attached. Using a Soxhlet device, the dried and crushed fruit was extracted with ethanol. A rotary evaporator was used to reduce the extract to dryness.

Animal handling conditions

Non-pregnant Sprague Dawley (SD) rats weighing between 125 and 160 g were obtained and placed in groups of five (5) in plastic cages with a wire screen top for adequate ventilation and wood shavings as the bedding material. The animals were supplied clean water and fed with commercial rat pellet (Chikun feed) manufactured by Olam Agricultural enterprise ad libitum. The processes applied in animal handling were in accordance with the National Institute of Health Guidelines for the Care and use of Laboratory Animals. All procedures for using experimental animals were approved by the Research Ethics Committee of the Faculty of Pharmacy, University of Benin (EC/FP/023/04).

Dosing of experimental animals

Doses of *T. tetraptera* extract used in this study were selected based on the LD_{50} of the plants fruit which is greater than 5000 mg/kg [14]. The SD rats were given doses via gavage. Throughout the experiment, animals were dosed once a day, with each dose volume determined by the animal's weekly recorded body weight. The oral route of administration was chosen because it is the commonly utilized route by humans.

Sub-chronic toxicity test

SD rats were divided into four groups comprising of 6 animals each. Group A received 0.5 mL distilled water (control). Groups B, C and D were orally administered different doses of the extract (200, 400 and 800 mg/kg BW), respectively, daily for 28 days. Body weights of the rats were taken on day 0, 7, 14, 21 and 28. Every day, the animals were closely monitored for any changes in their clinical symptoms. Tremors, convulsions, salivation, diarrhea, lethargy, sleep and coma were the main areas of focus [15]. On the last day of gavage, the rats were fasted for a period of 12 h before being killed using a chloroform chamber. The blood was drawn by cardiac puncture into two distinct kinds of bottles: Ethylenediaminetetraacetic acid (EDTA) bottles were used to collect the blood's hematological parameters, while plain bottles were used to acquire serum for the analysis of biochemical parameters. Organs for histological analysis were obtained, including the kidney, liver, heart and uterus.

Biochemical analysis

Samples of blood were taken into plain tubes and left to stand at room temperature for 45 min before being centrifuged for 10 min at 3400 rpm. The collected serum stored at − 25 °C was utilized to assess the lipids, renal and liver function tests. These parameters were assessed using an automated chemistry analyzer (Selectra Pro S, Germany). Electrolyte assay was by ion-selective electrode (SFRI 4000, France). The parameters assayed included creatinine (Cr), urea (Ur), uric acid, aspartate aminotransferase (AST), alanine aminotransferase (ALT) and alkaline phosphatase (ALP), serum proteins (Tp), total bilirubin (Tb), triglycerides (TG), total cholesterol (T-CH), low-density lipoproteins (LDL), high-density lipoprotein (HDL) and serum electrolytes (Na^+,K^+,Cl^-, HCO_3^-).

Hematological analysis

Additionally, hematological parameters were evaluated by a blood count utilizing an automated hematology analyzer on blood collected into EDTA bottles (Dymind 2000, China). The parameters analyzed include white blood cell (WBC), red blood cells (RBC), red blood cell distribution width (CV), red blood cell distribution width (SD), hemoglobin (Hb), mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), mean corpuscular hemoglobin concentration (MCHC), granulocytes (GRAN), platelets count (PCT) and hematocrit (HCT).

Histopathology analysis of organs

For histological analysis, the liver, heart, kidney and uterus from the killed animals were fixed in 10% neutral buffered formalin solution. These tissues were subsequently dehydrated in ascending grades of alcohol (70%, 90%, 96% and 100%), cleared in xylene, impregnated with molten paraffin wax and sectioned to slides. These sections (4–5 µm thick) were stained with hematoxylin after dewaxing with xylene and hydrating in descending grades of alcohol (100%, 96%, 70%) and water. Differentiation was done in 1% acid alcohol and the sections counter stained with eosin. Dehydration in ascending grades of alcohol was carried out again, and the sections were cleared in xylene and mounted with dibutylphthalate polystyrene using cover slips prior to microscopic examination [16].

Antileiomyoma effect of *Tetrapleura tetraptera* fruit (TTF)

Experimental procedures

Preventive study

This was carried out following the method described in the literature [7]. Female SD rats were placed in five groups of five rats each. Dosing was done once a day through the oral route. Group A (Control) was the no treatment group, given only food and water. Group B was treated with 800 mg/kg monosodium glutamate (MSG) (Lobachem, India) only. Groups C, D and E were treated with 800 mg/kg MSG and *T. tetraptera* fruit extract (100, 200 and 400 mg/kg) concurrently. All treatments were given concurrently for a 30-day period. On the 31st day, the animals were killed by anesthetizing them in a chloroform saturated chamber and their blood collected through cardiac puncture and transferred into plain bottles which were used to determine total serum cholesterol, protein and estradiol content. The uteri were surgically removed and transferred into sterile tissue bottles containing 10% neutral buffer formalin for histopathology assessment.

Curative study

Following the method described in the literature [4], female SD rats were treated with 800 mg/kg MSG for 30 days to

induce the development of uterine leiomyoma. The rats were housed in five groups of five rats each. Treatment with extracts commenced on the 31st day. Group A was the control group, given no MSG but only food and water for the duration of the experiment. Group B, after being administered 800 mg/kg MSG for 30 days, was given food and water only from the 31st to 60th day. Groups C-E were treated with 100, 200 and 400 mg/kg *T. tetraptera* fruit extract, respectively, from the 31st to 60th day, after the 30-day MSG administration. The animals were killed by anesthetizing them in a chloroform saturated chamber and their blood collected through cardiac puncture into plain bottles to determine the total serum cholesterol, protein and estradiol content. The uteri were surgically removed and transferred into sterile bottles containing 10% neutral buffer formalin for histopathology assessment.

Biochemical assays

Determination of total cholesterol content

A day after the experimental period (30 days for preventive treatment and 60 days for curative treatment), the animals' blood was collected and serum separated by centrifugation at 3000 rpm for 10 min, which was used for the experiment.

Total cholesterol content was determined using the semi-automated chemistry analyzer (Mindray BA-88A Reagent system) and the AGAPPE test kit. The total cholesterol kit was programmed on the semi-automated biochemistry analyzer using the information on the instruction manual. In a microtube marked "blank," 1000 µL of cholesterol biuret reagent was added. 10 µL of standard cholesterol and 1000 µL of the reagent were added to and properly mixed in a tube marked "standard." 10 µL of sample A_1 and 1000 µL of cholesterol reagent were added to and properly mixed in a tube with the label "A_1." The same procedure was carried out for the remaining samples (A_1–E_5) in their respective tubes. This was done for samples obtained from both the preventive and curative experiments. All tubes were incubated for 10 min at 37 °C. After incubation, the content of the blank tube was aspirated into the flow cell of the analyzer to measure the absorbance, after which the content of the standard tube was also aspirated into the flow cell to measure the absorbance. Reaction mixture for each sample was then aspirated into the flow cell to measure the absorbance. The values of absorbance for each tube were recorded accordingly [10].

Determination of total protein content

The information in the instruction manual was used to program the kit on the semi-automated biochemistry analyzer. In a microtube marked "blank," 1000 µL of total protein biuret reagent was added. 20 µL of standard total protein and 1000 µL of the reagent were added to and properly mixed in a tube marked "standard." 20 µL of sample A_1 and 1000 µL of total protein reagent were added to and properly mixed in a tube with the label "A_1." The remaining samples (A_1–E_5), from both the preventive and curative experiments in their respective tubes underwent the same procedure. All tubes were incubated for 10 min at 37 °C. After incubation, the content of the blank tube was aspirated into the flow cell of the analyzer to measure the absorbance, after which the content of the standard tube was also aspirated into the flow cell to measure the absorbance. Reaction mixture for each sample was then aspirated into the flow well to measure the absorbance. The value of absorbance for each tube was recorded accordingly [10].

Determination of estradiol content

Estradiol was assayed using the microplate reader (mindray MR-96A), microplate washer (Mindray MW-12A) and E2 AccuBind ELISA Kit. 25 µl of the serum reference and 25 µl of each sample (A_1–E_5) were pipetted into the assigned wells, after which 50 µl of estradiol biotin reagent was added to all wells. Plates were swirled gently for about 30 s and then incubated for 30 min followed by the addition of 50 µL of estradiol enzyme reagent to all the wells and incubation for 90 min at room temperature. The contents of the microplate were discarded by decantation and the plates dried with absorbent paper afterward. 350 µL of the wash buffer was added and the content decanted thrice. 100 µL of substrate was added and incubated for 20 min, after which 50 µL of the stop solution was added to each well and gently mixed for 20 min. The absorbance was read at 450 nm within 15 min of adding the stop solution. The concentration of estradiol in samples was extrapolated from a dose response curve [14].

Histopathology analysis of the uterus

This was carried out following the method earlier stated [16].

HPLC procedure

The HPLC procedure was carried out at Bato Chemical Laboratory in Lagos, Nigeria. HPLC make was Shimadzu (Nexera mx). Column used was ubondapak, a C18 reverse-phase chromatographic column, with dimensions of length: 100 mm, internal diameter: 4.6 mm and thickness: 7 µm. Mobile phase employed was acetonitrile/water, 70:30. The HPLC system was attached to a UV–Vis diode array detector set at an analytical wavelength of 254 nm, within the UV–visible region. Pump pressure employed was 15 mpa. Solutions of standards were first injected into the HPLC system to generate a chromatogram with a given peak and peak profile. These were used to create a window in preparation for the test sample analysis. The analysis adopted a 2 ml/min constant flow rate as 5 ul of extract was injected into the HPLC system also to obtain a corresponding peak area and peak profile in a chromatogram [18].

Data analysis

Bar graphs were obtained by the software GraphPad Prism for Windows, version 6.01, and data were subjected to one-way analysis of variance (ANOVA) with Tukey–Kramer multiple comparison test. $P \leq 0.05$ was considered statistically significant in all analysis.

Results

Sub-chronic toxicity results

Effect of *T. tetraptera* fruit on food consumption and body weight

In test animals, repeated dosing over a 28-day period did not result in mortality or systemic toxicity indicators. Normal eating habits were observed and a gradual increase in weight was seen in all the test groups, although the control group showed marked weight gain ($P<0.05$) compared to the groups administered the extract (Table 1).

Table 1. Change in mean body weights of the rats at different days of the experiment

Dose (mg/kg)	Change in mean body weights (g) at different days				
0	7	14	21	28	Control
125.86 ± 14.92	9.87 ± 5.56	9.30 ± 2.14	8.30 ± 1.14	9.96 ± 3.34	200
138.30 ± 10.89	7.90 ± 4.45[a]	8.29 ± 2.43	7.30 ± 2.14	7.22 ± 1.43[b]	400
143.74 ± 10.18	6.30 ± 3.14[b]	6.86 ± 4.71[a]	7.90 ± 3.43	6.87 ± 4.52[b]	800

Data are expressed as mean ± SEM, $n=6$, a = $p<0.05$, $b = p<0.01$ compared to control

Effect of *T. tetraptera* fruit on serum biochemical parameters

Effect on lipid profile tests

All the lipid profile parameters obtained from the serum of the control and test groups at different doses were not significantly different ($p>0.05$), though a slight reduction in total cholesterol was observed at 400 mg/kg compared to the control (Table 2).

Table 2. Lipid profile parameters after 28 days of administration

	Doses (mg/kg)			
Parameters	Control	200	400	800

T-CH (mg/dL)	71.80 ± 2.80[a]	87.60 ± 8.16[ab]	66.60 ± 2.84[ac]	71.60 ± 2.54a
TG (mg/dL)	96.20 ± 13.60[a]	120.6 ± 27.83[a]	82.00 ± 12.63[a]	97.20 ± 7.59[a]
HDL (mg/dL)	34.80 ± 2.27[a]	38.40 ± 1.63[a]	33.40 ± 3.17[a]	34.60 ± 2.50[a]
LDL (mg/dL)	21.80 ± 1.63a	24.80 ± 2.75[a]	16.80 ± 1.20[a]	18.40 ± 3.14[a]

Data are expressed as mean ± SEM, $n = 6$. Values in the test groups carrying the same letters as the control group are not significantly different according to Tukey–Kramer multiple comparison test $p > 0.05$.

T-CH total cholesterol, *TG* triglyceride, *HDL* high-density lipoprotein, *LDL* low-density lipoprotein

Effect on kidney function test parameters

For the kidney function tests, extract administration at all doses did not significantly alter the concentration of sodium, potassium, chloride, urea and creatinine ($P > 0.05$) (Table 3).

Table 3. Kidney function test parameters after 28 days of administration

	Doses (mg/kg)			
Parameters	Control	200	400	800
Na^+ (mmol/L)	139.4 ± 0.68	138.8 ± 0.80	139.4 ± 0.81	140 ± 1.14
K^+ (mmol/L)	5.06 ± 0.12	5.10 ± 0.21	5.22 ± 0.21	5.26 ± 0.24
HCO_3^- (mmol/L)	21.40 ± 0.81	19.60 ± 0.93	20.00 ± 0.77	20.20 ± 0.80
Cl^- (mg/dL)	102.80 ± 0.8	102.00 ± 0.95	100.60 ± 1.10	101.80 ± 0.80
Urea (mg/dL)	43.00 ± 1.92	39.80 ± 3.20	38.40 ± 2.58	43.40 ± 2.09
Creatinine (mg/dL)	0.84 ± 0.09	0.84 ± 0.08	0.80 ± 0.06	0.86 ± 0.08

Data are expressed as mean ± SEM, $n = 6$. There was no significant difference between the groups according to Tukey–Kramer multiple comparison test $P > 0.05$

Effect on liver function test parameters

The liver function test parameters were also not significantly altered by administration of the extract (Table 4) although there was a slight elevation in alkaline phosphatase content.

Table 4. Liver function test parameters after 28 days of extract administration

	Doses (mg/kg)			
Parameters	Control	200	400	800
ALP (μ/L)	210.20 ± 32.91	251.20 ± 8.79	242.80 ± 28.9	249.80 ± 16.73

GLo (g/dL)	3.02±0.19	3.30±0.17	3.02±0.17	2.98±0.22

Data are expressed as mean±SEM, $n=6$. There was no significant difference between the groups according to Tukey–Kramer multiple comparison test $P>0.05$, alkaline phosphatase (ALP), alanine aminotransferase (ALT) Aspartate aminotransferase (AST), total bilirubin (Tb), conjugated bilirubin (Cb), total protein (Tp), albumin (ALB), globulin (GLo)

Effect of *T. tetraptera* fruit on hematological parameters

The results of the hematological parameters (Table 5) revealed a decrease ($p<0.05$) in white blood cell count at 200 and 400 mg/kg BW. The extract did not have a significant effect ($p>0.05$) on all other hematological parameters tested as they were all within normal range (Table 5).

Table 5. Results of hematological assay after 28 days administration

Histological evaluation of the rat organs

The rat heart muscles were made up of cardiomyocytes arranged in bundles. At 200 mg/mL of the extract, the architecture of the heart was normal (Panel A). 400 mg showed the presence of polymorphs. At 800 mg, there was induction of inflammation around the blood vessels of the heart (polymorphs and fibroblasts) and the blood vessels looked ulcerated.

The liver at 200 mg had increased blood flow in the veins and normal hepatocytes (Panel B). 400 mg revealed the presence of activated Kupffer cells in the sinusoids which is evidence of a boost in the immune system; this can be seen as an extra quality of the extract. At 800 mg, polymorphs around the portal triad were observed along with Kupffer cells. The kidney is made up of the renal corpuscle; there was increased blood flow (active congestion) in the interstitial space and normal architecture was observed even at 800 mg/kg, as no necrosis of tubular epithelium was seen. The uterus at 200 mg showed normal structures (Panel D), but stromal fibrosis and glandular epitheliosis were observed at 800 mg (Fig. 1).

Fig. 1 [Images not available. See PDF.]

H&E × 400 SD Rat organ sections: Panel **a** shows normal heart architecture, bundles of cardiomyocytes (CM), coronary artery (CA), interstitial space (IS), at 400 and 800 mg/kg perivascular mobilization of inflammatory cells (PI) are seen. Panel **b** shows normal liver architecture, hepatocytes (HC), sinusoids (SI), portal vein (PV), bile duct (BD). 800 mg/kg shows normal hepatocytes with conspicuous nucleoli (HN), periportal infiltrates of inflammatory cells (PI), vascular congestion (VC). Panel **C** shows normal kidney architecture: tubules (TU), interstitial space (IS), glomeruli (GL). Panel D shows normal uterus architecture: cavity (CA), endometrial lining (EL), stroma (ES), glands (EG), 800 mg/kg shows glandular epitheliosis (GE), stromal fibrosis (SF)

Antileiomyoma evaluation results

Total serum cholesterol

There was significant elevation [64.37% ($P \leq 0.05$)] in serum cholesterol in the group administered MSG only for the preventive treatment. When the extract was administered concurrently with MSG, this action was observed to a lesser degree, with 100 and 200 mg/kg having only 20.77 and 6.56% increase in serum cholesterol compared to the

control ($P \geq 0.05$) (Fig. 2). After MSG induction of uterine leiomyoma where serum cholesterol was elevated (45.85%), the curative treatment with different doses of the extract decreased this parameter to normal especially at 200 and 400 mg/kg doses ($P \geq 0.05$) which was vastly reduced compared to the MSG group ($P \leq 0.01$) (Fig. 3).

Fig. 2 [Images not available. See PDF.]

Preventive effect of the ethanol extract of *T. tetraptera* fruit on total serum cholesterol in female SD rats administered 800 mg/kg MSG. Compared to normal group *$P<0.05$

Fig. 3 [Images not available. See PDF.]

Curative effect of the ethanol extract of *T. tetraptera* fruit on total serum cholesterol in female SD rats pre-treated with 800 mg/kg MSG. Compared with normal group *$P<0.05$, compared with MSG group.$^{\#\#}P<0.01$

Total protein content

Treatment with MSG alone and concurrent treatments with MSG and the extract at various doses did not have any significant ($P \geq 0.05$) effect on serum protein in relation to the normal rats (Fig. 4). Pre-treatment of normal rats with MSG also did not cause significant elevation of serum protein (Fig. 5).

Fig. 4 [Images not available. See PDF.]

Fig. 5 [Images not available. See PDF.]

Curative effect of the ethanol extract of *T. tetraptera* fruit on total protein in female SD rats pre-treated with 800 mg/kg MSG

Total serum estradiol

MSG treatment gave rise to a very significant elevation in estradiol (90.98% $P \leq 0.05$). Concurrent treatments with MSG and extract at various doses produced reduced levels of elevation of 35.35, 52.97 and 8.07% in estradiol content with 100, 200 and 400 mg/kg doses ($P \geq 0.05$) in relation to the normal group (Fig. 6). Significant difference at $P \leq 0.05$ was observed between the MSG and the 400 mg/kg group. In the curative treatment, serum estradiol in the rats was raised by 90.68% ($P \leq 0.05$) in the MSG group. Pre-treatment of normal rats with MSG and treatment with the extract in graded doses, however, caused significant amelioration of this parameter as elevations of 62.94 and 20.39% were observed with 100 and 200 mg/kg doses (Fig. 7). At 400 mg/kg, there was a significant inhibition of serum estradiol elevation caused by MSG ($P \leq 0.05$). The extract dose-dependently decreased elevated serum estradiol to normal.

Fig. 6 [Images not available. See PDF.]

Preventive effect of the ethanol extract of *T. tetraptera* fruit on total serum estradiol in female SD rats administered 800 mg/kg MSG. Compared with normal group *$P<0.05$, compared with MSG group.$^{\#}P<0.05$

Histopathology results of the uterus

Section of the uterus showed normal tissue architecture: endometrial stroma (ES), endometrial lining (EL), endometrial glands (GL) and uterine cavity (UC). When the female rats were treated with 800 mg/kg MSG only, the sections showed thick bundles of smooth muscle fibers which were spindle-shaped (SP), arranged in haphazard fashion and crisscrossing the endometrial glands and stroma which is characteristic of leiomyoma. Simultaneous administration of graded doses of *T. tetraptera* fruit and MSG showed an amelioration of the

proliferating fibroid cells. The activity of the extract was more evident in the curative experiment as the thick band of smooth muscle fibers indicating the formation of leiomyoma was minimal at 200 and 400 mg/kg and normal tissue architecture was mostly observed (Fig. 8).

Fig. 8 [Images not available. See PDF.]

H&E × 400 SD Rat uteri sections: Panel A shows normal uterus architecture: uterine cavity (UC), endometrial lining (EL), endometrial stroma (ES) , endometrial glands (GL) are seen. Panel B shows rat uterine wall given MSG only: composed of endometrial glands (GL) and stroma (ES) flanked by spindle-shaped proliferating bundles of smooth muscle fibers (SP) characteristic of leiomyoma. Panel C shows 100 mg/kg treated group: Composed of endometrial glands (GL) and stroma (ES) with reduced spindle-shaped proliferating bundles of smooth muscle fibers (SP) in both treatments. Panel D shows 200 mg/kg treated group: composed of stroma (ES) with mild form of proliferating bundles of smooth muscle fibers (SP). Panel E shows 400 mg/kg treated group: preventive group shows mild form of proliferating bundles while curative is mostly normal uterus architecture, uterine cavity (UC), endometrial lining (EL), stroma (ES), glands (GL)

HPLC analysis result

HPLC analysis of the ethanol extract of *T. tetraptera* revealed the presence of majorly umbelliferone, ferulic acid, echinocystic acid, piperazine, aridanin and naringenin. Other compounds present but in lesser amounts were octodrine, hentriacontane, butein and isoliquiritigenin (Table 6). HPLC chromatogram showing the various peaks of the identified compounds is presented in Fig. 9.

Table 6. HPLC result of *T. tetraptera* fruit ethanol extract

S/N	Component	Retention time (mins)	Area	Height
1	Ferulic acid	1.350	303.6740	23.900
2	Echinocystic acid	1.650	422.7495	47.384
3	Umbelliferone	1.983	8447.0015	222.357

High-performance liquid chromatography (HPLC) chromatogram of compounds in *T. tetraptera* ethanol fruit extract

Discussion

Loss of body weight is typically seen to be a harmful impact of the extract on the animal, caused by less consumption of food and liquids. The extract induced a gradual rise in body weight, indicating the extract's relative safety for the rats; yet, there was a noteworthy distinction in the average weekly change in weight acquired ($p<0.05$) when compared to the control group (Table 1). In fact, a number of earlier studies have shown that *T. tetraptera* fruit extract has antiobesity potential [19].

LDL, total cholesterol and triglycerides are three primary components of the lipid profile that are linked to cardiovascular disease. A dysregulated lipid metabolism is indicated by changes in LDL and HDL levels, which may be caused by interference with lipolysis and the release of free fatty acids from peripheral depots [20]. Although the levels of triglycerides, LDL, HDL and total cholesterol were not significantly different ($p>0.05$) from the control group, other studies have shown that *T. tetraptera* fruit extract has the ability to decrease lipids [21]. It has been reported to elicit reduction in serum triacylglycerols as well as elevation of LDL in male rabbits [22].

The primary function of the kidneys is to remove the harmful waste produced by the normal functioning of the body and transported by the blood. In fact, additional research amply supports the capacity of plant extracts to function as potent free radical scavengers in the kidney, avoiding their harmful effects on lipid peroxidation, which raises biochemical markers like creatinine and urea by rupturing membranes [10]. *T. tetraptera* fruit has been reported to possess alkaloids, tannins, triterpenes, flavonoids, steroid glycosides and coumarins as dominant secondary metabolites [21, 23].

The protective effect of the extract could be explained by the antioxidant potential of some of *T. tetraptera* extract's constituents, such as flavonoids and total phenols, which would inhibit membrane lysis and contribute to the nephroprotective action of the extract [24]. This study's findings support those of another, which established that some methanol plant extracts protect kidney cells by inhibiting xanthine oxidase, an enzyme that causes lipid peroxidation and membrane instability [25].

The liver is essential for the detoxification and excretion of several endogenous and exogenous substances, and any harm or impairment to it can have a wide range of health effects on both humans and animals. Cellular necrosis, elevated tissue lipid peroxidation and glutathione depletion are linked to liver injury. Furthermore, liver illness is associated with increased serum levels of many biochemical indicators, including transaminases, alkaline phosphatase, triglycerides and cholesterol [26]. All of these parameters, at all tested doses, revealed no significant difference ($p>0.05$) compared to the control. These findings suggest that the extract had no effect on the liver's ability to function normally because any hepatocellular damage would have raised ALT and AST levels in the serum [27]. The extract's phenolic components, which function as antioxidants to inhibit membrane lipid peroxidation, may have a hepato-protective effect and could be the reason for this [24].

Significant changes in blood indices (white blood cells, red blood cells, platelets and their differentials) suggest that the chemical being administered is either toxic or protective to the hemopoietic tissue. The blood indices are used to monitor the physiological and pathological state of the body. Findings from our study report nonsignificant effects on most of the important blood indices by the ethanol extract of *T. tetraptera* fruit. The major functions of WBCs and its differential are to provide immunity and defend the body against invasion by pathogens or toxins. A significant reduction in WBC count at 200 and 400 mg/kg showed that this defense mechanism was not unusually elicited, which proves further the non-toxic nature of the extract. This is consistent with past studies that found that treating white rabbits with an ethanol extract of this plant's fruits reduced the number of white blood cells [22]. Conversely, the dichloromethane methanol extract of this plant resulted in a rise in WBC, which may be explained by the different chemicals that the extraction solvent produced [28]. The extract's nonsignificant effect on the RBC could mean that there was no change in the balance between blood corpuscle destruction to erythropoiesis and the rate of blood production. HGB, PCT and MCH levels did not significantly decrease ($p>0.05$) in female rats treated with the various doses; this could indicate that hemoglobin incorporation into red blood cells and red blood cell morphology were unaffected [16]. The dichloromethane methanol extract showed an alteration in this regard.

Toxicity generally happens at the cellular and sub-cellular levels before being seen in tissues. In this study, the low

extract dose levels (200 and 400 mg/kg) exhibited little or no significant effect on the histomorphology of the vital organs (Fig. 1). The presence of activated Kupffer cells in the sinusoids at 400 mg/kg is evidence of a boost in the immune system; this can be seen as an extra quality of the extract. Normal architecture observed in the kidney at all doses used shows the level of safety of the extract. This is in tandem with the normal features reportedly observed with the dichloromethane methanol extract of the fruit [28].

The potential benefits of TTF in preventing uterine fibroids were examined in this study. A vital building block for the manufacture of several steroid hormones, which are potent signaling molecules that control a number of bodily processes, is cholesterol [29]. A rise in total serum cholesterol is usually attributed to the activation of the enzyme 3-hydroxyl-3-methoxylglutamyl-CoA reductase (HMGR) which catalyzes the conversion of HMG-CoA to mevalonate; this is the rate-limiting step of cholesterol synthesis [17].

It has been demonstrated that ovarian steroid hormones are important molecular indicators linked to the formation and proliferation of uterine fibroids. The formation and development of uterine fibroids has been attributed primarily to estrogen, but progesterone and its receptors may also have a significant impact [10].

Due to its ability to bind to ERα receptors in the uterus and form a complex that interacts with DNA in the nucleus to activate transcriptional promoter and enhancer regions that govern gene expression, estradiol is unique in its ability to promote the growth of uterine cells. This enables RNA polymerase II binding and the subsequent start of transcription, which results in the production of proteins and higher uterine and ovarian cell proliferation [10].

T. tetraptera fruit extract at graded doses of 100, 200 and 400 mg/kg was evaluated in this study for its ability to inhibit the effect of MSG on these biochemical parameters tested as well as the histology of the uterus because it has been reported to be non-toxic at oral doses as high as 5000 mg/kg [30].

There was a significant ($P<0.05$) increase in serum cholesterol levels of the MSG group compared with the normal group (Fig. 2). Treatment with the ethanol extract of *T. tetraptera* fruit reduced the elevated cholesterol levels almost to normal ($P>0.05$) in our study, in both the curative and preventive experiments. The fruit extracts ability to lower cholesterol may be due to a decrease in dephosphorylated HMGR levels as well as an adverse effect on cholesterol production caused by the activation of glucagon and adrenaline [11]. Indeed, the fruit of this plant has been shown in numerous earlier studies to have a lipid-lowering impact [21].

Total protein content in the MSG and treated groups showed no significant difference in relation to the normal. This is similar to results obtained in previous works [7, 17].

Treatment with the ethanol extract of *T. tetraptera* fruit reduced the elevated estradiol levels in a dose-dependent manner (Fig. 6), in both the curative and preventive experiments. Its action on estradiol could possibly be attributed to suppression of the enzyme aromatase responsible for aromatization of androstenedione and testosterone to estrogens in the biosynthesis of estradiol from cholesterol [4]. It might also be due to an inducer of liver microsomal enzyme that increases the metabolism of estradiol, or it might contain phytochemicals that act as gonadotropin-releasing hormone (GnRH) agonists, which when stimulated continuously reduce the expression or downregulates GnRH receptors on the anterior pituitary [31]. Consequently, less estradiol would be produced. The decline in cholesterol production may potentially also be the cause of the estradiol decline.

Additional histology investigations demonstrated *T. tetraptera's* impact on the proliferation of leiomyoma cells in the uterus. A section of the uterus in rats given only food and water revealed normal tissue architecture, but after the female rats were administered 800 mg/kg of MSG, the sections revealed thick bands of spindle-shaped, haphazardly arranged smooth muscle fibers that crisscrossed the endometrial glands and stroma, a characteristic of the formation of leiomyoma.

Gradually increasing dosages of the extract and MSG were administered simultaneously, and the results showed a dose-dependent, stepwise improvement of the proliferating leiomyoma lesion, with the highest dose having the most effective impact. The curative treatment showed a greater reduction in the production of leiomyoma cells than the preventive treatment (Fig. 8).

T. tetraptera fruit has been observed to contain flavonoids, alkaloids, tannins, saponins, steroids, sterols and phenols [23, 28].

Part of the health benefits of saponins include immune system activation and a reduction in cholesterol levels in the body [21]. Additionally, studies have shown that saponin inhibits the enzyme aromatase [14], which is involved in the production of estrogen. Our results are supported by a previous investigation that found a substantial reduction in estrogen induced by a methanol extract of *T. tetraptera* fruit [32].

Phenols' antioxidant properties are also crucial in preventing chronic diseases because they can shield essential molecules like DNA, lipids and proteins from oxidative damage brought on by reactive oxidant species. While dietary antioxidants can have preventive effects, a low-antioxidant diet can raise the incidence of uterine fibroids [33].

HPLC analysis of the extract of *T. tetraptera* revealed the presence of major constituents such as umbelliferone, ferulic acid, echinocystic acid, aridanin and naringenin, with hentriacontane, butein and isoliquiritigenin present in reduced amounts (Table 6).

It has been found that the phenylpropanoid umbelliferone possesses antioxidant qualities and effectively inhibits type 3 17β-hydroxysteroid dehydrogenase, which is the main enzyme responsible for converting 4-androstene-3,17-dione into testosterone [34].

Ferulic acid is also a phenolic substance with a variety of biological activities, especially in oxidative stress and inflammation, and also plays an antifibrosis role [35].

Echinocystic acid has been reported to possess antiviral, anti-inflammatory and antioxidation activities [13] while naringenin, a flavanone, has anti-inflammatory, antioxidant and antiproliferative activities [36], and it also showed lipid-lowering properties. Butein, hentriacontane and isoliquiritigenin have numerous pharmacological properties including anti-inflammatory and antioxidative activities [13].

In conclusion, the decreased level of cholesterol and estradiol by effect of *T tetraptera* fruit extract contributed largely to decreased uterine leiomyoma proliferation. Further studies to determine its exact mechanism as antifibrotic agent against uterine leiomyoma needs to be established.

Conclusion

When administered acutely, *T. tetraptera* ethanol fruit extract is safe. The biochemical and hematological markers examined did not show any discernible alterations; nonetheless, long-term high-dose consumption may have harmful consequences on organs like the heart and uterus. This work aimed to demonstrate the antileiomyoma activity of the ethanol extract of *T tetraptera* fruit on Sprague Dawley rats. The results shown suggest that the extract is effective in reducing the biochemical parameters elevated by MSG and also inhibiting the formation of leiomyoma cells. This validates its usage in ethnomedicine in the management of uterine leiomyoma.

Acknowledgements

The authors wholeheartedly acknowledge the staff of the Animal house of pharmacology department, University of Benin, Benin city, for their assistance during the course of the experiment. We also wish to thank the laboratory staff of the Centre for Excellence in Reproductive Health Innovation (CERHI) for assistance in carrying out the biochemical tests. Last but not the least, we sincerely appreciate Mrs Queen Okoro from University of Benin teaching hospital, for preparation of the slides and prof. Gerald Eze of the department of anatomy, University of Benin, for his assistance in interpreting the histopathology slides.

Author contributions

ROI, BAA, and AU conceptualized the project and designed the study and methodology, SI, AAU, OVA and JMA performed the study, ROI performed the statistical analysis and data interpretation, ROI wrote the paper, and the final manuscript was proofread and approved by all authors.

Funding

This research was funded by the TETfund Institutional Based Research Fund (2022).

Availability of data and materials

The datasets used and/or analysed during the current study are available from the corresponding author on reasonable request.

Declarations

Ethics approval and consent to participate

Approval for the use of experimental animals was obtained from the Research Ethics Committee of the Faculty of Pharmacy, University of Benin, Nigeria (EC/FP/023/04). Appropriate permission to research on the study plant was duly solicited from the local legislations.

Competing interests

Authors declare no conflict of interest

Solvent fractions of Vitellaria paradoxa root extract suppress phenylhydrazine-mediated jaundice in Wistar rats

Anyebe, Daniel Abu1 ; Turaki, Abdullahi Aliyu1; Yusuf, Abdulrahman Bashir1; Shemishere, Ufuoma Bigila1; Okwanya, Musa Idu2; Tajudeen, Yahaya31 Federal University, Birnin Kebbi, Department of Biochemistry and Molecular Biology, Birnin Kebbi, Nigeria (GRID:grid.475123.6) (ISNI:0000 0004 6023 7915)2 Modibbo Adama University, Department of Biochemistry, Faculty of Life Sciences, Yola, Nigeria (GRID:grid.475123.6)3 Federal University, Birnin Kebbi, Department of Biological Sciences, Birnin Kebbi, Nigeria (GRID:grid.475123.6) (ISNI:0000 0004 6023 7915)

ABSTRACT (ENGLISH)

Background

In the first few days of life, jaundice has continued to be a major health concern. It typically manifests as a yellowing of the skin, mucous membranes, and sclera as a result of bilirubin deposition from excessively high concentrations in the body. It affects 80% of preterm and 60% of term new-borns within the first seven days of life, which is of great concern. According to the World Health Organization, the widespread acceptance of traditional medicines can be attributed to their accessibility and affordability. In West African arid savannah, there is a tree called *Vitellaria paradoxa* (Sapotaceae) that grows naturally. This well-known herb has numerous applications in medicine. Various plant components, including the leaves, roots, seeds, and fruit, have all been used in traditional medicine to cure a variety of illnesses. The purpose of this study is to objectively ascertain the efficacy of *V. paradoxa* root extracts on jaundice. Rats given phenylhydrazine (PHZ) to induce hyperbilirubinemia were orally administered ethylacetate, *n*-

butanol, *n*-hexane, and aqueous fractions.

Result

Results indicated the presence of terpenoids, flavonoids, and phenol. *n*-hexane and ethylacetate fractions showed activity against jaundice in rats. This observation was due to the fact that they significantly improved all biomarkers that were examined, namely body weight change, liver function parameters (total bilirubin, direct bilirubin, aspartate aminotransferase, albumin, and total protein), haematological parameters (white blood cells, haemoglobin, red blood cells, haematocrit, and platelets), and antioxidant enzymes (superoxide dismutase and malondialdehyde).

Conclusion

n-Hexane and ethylacetate fractions of the extract showed significant activity against PHZ-induced jaundice in rats. However, *n*-hexane fraction was the most active fraction.

FULL TEXT

Background

Lately, jaundice is now a serious health problem in neonates. According to Khoshnur et al. [13], jaundice is typically identified by the yellowing of the skin, mucous membranes, and sclera as a result of bilirubin deposition when the blood's bilirubin concentration is excessively high (>3 mg/dl). Changes in bilirubin metabolism often result in hyperbilirubinemia. Increased levels of unconjugated bilirubin are caused by higher rate of red blood cell breakdown, whereas higher levels of conjugated bilirubin are caused by liver injury and/or biliary system blockages [10]. Neonatal jaundice is the term used to describe jaundice in new-borns [6]. Within the first seven days of life, an alarming 60% of term and 80% of preterm new-borns develop jaundice [23]. The use of natural resources such as plant materials to treat or control illnesses is as old as man [27].

According to the World Health Organization, the widespread acceptance of traditional medicine can be attributed to its accessibility and affordability. With increased data generated from scientific research on the use of traditional medicine in the management of chronic diseases, usage is becoming more widespread [26]. An estimated 80% of people in impoverished nations like Nigeria use herbal medicine to treat common medical conditions like jaundice [9]. In the dry savannah region of West Africa, *Vitellaria paradoxa* (Sapotaceae) grows naturally [18]. This well-known herb has numerous applications in conventional medicine. It goes by several names: Ökwuma in Igbo, Ëmi in Yoruba, Kadanya in Hausa, Kareje in Fulfulde, and Shea butter in English [1]. Many African ethnic groups consider it to be a sacred tree, and it is used in many religious and cultural practices [18].

Various parts of *Vitellaria paradoxa*, such as leaves, roots, seeds, fruit, and stem bark, have been used in traditional medicine to treat microbial infections including helminths, dysentery, diarrhoea, and other infections affecting the gastrointestinal tract, skin, and wounds [2]. The stem bark has been reported to be used in the treatment of leprosy and cough [7]. The plant's kernels yield Shea butter, which is oil-rich and used as a source of edible oil in many homes throughout Sahel Africa especially Northern Nigeria. In addition, Shea butter is used to treat rheumatism, ulcers, dermatitis, rashes, and inflammation [16]. In the north and other parts of Nigeria, chewing sticks made from *Vitellaria paradoxa* roots are widely used to clean teeth and mouths. Root and root bark of *Vitellaria paradoxa* are typically made into a paste and administered orally [17]. The purpose of this study is to objectively establish if *Vitellaria paradoxa* root extracts are effective in treating jaundice.

Methods

Collection and identification of plant material

Vitellaria paradoxa roots and fresh leaves were collected. A sample of the leaf was identified at a herbarium and a voucher number assigned. Roots of the plant were carefully washed in clean, chopped into tiny pieces, shade-dried for 14 days, pulverized, and stored in airtight containers.

Preparation of methanol extract

Methanol root extract *Vitellaria paradoxa* was made by macerating 1500 g of the pulverized material root in 9 litters of methanol for 72 h. It was then filtering using Whatman No. 1 filter paper, concentrated using a rotary evaporator at 40 °C. The extract obtained was freeze-dried giving rise to 7.3% w/w yield.

Fractionation of methanol extract of *Vitellaria paradoxa* root

Using Almohaimeed et al. [3] approach, methanol extract was partitioned into ethylacetate, *n*-butanol, *n*-hexane, and an aqueous fraction.

Qualitative phytochemical screening of *Vitellaria paradoxa* root

Using standard protocol as outlined by Shemishere et al. [20], a chemical test was performed to screen and identify phytochemicals (saponins, terpenoids, alkaloids, tannins, carbohydrates, phenols, steroids, flavonoids, and cardiac glycosides) in the methanol extract of *Vitellaria paradoxa* root.

Quantitative determination of total phenolic and flavonoid content of methanol extract of *Vitellaria paradoxa* root

Total phenol and flavonoid content of *Vitellaria paradoxa* methanol root extract was calculated using the method described by Shemishere et al. [21, 22].

Animal protocol

42 rats, ages 10 to 12 weeks and weighing between 70 and 90 g, were bought from a standard Animal House. The rats were kept in metal cages and given free access to food and water in a natural environment with a 12-h light/dark cycle for two weeks to acclimatize before administration. Rats were maintained in accordance with the Animal Ethics Committee's guide for the care and use of animals in research and education and the National Institutes of Health's guide for the care and use of laboratory animals (NIH Publications No. 8023, revised 1978). The experimental protocol was approved in accordance with ethical standards.

Rats were divided into 6 groups of 7 rats each and administered as follows. Rats except those in the control group received 1 dose of phenylhydrazine (PHZ) through intraperitoneal route at 40 mg/kg body weight for three consecutive days to induce jaundice. This approach slightly differs from that which Kolawole et al. [14] used. Rats were administered as follows for 21 days. Rats in PHZ + Aqueous group, PHZ + n-hexane, PHZ + n-butanol, PHZ + Ethylacetate, and PHZ alone group were each administered 50 mg/kg body weight of the extract fractions. The rats were killed twenty-four hours following the last administration.

Haemoglobin concentrations, blood platelets and haematocrit scores, white blood cell and red blood cells counts, and haemoglobin concentration were measured after blood samples were drawn into EDTA specimen bottles. The residual blood sample was transferred into simple sample bottles, centrifuged, and serum extracted with care to measure the levels of malondialdehyde (MDA) and superoxide dismutase (SOD), total and direct bilirubin, aspartate aminotransferase, alkaline phosphatase, alanine amino transferase, albumin, and total protein using appropriate kits.

Body weight change determination

On days 0, 7, 14, 21, and 28 of the treatment, body weight was measured and recorded. Rats' body weight on day 0 was subtracted from their body weight on day 28 to calculate the changes in the body weight.

Determination of superoxide dismutase (SOD) activity

The activity of superoxide dismutase (SOD) was determined using the method of [25] with slight modifications. An aliquot of 0.4 ml of colon sample was added to 5 ml of 0.05 M carbonate buffer in a quartz cuvette and the reaction started by the addition 0.6 ml of 0.3 M adrenaline. Reference cuvette contained 5 ml of carbonate buffer, 0.6 ml of adrenaline and 0.4 ml of distilled water. Increase in absorbance at 480 nm was monitored every 30 s for 120 s. Enzyme activity was expressed as units/mg protein. One unit of an enzyme is defined as the enzyme activity that inhibits auto-oxidation of adrenaline by 50%.

Determination of malondialdehyde (MDA)

Colon tissue samples were subjected to the lipid peroxidation analysis using the methodology outlined by Ayodeji et al. [5]. This experiment is predicated on the reaction between MDA and 2-thiobarbituric acid, a chromogenic reagent. A pink chromophore with an absorbance maximum at 532 nm is produced when one molecule of MDA interacts with two molecules of 2-thiobarbituric acid by a Knoevenagel-type condensation. A mixture of 1.6 ml of phosphate buffer, 0.5 ml of colon sample, 0.5 ml of 30% TCA, and 0.5 ml of 75% 2-thiobarbituric acid (TBA) in 0.1 mol/l HCl comprised the reaction mixture. For two hours, the mixture was heated in a water bath at 90–95 °C. The resulting mixtures were centrifuged at 3000*g* for 15 min after being chilled on ice. At 532 nm, the absorbance of the turbidity-free

supernatant was measured. The molar extinction coefficient concentration in nmole/L is used to compute MDA, which is equal to absorbance × (1000/1.56).

Determination of blood parameters

An auto-haematological analyser (Beckman Coulter, USA) was used to determine the red blood cell count (RBC), white blood cell count (WBC), haemoglobin concentration (HGB), blood platelet count (PLT), and haematocrit value (HCT) from blood samples collected in EDTA bottles.

Determination of Liver function parameters

Standard test kits from Ultracare Diagnostics were used to measure the following liver function parameters: total bilirubin (TB), direct bilirubin (DB), aspartate aminotransferase (AST), alanine amino transferase (ALT), and albumin (ALB). Standard kits from Randox, UK, were used to measure total protein (TP), aspartate aminotransferase (ALP), and albumin (ALB).

Data analysis

For testing significance levels ($p<0.05$), the statistical programme for social sciences (SPSS) version 20 was utilized.

Results

Extract yield

The crude methanol extract yield at the conclusion of the extraction procedure was 19.75% (w/w). The percentage yields for the other fractions were as follows: 9.36 g, 2.41 g, 3.53 g, and 0.43 g for *n*-hexane, *n*-butanol, ethylacetate, and water, respectively.

Qualitative phytochemical constituents

According to the findings from the analysis of the phytochemical components of the methanol extracts, phenols were found to be present in significant amount. There was a medium concentration of terpenoids and carbohydrates, and trace amounts of saponins, alkaloids, tannins, steroids, and flavonoids. Heart glycosides, however, were not found in the sample (Table 1).

Table 1. Qualitative phytochemical constituents of methanol extract of *Vitellaria paradoxa* root

Phytochemicals	Status
Saponins	+
Terpenoids	++
Alkaloids	+
Tannins	+
Carbohydrates	++
Phenols	+++
Steroids	+
Flavonoids	+
Cardiac glycosides	−

+: Present in a trace concentration; ++: present in a medium concentration; +++: present in a high concentration; − absent or in negligible amount

Quantitative phytochemical constituents

Two phytochemicals, namely total phenol and total flavonoids, were quantified. Total phenols obtained were 39.85 ± 0.91 mg garlic acid equivalent per gram of extract. On the other hand, the total flavonoids obtained were 0.9 ± 0.04 mg quercetin equivalent per gram of extract (Table 2).

Table 2. Total phenolic and flavonoid content of methanol extract of *Vitellaria paradoxa* root

Phytochemicals	Quantitative value
Total phenols (mg garlic acid equivalent/g of extract)	39.85 ± 0.91
Total flavonoids (mg Quercetin equivalent/g of extract)	0.90 ± 0.040

All values are expressed as mean ± SEM (n = 3)

Effect of methanol and solvent fractions of *Vitellaria paradoxa* root extracts on body weight changes in phenylhydrazine-induced hyperbilirubinemic in Wistar rats

According to the body weight changes results, the PHZ alone group lost a substantial amount of weight in comparison with the control group. The PHZ + *n*-butanol, PHZ + ethylacetate, and PHZ + aqueous groups all gained weight as compared to the control group, but the weight gain was not statistically significant (P<0.05). Rats in the PHZ + *n*-hexane group did not substantially vary in body weight gain from the control group. Overall, Table 3 shows that the PHZ + *n*-hexane fraction was more effective at reversing weight loss.

Table 3. Body weight changes in phenylhydrazine-induced hyperbilirubinemic Wistar rats treated with solvent fraction of *Vitellaria paradoxa root extracts*

GROUP	DAY 1 (g)	DAY 28 (g)	BWC (g)
Control	81.77 ± 16.91	123.39 ± 17.21	+ 41.62 ± 0.30^{bc}
PHZ only	84.35 ± 18.16	53.17 ± 17.31	− 31.18 ± 0.85*
PHZ + *n*-hexane	85.21 ± 16.21	126.57 ± 17.02	+ 41.36 ± 0.81^{bc}
PHZ + *n*-butanol	86.50 ± 11.08	73.67 ± 13.3	+ 32.17 ± 2.22 *^{c}
PHZ + ethylacetate	73.29 ± 19.13	63.27 ± 20.21	− 10.02 ± 1.08*^{c}
PHZ + aqueous	83.86 ± 11.89	54.34 ± 13.54	− 29.52 ± 1.65*

50 mg/kg of phenylhydrazine intraperitoneal (PHZ): *n*-hexane, *n*-butanol, ethylacetate and aqueous represents the different fractions of the extracts: BWC: body weight change: values are presented as mean ± SD (n = 7):*values differ significantly from control (p<0.05): ^{b}values are not significantly different from each other (p<0.05): ^{c}values differ significantly as compared with PHZ only (p<0.05)

Effect of solvent fractions of *Vitellaria paradoxa* root extracts on SOD and MDA in phenylhydrazine-induced hyperbilirubinemic in Wistar rats

Data produced showed that, in comparison with the PHZ only group, the *n*-hexane fraction of the extract

considerably enhanced the levels of SOD and decreased the levels of MDA. SOD levels in the *n*-hexane fraction increased to control values, with no discernible change ($P<0.05$). The n-hexane fraction's activity resulted in a reduction of MDA levels, a sign of lipid peroxidation, according to the same observation. While SOD and MDA levels were improved by two other extract fractions, *n*-butanol and ethylacetate, the effects were not as great as they were in the PHZ only. For the two indicators tested, there was no discernible improvement in the extract's aqueous fraction (Table 4).

Table 4. Superoxide dismutase activity (SOD) and malondialdehyde (MDA) levels changes in phenylhydrazine-induced hyperbilirubinemic Wistar rats treated with solvent fraction of *Vitellaria paradoxa* root extracts

Group	SOD (units/mg)	MDA (nmol/l)
Control	2.64 ± 0.35^{bc}	24.35 ± 0.36^{bc}
PHZ only	1.22 ± 0.13*	44.08 ± 0.23*
PHZ + *n*-hexane	2.30 ± 0.35^{bc}	22.39 ± 0.81^{bc}

PHZ + ethylacetate	1.38 ± 0.23*^{c}	38.74 ± 0.41*^{c}
PHZ + aqueous	1.43 ± 0.16*	38.04 ± 0.41*

50 mg/kg of phenylhydrazine intraperitoneal (PHZ): *n*-hexane, *n*-butanol, ethylacetate and aqueous represents the different fractions of the extracts: SOD: superoxide dismutase: MDA: malondialdehyde: values are presented as mean ± SD (n = 7):*values differ significantly from control ($p<0.05$): ^{b}values are not significantly different from each other ($p<0.05$): ^{c}values differ significantly as compared with PHZ only ($p<0.05$)

Effect of solvent fractions of *Vitellaria paradoxa* root extracts on blood parameters in phenylhydrazine-induced hyperbilirubinemic in Wistar rats

Results showed that the *n*-hexane fraction of the plant extract significantly improved the blood parameters measured when different fractions of the extract were tested to determine their effects on some haematological parameters in PHZ-induced hyperbilirubinemia. Conversely, the extract's ethylacetate fraction was found to generally improve all blood parameters examined; however, only HCT and PLT showed significant ($P<0.005$) improvements in comparison with the control group. When compared to the control group, the butanol fraction greatly improved the parameter, but not as much as it did when compared to the PHZ alone group. When compared to the control and PHZ alone groups, the aqueous extract had no significant impact on the haematological parameters (Table 5).

Table 5. Changes in haematological parameters in phenylhydrazine-induced hyperbilirubinemic Wistar rats treated with solvent fractions of *Vitellaria paradoxa* root extracts

Effect of solvent fraction of *Vitellaria paradoxa* root extracts TB, DB, AST, ALP, ALT, ALB and TP in phenylhydrazine-induced hyperbilirubinemic in Wistar rats

By lowering the levels of both TB and DB, the *n* hexane fraction successfully counteracted the effects of PHZ, according to the results of the biochemical assay used in this study. ALT, ALP, and AST all showed the same pattern. Conversely, in comparison with the control, there was a substantial (P<0.005) rise in the levels of ALB and TP. Additionally, ethylacetate fraction was found to significantly lower TB and DB. The levels of AST, ALP, ALT, ALB, and TP improved, although the difference was not statistically significant (P<0.005). All liver markers that were tested for indicated improvement in the butanol fraction as well, but the improvements were not statistically significant (P<0.005) when compared to the control. The extract's aqueous fraction had no effect on the liver indicators tested for (Table 6).

Table 6. Changes in liver function parameters in phenylhydrazine-induced hyperbilirubinemic Wistar rats treated with solvent fraction of *Vitellaria paradoxa* root extracts

Discussion

Data generated from this study have highlighted the importance of using scientific experiments to validate claims by traditional medical practitioners on the efficacy or otherwise on products used in the management and treatment of human ailments. Data from this study have shown the activity of *Vitellaria paradoxa* extracts on jaundice. The use of PHZ to induce jaundice in rats has long been established [12]. Its results obtained from this studies seem to show that only the n-hexane and ethylacetate fractions of the extract showed activity against jaundice. It is important to establish that data from previous study in which Wistar albino rats were exposed to root extract of *Vitellaria paradoxa* at a concentration of 50 mg/kg body weight did not show any toxic effect. At a dose of 100 mg/kg body weight some toxic effects were observed [8]. This informed the selection of the dose of 50 mg/kg body weight for this study.

Response to treatment in jaundice is usually associated with weight gain as shown from this study where n-hexane group showed significant weight gain when compared with the PHZ only group [12]. The anti-lipid peroxidative and antioxidant properties of phenols and flavonoids have been reported. Both phenols and flavonoids were detected from the screening process used to identify the phytochemical components present in the extract. Numerous sources of free radicals within cells have been identified. The xanthine oxidase system, the mitochondrial electron transport system, and an increase in intracellular calcium levels are a few of the sources [4]. These free radicals set off series of biochemical reactions in vivo that disrupt cell membrane integrity and increase endotoxin release, changing how cells behave. The cell membrane finally disintegrates as a result of the injury. It is commonly recognized that oxidative stress and subsequent cell damage are reduced when enzymatic and non-enzymatic antioxidant levels in vivo increases [4]. One of the etiologic variables linked to the RBC breakdown and subsequent hyperbilirubinemia seen in anaemia has been identified as oxidative stress [4]. Oxidative stress occurs when the body's antioxidant system is unable to eliminate the free radicals that are produced. From the data presented in Table 4, *n*-hexane fraction of the extract significantly (P<0.005) increased the activity of SOD (2.60 ± 0.35) when compared to PHZ group. The administration of n-hexane fraction considerably decreased the levels of lipid peroxidative marker MDA when compared with the PHZ group. There was no significant variation found between the control and n-hexane group. This outcome is in line with the result of Uz et al. [24] where the levels of MDA in renal ischaemia and reperfusion (I/R) damage showed that ginger extract reduced I/R damage but serum MDA levels did not show any difference between control and treatment group.

Elevated bilirubin levels, a by-product of red blood cell breakdown, are indicators of jaundice [4]. In other words, jaundice is a medical disorder whose course is determined solely by the health of the red blood cells. One essential step in determining if a treatment is successful in curing jaundice is assaying for red blood cells and other blood parameters. A study by Raicevic et al. [19] demonstrated the connection between the onset of neonatal jaundice and some haematological markers in new-borns. According to the research findings, new-borns with low RBC and high bilirubin levels subsequently experienced jaundice. From our result in Table 5, the levels of RBC, HGB, HCT, and PLT all increased significantly for both the *n*-hexane and ethylacetate fraction when compared with control. In contrast, WBC decreased considerably in comparison with the PHZ alone group. Nan et al. [15] in a study on the relationship between maternal blood parameters and new-born jaundice found that mothers with high WBC and mean corpuscular volume (MCV) levels frequently give birth to infants who experience neonatal jaundice.

In addition to providing information on liver cell damage, the liver function test panel makes it evident how functional the liver is. According to a study by Hayat et al. [11] on human subjects, jaundice is typically associated with abnormal levels of liver function indicators. In another study published by [4], treatment with ursodeoxycholic acid led to a significant decrease in the levels of AST, ALT, and GGT in rats that developed obstructive jaundice. This study's findings demonstrated that the *n*-hexane fraction considerably lowered the blood levels of TB, DB, AST, ALP, and ALT. In addition, the levels of TP and ALB were substantially higher than those of the PHZ alone group. The liver function indices AST, ALT, urea, creatinine, uric acid, and bilirubin were all improved in a 2019 study by Ali

utilizing an extract of *Vitellaria paradoxa* in diabetic rats. Following the injection of *Vitellaria paradoxa* extract, the activity of antioxidant enzymes such as SOD and CAT increased. The decrease in MDA levels followed the same pattern. This is in line with the study's findings, which indicated that the extract's *n*-hexane fraction was the only one that exhibited activity. This observation also suggests that the n-hexane fraction of the extract may likely contain the active component of the extract that accounts for the activity reported in this investigation.

Conclusion

Result from this study has shown that root extract of Vitellaria paradoxa reversed all the markers associated with jaundice induced in rats with PHZ. An attempt to also identify the solvent fraction of the extract containing the active principle was also achieved. *n*-hexane fraction of the root extract of Vitellaria paradoxa showed activity for all the markers of jaundice checked in this study. Following closely is the ethylacetate fraction of the extract which showed activity for all the haematological parameters. Findings from this studies are limited with regard to why *n*-hexane fraction showed positive result for all the markers assayed for as against the ethylacetate fraction which showed activity for only the haematological parameters assayed for. Further studies will be required to identify the active principle responsible for the observable activity and to unravel the biochemical basis of the action.

Plant identification

Fresh leaves and root of Vitellaria paradoxa were collected from Yelwa, Yauri local government area in Kebbi State, North-West Nigeria in August, 2023. Plant leaf sample was identified at the Herbarium section of the Federal University Birnin-Kebbi, and a sample of the authenticated materials with the voucher number FUBK/PIN/0219 was deposited.

Author contributions

DAA contributed to conceptualization; writing—original draft; writing—review and editing; project administration; supervision; resources; funding acquisition; and investigation. AAT was involved in writing—original draft; methodology; visualization; writing—review and editing; investigation; and formal analysis. Characterization of biochemical and optical properties of Nile tilapia (Oreochromis niloticus) corneal collagen

Abd-Elrahman, Hatem Hassan1 ; Omar, Wael Abdel-Moneim2 ; Elnashar, Hazem Abdallah3 1 National Institute of Oceanography and Fisheries, Cairo, Egypt (GRID:grid.419615.e) (ISNI:0000 0004 0404 7762)2 Taif University, Department of Biology, College of Science, Taif, Saudi A rabia (GRID:grid.412895.3) (ISNI:0000 0004 0419 5255)3 Giza Memorial Institute for Ophthalmic Research (MIOR), Giza, Egypt (GRID:grid.412895.3)

ABSTRACT (ENGLISH)

Background

Collagen extracted from fish body parts is a promising biological material. It has an important role in many pharmaceutical, medical applications and tissue engineering such as corneal regeneration and stromal replacement. The present work investigates a new trend to extract collagen from the fish cornea, as a prospected substituent of human corneal collagen by characterizing some biochemical and optical properties of the fish corneal collagen.

Results

Examination of the corneal tissue of Nile tilapia; *Oreochromis niloticus* was conducted using electron microscopy, Fourier transform infrared (FTIR) spectroscopy, UV–visible spectrophotometry, optical properties, and thermal properties. The fish were divided into 10 groups each of which consisted of 5 fish. 2 groups of fish were examined for each technique. Results indicated that the corneal layers of *O. niloticus* are thin at the center and thicker at the periphery with the stroma consisting of a triple helical structure collagen type I. The fish cornea showed very weak transmission at the UV regions (190 nm) and maximum transmission at the visible regions. The values of transmission (*T*), reflected light (*R*) and scattered light (*S*) were 2.685 mw, 100×10^{-3} mw at 45° and 40×10^{-3} mw, respectively. Consequently, the percentage of absorbed light is 21.76%. The denaturation temperature of the fish corneal stroma is 22.27 °C.

Conclusions

The method for obtaining fish collagen affects the specific properties of collagen and consequently its further uses as a potential biomedical substituent for mammalian collagen. Specification of the fish species and tissue type is crucial in identifying the quality as well as the physical and functional properties of the extracted collagen.

FULL TEXT

Background

The link between aquaculture production and fish waste is direct. This problem represents a worldwide environmental challenge. Recycling fish waste and obtaining valuable biomaterials is an environmentally accepted solution for this problem. Several authors stressed the importance of isolating and converting collagen from fish waste into marketable products, as well as the positive influence of this process on the environment [1, 2]. Compensatory corneal tissues represent another added value that could be achieved from recycling fish collagenous byproducts. Human corneal damage and corneal diseases represent the main causes of vision loss [3]. Human corneal transplantation is a vision rehabilitation procedure, used when the corneal clarity is negatively affected. Regardless of the used technique, the scarcity of a donor for corneal tissue is the greatest limiting factor in developing countries, while globally this problem results in approximately 10 million untreated patients [4, 5]. Recently, corneal tissue could be obtained from several animal species [6]. However, when selecting an animal species for conducting a human corneal xenograft, the biochemical composition, and structural differences of corneal proteins between humans and other animal species must be considered to minimize the immune response and improve xenotransplantation outcomes [7]. Although several authors discussed the extraction of collagen from fish skin, scales, and bone, as far as known, no previous research has investigated the extraction of collagen from fish cornea.

Studies investigating the histological and biochemical structure of vertebrate corneas have identified several regions that constitute the corneal tissue [8, 9]. The outer peripheral non-keratinized epithelium is supported by a thin dense membrane called the basement membrane and followed by Bowman's layer which is a thin dense acellular sheath in between the basement membrane and the anterior stroma of the cornea. The corneal stromal layers are collagenous, soft, and flexible. Stroma provides the thickness of the cornea. Differences in shape and structure between vertebrate corneas are related to the differences in stromal thickness and nature of the basement membrane. Beneath the stroma lies the Descemet's membrane, which is a dense and thick layer that supports a single layer of endothelial cells. The endothelial layer constitutes the innermost layer of the cornea.

The cornea is a transparent avascular tissue that has refractive power. Light passes through the cornea to the lens then reaches the retina inside the eyeball [10]. The cornea also protects the internal constituents of the eyeball. Consequently, clarity, tensile strength and proper shape are the main features of the corneal tissue. Fish have a wide range of corneal phenotypes depending on their habitats. Differences in biochemical and structural properties of vertebrate collagen fibers are the main reasons for the presence of different collagen types [11, 12].

The advantages of marine collagen draw attention to its use instead of mammalian collagen in the manufacture of medical dressings such as sponges and wound-treatment membranes. Marine collagen is fat-free, shows weak antigenicity, compatible with mammalian collagen and is easily absorbed by the human body [13, 14]. Marine collagen is used as a biomaterial for ophthalmic medical devices due to its low toxicity and low antigenicity [15, 16]. The low melting point, difficulties of extraction and low mechanical strength are the main disadvantages that restrict the use of marine collagen as an alternative to mammalian collagen [17–20].

The present study aims to investigate utilization of collagen obtained from the cornea of Nile tilapia fish; *Oreochromis niloticus* as a potential alternative to mammalian corneal collagen by examining its biochemical and optical properties.

Methods

Experimental fish

A total of 50 healthy specimens of unisex Nile tilapia *O. niloticus*, with an average body weight of 250.0 ± 10.0 g, an average body length of 20.0 ± 1.0 cm and an average corneal diameter of 12.0 ± 1.0 mm were used. Fish were transferred to the laboratory in well-aerated 150 L fiberglass tanks to avoid fish hyperactivity, physical injuries, and stress. Upon arrival, the fish were immersed in 5.0 g/L NaCl sterile solution, followed by 1.0% $KMnO_4$ sterile solution to eliminate any possibility of the presence of ectoparasites. Fish were screened for any pathological symptoms and acclimatized under laboratory conditions for 2 weeks in a fiberglass tank (1.0 m^3) supplied with de-chlorinated tap water under natural photoperiod and temperature. Renewal of 50% of water was done every week. Ammonia and ammonium concentrations were checked twice a week. Fish were fed twice daily on a conventional fish diet (30% crude protein) at a rate of 3% of the body weight. Water temperature, pH, alkalinity, total hardness and dissolved oxygen were measured daily and maintained at normal conditions during the whole study period. A total of 5 healthy fish were considered as a single group to conduct duplicate group treatments for each of the following techniques.

Collagen purification

Fish were anaesthetized with MS-222 (50 ppm), and then the whole cornea was examined using a slit lamp. After that, the eyes were enucleated and the corneas were isolated for scanning electron microscopy (SEM), UV–visible spectrophotometry and optical properties. Corneal epithelium, endothelium and basement membrane were removed by scratching and lamellae were collected and processed for the Fourier transform infrared (FTIR) spectroscopy and thermal properties investigations.

Scanning electron microscopy (SEM)

The morphological structure of the fish cornea and its quality in terms of collagen layers' smoothness and regularity was observed under SEM. Samples were dehydrated in ascending concentrations of ethyl alcohol, dried, examined and photographed at different angles using a VEGA3 TESCAN electron microscope at accelerating voltages of 5 or 10 kV.

Fourier transform infrared (FTIR) spectroscopy

For the identification of collagen type, FTIR spectra were recorded (Thermo Scientific FTIR, model Nicolet 5s Madison, WI, USA). The equipment consists of an ATR ID3 accessory for germanium crystal reflection. The spectral resolution was 4 cm^{-1}. 64 scans were obtained in the range of 400–4000 cm^{-1}. Fresh corneal lamellae were cut manually into small pieces and stored in phosphate-buffered saline (PBS) solution. The C=O, NH_2 and C–N groups were tested for absorption of amid I, II and III bands, respectively.

UV–visible spectrophotometry

The UV–visible absorption-transmittance spectrum of the *O. niloticus* corneal tissue samples were quantified using UV–visible spectrophotometry (Thermo Scientific, Genesys 10S UV–Vis, USA). The absorbance was quantified at different lengths in the scope of 180–1000 nm (5 nm intervals). The spectrophotometer was set up so the cornea and microscope cover glass could be placed perpendicular to the estimating beam. The cover glass was placed on the cuvette holder. The transmission percentage indicator was chosen. First, the base spectrum of the microscope cover glass was measured. Second, the corneal sample was placed on the cover glass with the epithelium directed downward. By placing the samples in this orientation, the estimated light beam of the spectrophotometer entered the cornea from the epithelial side, that is, from the identical direction as the cornea in situ. The cover glass and the cornea were replaced. Their position was adjusted so that the rectangular estimating beam was in the center of the cornea. After adjustments were made, the cornea samples were scanned.

Optical properties (transmission, reflection, scattering and absorption)

A laser-based bench-top optical system was used. A 650 nm red laser was applied to detect the percentage of transmission (T), reflection (R) of light at 45° and scattering (S) of incident light on fish cornea at incident light intensity (P_o) of 3.61 mw. Where, $T\% = T/P_o \times 100$, $R\% = R/P_o \times 100$ and $S\% = S/P_o \times 100$. The absorption percentage ($A\%$) is calculated as $100\text{-}(T\% + S\% + R\%)$. Fresh fish eyeballs were obtained, and the cornea was cut along with a part of the eyeball to maintain the tensile strength of the cornea. It was cleaned of pigments and then tested.

Thermal properties (denaturation temperature)

The thermal properties were determined using a differential scanning calorimetry thermogram method (DSC-60 detector). The stromal sample (weight 2.070 mg) was sealed in an Aluminum seal cell and was subjected to the test in a nitrogen gas atmosphere on a scale from −50 to 50 °C and a temperature rate of 10 °C/min.

Results

Figure 1A shows that the cornea is thin at the center and thicker at the periphery. The collagen fibers were amalgamated during the processing of the corneal tissue for SEM imaging (Fig. 1B). Figure 1C shows the junction between epithelium and stroma. Figure 1D shows the multiple patterns of the configuration of the collagen fibers at the central sections as well as the anterior and posterior parts of the stroma. The FTIR spectroscopy results (Fig. 2) showed a clear sharp peak at 3285.85 cm^{-1}. The source of the signal is the N–H stretch coupled with a hydrogen bond indicating the presence of amide A. The extremely small peak at 2900 cm^{-1} may refer to amide B. The peak at 1633.41 cm^{-1} was related to amide I. Amide II was measured at 1553.09 cm^{-1}. Amide III was measured at 1233 cm^{-1}. The present findings confirm the presence of a triple helical structure characteristic of collagen type I. Figure 3 shows little transmittance of UV in the C region ranging from 100 to 280 nm. A 650 nm red laser beam was used to determine the optical properties of the cornea. The detected results showed that transmission (T), reflected light (R) and scattered light (S) were 2.685 mw, 100×10^{-3} mw at 45° and 40×10^{-3} mw, respectively. The T, R and S percentages were 74.37%, 2.77% and 1.1%, respectively. Consequently, the absorbed light (A) percentage is 21.76%. Results of the present study illustrated that the denaturation temperature of *O. niloticus* corneal stroma was 22.27 °C (Fig. 4).

Discussion

The present study highlights the biochemical and optical properties of Nile tilapia; *O. niloticus* corneal tissue. The principal objective of the assessment of the fish cornea by SEM is to observe the quality (rough or smooth), thickness and to estimate the presence of burrs, curls, or tissue bridges in the stroma region. The cornea of freshwater teleost has one continuous stroma that consists of collagen fibers arranged in bundles with the keratocytes distributed in between [9, 21]. The stroma of fish and human corneas have thin collagen fibers that together appear to indicate an overall parallel collagen direction. The human cornea consists of collagen fibers of different types with unique stacked spacing and arrangement which is an important factor affecting corneal transparency [22].

FTIR spectroscopy analysis is used to detect the functional groups that appear to characterize a compound by estimating its absorption of infrared radiation over different wavelengths. FTIR spectroscopy is used to assess the structure and type of collagen material. In addition, it serves to distinguish between methods of collagen extraction [23–25]. Similar pattern of FTIR spectroscopy results was indicated by Wang et al. [26] who explained the connection with the asymmetric stretching of C–H. The peak at 1633.41 cm^{-1} was related to amide I as a sign of the peptide's secondary structure, and the source of the signal is the C=O [27]. Amide II was measured at 1553.09 cm^{-1} , which is due to the stretching of the carbonyl group attached to a carboxyl group. Amide III was measured at 1233 cm^{-1}, which was determined by combining the C–N stretching and N–H bending modes (Fig. 2). The detected triple helical structure agrees with results reported by Sun et al. [28] for collagen extracted from Nile tilapia; *O. niloticus* skin. Figure 2 also shows that the functional groups found in the triple helix were not damaged owing to the method used to obtain collagen directly by removing both the epithelium and endothelium cells. Variations in width and height of the corresponding signals in several graphs could be attributed to the different experimental conditions of each study such as different solvents with different concentrations [14].

The wavelength of the UV spectrum ranges from 100 to 400 nm. The range is divided into three regions: C, B and A ranging from 100 to 280 nm, 280–315 nm and 315–400 nm, respectively. Figure 3 shows little transmittance of UVC. This may be attributed to the low thickness of the fish cornea in general. The UV absorption of collagen could be attributed to the peptide bonds and side chains in the corneal collagen structure. The collagen isolated from tilapia skin showed maximum absorbance at 230 nm [27] which is consistent with the characteristic absorbance of collagen type I in the present study. Similar findings were reported by several authors for collagen extracted from different marine species [26–29]. The human cornea transmits radiation only at 295 nm and above. The transmission of the human cornea is highest in the long wavelength area of the visible spectrum from 600 to 700 nm. Meanwhile, transmission of *O. niloticus* cornea is highest in the long wavelength region of the visible spectrum ranging from 600 to 700 nm and lowest in the short wavelength region below 500 nm (Fig. 3).

Huibertus et al. [30] measured light scattering and light transmission in fish scale-derived collagen (FSDC) and they concluded that FSDC is proposed as an alternative for mammalian donor corneal tissue which supports the present findings. The refractive index of corneal tissues of human and *O. niloticus* fish are 1.363 ± 0.011 and 1.360 ± 0.009, respectively [9].

Regarding the thermal properties, it was noticed that one of the most important characteristics of biomaterials is their denaturation temperature because it affects their thermal stability and consequently their physical and mechanical

properties [31]. The denaturation temperature is defined as the temperature degree at which the deformation of collagen helical structure occurs [32]. The denaturation temperature of skin collagen of *O. niloticus* ranged between 25 and 26 °C depending on the conducted extraction procedures [33]. Meanwhile it was detected at 34.85 °C for collagen extracted from *O. niloticus* scales [34]. The denaturation temperature of collagen depends on both the source tissue and the extraction procedures. Freshwater fish collagen generally show high thermal stability which could be attributed to its high content of proline and hydroxyproline [34–37]. In agreement with this finding, Yamamoto et al. [18] documented a higher denaturation temperature of Nile tilapia; *O. niloticus* collagen in comparison with other marine sources.

Conclusions

The present study confirms that the method for obtaining fish collagen (extraction, isolation, purification, etc.) may affect its specific properties and consequently the further uses of collagen as a potential biomedical substituent for mammalian collagen. Specification of the fish species and tissue type is crucial in identifying the quality of the extracted collagen as well as its physical and functional properties. Further studies are recommended to evaluate the potential uses of *O. niloticus* corneal collagen as a biological substituent for mammalian collagen.

The authors would like to acknowledge Deanship of Scientific Research, Taif University, KSA, Giza Memorial Institute for Ophthalmic Research (MIOR), Giza, Egypt, and National Institute of Oceanography and Fisheries, Cairo, Egypt.

Author contributions

HHA-E: idea formulation, primary data collection, generation of database, writing of the manuscript, development of data analysis methodology, interpretation of results, editing of the manuscript; WAO and HAE: data analysis, preparation and editing of the manuscript. All the authors participated in the discussion of the results.

Funding

This work was self-funded.

Availability of data and materials

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Declarations

Ethics approval and consent to participate

The present experimental investigation was not conducted with humans. Consent to participate is not applicable. All international, national, and/or institutional standards for the use of fish in experiments and conditions of fish care have been followed. The study received approval of the National Institute of Oceanography and Fisheries-Committee for ethical care and use of animals/aquatic animals (NIOF-IACUC) under ethical clearance reference number NIQF-FW3-F-23-R-043.

Consent for publication

Not applicable.

Dual drug-loaded cubosome nanoparticles for hepatocellular carcinoma: a design of experiment approach for optimization and in vitro evaluation

Badiger, Poorvika1; Mannur, V. S.1 ; Koli, Rahul1 1 KLE College of Pharmacy, KLE Academy of Higher Education and Research, Department of Pharmaceutical Quality Assurance, Belagavi, India (GRID:grid.411962.9) (ISNI:0000 0004 1761 157X)

ABSTRACT (ENGLISH)

Background

Liver cancer, a formidable and complex disease, poses a significant global health threat, stemming from various causes, including chronic infections like hepatitis B and C, cirrhosis, and lifestyle factors. In liver cancer treatment, targeted delivery revolutionizes precision therapy, minimizing side effects by directing drugs specifically to cancer cells. This study aims to develop and statistically optimize cubosomal formulations containing piperine and quercetin with the goal of augmenting their activity against hepatocellular carcinoma.

Results

Employing a central-composite design, we utilized Design-Expert® software to guide the experiment. The key formulation variables were the concentration of glyceryl monooleate (GMO) and Poloxamer-407, while the dependent responses were particle size (PS) and entrapment efficiency (EE%). The optimized cubosomal formulation was validated through the utilization of high-resolution transmission electron microscopy (HR-TEM), in vitro release studies, and an in vitro cell proliferation assay conducted on the HepG2 cell line. High-performance liquid chromatography was employed for the determination of piperine and quercetin in the optimized cubosomal nanoparticle. The optimized formulation had a composition of 2.5 (w/w%) GMO and 0.5 (w/w%) Poloxamer 407. The predicted values for PS and EE% were 102.34 and 75.11%, respectively. The cytotoxicity of the optimized cubosomal formulation exhibited enhanced efficacy on the HepG2 cancer cell line, even at lower concentrations, when compared to the standard. Notably, it demonstrated a superior cytotoxic effect on the liver cancer cell line.

Conclusion

The findings of the study indicated that cubosomes exhibit promise as an effective carrier for delivering piperine and quercetin, addressing hepatocellular carcinoma effectively.

FULL TEXT

Background

In the realm of cancer incidence, primary liver cancer holds the fifth position in terms of frequency, solidifying its status as the second most widespread cancer type [1, 2]. Over the course of several decades, the frequency of cancer cases has consistently risen. This underscores the ongoing significance of cancer as a major public health concern, remaining among the primary contributors to global mortality [3–5]. Despite the emergence of innovative methods like vaccines, immunotherapy, and gene therapy, which exhibit encouraging treatment outcomes for diverse cancer forms, chemotherapy retains its position as a fundamental strategy in the medical management of cancer [6–8].

Natural phytoconstituents play a vital role in impeding diverse mechanisms linked to cancer, including cellular division, cell proliferation, angiogenesis, programmed cell death (apoptosis), and the spread of cancer cells (metastasis) [9, 10]. Numerous herbs and phytoconstituents are utilized for the treatment of chronic liver ailments due to their cost-effectiveness, high safety thresholds, long-lasting positive effects, and minimal adverse reactions [11, 12]. Previous studies suggest that these natural compounds can protect liver cells through diverse mechanisms, including virus elimination, suppression of fibrogenesis, inhibition of oxidative damage, and reduction of carcinogenesis [13–15]. These herbal remedies effectively inhibit cell growth at different stages of the cell cycle, disrupt signaling pathways, and suppress gene expression, leading to the prevention of multiple types of cancer [16–18].

Quercetin, a member of the flavonoid family, possesses notable antioxidant, anti-inflammatory, and immunoregulatory properties, which contribute to its potential in preventing and treating conditions such as cardiovascular diseases, diabetes, neurodegenerative disorders, and cerebrovascular diseases [19–21]. Moreover, studies have reported the inhibitory effects of quercetin on hepatocellular carcinoma (HCC), showing that it can hinder HCC growth by suppressing proliferation and/or promoting apoptosis [22–25]. Numerous pharmacological investigations have indicated the promising capacity of piperine as a viable medication against cancer [26–28]. Its mechanism involves the suppression of pro-survival pathways and the initiation of apoptosis across diverse cancer cell variations. Piperine, identified as a potential anticancer compound capable of regulating autophagy, has demonstrated impressive success in combatting cancer within living organisms [29–31]. Recent research indicates that piperine has been utilized both as a standalone treatment and in combination with other drugs to enhance their anticancer effects and effectively manage the process of carcinogenesis [32].

Regrettably, these two medications exhibit limited solubility in water and lead to significant problems linked to sensitivity to light. Furthermore, quercetin has a tendency to experience swift chemical deterioration under conditions of acidic gastric pH. Hence, the integration of these two pharmaceutical agents into a well-suited, singularly lipid-mediated nanostructured arrangement, particularly through cubosomes, proves advantageous in surmounting crucial challenges. Cubosomes emerge as nanoparticles containing lipids and surfactants, showcasing an exceptional cubic liquid crystalline configuration [33, 34]. These minute entities, smaller than a micron, display a dual continuous character, boasting a substantial expanse of surface. Comprising amphiphilic components like polar and nonpolar polymers, lipids, and surfactants, cubosomes possess the innate ability to autonomously structure themselves. The genesis of cubosomes hinges on the self-organization of particular surfactant entities [35, 36].

The clinical effectiveness of anticancer drugs is limited because they tend to spread throughout the body without precision, resulting in unintended harm to healthy tissues and consequent side effects [37]. To address this challenge, researchers have introduced diverse drug transporters designed to transport therapeutic substances with precision to particular locations. One of the most successful approaches involves the utilization of nanocarriers, which capitalize on the enhanced permeation and retention phenomenon, allowing them to accurately target the afflicted areas while minimizing impact on unaffected tissues [38, 39].

Consequently, within this current investigation, our contemplation revolves around crafting a cubosome-based nanoformulation that encapsulates quercetin and piperine. The attainment of desired therapeutic effects from any medicinal agent hinges on precise assessments of the entrapped substances within the nanoformulation. Hence, our objective resides in the development of a reverse phase-high-performance liquid chromatography (RP-HPLC) technique, enabling the simultaneous quantification of both quercetin and piperine loaded within the cubosomes.

Methods

Materials

Quercetin (≥95%) was procured from Ausen Chemical Co., Ltd. in China, while piperine (≥97%) was acquired from Sigma-Aldrich India. Glyceryl monooleate (GMO) was kindly provided by Mohini Organics India. Poloxamer was obtained from Sigma-Aldrich in India, while potassium dihydrogen phosphate and sodium hydroxide were sourced from Merck Life Science Pvt. Ltd., India. Fetal bovine serum (FBS) and Dulbecco's Modified Eagle Medium (DMEM) solutions were acquired from Sigma-Aldrich in India. High-performance liquid chromatography (HPLC) grade methanol and various other essential chemicals were obtained from Merck Life Science Pvt. Ltd.

Compatibility studies

To evaluate the compatibility of piperine and quercetin and search for any possible interactions between the two compounds, Fourier transform infrared spectroscopy (FT-IR) was performed [40]. In a nutshell, piperine and quercetin were mixed together in a 1:1 ratio (2 mg), and the mixture was kept at 25 ± 2 °C and 60 ± 5% relative humidity (%RH) for 28 days. Piperine, quercetin, and the mixture underwent FT-IR analysis. The effects of piperine, quercetin, and their combination were studied using FT-IR.

Experimental design

Design-Expert software version 13.0 was used to create the experiments (Stat-Ease Inc., Minneapolis, MN, USA). The program was used to design and produce a total of 11 formulations [41–43]. To optimize the prepared cubosome formulations, a two-factor three-level (3^2) experimental design was employed. The independent variables considered were the amount of glyceryl monooleate (X_1) and Poloxamer 407 (X_2). Meanwhile, the dependent variables assessed were particle size (Y_1) and entrapment efficiency (Y_2). The statistical plan included three different concentrations of Poloxamer 407 (0.5, 1.25, and 2%) and three different concentrations of glyceryl monooleate (2.5, 3.75, and 5%) (Table 1).

Table 1. Coded values of 3^2 full factorial design for formulation of cubosomes

Independent variables	Levels		
Low (− 1)	Medium (0)	High (+1)	X_1 = GMO
2.5	3.75	5	X_2 = Poloxamer 407
0.5	1.25	2	Independent variables
Constraints	Importance		X_1 = GMO

Y_2 = % EE	Maximum	+++

Preparation of cubosomes

Piperine- and quercetin-loaded cubosomes were prepared using the top-down method with the aid of a magnetic stirrer and homogenizer. The process began by melting the lipid (2.5 to 5%), followed by dissolving a precisely weighed quantity of the drug (0.1%) in the melted glyceryl monooleate (GMO). This mixture was then transferred into the melted Poloxamer 407 (0.5 to 2%), resulting in the formation of a cubic phase [44–47]. To reach the desired volume (30 mL), a measured amount of water was added dropwise using a syringe. The mixture was homogenized using an Ultraturaxx homogenizer at 12,000 rpm for 15 min and subsequently sonicated for 15 min to obtain cubosomes. The prepared cubosomes were then stored in a cool environment. Various formulations of PQC (piperine–quercetin cubosomes) were meticulously prepared, and their respective compositions are elucidated in Table 2.

Table 2. CCD experimental runs with obtained response

Formulation code	X_1 (%)	X_2 (%)	Y_1	Y_2
C1	2.5	0.5	102.36	76.43
C2	2.5	1.25	109.75	59.54
C3	2.5	2	118.24	53.28
C4	3.75	0.5	124.44	79.83
C5	3.75	1.25	149.36	61.2
C6	3.75	1.25	151.27	62.3
C7	3.75	1.25	154.2	64.83
C8	3.75	1.25	172.7	65.9
C9	5	0.5	179.6	81.23
C10	5	1.25	216	67.28
C11	5	2	222.4	54.01

X_1 = amount of GMO, X_2 = amount of Poloxamer 407, Y_1 = Particle size, Y_2 = Entrapment efficiency

Particle size, PDI and entrapment efficiency

The mean vesicle size and polydispersity index (PDI) of cubosomes loaded with piperine and quercetin were

analyzed using a zetasizer. For the analysis, 1 mL of the formulation was diluted with 20 mL of milli-Q water. To separate the untrapped drug, samples from each formulation were subjected to centrifugation at 15,000 rpm and 4 °C for a duration of 1 h. The resulting supernatant was collected and then appropriately diluted with methanol. The estimation of the unbound drug was performed using UV–Vis spectroscopy at a wavelength of 273 nm. The percentage of drug entrapment was calculated using the relevant formula [48, 49].

In vitro release study of cubosomes

The in vitro release study of cubosomes was conducted using the dynamic dialysis method (USP II method). The investigation into drug release employed a tablet dissolution testing apparatus (Electrolab, EDT-08LX) featuring a low-volume conversion kit (EDT-08L/08L × 150 ml). This specialized setup was specifically chosen for assessing the release of the drug from the nanoformulation. Prior to the study, the dialysis membrane was soaked overnight [50–52]. Briefly, PQC nanoformulation (5 ml) was transferred to a dialysis bag, which was immersed into a 100 ml of PBS (pH 5.5) containing tween 80 (0.1%). The temperature of dissolution medium was kept at 37 ± 0.5 °C with a stirring speed of 50 rpm. At predetermined time intervals (0.5, 1, 2, 3, 4, 6, 12 and 24 h), aliquots of 1 mL were withdrawn for analysis. The withdrawn aliquots of the drug release medium were replaced with same volume of fresh buffer to maintain the sink condition. The drug concentrations in the samples were analyzed using spectrophotometry at the maximum wavelength (λ max) of 273 nm.

Transmission electron microscopy (TEM)

The surface morphology and structure of optimized cubosomes were examined using a high-resolution transmission electron microscope (JEM-2100, Jeol, Tokyo, Japan). A small volume of the optimized cubosomes was applied onto a carbon-coated grid, allowing the sample to adhere. Subsequently, the specimen was stained with uranyl acetate for a duration of 5 min, followed by staining with lead citrate for 2 min. The grid containing the stained sample was then observed using a transmission electron microscope, with an appropriate level of magnification (20 nm and 100 nm) chosen to capture images [53, 54].

High-performance liquid chromatography (HPLC)

The Agilent Technologies 1220 Infinity II HPLC system was used for quantification of piperine and quercetin in optimized cubosomal formulation. Utilizing a reversed-phase C-18 column (5 µm, 250 × 4.6 mm, ZORBAX), chromatographic separation was accomplished [55–58]. After conducting numerous trials, the chromatographic conditions were fine-tuned by considering factors such as peak area, retention time, tailing factor, and theoretical plates. The optimal mobile phase was composed of methanol and 0.1% formic acid in water, in the ratio of 80:20. Samples were analyzed at the flow rate of 1 mL/min, and the detection wavelength was set at 273 nm. The prepared cubosomes were centrifuged for 30 min at 15,000 rpm. The supernatant (0.1 mL) was pipetted using a micropipette and made up the volume up to 10 mL of volumetric flask using mobile phase. For each analysis, a 10 µl sample was injected into the column. According to ICH Q2 (R1) criteria, the developed HPLC method's validation was carried out. Linearity, LOD, LOQ, precision, accuracy and robustness were all used to thoroughly evaluate the optimized method.

Cytotoxicity analysis

For this study, the HepG2 cell line, derived from human hepatocellular adenocarcinoma, was procured from NCCS in Pune, India. The cells were cultivated in DMEM-high glucose medium supplemented with 10% Fetal Bovine Serum (FBS) and 1% antibiotic–antimycotic solution [59, 60]. Maintaining optimal conditions, the cells were cultured in a controlled environment with 5% CO_2, 18–20% O_2 and a temperature of 37 °C within a CO_2 incubator. Sub-culturing of the cells was carried out every 2 days, and passage number 34 was employed for the experimental procedures. Transfer 200 µl of cell suspension into individual wells of a 96-well plate, targeting a cell density of 20,000 cells per well. Avoid introducing the test agent at this stage. Allow the cells to proliferate for approximately 24 h. Distinct concentrations of cubosomal solutions (50, 60, 70, 80, 90, and 100 µg/ml) were prepared in a solution containing 0.1% DMSO. Subsequently, 50 µl of each concentration's solution was individually introduced into designated wells containing the cells. The plate was then placed in an incubator set at 37 °C, 5% CO_2, and 90% humidity for a 24-h duration. A control group was processed without the addition of this formulation. Following the

incubation period, 15 µl of MTT solution (5 mg/ml in PBS) was added to the wells, and the plate was further incubated for 4 h at 37 °C. Post-incubation, 100 µl of DMSO was introduced to dissolve the formazan crystals that had formed. The absorbance of the cells was measured at 570 nm utilizing an ELISA plate reader. The mean values for cell viability were compared against the control to assess the impact of cubosomes on the cells. A graphical representation was plotted, correlating cell viability (%) against the concentration levels of the formulation.

Statistical optimization

The experiments conducted in this study were replicated in triplicate, and the outcomes were reported as the mean accompanied by the standard deviation. Both ANOVA and Student's *t* test were executed, determining statistical significance for results at a threshold of $p<0.05$.

Results

Compatibility studies

The Fourier transform infrared (FTIR) analysis of piperine and quercetin, as depicted in Fig. 1, unveiled the presence of various discernible functional groups. Notably, the spectrum exhibited distinct peaks corresponding to specific vibrational modes, including the aromatic C-H stretch at 2922.61 cm^{-1}, the alcohol O–H stretch at 3393.02 cm^{-1}, the C–O stretch at 1246.50 cm^{-1}, and the aromatic C–C stretch at 1640.32 cm^{-1}. Intriguingly, the physical mixture of the drug and excipients manifested the persistence of these characteristic peaks, underscoring the compatibility of the components. This observation serves to corroborate that the unique chemical identities of both the drug and the excipients remain intact in the composite system.

Fig. 1 [Images not available. See PDF.]

FTIR spectrum of physical mixture (GMO, Poloxamer 407, piperine, and quercetin)

Experimental design

Based on the regression coefficient determined in the ANOVA study, it was discovered that independent variables X_1 (GMO) and X_2 (Poloxamer-407) have a positive sign, indicating a synergistic influence on the outcome Y_1 (PS). It was discovered through graphical presentation, namely the response surface plot that raising the level of variable X_1 and X_2 tends to raise the value of response Y_1 (Fig. 2). Both independent variables X_1 and X_2 had a negative sign, indicating an antagonistic influence on the response Y_2. Graphical evidence revealed that as the level of both variables, X_1 and X_2, is increased, the value of response Y_2 was dropped (Fig. 3). Utilizing the Design-Expert software by Stat-Ease, Inc. (version 13.0), it was determined that all responses yielded satisfactory outcomes. The shaded zone with yellow color in the design space (Overlay plot) depicted in Fig. 4 represents the region of successful operating ranges. Design space facilitated the identification of optimal values for the independent parameters: GMO (2.5%) and Poloxamer (0.5%) under these specific concentrations. The model's exceptional ability to forecast values for the response variables was showcased by the remarkably low prediction error (5%) observed between the predicted values and the actual observations.

Particle size, PDI and entrapment efficiency

The drug-loaded cubosome nanoformulation was prepared through homogenization method, resulting in mean particle sizes of 102.36 nm and 222.4 nm, respectively. The cubosomes exhibited an average PDI in value range 0.1831 to 0.8894. These PDI values are indicative of a narrow and homogeneous particle size distribution, as they

are less than 0.9. The zeta potential is a significant variable for evaluating the stability of nanoparticulate systems. Zeta potential was recorded to be between − 13.6 and − 38.9 mV. These zeta potential readings suggest that the cubosome nanoparticles are moderately stable. The presence of free fatty acids within glycerol monooleate's lipid structure, which imparts this negative charge, is the cause of the negative charge that was detected.

Our analysis of the percentage of free and total drug in the cubosome nanoformulation revealed that the encapsulation efficiency (EE) for piperine and quercetin exhibited a range of 53.28% to 81.23%. The optimized concentration of surfactants used is probably responsible for the cubosomes substantially higher EE percentages. Significant amounts of quercetin and piperine were successfully solubilized by these surfactants within the lipid vesicles. The amounts of these substances were thereby markedly increased within the cubosome formulation.

In vitro release study of cubosomes

The in vitro drug release profiles of piperine and quercetin from cubosomes are meticulously illustrated in Fig. 5. The release study, specifically focusing on the optimized batch of the PQC nanoformulation (designated as PQC1), was conducted in a buffer with a pH of 5.5. This investigation was carried out utilizing a tablet dissolution testing apparatus equipped with a low-volume conversion kit. Broadly, the bicontinuous cubosome nanoformulations exhibited a biphasic burst release characterized by a diffusion-based mechanism emanating from the cubic-phase matrix structure. The release of both piperine and quercetin from the cubosome formulation displayed a biphasic pattern. In the initial hour, there was a notable burst release, accounting for approximately 22.43% of piperine and 16.40% of quercetin. Subsequently, after a 24-h duration, the cumulative release escalated to 82.92% for piperine and 61.04% for quercetin.

Fig. 5 [Images not available. See PDF.]

Cumulative drug release of PQC formulation

Transmission electron microscopy (TEM)

The surface morphology and structural integrity of the optimized PQC nanoformulation (PQC1) were meticulously scrutinized and substantiated through high-resolution transmission electron microscopy (HR-TEM) imaging. The resulting images revealed that the cubosome particles exhibited a distinctly cubic shape, characterized by a uniform and smooth surface with minimal curvature, as depicted in Fig. 6A, B. Notably, the particles displayed a scattering pattern indicative of their nanoscale dimensions, further accentuating their finely tuned and compact structure.

Fig. 6 [Images not available. See PDF.]

HR-TEM images of optimized cubosomal nanoformulation (PQC1)

High-performance liquid chromatography (HPLC)

The optimized method has proven its efficacy in the determination of formulated cubosomes, revealing distinct peaks for both quercetin and piperine. Notably, these peaks were precisely measured at 3.055 and 5.067 min, respectively. The consistent retention times underscore the robustness of the separation method, offering compelling evidence for the successful application of this approach in isolating the two pharmaceuticals within the cubosomes, as illustrated in Figs. 7 and 8. To ensure that the optimized HPLC method is appropriate for the intended use as outlined in ICH Q2 (R1) standards, it has undergone validation. Table 3 provides a summary of the proposed HPLC method's validation parameters, which were determined to be within the ICH Guidelines' standard limits.

Cytotoxicity analysis

The statistical findings from the MTT cell cytotoxicity study revealed that the examined compounds exhibited noteworthy cytotoxic attributes against HepG2 cells. Following a 24-h incubation period, the % cell viability of cubosomes at a concentration of 100 µM/mL was determined to be 4.05%. A standard control utilizing 1 µM/mL of doxorubicin was employed, and the cell viability for the standard was established at 32.25% (Fig. 9). The determination of the IC50 value for the cubosomes, based on the percentage drug loading, unequivocally indicates that the designed nanoformulation possesses a superior anticancer effect compared to the standard drug. This superiority may be attributed to its nanosized dimensions, sustained release properties and targeted delivery to cancer cells.

Discussion

This study takes a step toward enhancing liver cancer treatment by focusing on cubosomal formulations containing

piperine and quercetin. Piperine and quercetin are compounds known for their potential anticancer properties. By formulating these compounds into cubosomes, the aim is to augment their activity against hepatocellular carcinoma. To assess the compatibility of piperine and quercetin and explore potential interactions between these two compounds, Fourier transform infrared spectroscopy (FT-IR) was conducted. The obtained spectrum revealed clear peaks associated with specific vibrational modes, such as the aromatic C–H stretch observed at 2922.61 cm^{-1}, the alcohol O–H stretch at 3393.02 cm^{-1}, the C–O stretch at 1246.50 cm^{-1}, and the aromatic C–C stretch at 1640.32 cm^{-1}. This observation serves to corroborate that the unique chemical identities of both the drug and the excipients remain intact in the composite system.

The experimental design of this study utilized a central-composite design, guided by the Design-Expert® software. Key formulation variables were the concentration of glyceryl monooleate (GMO) and Poloxamer-407, while particle size (PS) and entrapment efficiency (EE %) were chosen as dependent responses. This approach provides a systematic and statistical method to optimize the formulation for the desired properties. The optimized cubosomal formulation, with a composition of 2.5% (w/w) GMO and 0.5% (w/w) Poloxamer 407, was validated using various techniques. The predicted values for PS and EE% were 102.34 and 76.43%, respectively, indicating successful optimization based on the experimental design. The optimized nanoformulation of piperine and quercetin (PQC1) underwent thorough examination of its surface morphology and structural integrity using high-resolution transmission electron microscopy (HR-TEM) imaging. The images obtained depicted cubosome particles with a well-defined cubic shape, showcasing a consistently smooth and uniform surface with minimal curvature.

The in vitro release study, specifically focusing on the optimized batch of the PQC nanoformulation (designated as PQC1), was conducted in a buffer with a pH of 4.5. After a 24-h duration, the cumulative release escalated to 82.92% for piperine and 61.04% for quercetin. High-performance liquid chromatography was utilized to quantify the concentration of piperine and quercetin within the optimized cubosomal nanoparticles. Significantly, the distinct peaks for piperine and quercetin were precisely identified at 3.055 and 5.067 min, respectively. The consistent retention times emphasize the reliability of the separation method, providing compelling evidence for the effective application of this approach in isolating the two pharmaceuticals within the cubosomes. The cytotoxicity assessment revealed that the optimized cubosomal formulation exhibited enhanced efficacy on the HepG2 cancer cell line, even at lower concentrations compared to the standard treatment. This superior cytotoxic effect specifically on the liver cancer cell line suggests the potential of cubosomes as an effective carrier for delivering piperine and quercetin to address hepatocellular carcinoma.

The findings of this study highlight the promise of cubosomes in liver cancer therapy. The targeted delivery system not only optimizes drug efficacy but also minimizes side effects, addressing a critical need in the complex landscape of liver cancer treatment. The use of advanced techniques such as HR-TEM and high-performance liquid chromatography adds credibility to the study, ensuring a thorough validation of the optimized cubosomal formulation. In conclusion, this research contributes to the growing body of knowledge seeking innovative solutions for liver cancer treatment. The effectiveness of cubosomal formulations containing piperine and quercetin against hepatocellular carcinoma suggests a potential breakthrough in precision therapy. As further research and clinical trials unfold, these findings may pave the way for a more targeted and efficient approach to combat liver cancer, ultimately improving patient outcomes on a global scale.

Conclusion

The objective of this research was to develop precision-targeted cubosomes containing piperine and quercetin to address Hepatocellular carcinoma. Effective formulation and fine-tuning of cubosomes loaded with piperine and quercetin were accomplished employing central composite factorial design methodology in conjunction with the Design-expert software. The prepared cubosomes demonstrated well-suited nanoscale vesicles, with particle dimensions falling within the nanoscale and achieving peak entrapment efficiency levels. Following the design of experiments (DoE) and the desirability criteria, it was determined that formulation (C1) containing GMO (2.5%) and Poloxamer 407 (0.5%) stood out as the most favorable selection, exhibiting the most compact particle size (102.3 nm) and greatest entrapment efficiency (76.43%). An analytical technique was established for piperine and

quercetin using HPLC under standard environmental conditions. The solvent system utilized consisted of HPLC-grade methanol and 0.1% formic acid in water an 80:20 ratio. The quantitative analysis demonstrated well characteristics peaks for both drugs in the optimized cubosomal formulation, with a retention time of 3.0 min for quercetin and 5.0 min for piperine. The investigation on the HepG2 cell line using the cubosomes loaded with piperine and quercetin, carried out through the MTT assay. Following a 24-h incubation period, the % cell viability of cubosomes at a concentration of 100 µM/mL was determined to be 4.05%. A standard control utilizing 1 µM/mL of doxorubicin was employed, and the cell viability for the standard was established at 32.25%. This outcome serves as confirmation of the formulation's effectiveness in treating hepatocellular carcinoma; this formulation stands as a promising and preferred dosage form poised to be a leading option in the near future.

ABSTRACT (ENGLISH)

Background

Enterococci, known for their disturbing involvement in nosocomial infections, possess a diverse set of virulence factors, regulated by multiple genes. A key virulence regulator is the fecal *Streptococcus* regulator (Fsr) quorum sensing system. Multiple reports describe the involvement of *fsr* genes in several virulence mechanisms, notably gelatinase production and biofilm formation; however, the presence of *fsr* genes does not necessarily predict those virulence phenotypes. This study investigates the factors affecting the relation between molecular detection of *fsr* genes and accurate prediction of gelatinase activity and biofilm formation intensity.

Methods

One hundred enterococcal samples were collected from patients suffering from urinary tract infections. The isolates were identified through the use of a polymerase chain reaction (PCR) technique targeting the *ddl* gene. Biofilm formation was quantified by the crystal violet assay, while gelatinase activity was evaluated on gelatin agar plates. PCR was used to detect the *fsr*A and *fsr*B genes, as well as the gelatinase enzyme-encoding gene (*gel*E).

Results

Out of the collected 100 isolates, 93% were identified as *Enterococcus faecalis*. The isolates formed biofilm with different intensities: 47% were strong biofilm producers, 28% moderate, and 21% weak, while only four isolates (4%) did not form biofilm. Only 14% of all isolates had detectable gelatinase activity. The *fsr*A and *fsr*B genes were detected in 26% and 28% of the tested isolates, respectively, while *gel*E was detected in 57% of the isolates. Whereas no association was found between biofilm formation intensity and *fsr* locus genes or gelatinase activity, a strong positive correlation ($r = 1$) was found between the detection of both *fsr*A and *fsr*B genes and the gelatinase activity.

Conclusion

*fsr*A and *fsr*B have a diagnostic value and may be used as biomarkers for gelatinase activity in *E. faecalis*.

FULL TEXT

Background

Enterococci are Gram-positive members of the intestinal microbiota; however, they frequently act as opportunistic pathogens with the ability to cause community- and hospital-acquired infections. *E. faecalis* and *E. faecium* are the

enterococcal species most frequently linked to infections [1].

Infections of the urinary tract represent the most prevalent type of infection caused by *Enterococcus* spp., which is responsible for more than 30% of nosocomial urinary tract infections and has been identified as the second most common pathogen after *Escherichia coli* in catheter-associated urinary tract infections [2].

To be able to cause such diseases, enterococci possess several virulence factors that give them an advantage over their host's immune system. Quorum sensing is one of the important virulence mechanisms, and can be regulated by the *fsr* locus, made up of *fsr*A, *fsr*B, *fsr*D, and *fsr*C genes [3]. FsrA protein has a DNA-binding domain from the LytTR family [4]. The attachment of phosphorylated FsrA to LytTR-binding sites located in the regions preceding *fsr* B and *gel*E suggests that FsrA acts as the response regulator within this control system [4]. FsrB, a protein found within the cell membrane, is a member of the accessory gene regulator protein B family. It is responsible for transforming FsrD into an active form that stimulates the production of gelatinase, through the activation of the pheromone GBAP, which is subsequently exported outside of the cell [5]. The fourth gene within this locus, *fsr*C, is responsible for coding the transmembrane histidine kinase, FsrC, serving as the sensor-transmitter for the *fsr* operon [4].

The *fsr* locus regulates the synthesis of the gelatinase and serine protease enzymes, in addition to regulating the expression of EF1097 and EF1097b genes, which encode for enterocin [4]. Studies of the transcriptome have shown that, beyond its role in controlling *gel*E, *spr*E, and EF1097, the Fsr system plays a part in regulating approximately 75 other genes. These include genes associated with surface proteins (EbpR), biofilm formation (BopD), and various metabolic activities [6]. These proteins are engaged in a variety of biological processes and contribute to *E. faecalis* virulence and pathogenicity [3].

Downstream of the *fsr* locus lies the gene responsible for gelatinase production (*gel*E gene) [3]; The gelatinase enzyme, produced by *E. faecalis*, serves as a crucial virulence factor, enabling it to break down gelatin, collagen, casein, hemoglobin, and other peptides [7]. This enzyme facilitates the degradation of host tissues, aiding *E. faecalis* in colonizing and infiltrating host structures [8].

Quorum sensing also regulates another important virulence mechanism, which is biofilm formation. A biofilm is a community of microorganisms that are adhered to either living (biotic) or non-living (abiotic) surfaces, usually encased within a protective layer made up of extracellular polymeric substances [9]. Biofilm formation is an important element of *E. faecalis* pathogenicity because it helps the bacteria colonize a variety of settings, including host tissues and medical devices [10].

In addition to quorum sensing, gelatinase activity has also been linked to biofilm formation through degrading other bacterial cells and stimulating the release of AtlA, the major autolysin involved in biofilm formation [11].

A critical gap still remains in our understanding of the relationship between molecular detection of *fsr* genes and the accurate prediction of gelatinase activity, as well as biofilm formation intensity in enterococcal infections. The observed discrepancy between the presence of the *gel*E gene and actual gelatinase activity, along with the ambiguous role of the *fsr* locus in biofilm formation intensity, underscores the complexity of translating molecular diagnostics into effective clinical predictions and treatment strategies for *Enterococcus*-related infections.

Methods

Bacterial strains and culture condition

E. faecalis ATCC 29212 and *Bacillus subtilis* ATCC 6633 were used as positive control strains. One hundred isolates were retrospectively collected from Al-Borg Medical Laboratories from patients in Egypt diagnosed with urinary tract infections during the period of 2020 to 2021. These isolates were preserved at −80 °C in Brain Heart Infusion broth supplemented with 25% glycerol. For culturing purposes, samples from the stock were isolated on bile esculin agar and incubated at 37 °C overnight.

Identification of bacterial isolates

Pure bacterial colonies were obtained through surface streaking on bile esculin agar and identified to the genus level using Gram staining, catalase test, and their ability to tolerate 6.5% NaCl broth.

Identification of the enterococci to the species level

DNA extraction

DNA from the isolates under examination was extracted using the boiling method [12], wherein 3 to 5 well-separated colonies from the culture being tested were suspended in 100 µL of nuclease-free water and subjected to heating at 100 °C for 5 min. Following this, the suspension was rapidly cooled to −20 °C for 5 min and then centrifuged at 10,000 rpm for 10 min. The supernatant, which contained the crude DNA extract, was then stored at −20 °C for preservation.

Polymerase chain reaction (PCR)

The PCR was conducted in a total reaction volume of 50 µL, which included 25 µL of DreamTaq Green PCR Master Mix (Thermo Scientific, USA), 10 pmol of both the forward and reverse primers specific to the *ddl* genes (Table 1), and 2.5 µL of the extracted crude DNA. The multiplex PCR process encompassed an initial denaturation phase of 2 min at 95 °C, followed by 30 cycles that each included a denaturation step at 95 °C for 30 s, an annealing step at 52 °C for 30 s, and an extension step at 72 °C for 30 s. The procedure was concluded with a final extension step that lasted for 5 min at 72 °C [13].

Table 1. Primers used in this study and their sequence

Target gene	Primer pair	Amplicon size (bp)	References
ddl of *E. faecalis*	Forward: ATCAAGTACAGTTAGTCTTTA	942	[13]
Reverse: AACGATTCAAAGCTAACT	*ddl* of *E. faecium*	Forward: CCAAGGCTTCTTAGAGA	535
[13]	Reverse: CATCGTGTAAGCTAACTTC	*fsr*A	Forward: CGTTCCGTCTCTCATAGTTA
474	[14]	Reverse: GCAGGATTTGAGGTTGCTAA	*fsr*B
Forward: TAATCTAGGCTTAGTTCCCAC	428	[14]	Reverse: CTAAATGGCTCTGTCGTCTAG
*gel*E	Forward: GGTGAAGAAGTTACTCTGAC	704	[14]

The PCR products were visualized by electrophoresis on a 1.5% agarose gel (w/v), stained with ethidium bromide, using a electrophoresis system (Mupid exU, Japan). A Generuler 100 bp DNA ladder (Fermentas, Germany) served as the marker. The presence of the *ddl* gene in *E. faecalis* and *E. faecium* was confirmed by the visualization of 942 bp and 535 bp bands, respectively. *E. faecalis* ATCC 29212 was used as the positive control in these experiments.

Biofilm assay

Biofilm formation was evaluated through the use of the crystal violet assay method [15], with certain modifications.

The process for assessing biofilm formation began with inoculating an overnight culture of the tested isolates into trypticase soy broth (TSB) enriched with 1% glucose, followed by a 24-h incubation at 37 °C. Post-incubation, the optical density (OD) of the culture was adjusted to a 0.5 McFarland standard, with further dilution of the cultures to a 1:100 ratio in TSB. This diluted culture (200 µL) was then transferred to the wells of a sterile flat-bottomed 96-well plate and incubated again at 37 °C for 24 h.

After this incubation, the contents of the wells were discarded, and the wells were washed with saline and left to dry. The biofilm, comprised of adherent microbial cells, was fixed with absolute methanol and then stained with a 0.1% crystal violet solution for 15 min. Subsequent to the staining, the excess crystal violet was removed, and the wells were washed with distilled water before the plates were left to dry.

The adhered stain was dissolved using 33% glacial acetic acid, and the OD of the dissolved stain was measured at 570 nm using a plate reader (Unicam, UK). TSB containing 1% glucose without tested isolate served as the negative control. The experiment was conducted in triplicate.

The degree of biofilm formation by each isolate was classified based on the OD of the dissolved stain as follows: strong biofilm formation was indicated if $OD > 4 \times OD.c$, moderate biofilm formation if $2 \times OD.c < OD \leq 4 \times OD.c$, and weak biofilm formation if $OD.c < OD \leq 2 \times OD.c$, where OD.c represents the optical density of the negative control plus three times the standard deviation of the negative control [16].

Gelatinase assay

Gelatinase production was assessed by the nutrient gelatin plate method [17], with slight adjustments. In summary, the isolates under investigation were streaked onto the surface of nutrient agar plates that were supplemented with 5% gelatin. These plates were then incubated at 37°C for a 24-h period. Following the incubation, Frazier solution was applied dropwise onto the agar surface. The appearance of a clear zone surrounding the microbial growth served as an indicator of positive gelatinase activity. *Bacillus subtilis* ATCC 6633 served as the positive control for the experiment.

Genotypic screening for *fsr*A, *fsr*B, and *gel*E genes

For the detection of the *fsr*A, *fsr*B, and *gel*E genes, PCR was used. The PCR protocol for each reaction started with an initial denaturation phase at 95 °C for 2 min, followed by 30 cycles of denaturation at 95 °C for 30 s. Annealing temperatures were set at 50 °C for *fsr*A, 49 °C for *fsr*B, and 47 °C for *gel*E gene detection (Table 1), each for 30 s, with an extension at 72 °C for 30 s. This was concluded by a final extension step lasting 5 min at 72 °C.

The PCR products were then subjected to electrophoresis in a 1.5% agarose gel (w/v), stained with ethidium bromide for visualization. A 100 bp DNA ladder was used as a marker, and the identification of the *fsr*A, *fsr*B, and *gel*E genes was confirmed by the visualization of amplification products measuring 474 bp, 428 bp, and 704 bp, respectively.

Statistical analysis

Experiments were performed in triplicates. All correlations were tested by the Pearson correlation coefficient. The association between the presence/absence of genes and different phenotypes was tested by Chi-Square test, for multiple categories (i.e., biofilm strength), or Fisher's Exact test, for two-category comparisons (i.e., gelatinase activity). *P*-value < 0.05 was considered significant. Visualization and statistical tests were performed in GraphPad Prism 9.5.0 (GraphPad, San Diego, CA).

Results

One hundred isolates were confirmed to be *Enterococcus* species based on their appearance as brownish-black colonies encircled by a black zone on bile esculin agar. Gram staining of these samples revealed Gram-positive coccobacilli, which were typically arranged in pairs or short chains. Additional identification procedures involved catalase and 6.5% NaCl tolerance tests. The results demonstrated that the isolates were catalase-negative and capable of growing in high concentrations of NaCl.

PCR identification of the isolates indicated that 93% of them were *E. faecalis* and 7% were *E. faecium*. All *E. faecium* isolates were excluded from further study.

The crystal violet assay, used to evaluate bacterial biofilm formation, showed that only four isolates did not form

biofilm, while the majority were strong biofilm producers (n = 44; 47%). About 28% of the isolates were moderate biofilm producers (n = 26), and the remaining isolates were weak biofilm producers (n = 19; 21%; Fig. 1).

Fig. 1 [Images not available. See PDF.]

Biofilm-formation by the tested *Enterococcus faecalis* isolates. The intensity of the biofilm formation by each clinical isolate is expressed as the absorbance of the dissolved dye from stained biofilms at 570 nm. The horizontal lines represent the absorbance cutoff values for non-, weak, moderate, and strong biofilm formation

The nutrient gelatin plate method confirmed that 13 isolates had gelatinase activity, while the majority of the collected isolates (86%, n = 80) were unable to produce detectable gelatinase activity.

Using PCR allowed the detection of the *fsr*A and *fsr*B genes in 24 and 26 isolates, respectively (26% and 28% of the isolates, respectively, Fig. 2).

Fig. 2 [Images not available. See PDF.]

The gelatinase activity, and the detectability of *gel*E, *fsr*A, and *fsr*B genes in the tested *Enterococcus faecalis* isolates. (Yellow: Present; black: Absent)

No significant correlation was found between the intensity of biofilm formed by different isolates and the PCR detection of quorum sensing genes *fsr*A ($r = -0.14$), and *fsr*B ($r = -0.11$), or the gelatinase-encoding gene *gel*E ($r = -0.04$). Additionally, the intensity of the formed biofilms was not correlated with the gelatinase activity ($r = -0.06$; Fig. 3).

Fig. 3 [Images not available. See PDF.]

The correlation between the detectability of *fsr*A, *fsr*B, and *gel*E genes, the gelatinase activity, and the intensity of formed biofilm. The correlation was estimated by the Pearson correlation coefficient. The color scale on the right represents the correlation coefficient

The *gel*E gene was detected in all gelatinase-positive isolates, and 50% (n = 40) of gelatinase-negative isolates, with a significant association ($p = 0.0004$; Table 2), but weak positive correlation ($r = 0.35$; Fig. 3).

Table 2. Association of gelatinase production, biofilm production, and the detectability of *fsr*A, *fsr*B, and *gel*E genes

Gelatinase production genotype	Number of isolates		*P* value (Fisher exact test)
Positive	Negative	*fsr*A+	13
11	< 0.0001	*fsr*A−	0
69	*fsr*B+	13	13
< 0.0001	*fsr*B−	0	67
*gel*E+	13	40	0.0004

Biofilm intensity genotype	Number of isolates				*P* value (Chi-Square test)
Strong	Moderate	Weak	Non	*fsr*A+	9

6	8	1	0.3344 (NS*)	*fsr*A−	35
20	11	3	*fsr*B+	11	6
6	2	0.6658 (NS)	*fsr*B−	33	20
13	2	*gel*E+	26	11	12
4	0.1283 (NS)	*gel*E−	18	15	7

NS not significant ($p \geq 0.05$)

The *fsr*A gene was detected in all gelatinase-positive isolates and 14% (n = 11) of gelatinase-negative isolates, while the *fsrB* gene was present in all gelatinase-positive isolates and in 16% (n = 13) of the gelatinase-negative isolate. The PCR detection of *fsr*A and *fsr*B was positively and significantly correlated with gelatinase production ($r = 0.68$ and 0.65, respectively, $p < 0.0001$; Fig. 3 and Table 2).

The molecular detection of the *fsr*A, *fsr*B, and *gel*E genes together was directly correlated with the gelatinase activity ($r = 1$). Likewise, the presence of just *fsr*A and *fsr*B together was directly correlated with the gelatinase activity ($r = 1$; Fig. 3).

Discussion

In this study, 100 clinical enterococcal isolates were collected from patients with urinary tract infections and identified to the species level, where most of the isolates were *E. faecalis* (n = 93). A similar predominance of *E. faecalis* infection was reported in Egypt [18] and worldwide [19]. Most of the tested *E. faecalis* isolates (96%) were capable of biofilm formation to different intensities; only four isolates were non-biofilm former. Similar results about biofilm formation capabilities in *E. faecalis* are available [20]. In accordance with previous studies [21, 22], most of the isolates formed biofilms with either strong or moderate intensity (72%).

Only 14% of the tested isolates had detectable gelatinase activity on gelatin-agar plates. The low frequency of detected gelatinase activity in *E. faecalis* isolates was previously reported [23, 24]; however, in a study by Robert and colleagues (2004), the percentage of gelatinase-producing *E. faecalis* isolates from clinical and community settings reached 67% [25].

It is worth noting that available information about the role of the *fsr* locus in biofilm formation and intensity is still contradictory. Here, a lack of correlation was observed between the *fsr* locus presence and biofilm intensity, and similar results were previously reported [26]. To the contrary, other studies reported reduced biofilm formation among *fsr* mutants [27].

A direct correlation was observed in this study between the presence of the *fsr*A and *fsr*B genes and the gelatinase activity, and the presence of both genes together with the *gel*E genes was detected in all isolates with positive gelatinase activity. The correlation between the Fsr system and gelatinase activity was previously reported [3]; however, a study by Hashem et al. [21] reported *fsr*B as a stronger predictor of gelatinase activity.

The gelatinase activity was suggested to affect biofilm production and to be important for pathogenicity in different infection models [28]. Here, we did not find any correlation between gelatinase production and the intensity of biofilm formation. Similar results about the lack of correlation between biofilm intensity and gelatinase production in *E. faecalis* isolates were reported [21, 29]. On the other hand, some studies on *gel*E mutant strains confirmed the role of gelatinase production in biofilm formation [30, 31]. Therefore, further studies are needed to determine the exact role of gelatinase in biofilm production.

In this study, *gel*E gene was detected in 57% of collected isolates. However, gelatinase activity was only found in 14% (n = 13) of the isolates. This may have resulted from the partial deletion in the *fsr* locus as previously discussed by Qin et al. [32], who found that gelatinase activity was abolished after the deletion of the *fsr* locus. This loss of

activity was documented [3].

In terms of diagnostic value of the *fsr* locus genes as biomarkers for gelatinase production, the finding that both *fsr*A and *fsr*B were positively correlated with the gelatinase production phenotype suggests that, while the molecular detection of these two genes is not fully correlated with the gelatinase phenotype, it still might be useful for rapid molecular screening or when culturing the bacteria is not possible. For example, in microbiome analysis studies, the detection of these genes in DNA extracted from fecal specimens or sewage samples could suggest potential for gelatinase activity.

Conclusions

The gelatinase activity of *E. faecalis* clinical isolates is strongly positively correlated ($r = 1$) with the presence of the quorum sensing-associated *fsr*A and *fsr*B genes, and no gelatinase activity was measurable when *fsr*A and *fsr*B were absent. Although reported in many studies, no direct correlation was found between *fsr*A, *fsr*B, or gelatinase production and biofilm formation intensity, which suggests that other genetic factors are associated with biofilm intensity.

ABSTRACT (ENGLISH)

Background

Atrial fibrillation (AF) is the most prevalent cardiac condition linked to increased mortality due to complications such as stroke. Oral anticoagulant (OAC) is the mainstay in preventing cerebrovascular accidents in patients with AF. Recent evidence identified gaps in physician's knowledge in diagnosing and managing patients with AF. This study aims to assess Syrian physicians' knowledge, attitude, and practices regarding the use of anticoagulant therapy in

non-valvular AF (NVAF) patients. A cross-sectional study was conducted using a validated web-based questionnaire, which included 56 items separated into four sections that collected information about demographics, knowledge, attitude, and practices. Chi-square and Kruskal Wallis were performed to analyze the statistical relationships between the knowledge, attitude, practice, and demographic variables.

Results

A total of 497 participants completed the survey, of which 62.6% were between the ages of 25 and 35. The average participant scores for knowledge, attitude, and practices were (48.18 ± 21.57), (81.54 ± 9.26), and (62.83 ± 12.42), respectively. Participants who demonstrated good understanding, a positive attitude, and good practices were 22.3%, 87.3%, and 25.4%, respectively. The fear of bleeding was identified as the most significant barrier to initiating anticoagulant medication in AF patients (55.5%). Doctors who attended training had a better knowledge score than those who did not (mean ± S.D. = 57.24 ± 20.7). Participants who stated that over 70% of their AF patients use aspirin received the highest attitude score (mean ± S.D = 86.98 ± 21.17). PhD participants reported higher practice scores than those with other educational backgrounds (mean ± S.D = 73.96 ± 11.3).

Conclusion

This research showed that primary care physicians in Syria had optimistic views regarding OAC therapy, suggesting that training interventions targeting physicians may lead to improvement in the treatment of patients with NVAF in Syria.

FULL TEXT

Introduction

Atrial fibrillation (AF) is the most prevalent persistent arrhythmia, with more than 33 million globally diagnosed. Various severe cardiovascular and cerebrovascular complications, such as myocardial infarction, heart failure, stroke, and premature death, are linked to atrial fibrillation [1]. Globally, the incidence and prevalence rates of AF are increasing as the life expectancy for more people is rising. The prevalence of atrial fibrillation has tripled during the last 50 years. The number of patients diagnosed with AF in Asia by 2050 is expected to be at least 72 million, with 3 million people expected to suffer from strokes secondary to AF [2].

Numerous recognized cardiovascular risk factors, such as hypertension, valvular heart disease, and diabetes mellitus, have been identified as independent predictors of atrial fibrillation. Other risk factors include obesity, excessive alcohol consumption, male sex, and left ventricular hypertrophy. Thus, screening patients with these risk factors may be advantageous to diagnose AF before complications occur [3].

Although paroxysmal AF is linked with a slightly lower risk of stroke and systemic embolism in comparison to permanent AF, it is still accompanied by a high possibility of stroke incidence [4]. Paroxysmal AF and atrial arrhythmia, or atrial high-rate events (AHRE), may be identified via comprehensive screening utilizing equipment like pacemakers, implanted cardiac monitors, patches, or smartphones [5].

Atrial fibrillation patients have a high risk of morbidity and mortality due to ischemic stroke; as a result, stroke prevention in the case of non-valvular AF (NVAF) is a top concern for doctors, patients, and their families, as well as for society. Several approaches have been developed to prevent strokes [6]. The CHA2DS2-VASC score is the gold standard for stroke prediction in AF patients since the European Society of Cardiology (ESC) guidelines recommended in 2012 to use this score for stroke risk stratification [7].

Oral anticoagulation (OAC) therapy primarily prevents thromboembolic events and stroke in patients with NAVF [8]. In patients with AF, stroke risk reduction is prioritized when considering anticoagulant medications, and higher bleeding risk in favor of reducing stroke risk is usually accepted. However, patient preferences should be considered when deciding the type of OAC treatment [9].

Antiplatelet and vitamin K antagonists were the only options to prevent stroke in AF until 2009. However, vitamin K antagonists' use limitations have been established, such as a narrow therapeutic index, serious interactions with food and other medications, and the need for monitoring. New OACs (NOAC) are easier to administer than warfarin since they are given at a constant dosage without frequent monitoring [10–12]. However, recent studies have shown that in patients with cardiovascular disease, the nonadherence rate to treatment may approach 50% after

12 months. Since NOACs' anticoagulant action lasts only 12–24 h after each dose, poor adherence would put NOAC therapy at risk [13]

A recent study encompassing six European countries found that physicians needed to be more confident in handling anticoagulant medication in patients with complex AF and identified significant gaps in physicians' Knowledge and abilities in all aspects of AF treatment [14]. Another study showed that the main factors for underusing vitamin K antagonists among patients were the lack of knowledge and comprehension [15]. In contrast, the significant concerns among physicians were uncertainty and the need for personalized decision-making. Providing decision-making tools and improving primary care-hospital cooperation might help atrial fibrillation patients adopt this crucial therapy option. Increasing physician knowledge will aid general practitioners in treating AF with anticoagulation in primary care facilities. If these obstacles are addressed and a shared care plan is developed, AF may be better managed within primary care [16].

This cross-sectional study aimed to assess Syrian physicians' knowledge, attitude, and practice regarding the use of anticoagulant therapy in NVAF patients. The findings will contribute to the present knowledge and will be helpful for decision-makers and policymakers in guiding AF treatment.

Methods

Study setting and design

This online cross-sectional study was performed between 21 December 2022 and 3 February 2023. Each respondent was informed of the study objectives and the research team identification. Additionally, the right to withdraw from the study at any time and the total confidentiality of the personal information was assured, and the fact that only fully reported data would be analyzed. This study included cardiologists, other internists, consultants, and resident doctors within the general internal medicine department or its sub-specialties. Physicians who were unwilling to participate and practitioners from different specialties were excluded from this survey. The questionnaire was based on a previous study conducted in China [17].

The questionnaire was translated into Arabic to ensure complete comprehension of the items. The link for the Google form with the questionnaire was sent to respondents through social media platforms, such as WhatsApp, Facebook, and Telegram. Another source for collecting data was face-to-face interviews between data collectors and physicians within governmental and private hospitals. The minimal sample size was estimated by applying a single proportion of the population formula [$n=[(Z\alpha/2)2.\ P\ (1-P)]/d2$]. With a 95% confidence level ($Z\alpha/2=1.96$), and a 5% margin of error, the KAP level was assumed at 50% to ensure the largest sample size. The required sample size was 385. However, we enrolled 498 participants in this study.

Measures

A modified and validated KAP questionnaire model developed by Ye et al. was used as a measurement tool 15. The questionnaire of this study included 56 items divided into four sections. The first part represented the demographic information of the study population and their previous experience in dealing with AF patients. The second, third, and fourth sections assessed knowledge, attitude, and practice toward anticoagulant therapy in patients with NVAF, respectively. Knowledge, attitude, and practice were rated as either poor (below 39.0%), average (40.0–69.0%), or good (above 70.0%), where these cut-off points were predetermined based on the prior study.

Practitioners' demographics and their previous experience in dealing with AF patients

Overall, this domain contained 19 questions. We obtained the main properties of the study's respondents by asking them 13 questions about their sociodemographics, including age, gender, academic specialty, number of years of work experience, and professional title. The participant's monthly income was defined as poor, moderate, good and excellent if it was <30%, between 30 and 50%, between 50 and 80% and >80% of the area median income, respectively. In this part, participants were also asked six questions about their previous experience in dealing with AF patients, including the total number and age of the AF patients they have managed in the past year, the main obstacles of starting anticoagulant therapy in their AF patients, and whether their AF patients were treated with aspirin or warfarin.

Knowledge regarding anticoagulant therapy in patients with NVAF and the sources of information

Fourteen questions were included in this segment. We questioned the participants on issues such as AF diagnosis, the scores used to predict stroke risk and bleeding threat in AF patients, laboratory tests used to monitor AF patients treated with warfarin, the target range of International normalized ratio (INR) in AF patients managed with warfarin under 75 years old and above it, and about NOAC use. In the context of knowledge, participants were asked about their source of information concerning AF and the sources they prefer to use to gather knowledge about AF. Each knowledge item question scored one point for a correct answer and zero for an incorrect answer. The total knowledge score was computed by the addition of all score items.

Attitude toward anticoagulant therapy in patients with NVAF

This section included 13 questions to measure participants' attitudes toward anticoagulant therapy in NVAF patients. Participants were investigated about their degree of agreement with the necessity of using the stroke score tool to calculate the risk of stroke in AF patients before anticoagulant therapy, the necessity of using the bleeding score tool to evaluate the risk of bleeding in AF patients before anticoagulant treatment, the need of understanding the risk of stroke and bleeding in AF patients, and the necessity to tell AF patients about medication and food that affect warfarin's anticoagulant effects. A 5-point Likert scale (1 = strongly disagree, 5 = strongly agree) was used to examine participants' attitudes toward anticoagulant therapy in NVAF patients.

Practice toward anticoagulant therapy in patients with NVAF

We included 18 questions in this domain to evaluate practitioners' experience dealing with non-valvular atrial fibrillation patients. This part showed different scenarios, and participants were asked to choose the appropriate management in each scenario. This part discussed issues such as the use of stroke risk score tools to assess stroke risk in AF patients, the use of bleeding risk score tools to assess bleeding risk in AF patients, informing the patient of the food and drugs that interact with warfarin, informing the patient of the increased risk of stroke related to AF. Respondents were also questioned about their previous attendance of training lectures about atrial fibrillation and anticoagulation therapy and their future desire to attend conferences on this topic. A 4-point scale (1 = never, 4 = always) was performed to measure participants' practice toward anticoagulant therapy in NVAF patients.

Pilot study

To confirm the validity and clarity of the survey, we administered it to 50 members of the public selected at random before accreditation. After performing pilot research and ensuring the questionnaire had strong internal consistency (Cronbach's alpha was between 0.712 and 0.861), we distributed it.

Ethical considerations

The Syrian Ethical Society for Scientific Research provided ethical approval and Aleppo University provided ethical clearance. Participants were given a link to access an online Google survey, and on the first page of the survey, they were asked if they agreed to complete the questionnaire. Before completing the questionnaire, participants were sent to the linked page containing important research information. The questionnaire took five to twelve minutes to complete, and the responses were saved in a secure online database.

Statistical analysis

We used IBM Statistical Package for the Social Sciences (SPSS) Statistics ver.28 and Microsoft Excel ver.365 for the performance of statistical analysis, considering *p*-values equal to or below 0.05 as significant values. For continuous data (scores) that were not normally distributed according to the Shapiro–Wilk test, the Kruskal–Wallis was performed to determine the difference between the scores and basic variables. However, the chi-square test was used to reveal the difference between the categorical variables. In addition, we carried out binary logistic regression to define the actual probabilities of each subgroup having adequate levels of knowledge, attitude, and practices of anticoagulant therapy in patients with NVAF.

Results

Participant demographics

The respondents' demographic data are summarized in Table 1. A total of 511 doctors were invited to participate in this study; however, 14 declined, reducing the final sample size to 497. Almost two-thirds of the participants (62.6%) were male, whereas most respondents (93.7%) were aged between 25 and 35. Less than half of the participants

(47.5%) reported moderate monthly income, while 83.5% were residents' doctors. 87.1% of the study sample reported less than five years of working experience. Nearly a third of respondents (34.0%) indicated they had attended training courses in their specialty. Just 11.3% of participants stated they had 20–49 AF patients in the past year; 20.5% stated 40–69% of their patients take aspirin. Lastly, 10.4% of participants revealed that 20–39% of their AF patients take warfarin.

Table 1. Demographic characteristics of participants

Variable	Frequency	Percentage %
Gender		
Male	311	62.6
Female	186	37.4
Age		
20–35	459	93.7
36–50	25	5.1
51–65	6	1.2
Residence		
Rural	117	23.5
Urban	380	76.5
Monthly income

Participant's knowledge assessment

Most participants knew how to diagnose AF, and 74.6% knew the tool that could be used to predict stroke risk in AF patients. Most respondents (81.7%) indicated the correct risk factors included in the CHADS2 score, while 21.3% did not. Approximately, 36.4% and 75.9% of respondents did not recognize the risk factors "Hypertension, Abnormal renal/liver function, Stroke, Bleeding history or predisposition, Labile INR, Elderly, Drugs/alcohol concomitantly" (HAS-BLED) score included and how long coagulation function should be monitored in AF patients with long-term warfarin therapy at a stable period, respectively. The target range of INR in AF patients with warfarin under 75 years old and the target range of INR in AF patients over 75 years old were identified among 42.9% and 45.7% of respondents, respectively. Most respondents (90.5%) and (94.2%) replied correctly about the factor that is susceptible to the anticoagulation effect of warfarin and the antagonist that antagonizes warfarin's anticoagulation, respectively (Table 2).

Most participants (85.7%) reported that electrocardiogram (ECG) made the diagnoses of AF, while 13.7% were done by Holter. 23.5% and 33% of respondents did not know the tool used to predict stroke risk in AF patients and can be used to predict bleeding risk in AF patients, respectively. Hypertension and diabetes were identified by 71% and 55.5% of respondents as risk factors in the CHADS2 score and CHADS2-VASc score, respectively. Only 3% of the participants used the Outcomes Registry for Better Informed Treatment of Atrial Fibrillation (ORBIT) score to predict bleeding risk in AF patients. Most of the respondents (83.5%) addressed INR as an indicator that should be monitored in AF patients with warfarin; however, 19.9% of respondents expressed that every seven days, the period coagulation function should be monitored in AF patients with long-term warfarin therapy at a stable period. A portion (42.9%) of participants thought the target range of INR in AF patients taking warfarin under 75 years of age was 2.0–3.0. Nearly two-thirds of respondents, 62.8%, identified food as a factor that is susceptible to the anticoagulation effect of warfarin (Table 3).

Participant attitude assessment

A total of 18.3% of the participants strongly agreed the type of AF would affect the doctor's initiation of anticoagulant therapy and choice of oral anticoagulants. In comparison, 12.9% and 11.1% didn't agree if it is necessary to use the stroke score tool to assess the risk of stroke in AF patients before anticoagulant therapy and if it is essential to use the bleeding score tool to measure the risk of bleeding in AF patients before anticoagulant treatment. Of the respondents, only 26.6% disagreed and were not more concerned about the risk of bleeding in AF patients than the risk of stroke in AF patients.

Reducing the risk of stroke and bleeding caused by AF is critical for AF patients, according to more than half of the respondents (56.7%). Of the participants, 6.2%, 2.0%, and 4.0% reported their disagreement that it is safe to maintain the INR between 2.0 and 3.0 for warfarin anticoagulation therapy in NVAF patients; that it is necessary to tell AF patients about medication and food that affect warfarin's anticoagulant effects, and they fully understand the views of AF patients on reducing the risk of stroke and bleeding caused by warfarin therapy, respectively. Finally, 53.7% and 63.8% of respondents addressed strongly they hope to have more Knowledge to discuss the advantages and disadvantages of stroke, bleeding risk, and anticoagulation, and they think doctors can improve the standard anticoagulant treatment rate in AF patients after training in atrial fibrillation, respectively (Table 4).

Participant's practices assessment

Only 38% of participants have never made a differential diagnosis according to the duration of the onset of atrial fibrillation. On the other hand, 22.5% and 20.9% indicated they sometimes made differential diagnoses between valvular AF and non-valvular AF in AF patients when they dealt with AF and used stroke risk score tools to assess stroke risk in AF patients, respectively. Moreover, 32.4% of respondents stated they often use bleeding risk score tools to evaluate bleeding risk in AF patients. Additionally, 36.4% of respondents reported they sometimes would give warfarin for anticoagulant treatment to a 75-year-old male NVAF patient with hypertension and no history of

diabetes and cardiovascular disease.

A proportion of 32.8% stated they would not provide the AF patient who had gastrointestinal bleeding three months ago and has stopped bleeding for 1-week oral anticoagulant therapy, whereas 38.8% expressed they would never give warfarin to the AF patient whose nose bleeds once and gum occasionally bleeds when brushing his teeth. Furthermore, 32.6% of participants expressed that the AF patient with coronary stent implantation for one month should often give antiplatelet and warfarin therapy (Table 5).

Fair	341	68.6
Good	126	25.4
Practice score (mean ± standard deviation)		
62.83 ± 12.42		

Barriers and obstacles to starting OAC

The main obstacle to starting anticoagulant treatment in AF patients identified by participants was the fear of the risk of bleeding (55.5%) participants; however, monitoring coagulation function tests, drug-drug interactions, and fees of coagulation were identified by 48.1%, 44.7%, and 41.2%, respectively of respondents. Regarding the significant barrier affecting AF patients' compliance, fees of coagulation were reported by 77.5% of respondents. However, monitoring coagulation function tests, lack of medications, and fear of the risk of bleeding were indicated by 51.3%, 49.1%, and 44.3%, respectively (Fig. 1).

Fig. 1 [Images not available. See PDF.]

The main obstacles for starting OAC therapy and barriers affecting patients' compliance

Demographic factors and participant's knowledge

From the total participants, 25.6% of males showed poor knowledge, whereas 14.9% of females showed fair knowledge. A good understanding was identified among 17.9% of those who live in the city, 11.5% of those with moderate monthly income, and 16.3% of singles. 35.4% of residents, 38.6% of participants with less than five years of practice, and 34.2% of those who didn't attend training reported poor knowledge. 11.3% of Participants with 1–9 AF patients in the past year indicated fair awareness. Good awareness was noticed among 6.8% of respondents who stated their AF patients aged 60–69 years, while 11.9% of participants who addressed 40–69% of their AF patients taking aspirin showed fair knowledge (Table 7). Doctors who attended training had a better knowledge score than those who did not (mean ± S.D. = 57.24 ± 20.7).

Demographic factors and participant's attitude

A good attitude was identified among 55.3% of males and 81.4% among those aged 20–35. 36.2% of participants had a good monthly income and 71.4% of singles reported good attitudes. A fair attitude was noticed among 11.3% of residents and 12.1% of those with less than 5 years of practice. 27.0% of participants with 1–9 AF patients in the past year indicated good attitude. Furthermore, a good attitude was noticed among 25.6% of respondents who

stated their AF patients aged between 60 and 69 years, while 19.9% of participants who addressed 40–69% of their AF patients taking aspirin showed a good attitude. (Table 8). Participants who stated that over 70% of their AF patients use aspirin received the highest attitude score (mean ± S.D = 86.98 ± 21.17).

Factors associated with knowledge score

In the binary logistic regression analysis, out of fourteen variables, only six predictors were statistically significant for predicting adequate knowledge of primary care physicians (PCPs) in anticoagulant therapy for NVAF patients (*p*-value < 0.05). Females were less expected to have good Knowledge than males (OR = 0.525). Respondents aged 36–50 years were less likely to have good Knowledge than those aged between 20 and 35 (OR = 0.038). Participants attending training had higher odds of understanding 2.369 times than those who didn't (Table 10).

Factors associated with attitude score

The Attitude of PCPs in anticoagulant therapy for NVAF patients was statistically correlated to two variables in the binary logistic regression analysis (*p*-value < 0.05). Participants with good practice grades were 5.872 times more likely to have a good attitude than those with bad\fair practice grades (Table 11).

Factors associated with practice score

We identified a statistically significant correlation between an adequate level of practice and four variables in the binary logistic regression (*p*-value<0.05). Physicians were more likely to have good practice than residents (OR= 5.679). Participants who scored good knowledge grades had higher odds of having good practice than those with bad\fair knowledge grades (OR=4.143) (Table 12).

Discussion

The risk of developing atrial fibrillation (AF) rises with age; it is the most common kind of cardiac arrhythmia affecting people over 60 [18]. According to the Global Burden of Disease Study findings conducted in 2010, more than one-third of all patients suffering from AF are above 80 [19].

The current study was aimed at evaluating Syrian physicians' knowledge, attitude, and practice regarding the use of anticoagulant therapy in NVAF patients and how their demographic characteristics may significantly impact it. Overall, the study findings indicate that Syrian physicians showed suboptimal knowledge and understanding regarding the diagnosis of AF and screening of bleeding risk, where 35% had a fair knowledge score. Furthermore, the results suggested that younger participants and those attending training exhibited better knowledge. Additionally, higher knowledge scores correlated with better practice, while better practice scores were linked to better attitudes. According to the study, a much lower percentage of Syrians diagnosed with AF sought medical care in community clinics than the expected number of Syrians who had AF. According to the survey results, 20.5% of physicians recommend aspirin to between 40 and 69% of their patients. This finding is particularly striking compared to the findings of a study in China, where 41.6% of primary care physicians employed aspirin as an OAC therapy for more than 70% of their NVAF patients. In addition, between 20 and 39% of those diagnosed with AF had reevaluation by

10.4% of the study's participants to initiate warfarin treatment. According to the findings of the Chinese research, however, just 0.4% of primary care physicians administered warfarin as an OAC medication to more than 70% of their patients who had NVAF [17]. This knowledge gap was further demonstrated in a recent study among physicians [20].

Elderly adults with AF need antithrombotic therapy to reduce the chance of a stroke Patients in the community diagnosed with NVAF should discuss with their PCPs the possibility of taking the anticoagulant warfarin [21]. The findings of this study show that PCPs have an insufficient grasp of the anticoagulant therapy options available for patients with NVAF. Despite this, most responders (87.3%) reported having a positive mindset. Our findings are corroborated by the results of another study, which found that 89.8% of PCPs there got excellent ratings in the survey's component that measured attitude [17]. Moreover, an Iraqi study conveyed positive attitudes toward the use of OAC for NVAF patients, despite lacking in knowledge, further verifying the current study findings [22].

This study identified that not all PCPs knew how to identify AF, and some do not frequently utilize evaluation techniques to evaluate the relevant risks faced by patients with NVAF in their clinical practice. It was observed that patients with NVAF needed a greater understanding of such methods for calculating the risk of stroke and bleeding. Based on this observation, we concluded that the treatment of OAC therapy in patients with NVAF was not optimal. Anticoagulant treatment with warfarin has several drawbacks including the impact of variability, which is connected to clinical and hereditary variables and drug-drug and drug-food interactions [23]. However, drug-drug interactions were found in 41.2% of the cases despite these limits, which are critical for patient education. This occurs less often than in research from China when 65.58% of PCPs gave incorrect answers to questions about the variables, genes, medicines, and nutrition that were likely to interact with warfarin [17].

Stroke and bleeding risk must be assessed before starting OAC therapy for NVAF. PCPs caring for patients with NVAF should weigh the risks of bleeding against the potential benefits of avoiding strokes when making treatment decisions. The best possible therapy choice may then be made. Even though the CHADS2-VASc score and the HAS-BLED score are crucial tools in generating such clinical judgments, most participants lacked an in-depth understanding of both measures. Therefore, we promote continued education among community-based PCPs, especially in using simple scoring systems to enhance clinical decision-making. In a recent study, PCPs admitted they utilized the HASBLED score and the CHA2DS2-VASc score to determine the patient's risk of bleeding and stroke, which also affected their decision to start anticoagulants which agrees with the findings of the current study [24].

Our findings indicate that 68.6% of respondents reported being at an appropriate level of practice for their roles, and 87.3% said they had a positive attitude. Thus, most likely, a lack of education was to blame for the underuse of OAC in NVAF patients. The average score for practicality was 83.33, with chief medical officers and those with 20 + years of experience scoring higher than those with less experience.

The results of the current study highlight the impact of training on knowledge level, where it reveals that respondents who received training had better knowledge scores compared to those without. This is consistent with previous studies where education and training were proven essential for ensuring optimal AF therapy [20]. Furthermore, research has demonstrated the importance of the role of training in enhancing PCP, knowledge in AF management [16].

The current findings revealed that the main obstacle to initiating anticoagulant treatment in AF was the fear of bleeding risk while the major barrier to OAC compliance was found to be coagulation fees followed by monitoring coagulation function tests, which complies with previous reported evidence [22, 25].

Community hospital PCPs in urban and rural regions scored best in Knowledge, followed by their urban counterparts, and finally by their rural counterparts in the country's geographic center. Previous research conducted in China [17] demonstrates similar results. Central urban areas have more medical resources when comparing center urban regions to urban–rural intersections and rural areas [26]. On the other hand, in a previous study, PCPs working in rural regions had a higher practice score in comparison to those working in urban centers. This contradiction may be explained by the small number of PCPs in the mentioned study hindering the generalization of

this finding [22].

As a result, many people with NVAF are encouraged by this aspect to seek care at the best facilities. Suburban residents have a low health literacy [27], which leaves primary care physicians in urban and rural regions with fewer patients suffering from NVAF. This might be why PCPs in the central urban and rural areas have lower average test results. However, there needs to be appropriate research conducted to explain these findings. Our study's sample size may be increased to evaluate these elements better.

The current study and previous reports identifying physician prescribing patterns helps enforce the importance of clinical decision-making and physician knowledge in appropriate anticoagulant prescribing [28].

Limitations

This is the first cross-sectional observational research of KAPs for PCPs on OAC treatment in patients with NVAF in Syria. We included a suitable sample size to decrease bias and analysis errors. However, as our study design is cross-sectional, the limitations consisted of difficulty in making causal inferences, the determined analysis relationships might be difficult to interpret, and susceptibility to nonresponse and recall biases. Furthermore, the significant reliance on mainly social media platforms for data collection may have introduced selection bias since it excludes those who could not be reached through those platforms.

Conclusion

OAC treatment effectively prevented embolization in patients with NVAF due to the understanding and actions of PCPs. This study showed that PCPs in Syria who participated had optimistic views and attitudes, despite suboptimal knowledge. The results indicated that participants attending training demonstrated better knowledge suggesting that training interventions aimed at PCPs play a crucial role in improving the treatment of patients with NVAF. Furthermore, higher knowledge scores correlated with better practice, while better practice scores were linked to better attitudes.

ABSTRACT (ENGLISH)

Background

A common condition known as endometriosis typically takes place in females in their reproductive age and develops

generally in the endometrial lining of females. Chronically, endometriosis has been associated with a reduction in the patient's quality of life (QOL) which can have a hazardous impact on their social working and functionality. Owing to the involvement of hormones in the development of endometriosis, drugs having the capability to modulate the hormonal concentrations, along with surgical techniques, have been designed to treat endometriosis.

Main body

There are certain drawbacks of the currently existing therapy for endometriosis which include the inability to improve the quality of life of the patient, treatment failures and unresponsiveness from the patient, and adverse effects of the drugs such as weight gain, mood swings, vaginal dryness, etc. Herbal medicines have attracted the attention of various researchers for the development of novel therapeutics against several gynecological disorders, mainly endometriosis. Our present review summarizes the precise pathogenesis of endometriosis along with its conventional therapy and novel developments in herbal medicines wherein we have compiled data from 15 completed clinical trials (conventional therapy: 7, herbal therapy: 8). Additionally, we have included data from four preclinical studies on herbal medicine that showed promising results in treating endometriosis highlighting the necessity for clinical trials to yield more definitive findings. The number of clinical trials carried out to assess the response of herbs in endometriosis is limited which is why additional studies could provide beneficial concrete evidence in the effective treatment of endometriosis and ensure improved patient outcomes.

Conclusion

Conventional therapies possess certain limitations to treat endometriosis due to which the attention of scientists has shifted toward herbal therapy due to its advantages such as improved safety and tolerability in treating endometriosis. However, additional clinical investigations into herbal therapy may prove to be fruitful in the discovery of novel therapeutics to treat endometriosis effectively.

FULL TEXT

Background

The endometrium constitutes the deepest layer of the uterus located within the female reproductive system, and it is composed of luminal and glandular epithelial cells [1, 2]. Any damage to the endothelial layer may disrupt the process of implantation and may lead to endometriosis (Fig. 1) [3–5].

Fig. 1 [Images not available. See PDF.]

An illustrative diagram representing the various factors causing endometriosis and the role of inflammation in its pathogenesis. Due to several factors including genetic, environmental, and lifestyle factors, dysfunction of the hypothalamic-pituitary axis (HPA-axis) takes place following which the production of female reproductive hormones such as LH, FSH, Anti-mullein hormone (AMH), *etc.* becomes impaired leading to an imbalance ultimately resulting in the release of inflammatory markers due to initiation process of inflammation. This can lead to damage in the endometrial layer and result in the formation of endometrial lesions resulting in pelvic pain and enlargement of the endometrium causing Endometriosis

Endometriosis can be identified by the development of tissues similar to endometrial tissues that grow outside of the uterine lining that can cause pain in the pelvic region and on a chronic basis may also lead to infertility. It usually occurs in females that are in their reproductive age, i.e., 18–54 years [6]. Although the exact factors or mechanisms behind endometriosis are still unknown, several theories have been proposed as to how its lesions arise [7]. Several symptoms arise due to endometriosis including intermenstrual bleeding, irregularity in menses (dysmenorrhea), dyschezia, dysuria, and also disruption in quality of life among patients which makes it a critical disease that needs to be dealt with [7, 8].

According to estimates, endometriosis usually is noticed in females falling between 18 and 54 years of age with its proportion of incidences varying from 10 to 15% [9]. The development of this disease has been observed to take place in up to 50% of women that have experienced infertility along with 47% of adults that have undergone laparoscopic procedures at some point in their life experiencing pelvic discomfort [7]. When the race-wise risk was calculated to develop endometriosis, it was noted that the Asian women population was at the highest risk of

developing endometriosis, while black women were observed to possess the highest possibility to develop endometriosis [10]. It has been observed that the prevalence of endometriosis in developed countries such as the USA, Russia, China, etc., was found to be 20% [11]. Similarly, the incidence rate of endometriosis was found to range from 34 to 48% in developing countries such as India [12]. Hormonal imbalances and their alterations can lead to elevations in the probability to develop endometriosis. Along with these menstrual factors, the early age at which menstruation commences and reduced menstrual period may also influence the likelihood of endometriosis [13–15]. Furthermore, lifestyle factors such as caffeine and alcohol intake are also associated with the development of endometriosis [16, 17]. Several factors leading to endometriosis are highlighted in Fig. 2.

Fig. 2 [Images not available. See PDF.]

Factors leading to endometriosis. Several factors may lead to endometriosis that include Genetic susceptibility towards particular genes, Immunological factors such as the stimulation of certain immune cells comprising Natural Killer cells, *etc.,* Environmental factors such as exposure to some trigger chemicals and lastly the activation of inflammatory markers such as Interleukins (IL-1,3), NF-κβ, and TNF-α

The conventional therapies for the management of endometriosis include hormonal agents (norethindrone, medroxyprogesterone acetate, cyproterone acetate, dienogest), contraceptive pills (estrogen–progesterone, progestin), gonadotrophin-releasing hormone (GnRH) agonists (leuprolide, buserelin) and antagonists (cetrorelix, ganirelix), and selective estrogen receptor modulator (tamoxifen, raloxifene) [18]. Patients suffering from endometriosis are known to experience pain in their pelvic region along with abdominal pain due to which they are usually given non-steroidal anti-inflammatory drugs (NSAIDs) to relieve them from their complaints of pain and steroids to regulate inflammation occurring in the endometrial region [19–21].

The majority of therapies designed to combat endometriosis are dependent on estrogen and other hormones as they constitute a majority of the disease's etiopathogenesis [22]. However, there are certain limitations of conventional therapy used in endometriosis such as risk of recurrences, safety and efficacy issues, risk of development of adverse events, etc. [23–25].

Due to the toxic effects of synthetic drugs, more attention has been shifted toward medicinal herbal drugs to cope with the harmful side effects of conventional therapy in various gynecological disorders. Herbal drugs have emerged as a more reliable source for the discovery of novel therapeutic approaches for endometriosis [26]. They target several mechanisms associated with endometriosis such as inflammatory markers, estrogen receptors, growth factors responsible for the angiogenesis of endometrial tissues, etc. The herb Epigallocatechin Gallate (EGCG) was shown to reduce inflammation by suppressing the release of NF-κB along with mitogen-activated protein kinase 1 (MAPK-1) in the endometrial lesions [27]. Similarly, Curcumin and Ginsenoside Rg3 can inhibit the effects of vascular endothelial-derived growth factor (VEGF) necessary for angiogenesis of the endometrial lining in rats suggesting their potency in endometriosis [28]. Furthermore, Curcumin, Ginsenoside Rg3, Resveratrol, Apegenin, and β-Caryophyllene decrease the levels of IL-6, IL-8, and NF-κB in human endometrial stromal cells. Also, Puerarin, Resveratrol, Curcumin, Ginsenoside Rg3, Genistein, and Herbal decoction method have been shown to attach to estrogenic receptors and compete with 17β-estradiol (E2), thereby inhibiting the production of estrogen. Their probable mechanism in endometriosis is to suppress the vascularization of the endometrial cells by targeting estrogen as it blocks the synthesis of estrogen through repression of the expression of aromatase cytochrome P450 (p450arom) in the endothelial stromal tissues as shown in Fig. 3 [29–32].

Fig. 3 [Images not available. See PDF.]

An illustration representing the various sites at which herbs act in lowering the progression of endometriosis. Several traditional herbs possess many properties through which they can influence the progression of endometriosis such as Anti-oxidative (Ginsenoside, Apigenin, β-Caryophyllene), Anti-inflammatory (EGCG, Ginsenoside Rg3, Xanthohumol, Geinstein), Hormone regulatory effects (Puerin, Resveratrol, Genistein), and Anti-apoptotic effects (Ginsenoside). These herbs can work individually or in combination to treat the underlying causes of Endometriosis

The present review compares conventional and herbal therapy based on literature evidences with the objective to identify prospective novel targets in the treatment of endometriosis. A literature search was conducted through an electronic database (PubMed, Medline, Clinicaltrials.gov, etc.) up to September 2023. The following key words were entered for search strategy: Endometriosis, Conventional therapy, GnRH agonist, Estrogens, Progestins, Selective estrogen receptor modulators (SERMs), Non-steroidal anti-inflammatory drugs (NSAIDs), Herbal therapy, Traditional medicine, Genistein, Curcumin, Ginsenoside Rg3, Herbal decoction method, Puerarin, Resveratrol, etc. Literature sources were assessed based on this search strategy and included into the present review. Additionally, it gives insights into the various conventional therapy used for endometriosis along with their limitations and whether herbal medicine have any benefits over conventional therapies.

Main Text

Conventional therapy for endometriosis

Estrogen–progestins and progestins

Also termed combined hormonal contraceptives (CHCs), they are given to the patients in the form of combined pills containing both estrogen and progesterone to balance the levels of female reproductive hormones. These pills are being administered to patients with endometriosis for a long time [33]. Both hormones possess their individual properties in lowering the damaging effects of endometriosis on the female body. Estradiol has the unique characteristics of anti-apoptosis and anti-inflammatory properties which can lower the amount of the inflammation process occurring at the endometrium, while progesterone also possesses anti-inflammatory properties but promotes apoptosis. Estradiol has the unique characteristics of anti-apoptosis and anti-inflammatory properties which can lower the amount of the inflammation process occurring at the endometrium while progesterone also possesses anti-inflammatory properties but promotes apoptosis [34]. Moreover, they lessen or stop menstruation entirely, which limits the number of endometrial cells that reflux into the tubules. These pills contain a higher level of progestin while having a low level of estrogen. They are involved with regularizing the menstrual cycle. As a result of this, it would lead to a delay in the inflammation process and oxidative stress occurring within the endometrial layer [35]. There have been several investigations that have been conducted in this context, and it has been reported that about two-thirds of the female population have benefitted from estrogen–progestin therapy and their dysmenorrhea also got corrected [33, 36–38]. Certain examples of progesterone include medroxyprogesterone, norethisterone acetate, desogestrel, etc. [39].

Gonadotrophin-releasing hormone (GnRH) agonists and antagonists

The mechanism behind GnRH analogues is that they cause the pituitary gonadotrophs to be stimulated and further promote the release of follicle-stimulating hormone (FSH), luteinizing hormone (LH), etc., thereby maintaining the normal female reproductive system function and the endometrial lining [40]. An effective strategy to combat endometriosis includes the withdrawal of the hormone (estrogen) which can be provided by administering GnRH agonist. However, a higher estrogen withdrawal may result in unpredicted adverse events including bone density loss, altered mental status, and risk for cardiovascular disorders which can lead to osteoporosis [33, 41]. Elagolix is a common drug included within the category of GnRH agonists and is used for endometriosis and it has shown significant results under clinical investigations [42]. The utilization of GnRH antagonists in a similar manner to GnRH agonists has also been evaluated in endometriosis. On evaluation, it was observed that treatment with GnRH antagonists like Cetrorelix, Abarelix, and Ozarelix can ensure the successful inhibition of gonadotrophins while also maintaining the levels of estrogen in the body. Due to this, the adverse events noted with GnRH agonists can be reduced along with the progression of the disease [41]. Hence, endometriosis now has a new avenue for medical treatment due to the administration of Cetrorelix which is an GnRH antagonist.

Progestins

Another promising avenue for the treatment of endometriosis includes therapy with progesterone-only pills which are available in the market in several dosage forms such as transdermal patches, oral pills, intrauterine devices, etc. They have been associated with alleviation in pain and irregularity in menses along with limiting the size of the endometrial lesion [43]. They may act through various mechanisms such as inhibiting angiogenesis around the

endometrial lining, inhibiting aromatase enzyme, catalyzing anovulation, modulating estrogen receptors, and decreasing the expression of 17β-HSD1 (hydroxysteroid dehydrogenase) [44]. Examples of progestins include medroxyprogesterone acetate, norethindrone, cyproterone acetate, lynesterole, etc. [45, 46]

Selective estrogen receptor modulators (SERMs) and selective progesterone receptor modulators (SPRMs)

These agents can attach themselves to estrogen or progesterone receptors and modulate their function resulting in modulating their signaling pathway. Due to this, the menstrual cycle gets restored due to regained balance between the estrogen and progesterone hormone levels. Certain examples of SERMs include tamoxifen, raloxifene, bazedoxifene, etc., while of SPRMs include mifepristone, asoprisnil, lonaprisan, etc. [43, 47, 48]. However, there is no hormonal therapy for endometriosis that is free from adverse events and a therapy should be designed in such a way that it doesn't influence the normal menstrual cycle of the body in any way and subsequently leads to endometrial lesion size reduction thereby decreasing the inflammation process occurring within it.

Non-steroidal anti-inflammatory drugs

As discussed above, inflammation is an important constituent in the development of endometriosis due to the release of prostaglandins and this ultimately leads to pain in the patient [49]. Due to this complaint of pain experienced by the patients, NSAIDs can be prescribed as a supplemental therapy to relieve the patients from their pain symptoms [46]. Drugs such as mefenamic acid, naproxen sodium, ketoprofen, and ibuprofen at doses of 400 to 600 mg in the form of oral tablets for the duration of 6 to 9 months [19, 50].

Figure 4 shows a brief timeline for the development of various drugs used as conventional therapies to treat endometriosis along with their mechanisms of action.

Fig. 4 [Images not available. See PDF.]

A diagram representing the timeline for the development of therapeutics employed in endometriosis treatment. This figure shows a timely development of the conventional agents for endometriosis in a progressive manner. The conventional agents comprise Anti-androgens (Danazol), Progestins (Norethindrone acetate, Medroxyprogesterone acetate), GnRH antagonists (Elagolix), GnRH agonists (Gosrelin, Leuprolide, Nafrelin). The year of authorization along with their mechanisms in endometriosis has been provided in the above figure

Shortcomings of conventional therapy in Endometriosis

Conventional therapy for endometriosis has been shown to possess certain drawbacks which include:

Tolerability issues

There have been instances wherein the current treatment options for endometriosis (majorly hormonal agents) have not been successfully tolerated. Estrogen and progestins can be given in the form of combined oral contraceptives (COCs) to balance the hormonal levels of the body. However, they are associated with several adverse events due to which their tolerability decreases in patients [24]. Certain examples of adverse events of estrogens include vaginal bleeding and itching, irregular menstruation, menstrual bleeding, gastric disturbances, hot flushes, mood swings, etc . [33]. Almost all therapeutics of endometriosis have safety and tolerability issues which is why they need to be checked in patients before giving it on a chronic basis [33]. Similar to estrogen, progestins are also associated with adverse events such as hirsutism, acne, mood alterations, and weight gain [43].

Safety and efficacy issues

In some studies, it has been found that when monotherapy is given to patients suffering from endometriosis, there has not been the achievement of successful therapeutic outcomes. In an clinical investigation performed by Giudice et al., they observed that monotherapy with Relugolix is not to be given for chronic use [25]. Additionally, Barbara and colleagues evaluated the safety and efficacy of GnRH agonists in endometriosis and observed that on a long-term basis, GnRH monotherapy cannot be administered to endometriosis patients it was not found to be safe for them due to the development of severe adverse events such as weight gain, hot flushes mood swings which were frequently noticed in patients [33]. In terms of oral progestins, conventional therapy has been linked to the development of various major adverse events such as neoplasms, malignancy, endocrine abnormalities, mental and behavioral disorders, and many more. The SAE incidence rate per 10,000 women-years was 3.67% in long-term

oral progestin users (treatment for more than 15 months) and 4.16% in short-term users (therapy for less than 15 months) which is why patients receiving conventional therapies are more prone to develop adverse drug reactions (ADRs) [51]. Due to the limited efficacy and safety of the conventional treatments, the patient ultimately has to undergo surgical procedures such as laparoscopy, hysterectomy, etc. [45, 52].

Cost issues

Treating endometriosis poses a substantial economic burden on the patients with the costs of therapy. This is the reason why an emphasis must be made on the cost of the therapy given in endometriosis [53]. In a study carried out by Soliman et al. wherein they evaluated the total direct costs and incremental costs between endometriosis patient and non-endometriosis control groups, they found a significant difference in both and concluded that there is a significant incremental cost to be paid in endometriosis treatment as high as $10,002 and $2132 for direct and indirect incremental costs [54]. Also, the adverse events incurred during the course of endometriosis and due to its treatment, such as pelvic pain, infertility, irregular menses, and mood swings add up to the incremental cost that the patient has to pay to deal with these complications [55].

Risk of recurrences

The greatest risk that the currently available treatments pose is the risk of recurrence of the disease due to the limited efficacy of the drugs. In most cases, the reason behind this recurrence is the presence of residual lesions or from de novo cells [23]. It was observed that the recurrence rates of endometriosis were 40–50% at a 5-year interval and 21–23% at the end of 2 years. In addition to this, the precise risk factors leading to the recurrence of endometriosis have not been identified yet [56]. Recurrence of endometriosis has also been observed in post-operative patients who have undergone surgical procedures for endometriosis [56]. Thus, it is necessary to control the recurrences of endometriosis to ensure better therapeutic outcomes in patients.

Clinical trial data of conventional therapy in endometriosis

Completed clinical trials

A list of completed clinical studies and trials for endometriosis patients and their findings are provided in Table 1. Certain examples of landmark clinical trials assessing the potency of conventional therapy in endometriosis are given below.

Table 1. A table showing the various completed clinical trials for conventional therapy in endometriosis

Phase	Study design	No of participants	Eligibility criteria	Arms of the study	Study findings	Inference	Study

Phase IV	A randomized, parallel, open-label study to determine whether endometrial implantation markers predict embryo transfer fertilization outcomes in vitro in subjects already administered leuprolide acetate	37 participants	Infertility patients, diagnosis of endometriosis patients, patients who have regular menses, normal ovarian reserve testing	Intervention: Leuprolide acetate in depot suspension 3.75 mg intramuscular every 28 days	The study found that there were no significant differences for outcomes such as rate of fertilization, stimulation of gonadotrophin hormones, etc. A high rate of fertilization rates was observed in the group of patients who were administered GnRH regimen which led to a larger frequency of implantations within them	It was concluded from this study that GnRH agonist administration in endometriosis can lead to an increase in the rates of pregnancies in comparison to the conventional ovarian stimulation techniques	Surrey et al. [58]
Phase II	A randomized parallel-assignment study to observe the efficacy of hormonal therapy in combination with GnRH agonist in patients suffering from endometriosis	53 participants	Women aged 13–22 years, body weight between 18 and 30 kg/m^2, surgical diagnosis of endometriosis, willing to comply with study requirements	Intervention: Norethindrone acetate 5 mg orally + Conjugated equine estrogens 0.625 mg orally Control: Norethindrone acetate 5 mg + placebo capsule 1 pill daily	At 12 months, the intervention group increased the bone mineral density (BMD) and the overall mineral content of the body, while the control group did not show these outcomes. Quality-of-life assessments showed greater improvements in physical functioning with the interventional group. There were no significant adverse events were reported	Add-back therapy with norethindrone acetate led to preservation of the skeletal health in endometriosis patients, the combination of norethindrone acetate and conjugated equine estrogens being led to higher elevations in the BMD of the body. The therapy was safe and effective, with no tolerability issues	DiVasta et al. [59]

Phase II	A randomized, parallel-assignment pilot study to determine the effect of dopamine receptor agonist therapy for pain relief in women suffering from endometriosis	10 participants	Women with confirmed case of endometriosis, age between 15 and 40 years	Intervention 1: Cabergoline (0.5 mg PO two times a week for 6 months duration) Intervention 2: Norethindrone acetate (5 mg po daily for 6 months)	It was observed from this study that many subjects taking cabergoline experienced a decrease in pain scores and improvement in pain complaints compared to subjects treated with Norethindrone acetate. Cabergoline was also well tolerated by the patients	It was concluded that Cabergoline could be a safe and effective therapeutic alternative for chronic pain in endometriosis resistant to standard care, according to a pilot study. Larger randomized trials are needed to confirm these findings	DiVasta et al. [60]
Phase not applicable	A prospective, randomized, parallel-assignment clinical trial to study the effect of administration of GnRH agonist before in vitro fertilization to observe fertilization rate and pregnancy rate in endometriosis patients	180 participants	Patients with infertility, endometriosis stage 1	Intervention: Leuprolide (single injection of 3.75 mg every 28 days) Procedure: In vitro fertilization (IVF)	The use of GnRH agonist resulted in a decrease in Follicular fluid cytokines in women compared to those who did not receive this regimen. However, no significant improvement took place in terms of embryo quality, rate of implantation, or rate of pregnancy	Low follicular fluid cytokine levels along with high rates of implantations were noticed in subjects receiving GnRH agonist for the duration of 3 months, with no significant difference in pregnancy and implantation rate	Kaponis et al. [61]

In a Phase-I randomized, multicentric trial performed to assess the efficacy and safety of Aromatase inhibitors (Anastrozole) and Progestin against Placebo in patients suffering from Endometriosis, 309 participants were recruited (NCT02203331). They were divided into four cohorts, (a) participants receiving Progestin (Levonorgestrel), (b) participants receiving Anastrozole in combination with levonorgestrel, (c) participants receiving leuprolide, and (d) participants receiving Placebo for the duration of 12 weeks. It was observed that all the drugs led to an improvement in the mean duration of endometriosis-associated pelvic pain (EAPP) which led to a reduction in the days that patient presented with pelvic pain [57].

In a similar Phase III study involving 815 participants, the potency of Elagolix was determined in patients suffering from Moderate to Severe endometriosis induced pain. The participants were divided into three cohorts: (a) patients receiving Elagolix 150 mg QD for a duration of 6 months, (b) patients receiving Elagolix 200 mg 4 times in a day for 6 months, and (c) patients receiving Placebo drug for a 6-month duration. It was observed after the treatment duration that Elagolix both lower and higher dose resulted in improvements in endometriosis-associated pelvic pain;

however, adverse events such as hot flushes, increased serum lipid levels, increase in bone mineral density (BMD) was observed. Therefore, it was concluded that conventional therapy, although effective led to the development of adverse events in patients of endometriosis [42].

Suspended or terminated clinical trials

There have been certain instances wherein patients suffering from endometriosis were administered conventional therapy led to the termination or suspension of the clinical trial due to certain complications occurring due to the conventional agents. An example of such trial includes a study in which 50 participants were enrolled who were clinically diagnosed with endometriosis and were divided into two groups: (a) receiving Dienogest 2 mg per day and (b) receiving Levonorgestrel (0.10 mg per day) in combination with ethinyl estradiol (0.02 mg per day) [62] are progestins which reduce endometrial lining thickness thus decreasing the chance of bleeding in patients of endometriosis [63]. The outcomes measured included the change in size of the endometrial lesions from their baseline observed via ultrasound within a time duration of 1 year. It was observed that Busrelin acetate which is a GnRH agonist was equally effective in treating endometriosis as Dienogest which is why these 2 drugs were given optionally to the patients. A significant improvement in the symptoms experienced by the patients and their pain score was observed with patients that were administered Dienogest. It also led to lower reduction in bone mineral density (BMD) as compared to Busrelin acetate. However, compared to Busrelin acetate, a higher instance of genital bleeding and hot flushes within these patients was noticed with Dienogest highlighting its concern. This was the reason due to which this trial had to be suspended to avoid complications in these patients [62]. Due to the safety concerns occurring in conventional agents, it leads to negative therapeutic effects and it has been proposed that they be monitored carefully during treatment and if they pose any risk to the patients, the trial should be terminated immediately. Also, novel drugs which are safer and more tolerable by the patients are required to prevent complications from occurring in them.

Herbal therapy for endometriosis

Epigallocatechin Gallate (EGCG)

Epigallocatechin-3-gallate (EGCG) is the main constituent of green tea due to which it can display its potency in cancer and endometriosis [64]. This herb has already been shown to possess anticancer and anti-oxidative properties. However, its effects in endometriosis were also evaluated by several researchers in endometriosis. It was shown to reduce inflammation by suppressing the release of NF-κB along with mitogen-activated protein kinase 1 (MAPK-1) in the endometrial lesions [55]. However, sufficient investigations have not been carried out as of yet to underline the exact mechanisms of EGCG through which it can cure endometriosis. The preclinical testing of EGCG in endometriosis was done by Ricci and co-workers in which they observed that treatment with EGCG inhibited the development of endometrial lesions along with decreasing the size of their lesions. It was able to modulate cellular proliferation, decrease the blood circulation to and from the endometrial lesions, and enhance the process of apoptosis [65].

Curcumin

It is the active ingredient of commonly occurring turmeric which has anti-inflammatory, anti-oxidative, and anti-proliferative properties [26, 66]. It can also block the actions of vascular endothelial-derived growth factor (VEGF) within the endometrial cells of the rats suggesting its effects as anti-angiogenetic agents as VEGF is crucial for endometrial blood vessels to grow further and proliferate [58]. Furthermore, it is able to decrease the levels of IL-6, IL-8, and NF-κB in human endometrial stromal cells (Fig. 4). Hence due to all these beneficial properties, it has been suggested that curcumin may also be employed as a potential therapeutic agent for endometriosis [26].

Ginsenoside Rg3

This is a Chinese traditional herb and is the active component of ginseng which originates from the plant genus Panax. Preclinical findings have revealed the ability of this herb in reducing the endometrial lesion size in rats [67]. Its main actions include anti-oxidative and anti-inflammatory activities [26, 59]. In addition to this, this herb can also repress the angiogenesis process by inhibiting the VEGF-mediated formation of blood vessels suggesting its efficacy in reducing endometriosis [60]. Furthermore, a study carried out by Huang et al. found that Ginsenoside Rg3

reduced inflammation by repression of NF-κB and TNF-α in ectopic endometrial cells and also modulated apoptosis by regulating the expression of caspase 3 and inhibiting VEGF-mediated angiogenesis [68].

Puerarin

It is the major active ingredient of Gegen which is extracted from the Chinese medical herb Radix puerariae and falls in the category of phytoestrogens but possesses a weak estrogenic effect. They have sown to attach to estrogenic receptors and compete with 17β-estradiol (E2) thereby inhibiting the production of estrogen (Fig. 4). Its probable mechanism in endometriosis is its ability to suppress the vascularization of the endometrial cells by estrogen as it blocks the synthesis of estrogen through repression of the expression of aromatase cytochrome P450 (p450arom) in the endothelial stromal tissues [62–65]. When preclinical analysis was carried out, it suggested that it could influence and inhibit the inflammatory microenvironment of the endometrial tissue in rats [32].

Resveratrol

Resveratrol is also a phytoestrogen that is derived from grapes, wine, peanuts, etc. It has been identified to act against the progression of endometriosis due to its effects of anti-inflammation, via the repression of prostaglandin synthesis along with the modulation of apoptosis [69]. It has the ability to influence the estrogenic receptors (ER1 and 2) and has a mixed mechanism of action i.e., agonist and antagonist [67]. In addition to this, it has also been shown to regulate various pathways associated with cellular maturation and death such as MAPK, protein kinase B (Akt), protein kinase C, and peroxisome proliferator activated receptor-gamma (PPAR-ϒ) [70–72].

Apigenin

Apigenin belongs to the category of flavonoids and is found in parsley, celery, oranges, wheat sources, etc. It possesses, anti-inflammatory, anti-proliferative, and anti-oxidant properties [73, 74]. Suou et al. in a study to undermine the effects of apigenin in endometriosis observed that it reduced inflammation via suppressing protein expression and regulating the levels of IL-8 and TNF-α (Fig. 4) [75]. Recently conducted studies also revealed its effect in acting through binding with the progesterone receptors (PR) behaving as a probable phyto-progestin [76]. It was also shown to correct endometriosis symptoms such as pelvic pain, dysmenorrhea, infertility, etc. [77].

β-Caryophyllene

It belongs to the category of sesquiterpenes and is the active ingredient of essential oils which are derived from spices and food plants and is an effective anti-inflammatory herb in vivo and was found to correct endometrial symptoms and infertility in adult rats [78, 79]. It was shown to mediate the inflammatory response by regulating their markers such as IL-1β, TNF-α, and toll-like receptors-4 (TLR-4) and angiogenesis by VEGF regulation. Recent findings also suggest its ability to block the generation of ROS through the MAPK pathway [74, 80].

Genistein

It is an iso-flavonoid which is extracted from soy. It has strong Phyto-estrogenic actions and has been demonstrated both in vivo and in vitro and has been indicated in the treatment for endometriosis [81]. Genistein was shown to limit the progression of endometrial carcinoma in adult women as it regulated the process of angiogenesis within the endometrium and apoptosis [82]. Additionally, it can modulate the estrogenic receptors (ER) to regulate the release of estrogen and the process of angiogenesis occurring due to it. Furthermore, it can regulate inflammation by mediating the release of IL-6 and TNF-α [81].

Xanthohumol

It is the active ingredient of *Humulus lupulus* L. and possesses a variety of actions including anti-angiogenetic, anti-inflammatory, and anti-proliferative effects. Inflammatory mediators such as NK-κβ, IL-1, Akt etc. can be regulated due to this herb [74, 83].

Herbal decoction method

These methods are commonly employed in China to treat a variety of gynecological disorders such as endometriosis since 1983 [84]. Certain examples of these methods include Qu Yi Kang (QYK), Yi Wei San (YWS), Xiaochaihu decoction (XCHD), Huoxue Xiaoyi (HX), and Xuefu Zhuyu (XZD) decoction methods based on their inventors [84]. Investigations into this have shown that XZD may relieve the symptoms of endometriosis, such as dysmenorrhea and ectopic lesions, and improve the issues of infertility in women and has resulted in greater efficacy of about 90%

in the past times [84, 85]. Furthermore, XCHD has been shown to reduce the levels of estradiol (E2) levels, aromatase enzymes and also modulate the inflammatory mediator synthesis through the blockade of the COX-2 enzyme [85]. Other methods of decoction include Cai Shi Nei Yi Fang, Neiyi Zhitong, Huazhuo Jiedu Huoxue, and Juan Tong Yin etc.[86].

In a study carried out by Ding et al. involving 80 patients wherein they compared the effects of Chinese traditional medicine and hormonal therapy (12.5 mg mifepristone orally each day) for Endometriosis. They observed that Chinese traditional medicine had a greater pregnancy rate (52.5%, 21/40) than hormonal therapy (37.5%, 15/40) within a 12-month period of follow-up and equivalent therapeutic effect to hormonal therapy suggesting a better potency of herbal therapy. Moreover, there were no SAE's associated with herbal therapy and the results of renal and hepatic profile parameters proved that herbal therapy was well tolerated by all the patients [87]. This proves the long-standing efficacy as well as safety of herbal medicine to treat Endometriosis.

Additionally, Zhao et al. carried out a study in which they compared the effects of Chinese herbal medicine and western medicine by the means of a randomized controlled trial in 208 patients (106 in Chinese herbal medicine group and 102 in the western medicine group). Patients in the western medicine group were treated with a GnRH agonist or gestrinone, whereas patients in the Chinese medicine group were treated with agents including Modified Guifu Decoction, Radix Aconiti lateralis Preparata, Ramulus Cinnamomi, Radix Linderae, Rhizoma Sparganii, Rhizoma Curcumae, Spina Gleditsia, Radix Salviae Miltiorrhizae, etc. For the patients in the Chinese medicine group, the mean time following surgery to achieve the first pregnancy was significantly shorter than for the patients in the Western medicine group ($t=-2.09$; $P=0.04$). A statistically significant difference existed between the 2 groups in terms of safety observed as after the treatment follow-up period, the western medicine group had increased ADRs such as fever, sweating, colpoxerosis, hypaphrodisia, weight gain, insomnia, irregular bleeding, headache, acne, and bone pain, while the patients in the Chinese medicine group only complained of occasional stomach pain that was immediately lowered after modifying the herbal remedies and dosages (83.3% vs. 9.4%, $P<0.01$) [88].

Herbal combination therapies were associated with improving pregnancy rates, reducing adverse events and inhibiting the growth of endometrial tissues in addition to decreasing inflammation in patients. Therefore, combination therapy comprising of certain herbs may prove to be beneficial in treating Endometriosis compared to conventional therapies. Furthermore, they have shown improvements in sub-populations of endometriosis patients including infertility patients, pre-menopausal syndromes, menstrual cycle irregularities, autoimmune disorders, etc. in terms of better hormonal balance restorations, ovulation induction, lowering inflammation proving their efficacy. The major herbal agents discussed in the present review such as curcumin, EGCG, Genistein, β-Caryophyllene, etc., have shown limited adverse events in comparison with conventional therapy in terms of gastric disturbances including diarrhea, stomach upset, gastric irritation, etc. which can be easily managed with supportive treatment thereby enhancing their safety profile. In addition to this, their low cost of therapy adds to their benefit in treating Endometriosis.

Herbal therapy has evolved over the recent times due to their offered advantages in the studies discussed above and other factors such as low cost, ease of convenience of preparing, reduced side effects and increased bioavailability. However, several additional investigations and clinical trials need to be conducted to evaluate efficacy and safety of different combinations of herbal therapies in Endometriosis which may also lead to the discovery of novel therapeutics to combat the disease effectively.

Preclinical and clinical trial data of Herbal novel therapy in endometriosis

The current ongoing preclinical trials in which the investigations into the effects of herbal medicine to treat endometriosis are carried out are highlighted in Table 2.

Table 2. A table showing the animal preclinical trials conducted to evaluate the potency of herbal medicine in endometriosis

Sr. No	Study objectives	Study design	Arms of the study	Study findings	Study
1	A study in order to find the association between the Ginsenoside Rg3 effect on endometrial growth and the PI3K/Akt/mTOR signaling pathway modulated by VEGFR-2	The rats were allocated on the basis of randomization into 5 groups which were treated with ginsenoside Rg3 and sacrificed 21 days post drug treatment. Measurement of the endometrial volume was carried out and the inhibitory rate was calculated. Serum estradiol (E2) and progesterone (P) levels were analyzed by Electrochemiluminescence Immunoassay (ECLI). Using immunohistochemical techniques, the protein expression of VEGF and VEGFR-2 was evaluated within the endometrium	Intervention 1: Ginsenoside Rg3 (5 mg/kgBW/d) Intervention 2: Ginsenoside Rg3 (10 mg/kgBW/d) Intervention 3: Gestrinone group (0.5 mg/kgBW/d) Intervention 4: Control group (10 mL/kg BW/d of 0.5% Carboxymethyl cellulose sodium) CMC-Na Intervention 5: Ovariectomized group (10 mL/kgBW/d of 0.5%CMC-Na)	It was observed that a dose-dependent suppression of endometrium size in rats in comparison to control group occurred. A down-regulation of the expression of VEGF and VEGFR-2 was also noticed in Ginsenoside Rg3 group	Cao et al. [67]
2	A study to evaluate the effect of EGCG in mice-model of endometriosis	The potential for EGCG as an anti-angiogenesis agent was investigated in mice suffering from endometriosis. Transplantation of endometrium was done in mice and they were divided into 3 groups to receive treatment for 4 weeks. Endometrial growth was measured through non-invasive in vivo imaging (IVIS). Post-treatment, the bioavailability, anti-oxidative and anti-angiogenesis effects were measured	Intervention 1: Dulbecco phosphate buffered saline Intervention 2: Vitamin E (20 mg/kg) Intervention 3: EGCG (50 mg/kg)	A significant reduction in the endometrial lesion size was observed in the group treated with EGCG from 2nd to 4th week of drug treatment. However, they failed to show effect on Ovarian follicles and uterine endometrial glands	Xu et al. [89]

3	A study to investigate the potency of puerarin in endometriosis (EMT) model rats and to find the probable mechanisms of action	The animals were allocated into 5 groups and endometriosis was induced surgically by auto-transplantation of endometrial tissues. Serum estradiol (E2) and prostaglandin E2 (PGE2) levels were analyzed and the dose of administration was calculated. Genes and proteins of the endometrial tissues were analyzed by polymerase chain reaction (PCR) and immunohistochemistry (IHC). Based on the results, appropriate inferences were made	Puerarin and Raloxifene (RLX) both mixed with CMC prorata after which the animals were allocated into five groups were respectively administered drug treatment for 4 weeks Intervention 1: low-dose group (0.1% CMC and 5 mg/kg puerarin) Intervention 2: 0.1% CMC and 20 mg/kg puerarin) Intervention 3: 0.1% CMC and 80 mg/kg puerarin) Intervention 4: positive control group (Raloxifene hydrochloride) RLX 10 mg/kg Intervention 5: Control group (CMC)	It was observed that Puerarin reduced the concentrations of E2 and PGE2 and also hindered the maturation of endometrium tissues by inhibiting the expression of aromatase cytochrome P450 (p450arom) and cyclooxygenase-2 (COX-2). Also, it modulated the metabolism of E2 by controlling the expression of the 17β-hydroxysteroid-2 (17β-hsd-2) enzyme of the endometrial tissues	Surrey et al. [58]
4	A clinical study to assess the effect of β-caryophyllene on endometriosis along with fertility status in adult female rats along with their roles in reproduction	Fragments of endometrium were implanted in the peritoneal cavity of the animals to induce endometriosis within them. Their growth was measured from baseline and after 4 weeks. Allocation was carried out of the animals into 2 groups and they were given drug therapy for a duration of 21 days	Intervention: β-caryophyllene (10 mg/kg or 30 mg/kg) Control: Vehicle	It was observed that β-Caryophyllene was able to hinder the maturation of endometriotic tissues 52.5% in rats compared with controls whereas β-caryophyllene led to apoptosis in the epithelium of the endometrial lesions	Abbas et al. [90]

Preclinical trials

Completed clinical trials

There are a relatively limited number of clinical studies carried out to evaluate the safety as well as efficacy of herbal medicine against endometriosis. Phase-I randomized, placebo-controlled trial was carried out in 185 participants to gain idea on the potency of green tea extract in endometriosis in which the effects of green tea or Epigallocatechin-3-gallate were compared with a placebo in order to assess its response. The investigators found that green tea

extract displayed anti-angiogenetic, anti-fibrotic, and anti-proliferative properties which led to beneficial outcomes in lowering the progression of endometriosis and was tolerable by the patients suggesting its importance [91]. Similarly, a relatively same type of clinical trial was performed to evaluate the potency of garlic in endometriosis. A total of 120 participants were recruited and one cohort was administered garlic tablets, while the other was given a placebo after which the response toward therapy was observed. It was noted that the patients that were receiving garlic therapy showed improvements in pain and statistical tests also showed its significance which concluded that herbal therapy can provide symptomatic relief also in addition to preventing the course of progression of endometriosis [92].

Ongoing clinical trials

Table 3 enlists the various investigations that are presently ongoing to investigate the effects of herbal therapy in endometriosis.

Table 3. Currently ongoing clinical studies for the evaluation of herbal therapy in endometriosis

NCT number, current phase	Study design	Eligibility criteria	Arms of the study	Primary endpoints
NCT04493476, Phase II	A double-blind, prospective and placebo-regulated clinical trial to assess the response of combination therapy of Chinese herbal medicine and curcumin to lower the symptoms of endometriosis	Women having a confirmed diagnosis of endometriosis, women aged 18–45 years (reproductive age), no allergy to the ingredients of the intervention or the control	Intervention: Daily dietary dosing of Chinese medicine and curcumin given in the form of 800 mg capsules Control: Placebo (Invo capsules given in daily dosing)	The overall benefit in the symptoms of the disease
NCT03016039	A randomized, parallel assignment study of curcumin supplementation for endometriosis	Age above 18, patient with a diagnosis of pelvic inflammatory disease/Tubo ovarian abscess, surgical wound infection, endometritis	Intervention: Curcumin supplementation	Change in the Levels of C-reactive protein, change in the levels of white blood cells
NCT03875261, Phase II	A randomized, single-group assignment study to examine the response of the effect of Cannabinoid (CBD) on pain experienced by endometriosis patients	Women falling in the age group of 18 and 40, having a confirmed diagnosis of endometriosis with clinical investigations, suffering from symptoms of pain, dysmenorrhea, etc.	Intervention: Participants administered cannabinoid derivates dosing between 1 and 12 puffs. Each puff contained 2–7 mg of delta-9-tetrahydrocannabinolan d 2–5 mg of cannabidiol	Pressure threshold in hypogastrium that induces pain

NCT02676713, Phase II	A randomized, prospective, multicentric study to evaluate the efficacy of Decoction (Chinese herbal medicine to treat infertility) in endometriosis	Women having a clinical diagnosis of endometriosis, endometriosis fertility index (EFI) score greater than 4 points, firstly undergoing laparoscopic surgery, the female of reproductive age (18–45 years)	Intervention: Decoction (Bupleurum 10 g, Cyperus 10 g, Salvia miltiorrhiza 20 g, Red peony 10 g, etc.) Placebo: Combination of maltodextrin, lactose, edible pigment, and taste masking agent	Pregnancy rate to an extent of six menstrual cycles
NCT04150406, Current phase not given	A multicentric, randomized clinical trial to evaluate the potency of Flexofytol in endometriosis	Women of reproductive age (18–51 years), diagnosed with endometriosis, moderate to severe pelvic pain	Intervention: Flexofytol (Curcumin 42 mg 2 capsules administered for 4 months) Control: Placebo	Alteration in the baseline pain score
NCT number not given	A randomized, multicentric clinical trial to evaluate the effect of Ashokarishta, Ashwagandha Churna, and Praval Pishti in patients suffering from menopausal syndrome	Females of age 40–55 years, suffering from amenorrhea for a period of greater than 12 months, were willing to comply with the study requirements, providing written consent to be included in the study	Intervention: *Ashokarishta* (25 mL *daily*), *Ashwagandha* (3 g *twice daily with milk*), *Praval Pishti* (250 mg *twice daily*) Control: Placebo	Improvement in the Menopausal rating scale (MRS), Incidences of adverse events (AEs)

Future prospects and opportunities

Up till now, the treatments under existence only aim to regulate the hormonal levels in the body and provide relief from symptoms of endometriosis such as pain, dryness, infertility, etc. However, no specific treatments are available that can cure endometriosis completely or reduce its course of progression into its more severe forms. They only aim to suppress ovulation or alter the levels of hormones such as estrogen and progesterone in the body. Thus, there is a need to develop individualized regimens pertaining to specific patients to lower the incidences and recurrences of endometriosis [93]. Therefore, herbal medicines can prove to be a means to develop novel therapeutics to be given to endometriosis patients as many drugs have shown potent effects in decreasing the size of endometrial lesions and reducing inflammation within them [81]. Herbal drugs are pleiotropic agents meaning they have multiple mechanisms of actions such as anti-oxidative anti-inflammatory, anti-angiogenetic, estrogen-modulating, analgesic, etc., which could resolve pelvic pain complaints of the patient along with lowering endometrial inflammation by blocking the release of inflammatory markers and protection from ROS species. By this, they can act as curative as well as symptomatic relief-providing agents [94]. Also, the improved safety and tolerability profile along with reduced cost of therapy makes them beneficial candidates over the conventionally available drugs presently in the market [84, 95]. Furthermore, recent data suggests that medicinal cannabis as a dietary intervention may have effects in treating Endometriosis as it acts through various mechanisms such as suppressing inflammation, alleviating bloating, and acting as a painkiller. However, it has not fully been studied and additional research into this can be fruitful [96, 97]. Herbal therapy can also be used to induce pregnancy in an individual who

cannot conceive due to endometriosis and can be utilized as a safer approach compared to conventionally existing drugs with almost no harm to the individual or the fetus [98]. Only further and larger number of studies need to be conducted in a similar manner to evaluate the extent of the benefit that herbal therapy provides or reducing the likelihood of developing endometriosis and curing it completely. Herbal therapy trials were limited in number, while trials for conventional therapy were found to be widely available. Therefore, when the results of trials for herbal therapy become available, they will strengthen the point discussed in this manuscript regarding the comparison of safety and efficacy of conventional and herbal medicine.

Conclusion

The currently existing conventional therapies are only aimed at inhibiting the hormonal parameters of the patient and providing symptomatic relief from symptoms such as pelvic pain, vaginal dryness, etc., but cannot completely cure the disease. Conventional therapy also possesses several other limitations such as increased cost of therapy, risk of recurrence of endometriosis, limited safety and efficacy profile, and tolerability issues. On the other hand, herbal therapies extracted from natural sources have shown promising effects in delaying the course of endometriosis progression and have better effects compared to conventional therapy along with improved tolerability and almost no adverse events to the patients making them a perfect candidate for the treatment of endometriosis concerning to efficacy, safety, and tolerability. The comprehensive studies data indicate that conventional therapy results in unsatisfactory therapeutic outcomes, disease recurrence, and an increase in the development of ADRs, whereas herbal combination therapy acts through multiple mechanisms, resulting in better clinical therapeutic outcomes and less ADRs, highlighting their benefit in terms of efficacy and safety in treating endometriosis. However, the number of preclinical and clinical trials investigations into this context is limited which is why additional studies are crucial to identify the potency of herbal drugs treating endometriosis effectively.

Acknowledgements

The authors are grateful to Prof. Gaurang B. Shah, Department of Pharmacology, L. M. College of Pharmacy, Ahmedabad, Gujarat, India, for kind support and guidance in manuscript preparation. The authors also extend their appreciation to the L. M. College of Pharmacy, Ahmedabad, India, for providing continuous library and resource support throughout the literature survey and data collection.

Disclosure

The authors have no financial or non-financial interest to disclose. All the investigators take responsibility for the integrity of the data and the accuracy of the data analysis. All data from clinical trials of the use of herbal therapy toward the treatment of endometriosis (https://clinicaltrials.gov/).

Author contributions

BD, SB, HR and MS contributed to manuscript first draft preparation and subsequent editing, literature and data collection, data analysis, figures and diagram conception as well as designing and writing the manuscript. AK and NP contributed to topic conception, design of content and skeleton, manuscript draft review and editing, figures and diagram conception, overall monitoring, and guidance throughout the study duration. All authors have read and approved the final manuscript.

Funding

This review did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Availability of data and materials

The datasets generated during and/or analyzed during the current study are available from the corresponding author upon reasonable request.

Declarations

Ethics approval and consent to participate

Not applicable.

Consent for publication

ABSTRACT (ENGLISH)

Backgrounds

The overall survival of patients with lower-grade gliomas and glioblastoma varies greatly. No reliable or existing procedures can accurately forecast survival and prognostic biomarkers for early diagnosis in glioma and glioblastoma. However, investigations are progressing in immunotherapy, tumor purity, and tumor microenvironment which may be therapeutic targets for glioma and glioblastoma.

Results

This study indicated the possible prognostic signatures that can be used to identify immune-related prognostic biomarkers in the prediction of the survival of low-grade glioma (LGG) patients which may be a possible therapeutic target. In addition, the Kaplan–Meier plot, ESTIMATE algorithm, and TIMER 2.0 analysis indicated that Krüppel-like factor 15 (KLF15) $p=0.030$, Aquaporin 7 (AQP7) $p=0.001$, and Human 1-acylglycerol-3-phosphate O-acyltransferase 9 (AGPAT9) $p=0.005$ are significantly associated in glioma. Hence, they may be possible prognostic biomarkers in glioma. Meanwhile, in the glioblastoma, only KLF15 has a significant association with glioblastoma ($p=0.025$). Stromal and immune scores of gliomas were determined from transcriptomic profiles of LGG cohort from TCGA (The Cancer Genome Atlas) using the ESTIMATE (Estimation of Stromal and Immune cells in Malignant Tumours using Expression data algorithm). The immune infiltration of the KLF15, AQP7, and AGPAT9 for low-grade glioma and glioblastoma was determined using TIMER immune 2.0 which indicates correlation with tumor purity for KLF15, AQP7, and AGPAT9, but only KLF15 and AGPAT9 are significantly associated in both glioma and glioblastoma, respectively.

Conclusions

These results highlight the significance of microenvironment monitoring, analysis of glioma and glioblastoma prognosis, and targeted immunotherapy. To our knowledge, this is the first time to investigate an analysis that revealed that KLF15, AQP7, and AGPAT9 may be important prognostic biomarkers for patients with glioma and KLF15 for patients with glioblastoma. Meanwhile, KLF15 and AGPAT9 are significantly associated in both glioma and glioblastoma, respectively, for tumor purity.

FULL TEXT

Backgrounds

Glioma is the most prevalent primary malignant brain tumor and can be divided into distinct categories. According to the WHO grading system, it can be categorized into astrocytomas, diffuse low-grade, intermediate-grade, oligodendrogliomas, and mixed oligoastrocytomas [1–3]. The most frequent treatment for glioma is surgical resection in combination with chemoradiotherapy. Due to its highly invasive nature, surgical resection may be difficult to treat, and residual tumor could lead to malignant progressions and even reoccurrence in the long run [4]. Although the classification of low-grade glioma (LGG) is recognized worldwide, it may not adequately predict its survival rate; however, clinicians tend to depend on genetic classifications to guide its treatment [5–7]. The survival outcomes of LGG vary widely among different patients [8]. However, some LGGs stay stable for a long period while some progress into glioblastoma [9–11]. Notwithstanding more investigations are required to elucidate whether gliomas progress to glioblastoma. Gliomas account for approximately 75% of primary cancerous brain tumors [12]. In the USA, about 13,000 people die and 18,000 new cases of CNS tumors and malignant brain tumors arise each year

due to glioma prognosis and occurrence [13, 14], hence a need for therapeutics and early diagnosis of the diseases [15].

Glioma is a cancerous tumor of the central nervous system that begins in the glial cells that surround and nourish the brain's neurons [16]. In the treatment of gliomas, great progress has been made in genomic, transcriptomic, and epigenetic profiling [17–21]. Astrocytoma, ependymoma, glioblastoma, and oligodendroglioma are some of the different kinds of glioma [22]. Glioblastoma (GBM), the most common and aggressive primary kind of malignant brain tumor, is assumed to have started in glial cells [23–25]. Scientific evidence, on the other hand, reveals that GBM could have developed from a variety of cells with neural stem cell characteristics [26, 27]. GBM is slightly more common in men than in women, as well as in Caucasians and other white races and ethnicities [28, 29]. GBM is usually found in the supratentorial region of the brain such as hypothalamus, pituitary gland, pineal, and the four lobes: temporal, parietal, frontal, and occipital lobes, with cerebellum being a rare exception [30, 31]. Sixty-one percent of all primary gliomas are found in the brain's four lobes: 20% in the temporal lobe, 25% in the frontal lobe, 3% in the occipital lobe, and 13% in the parietal lobe [32]. Glioblastomas are divided into primary and secondary subtypes that originate along different genetic routes and affect individuals of various ages [33, 34]. Quite recently, glioblastoma with oligodendroglioma component is an uncommon subtype of glioblastoma that features certain parts that resemble anaplastic oligodendroglioma, according to the WHO [35, 36].

In clinical practices, mutated genes such as isocitrate dehydrogenase 1 (IDHI), IDH2, tumor protein 53 (TP53), epidermal growth factor receptor (EGFR), and alpha-thalassemia/mental retardation, X-linked (ATRX) are factors for the prognosis of patients with LGG [37–39]. Some other biomarkers, including 1p/19q codeletion and methylguanine methyltransferase (MGMT) promoter methylation, are also well-recognized and essential prognostic factors for LGGs [40–42]. Sometimes, these genetic factors fail to indicate accurate survival outcomes [43, 44]. Hence, further investigations are required to elucidate the functions and the mechanisms of the prognostic signatures.

Several studies have shown that cancer recurrence and progression are caused not only by the tumor's underlying genetic changes but also by tumor microenvironment (TME) [45–47]. The TME is basically composed of numerous cytokines, extracellular matrix molecules, immune cells, chemokines, fluids, and stromal cells [23, 48, 49]. The cells found in the TME reflect the evolutionary nature of cancer and together, promotes the tumor immune escape, tumor growth, and metastasis [50, 51]. Cancer researchers are not vividly aware of the impact of the TME on immune response or tumor progressions although multiple genetic mutations increase the prevalence of cancer [52]. TME can induce metabolic stress on immune cell infiltration thereby causing local immunosuppression and limited reinvigoration of antitumor immunity [53, 54]. However, having an in-depth understanding of the epigenetic, molecular composition, and function of the TME is essential to manage and treat cancer progressions, recurrence, and immune response [55–57]. Integrating multiple gene biomarkers instead of a single model would improve the accuracy of the prediction significantly [58–61].

The survival of glioma patients has received so much research and discovery in the aspect of neurosurgery, radiotherapy, and chemotherapy. However, a lot of challenges of glioma are yet to be solved. Currently, immunotherapy has unveiled possible therapy for cancer [54, 62, 63]. Investigations are currently going on in the area of immunotherapy, but there is still need for efficient molecular biomarkers to differentiate patients with possible sensitivity to immunotherapy [64, 65]. Therefore, it is very crucial to identify immune-related prognostic biomarkers which may be a possible therapeutic target and may be utilized for immunotherapy in patients.

Taken together, differential expressed genes (DEGs) using an immune stromal score in glioma and glioblastoma, transcriptional microarray of glioma cases from multiple TCGA cohorts were investigated to predict the survival of LGG and GBM patients. The following prognostic signatures, such as KLF15, AQP7, and AGPAT9, were used in this investigation to determine whether they have a significant association with glioma and glioblastoma using TCGA and the immune infiltration was unveiled for precise immunotherapy. To our knowledge, this is the first time to use these signatures for glioma and glioblastoma, hence unveiling prognostic biomarker and immune infiltration.

Methods

In this investigation, utilization of the Kaplan–Meier plots using Xena bower (http://xena.ucsc.edu/), ESTIMATE

algorithm (Estimation of Stromal and Immune cells in Malignant Tumours using Expression), Timer 2.0 (http://timer.comp-genomics.org/timer/), and The Cancer Genome Atlas (TCGA) database were used to unveil the prognostic signature and immune infiltration of glioma and glioblastoma analysis.

Bioinformatics approaches were applied to integrate copy number variations and differential expressed genes of low-grade glioma. The immune cell proportion of the prognostic signatures, such as KLF15, AQP7, and AGPAT9, were determined using TIMER immune 2.0. In TIMER, the Gene module was used to identify the relationship between tumor gene expression and immune infiltration in low-grade glioma and glioblastoma. Stromal and immune scores of gliomas were estimated in transcriptomic profiles of LGG cohort from TCGA using the ESTIMATE. One hundred entries of TCGA cohort were entered and used to plot the graph showing the presence of stromal scores in tumor tissues, immune scores for the infiltration of immune cells in tumor tissues, and the ESTIMATE scores that infers tumor purity. Herein, we analyzed the immune infiltration landscape in LGGs, by applying single-sample gene set enrichment analysis (ssGSEA) to evaluate the relative abundance of each immune cell subpopulation using RNA sequencing (RNA-Seq V2) data of 100 LGGs from TCGA. The survival analysis of significant DEGs in glioma using TCGA database was determined. Kaplan–Meier curves were used to produce graphs showing the survival probability of prognostic signature genes of glioma and glioblastoma and their statistical significance. For example, p values of less than 0.05 in all tests were significantly linked to low-grade glioma and glioblastoma. The gene expression profiles of the prognostic signatures (KLF15, AQP7, and AGPAT9) were determined using TIMER immune 2.0.

Results

Kaplan–Meier curve showing the expression of KLF 15, AQP7, and AGPAT9 gene in glioma

Herein, we unveiled the survival analysis for glioma patients using the TCGA database and Kaplan–Meier plots and discovered that the KLF 15 is significantly associated ($p=0.03$) with the overall survival of the patient which indicates that it may be a very possible prognostic biomarker useful for glioma patients Fig. 1a. In our investigations, the Kaplan–Meier plot showed that AQP7 is significantly associated ($p=0.001$) with overall survival of the glioma patients using the TCGA database Fig. 1b. Hence, it showed that it may be a prognostic biomarker which may be useful for the glioma patient. The Kaplan–Meier plot showed that AGPAT9 is significantly associated ($p=0.005$) with overall survival of the glioma patients using the TCGA database (Fig. 1c).

Fig. 1 [Images not available. See PDF.]

Kaplan–Meier curve showing the expression of KLF 15, AQP7, and AGPAT9 gene in glioma

Kaplan–Meier curve showing the expression of KLF 15, AQP7, and AGPAT9 gene in glioblastoma

This is a visual representation of expression level of prognostic signature KLF15, which indicates that the p value is 0.025 that means it has a significant association with glioblastoma and thus can be used as a prognostic signature in the early detection of glioblastoma (Fig. 2a). Meanwhile, the expression level of prognostic signature AQP7 has p value of 0.59 that means it has no significant association with glioblastoma and thus cannot be used as a prognostic signature in the early detection for glioblastoma patients (Fig. 2b). Also, AGPAT9 has a p value of 0.10 that means it has no significant association with glioblastoma and thus cannot be used as a prognostic signature in the early detection of glioblastoma. Thus, AQP7 and AGPAT9 have no significant association and so they are predictive biomarkers and may not be potential prognostic signatures for glioblastoma patients. However, KLF15 showed a significant association with glioblastoma and so can be a prognostic biomarker in glioblastoma patients.

Fig. 2 [Images not available. See PDF.]

Kaplan–Meier curve showing the expression of KLF 15, AQP7, and AGPAT9 gene in glioblastoma

The stromal, immune, and estimate scores of low-grade glioma

To analyze the immune infiltration landscape in LGGs, single-sample gene set enrichment analysis (ssGSEA) was applied to evaluate the relative abundance of each immune cell subpopulation using RNA sequencing (RNA-Seq V2) data of 100 LGGs patients from The Cancer Genome Atlas (TCGA). By performing single-sample gene set

enrichment analysis (ssGSEA), we calculated stromal and immune scores to predict the level of infiltrating stromal and immune cells and these form the basis for the ESTIMATE score to infer tumor purity in tumor tissue Fig. 3.
Fig. 3 [Images not available. See PDF.]

The stromal, immune, and estimate scores of low-grade glioma

The expression levels of KLF15 in LGG using different immune infiltrate variables

KLF15 has a correlation with low-grade glioma. Correlation value of 0.124 and the genes are highly expressed in the tumor cells which show a positive correlation with tumor purity and significantly association ($p=0.000005$) Fig. 4. B cell, CD8+ T cell, CD4+ T cell, macrophages, neutrophil, and dendritic cells are the immune infiltrates which show that the expression level of KLF15 has a partial correlation, and it is significantly associated with immune infiltration in all the cells except that of the macrophages where the P value is 0.07.
Fig. 4 [Images not available. See PDF.]

The expression levels of KLF15 in LGG using different immune infiltrate variables

The expression levels of AQP7 in LGG using different immune infiltrate variables

Based on investigations, it shows that the tumor purity of AQP7 has a negative correlation with low-grade glioma; correlation value = −0.007 (Fig. 5). Also, purity and B cells do not show a significant association with glioma; *p* values = 0.8, 0.4, respectively. CD8+ T cell, CD4+ T cell, macrophages, neutrophil, and dendritic cells show that the expression level of AQP7 has a partial correlation with the infiltration level and significantly associated. CD8+ T cell, CD4+ T cell, macrophages, neutrophil, and dendritic cells also show a significant association with glioma with *p* values of 0.006, 0.05, 0.003, 0.003, and 0.01, respectively.
Fig. 5 [Images not available. See PDF.]

The expression levels of AQP7 in LGG using different immune infiltrate variables

The expression levels of AGPAT9 IN LGG using different immune infiltrate variables

Based on the investigation, it also shows that tumor purity of AGPAT9 has a negative correlation with low-grade glioma; correlation value = −0.238, and it shows a significant association with the tumor purity with *p* value ($p=0.000000014$) (Fig. 6). All the immune cells have positive correlation and show significant association with glioma except macrophages.
Fig. 6 [Images not available. See PDF.]

The expression levels of AGPAT9 IN LGG using different immune infiltrate variables

The expression levels of KLF15 in GBM using different immune infiltrate variables

The dendritic cells, CD4 T cell, neutrophil, and CD8+ T cell immune infiltrate are significantly associated with glioblastoma. Meanwhile, B cell, CD8+ T cell, CD4+ T cell, macrophages, neutrophil, and dendritic cells immune infiltrates indicated that KLF15 expression level is partially correlated with immune infiltration level in GBM, and purity immune infiltrate is correlated. Herein, during the analysis of the KLF15, we realized that the immune infiltrates are significantly association except that of the B cells ($p=0.1$) and the macrophages ($p=0.3$). The correlation value was 0.254 and the genes are highly expressed in the tumor cells. In the tumor purity, it shows positive correlation and significantly associated ($p=0.00000013$) (Fig. 7) in glioblastoma.
Fig. 7 [Images not available. See PDF.]

The expression levels of KLF15 in GBM using different immune infiltrate variables

The expression levels of AQP7 in GBM using different immune infiltrate variables

Here, no significant association ($p=0.26$). It was also indicated that the tumor purity of AQP7 has a negative correlation with its immune infiltration level; Correlation value = −0.055 (Fig. 8). However, neutrophil and CD4 T cells have partial correlation and significantly associated in glioblastoma patients with p value of 0.0000195 and

0.0000177, respectively.

Fig. 8 [Images not available. See PDF.]

The expression levels of AQP7 in GBM using different immune infiltrate variables

The expression levels of AGPAT9 in GBM using different immune infiltrate variables

B cells and macrophages show no significant association with glioblastoma multiforme. The purity, CD8+ T cell, CD4+ T cell, neutrophil, and dendritic cells show a significant association with glioblastoma multiforme. Based on the analysis, the tumor purity of AGPAT9 has a negative correlation with low-grade glioma; correlation value = − 0.363. It also shows a significant association $p = 0.000012$ (Fig. 9).

The expression levels of AGPAT9 in GBM using different immune infiltrate variables

Discussions

Krüppel-like factor 15 (KLF15) is a signature that is yet to be fully elucidated in the glioma patient, but previous investigations have been done in the area of clear cell renal cell carcinoma [66] adenocarcinoma lung cancer [67]. Krüppel-like factor 15 (KLF15) is useful in a lot of biological processes which include cell proliferation, cell cycle, adipogenesis, etc. [68–70]. KLF15 has an important role in RNA polymerase II-specific DNA-binding transcription factor activity [71, 72]. Hence, it is known to have significant functions in different types of cancer. KLF15 is responsible for the suppression and activation of genes in carcinogenesis. Previous investigation has shown that KLF15 is a positive regulator of carcinogenesis [73–76]. Therefore, KLF15 may be useful immune-related prognostic signature in glioma and glioblastoma patients.

Investigations have been conducted on the Aquaporin 7 (AQP7) association with lymphatic metastasis, breast cancer, liver cancer, and clear renal cancer [77–81]. It is otherwise known as water channels which have been known to be related to the invasion, proliferation, and migration of human breast tumors [77, 82–84]. However, investigations are yet to discover the potential roles of AQP7 in glioma and glioblastoma patients as a possible therapeutic target and prognostic biomarker. Aquaporin (AQP) family members were first investigated in 1992 [85–87]. Various investigations have shown that it can be expressed in epithelial and non-epithelial cells [88]. AQP7 is also important in fatty acid metabolism and enhances the migration of water and glycerol [78]. Human 1-acylglycerol-3-phosphate O-acyltransferase 9 (AGPAT9, also known as GPAT3 or LPCAT1) is correlated with tumor progression and tumor microenvironment [89]. It is related to fatty acid metabolisms and involved in a lot of biological processes. It catalyzes de novo synthesis of triacylglycerol [89]. Hence, AQP7 and AGPAT9 indicate usefulness as prognostic biomarker which may be advantageous for the glioma patient.

Stromal and immune scores were estimated from transcriptomic profiles of LGG cohort from TCGA using the ESTIMATE. One hundred entries of TCGA cohort were entered and used for the investigation. Hence, the presence of stromal scores in tumor tissues, immune scores for the infiltration of immune cells in tumor tissues and the ESTIMATE scores that infers tumor purity is observed [90–92].

Immune infiltration of malignancies correlates strongly with clinical outcomes. In terms of chemotherapy and immunotherapy, the makeup of tumor-infiltrating immune cells (TIICs) can serve as biomarkers for predicting treatment response and survival in distinct patient subgroups [93]. Hence, the immune cell proportion of the three-signature for LGG were determined using Timer immune 2.0. The Gene module allows a user to identify the relationship between tumor gene expression and immune infiltration in a fast, comprehensive, and unbiased way [94]. Therefore, the signatures may be a potential prognostic signature for glioma and useful for screening immunotherapy for glioma patients. Hence, this is in consistent with previous investigations [95, 96]. Therefore, B cell, CD8+ T cell, CD4+ T cell, macrophages, Neutrophil, and dendritic cells immune infiltrates indicated that AQP7 expression level is partially correlated with immune infiltration level in LGG [97], while purity infiltrate is correlated. Hence, it may be a potential prognostic signature for glioma and useful for screening immunotherapy for glioma patients [98].

B cell, CD8+ T cell, CD4+ T cell, macrophages, neutrophil, and dendritic cells show that the expression level of AGPAT9 has a partial correlation with the infiltration level. Purity, B cell, CD8+ T cell, CD4+ T cell, neutrophil, and dendritic cells show a significant association with glioma [99], while macrophages do not have any significant association with glioma. Therefore, B cell, CD8+ T cell, CD4+ T cell, macrophages, neutrophil, and dendritic cells immune infiltrates indicated that AGPAT9 expression level is partially correlated with immune infiltration level in low-grade glioma, while purity immune infiltrate is correlated [100].

Determination of immune cell proportion of the KLF15, AQP7, and AGPAT9 signatures on the glioblastoma multiforme prognostic using Timer immune 2.0 indicated that the tumor purity of KLF15 has a positive correlation with glioma and glioblastoma [101]. Hence, KLF 15 may be a potential prognostic biomarker and useful for screening immunotherapy for glioma and glioblastoma patients. B cell, CD8+ T cell, CD4+ T cell, macrophages, neutrophil, and dendritic cells show that the expression level of KLF15 has a partial correlation with the infiltration level. Therefore, CD8+ T cell, CD4+ T cell, neutrophil, and dendritic cells immune infiltrates indicated that KLF15 expression level is significantly associated with the GBM patients. Thus, KLF15 may be a useful signature for monitoring immunotherapy in GBM [102].

B cell, CD8+ T cell, CD4+ T cell, macrophages, neutrophil, and dendritic cells show that the expression level of AGPAT9 has a partial correlation with the infiltration level. CD4+ T cell, macrophages, and neutrophil cells do not show a significant association with glioblastoma multiforme. The tumor purity, dendritic cells, and CD8+ T cell immune infiltrate have a significant association with glioblastoma using the AGPAT9 gene [66]. Therefore, B cell, CD8+ T cell, CD4+ T cell, macrophages, neutrophil, and dendritic cells immune infiltrates indicated that AGPAT9 expression level is partially correlated with immune infiltration level in GBM [89], while purity immune infiltrate is correlated. Dendritic cells are known for their ability of promoting tumor immunosuppression [103]. Dendritic cells are divided into two forms, myeloid DC and plasmacytoid DC, which can produce large amount of Interferon gamma [104]. It can also induce T cell immunity or tolerance [105, 106]. Hence, AGPT9 may be useful for monitoring immunotherapy in glioblastoma patients. Concerning the association of CD8 T cells, it shows that CD8+ T lymphocytes are crucial components of the tumor-specific adaptive immunity that attacks tumor cells [107]. Clinical outcomes are highly connected to the immune infiltration of malignancies [108]. The composition of tumor-infiltrating immune cells (TIICs) may serve as biomarkers for predicting treatment response and survival in various patients subgroups in terms of chemotherapy and immunotherapy [109, 110].

Conclusions

The analysis revealed that KLF15, AQP7, and AGPAT9 may be prognostic biomarker genes that may be useful for prognosis of patients with glioma. Utilization of bioinformatics tools such as TIMER, ESTIMATE, Kaplan–Meier plot, TCGA database; the immune proportion, stromal and immune scores, various expression levels of the prognostic signatures, infiltrating levels, and tumor purity of glioma and glioblastoma multiforme were determined. Further investigations will be required using X-tile software, Database for Annotation, Visualization, and Integrated Discovery (DAVID), string, cytoscape, Kyoto Encyclopedia of Genes and Genomes (KEGGs) databases to unveil the molecular mechanisms of glioma and glioblastoma. Use of single cell sequencing will be of great usefulness in the treatment of glioma and glioblastoma. Investigations into hormone-based therapy will be fascinating. It would be enormously fascinating to validate maybe the biomarker predicts both precision immunotherapy and prognosis. The determination of real-time quantitative PCR analysis is also important.

Enhanced therapeutic approach for diabetic foot ulcers: comparative study and characterisation of mupirocin-loaded nanosponge gel with marketed formulation for accelerating wound healing and in vivo evaluation

Dhamak, Rushikesh S.1 ; Salve, Pramod S.1; Tiwari, Deepak R.1; Raut, Pradnya A.1; Waghmare, Darshan S.11 Rashtrasant Tukadoji Maharaj Nagpur University, Department of Pharmaceutical Sciences, Nagpur, India (GRID:grid.411997.3) (ISNI:0000 0001 1177 8457)

ABSTRACT (ENGLISH)

Background

The current investigation aimed to develop, optimise, and assess a mupirocin-loaded nanosponge-based topical delivery system for diabetic foot ulcer and to achieve prolonged drug release while improving drug deposition within the skin. The nanosponges carrying mupirocin were formulated using the emulsion solvent diffusion method. A 3^2 factorial design was utilised to investigate effect of two factors, specifically the concentration of ethyl cellulose and the stirring rate, on the physical attributes of the nanosponges. The optimised nanosponge formulation batch (F9) was subsequently incorporated into a Carbopol gel base, ensuring the desired physical attributes were achieved in the gel formulation containing nanosponges. The research included in vitro drug release evaluation, ex vivo drug deposition analysis, assessment of the antimicrobial action of the nanosponge formulation, and in vivo diabetic wound healing.

Results

Drug polymer compatibility analysis was conducted using FT-IR spectroscopy revealed no interactions among mupirocin and ethyl cellulose molecules. Further FT-IR spectroscopy, DSC spectroscopy, and XRD spectroscopy analysis of optimised formulation batch revealed that the drug was successfully entrapped in nanosponges. Scanning electron microscopy confirmed the spherical and porous nature of the prepared nanosponges. The drug release pattern across the cellulose dialysis membrane followed a diffusion-controlled release pattern, and the drug deposition analysis exhibited substantial retention of mupirocin in the skin from the nanosponges formulation for up to 24 h. Furthermore, the optimised nanosponges gel formulation demonstrated stability and non-irritant properties, as indicated by the HET-CAM test. In vivo evaluation of wound healing activity in a Streptozotocin-induced diabetes mellitus with excision wound model revealed significant actions pertaining to wound healing and closure after 16 days of treatment.

Conclusion

The mupirocin-loaded nanosponge gel contributed to remarkable and swift recovery and closure of wounds in diabetic rats. The nanosponges, acting as carriers for mupirocin, facilitated the effective delivery of the drug to the wound area, while the gel fostered an optimally humid environment conducive to wound care during the final stages of wound healing and sealing.

FULL TEXT

Background

Diabetes mellitus (DM) encompasses a cluster of persistent metabolic disorders marked by high blood glucose levels stemming from either inadequate insulin production or resistance to its effects [1]. The two clinically distinct types are type 1, caused by autoimmune beta-cell destruction resulting in complete insulin deficiency, and type 2, characterized by increased resistance to insulin action and insufficient insulin production [2]. Type 2 Diabetes Mellitus (T2DM) is the predominant form of diabetes, accounting for over 90% of cases globally. It is characterised by low insulin production and tissue insulin resistance [3]. The global prevalence of diabetes is rising, with projections estimating over 1.31 billion people will be affected by 2050 [4, 5].

Diabetic foot ulcers (DFUs) are substantial complications of diabetes, distinguished by ulceration linked with neuropathy and/or peripheral arterial disease [6–8]. DFUs can lead to severe complications such as infections, amputations, and mortality. Infections are observed in up to 58% of patients with new foot ulcers [9]. The prevalence of DFUs is higher in males (4.5%) than in females (3.5%) and in type 2 diabetics (6.4%) compared to type 1

diabetics (5.5%) [10]. Patients with diabetes experience varying foot sensitivity symptoms, ranging from pain and tingling in the early stages to numbness and toe weakening in the later stages [11]. DFUs are challenging to heal due to the presence of microbial biofilms, elaborate societies of microscopic organisms encased in a self-generated matrix of extracellular polymeric substances (EPS) [12, 13]. Diabetic mouse models hold clinical significance in relation to diabetic ulcers, while the excision wound mouse model is pertinent to both acute and chronic wound healing. Interestingly, the excision wound healing model in mice has potential applicability in diabetic wound healing as well, achieved by inducing diabetes prior to initiating the wound [14].

Nanosponge-Based Topical Drug Delivery: Conventional drug therapy for DFUs faces limitations due to neuropathy, hindering drug delivery to the injured site. Nanotherapeutics, particularly nanosponge-based topical delivery systems, offer advantages for chronic wounds like diabetic wounds, promoting effective wound healing and skin regeneration [15]. The proposed strategy involves preparing a mupirocin-loaded nanosponge topical dosage form capable of penetrating deeper tissue at the injured site. Mupirocin (Pseudomonic acid A), an antibiotic synthesised by Pseudomonas fluorescens, demonstrated pronounced efficacy against staphylococci and streptococci, as well as specific gram-negative bacteria like Haemophilus influenzae and Neisseria gonorrhoeae. Additionally, it supports wound healing by promoting keratinocyte proliferation and augmenting growth factor production. The therapeutic benefits of mupirocin (MP) can be enhanced by synergistically integrating it with other substances and implementing innovative approaches [16–19]. Nanosponges (NSs) are nanosized sponge-like structures with numerous cavities capable of accommodating payloads [20]. NSs exhibit self-sterilising properties due to their average pore size of 0.25 µm, effectively preventing bacterial penetration. Additionally, they enhance drug bioavailability and improve the solubility of poorly soluble drugs [21]. They present several advantages over microsponges, including smaller particle size (below 500 nm), enhanced stability (up to 300 °C), and lipophilicity, which allows masking unpleasant flavours and transforming the physical state of drug from liquid to solid [22]. This unique drug delivery technology holds promise for attaining controlled and extended drug release, addressing the challenges of conventional topical delivery systems for diabetic wound healing.

Materials and methods

Materials

MP was purchased from Horster Biotek, Pvt. Ltd., situated in Indore, India. Ethyl cellulose (EC), Carbopol 934 (CP 934), Polyvinyl alcohol (PVA), and Dichloromethane (DCM) were obtained from Loba Chemie Pvt. Ltd. in India. Every other substance and chemical employed were of analytical calibre.

Method

Fabrication of nanosponge (NSs)

The preparation of MP-loaded Nanosponge (MP-NSs) was done by the emulsion solvent diffusion (ESD) method. MP and EC were used in the ratios of 1:4, 1:6, and 1:8. The amount of MP was kept constant at 100 mg in the development of NSs. In the emulsion solvent diffusion method, the NSs were fabricated by incorporating different proportions of EC. The internal organic phase, consisting of MP and EC, was blended with 20 mL of dichloromethane (Alternative to DCM are Ethanol, Ethyl Acetate or Acetone) using ultrasonic agitation in an ultrasonicated bath (70 kHz frequency) for a duration of 2 minutes (Crest, Ultrasonic Corporation, Cortland, New York), and in the external aqueous phase of 100 mL of distilled water, 1 g of polyvinyl alcohol (PVA) was dissolved by heating up to 60 °C. Then the internal organic phase was dropwise added to the external aqueous phase while stirring at 1000 rpm for 2 hours (hrs), and the fabricated NSs were gathered by filtration followed by oven drying at 40 °C for 24 hrs [23].

Factorial experimentation and optimization using design of experiments (DoE) software

Initial experiments were conducted to investigate the effect of MP/EC ratios and stirring rates on the physical properties of NSs. Throughout all formulations, the concentration of MP, internal phase volume, and PVA concentration remained consistent. To optimise the dependent variables like production yield (PY), entrapment efficiency (EE), and mean particle size (MPS) of nanosponges, nine formulations were created using a 3^2-factorial design, with the independent variables being polymer concentration (X1) and stirring rate (X2) [24].

Physicochemical characterisation

Fourier transform infrared (FT-IR) spectroscopy analysis

FT-IR spectroscopy data of MP, EC, and optimised MP-NSs were recorded on an FT-IR spectrophotometer (Jasco FT-IR 6700) using the potassium bromide (KBr) press technique as per previously reported methods. Approximately 1–4 mg of sample was combined with dry KBr in a 1:1 ratio and scanned at transmission mode over 4000–400 cm^{-1} [25].

Thermal analysis by differential scanning calorimetry (DSC)

The thermal assessment of MP, EC, and MP-NSs was conducted using a differential scanning calorimeter (Mettler Toledo DSC, USA). Precisely measured quantities of samples (5 mg) were placed in aluminium containers and hermetically sealed. Each sample was subjected to a gradual temperature increase of 10 °C per minute within the temperature interval of 25–300 °C, all in a nitrogen environment [26].

Solid state characterisation

The X-ray diffraction (XRD) study was conducted to evaluate the solid-state character of the formulation. Powder XRD studies of MP, EC, and optimised MP-NSs were conducted using a powder X-ray diffractometer (Brucker D2 Phaser 2nd Gen). Samples were placed in the sample stage, and data were obtained over 2θ range from 5 to 50° using a step size of 0.019° per sec [27].

Particle size and zeta potential characterisation

The analysis of particle size for MP-NSs was executed employing the "Malvern Zetasizer NanoZS (Malvern Instruments, UK)". The specimen being investigated was diluted with distilled water (1:200) and introduced into a disposable polystyrene cuvette. The measurement of particle size and polydispersity index (PDI) was conducted based on the principles of dynamic light scattering (DLS). The identical procedure was adhered to for gauging zeta potential (ZP), albeit employing an electrode cuvette. Each sample was subjected to triplicate testing (n = 3) [28].

Entrapment efficiency (%EE)

The ultracentrifugation technique was used to assess the entrapment efficiency of MP-NSs. Samples were centrifuged at 10000 rpm for 30 min using an ultracentrifuge (Remi C-24, Mumbai, India). Unentrapped MP content in the supernatant was diluted with an appropriate medium before being measured using a UV-visible spectrophotometer at 222 nm [29]. Entrapment efficiency was calculated as per Eq. (1).

1

%EE=weightoftotaldrug-weightoffreedrug×100weightoftotaldrug

Scanning electron microscopy (SEM) analysis

The structure of NSs was investigated utilising a scanning electron microscope (GEOL 5400, USA) with an operational voltage of 20 kV. Prior to observation, dehydrated NSs underwent a 45-s coating with a gold–palladium alloy in an argon atmosphere. The SEM image was captured at a magnification of 3000 [30].

In vitro antimicrobial study of optimised MP-NSs formulation

Generation of bacteria inoculums

Inoculum was standardised, and 106 colony-forming units (CFU/mL) of the required density were achieved. Nutritious broth (5 mL) was mixed with a loopful of the *Staphylococcus aureus, Escherichia coli, and Pseudomonas aeruginosa*, and the mixture was then cultured for 24 h at 3 °C. To standardise the culture to 106 CFU/mL (equal to 0.5 McFarland standards), 0.2 mL of the microbes 24-h culture were poured into 20 mL of sterilised nutritious broth and cultured for 3–5 h. Cultures of test microbes on agar–agar and 8% nutritional broth were combined to create Nutritional Broth Medium (NBM), which was used to cultivate the bacterial strains. It was autoclaved at 15 lbs. pressure for 25–30 min. On petri plates, 15 mL of NBM were poured to prepare agar test plates in an aseptic condition, then subjected to stabilisation at room tempertature (RT). In peptone saline solution, bacterial cell cultures were routinely subcultured and incubated at 37 °C for 24 h.

Agar plates and test sample preparation

The bacterial strains were inoculated onto sterile agar plates by streaking the swab across the entire surface of the agar 2–3 times to ensure uniform distribution of the inoculum. The agar plate was rotated at a 60° angle during this

process. Subsequently, the plates were allowed to air-dry in a sterile environment at RT. Wells with a diameter of 9 mm were then carefully created in the plates under aseptic conditions. The preparation of the test samples (MP-NSs) at a concentration of 10 mg/mL and the reference drug Ciprofloxacin at 100 µg/mL in dimethyl sulfoxide (DMSO) was carried out. Using a sterile micropipette, 50 µL of both the reference and test samples were dispensed into the wells. The plates were positioned in an incubator adjusted to a temperature of 37 °C for a duration of 24 h and the zone of inhibition (ZOI) for each bacterial strain was measured in triplicate using a calibrated digital Vernier caliper.

Agar well diffusion method

By using this method, the antibacterial action of MP-NSs formulation was tested against *Staphylococcus aureus, Escherichia coli, and Pseudomonas aeruginosa.* These three microorganisms are most abundant in DFUs [31]. Sterile Muller Hinton plates of agar were formed, and wells of 6 mm were punched into the plates using a sterilised cup borer. The plates were swabbed with a 24 h culture of test organisms using sterile cotton swabs. To the wells, 100 µL of MP-NSs solution were added, and plates were subjected to incubation in an upward position at 37 °C for 24 h., after which the plates were checked for ZOI. Control was 100 µL of (10% v/v) DMSO solution. The experiment was performed in triplicate, and the mean of the zone sizes recorded was calculated.

Preparation of MP-loaded nanosponge gel

To prolong the retention time on the skin surface, an optimised formulation of MP-NSs was selected for conversion into a topical gel system. Carbopol-934 (0.5%w/v) was allowed to swell in double-distilled water for 12 h. The dry powder of MP-NSs (equivalent to 100 mg of the drug), propyl paraben (0.5%w/v), and methyl paraben (0.2%w/v) were added to 10 mL of propylene glycol, and the propylene glycol suspension was gradually added to the swelled CP-934 gel while continuously stirring to achieve a uniform mixture. To obtain a translucent gel, a 1:1 molar ratio of triethanolamine base and CP-934 was added to the homogenous mixture. This step was taken to ensure a well-mixed and visually appealing gel product [32].

Assessment of gel containing MP-nanosponges

Upon visual inspection of the gel for its texture, colour, and uniformity, a comprehensive evaluation was conducted on the following parameters:

pH measurement

The pH of the formulated gel was gauged using a pH metre that had been calibrated with a pH 7 buffer prior to use. The electrode tip was immersed in the gel, and the reading was taken after 2 min. This pH measurement procedure was performed in triplicate, and the average value was computed.

Spreadability analysis

The spreadability of the gel was determined by placing a known weight of the sample between two glass slides, and a weight of 500 g was applied over the slides for approximately 5 min, after which no further spreading was anticipated. The initial and final diameters of the spread circles were measured in centimetres, serving as comparative metrics for spreadability.

Viscosity measurement

Viscosity, which signifies a resistance of fluid to flow, was assessed using a Brookfield viscometer equipped with spindle No. 7, operating at various rotations per minute (rpm) at room temperature (RT).

Drug content analysis

1 g of MP-NSs gel was precisely weighed, dissolved in methanol, sonicated for 15 min, and then adjusted to the mark in a 100 mL volumetric flask using methanol. From this solution, 1 mL was withdrawn, further diluted to 10 mL with methanol, and then a final dilution was carried out using distilled water to achieve a concentration within the Beer's law range. The absorbance was measured at 222 nm using a UV spectrophotometer against a blank gel treated in the same manner as a sample [33].

In vitro drug release assay

In vitro drug release investigations were conducted using Franz diffusion cells with a receptor chamber capacity of 20 mL and an effective diffusion area of 3.14 cm2. A cellulose dialysis membrane from Himedia, Mumbai, India, was

soaked in the receptor medium (phosphate buffer, pH 5.8) for a period of 24 h prior to the commencement of the experiment. The donor side of the arrangement held a predetermined quantity of gel containing MP-NSs. During the experiment, the receptor solution was consistently agitated at 50 rpm and maintained at a steady temperature of 32 ±0.5 °C through a circulating jacket. At specific intervals, 1 mL samples were withdrawn from the receiving compartment, and an equal volume of fresh buffer was introduced to ensure sink conditions. The extracted samples were subjected to analysis using a UV-Spectrophotometer to quantify the quantity of released MP. To facilitate comparison, the release profiles of a conventional cream (Mupirocin Cream USP, 2%, Glenmark) and a commercially available MP ointment (T-bact, GlaxoSmithKline) formulation were also examined. The drug release data underwent linear regression analysis to determine the release kinetics, encompassing zero-order and first-order release kinetics, as well as the diffusion-controlled mechanism (Higuchi model). [34].

Ex-vivo drug deposition assay

A study involving drug deposition within the skin was conducted using a Franz diffusion cell and excised rat abdominal skin. The outer layer of the skin was exposed to the surrounding environment, while the inner layer faced the solution in contact. The surface of the skin facing the outside environment was the epidermal side, whereas the dermal side was directed towards the solution in contact. The receptor compartment was filled with 20 mL of phosphate buffer at pH 5.8, maintained at a temperature of 33±0.6 °C, and agitated at a rate of 50 rpm. Prior to the application of the sample, the skin was saturated with the diffusion medium for an hour. A 40-mg portion of the sample was applied to the donor compartment. For the quantification of the drug accumulated in the skin, the diffusion cell was disassembled after time intervals of 4, 8, 16, and 24 h. The skin was cautiously detached, and the mupirocin present on the surface was cleansed using distilled water [34].

Determining mupirocin concentrations in skin specimens

MP was recovered from the skin utilizing a technique outlined by Echevarria et al. [35]. In brief, the skin was fragmented into smaller sections and subsequently crushed and ground using 10 mL of methanol. Following this, the crushed mixture underwent a 15-min session of ultrasonication to ensure the comprehensive extraction of the drug. The methanolic extract that resulted was later centrifuged at a speed of 8,000 rpm for a duration of 15 min. The liquid portion above the sediment, which held the extracted substances, was meticulously gathered. This collected supernatant was then evaporated and subsequently mixed back with the suitable solvent. Prior to analysis, the sample was filtered using 0.2-µm Whatman filter paper and subjected to assessment using a UV spectrophotometer at 222 nm. Intact skin was enriched with predetermined quantities of the drug to determine the recovery rate of the drug from the skin Subsequently, the skin was fragmented into smaller sections, crushed, drug extracted, and analysed using the previously described procedure.

Skin irritation studies

The optimised gel formulation containing MP-NSs was subjected to skin irritation assessments using the HET-CAM (Hen's Egg Test-Chorioallantoic Membrane) technique [36]. Fertile white chicken eggs were sourced from commercial suppliers. Fresh eggs, which were nine days older and weighed between 50 and 60 g, were selected for the study. The irritation evaluation involved the negative control, which was sodium chloride (0.9%w/v NaCl), the positive control, which was sodium hydroxide (1%w/v NaOH), and the prepared MP-NSs gel. The HET-CAM test was used to assess irritation. The irritation scores from all treated groups were recorded at various time intervals, and the mean irritation score was calculated [37].

Stability studies

The MP-NSs gel was evaluated for its stability in an accelerated stability chamber (REMI) at three different temperatures (4±2 ºC, 25±2 ºC and 37±2 °C) and 75% relative humidity (RH) for three months. The gel was evaluated for physical appearance, viscosity, pH, and Spreadability. Any change in appearance, pH, viscosity, or Spreadability of the stored MP-NSs gel was recorded [38].

In vivo wound healing activity

Wistar albino female rats in good health, weighing 180 and 250 g, were selected. The Institutional Animal Ethics Committee (Approval number IAEC/UDPS/2022/02/08) granted approval to the study protocol in accordance with

Indian Committee for the Purpose of Control and Supervision of Experiments with Animals (CPCSEA) specifications. Throughout the study, animals were kept in a standard laboratory environment at a temperature of 25±2 °C with a relative humidity of 44–56% and fed a standard diet and water.

Diabetes animal model

The described experimental protocol involved inducing diabetes mellitus in Wistar rats through the intraperitoneal (I.P.) delivery of streptozotocin (STZ) at a dose of 60 mg/kg body weight. Prior to the STZ injection, the rats were subjected to an overnight fasting period. To safeguard pancreatic beta cells from excessive harm induced by STZ, niacinamide was administered intraperitoneally at a dosage of 120 mg/kg body weight, 15 min prior to the STZ injection. [39, 40]. The STZ was prepared in a 0.1 M citrate buffer with a pH 4.5 for the I.P. injection. After 72 h from the STZ injection, blood samples were collected from the rats using the retro-orbital method, which involves obtaining blood from the blood vessels located behind the eye socket, a commonly used technique in small laboratory animals like rats. To confirm the successful induction of diabetes mellitus in the rats, various parameters were measured. These included HbA1C (glycated haemoglobin), blood glucose levels, and CRP (C-reactive protein) levels. These measurements were taken both before the induction of diabetes (baseline) and after 72 h following the STZ injection. The changes in these parameters would indicate the development of diabetes mellitus in the rats [41–43].

Excision wound model

Every rat participating in the study was administered an intraperitoneal injection of thiopentone sodium at a dosage of 40 mg/kg to induce anaesthesia on the day designated for wound creation. The wound development procedure involved creating a rectangular pattern on the upper side of the rat's paw. Using a scalpel blade, a wound was created by separating a complete skin layer with a standardised dimension of 2 mm × 5 mm. The rats were then randomly distributed into various experimental groups for further study. The purpose of this experimental setup was likely to be to investigate wound healing or other related phenomena in response to different treatments or interventions [44].

Animal groups and treatment protocol

Rats were split into 6 groups (n=5), with 5 rats in each group, and exposed to the subsequent treatment:

- **Group I:** Control group with normal wound (NWC), Non-Diabetic animal with wound received citrate buffer and distilled water.
- **Group II:** Control group with Diabetic wound; Diabetic animals with wounds who received no treatment (DWC).
- **Group III:** Diabetic wound treatment by MP-NSs gel formulation.
- **Group IV:** Diabetic wound treatment by standard MP ointment (T-bact, GlaxoSmithKline).
- **Group V:** Diabetic wound treatment by standard MP Cream (Mupirocin Cream USP, 2%, Glenmark).
- **Group VI:** Diabetic wound treatment by standard Becaplermin gel (REGRANEX, Smith&Nephew).

Treatment was applied topically to treat excised wound area. This treatment was followed once a daily.

Determination of wound area, calculation of wound contraction

On predefined days 1, 4, 6, 8, 10, 12, and 16, a camera was used to document the progression of changes in the wound location. Image analysis software computed the wound area from the pictures. By using Eq. (2), the percentage (%) of wound closure can be calculated [45].

2

%Wound closure=Area of initial wound-Nthday area of wound×100Area of initial wound

GraphPad Prism VIII was used to plot the graph showing the % of wound closure vs the number of days since the

wound first developed.

Results

Formulation and optimization of nanosponges

The process of formulating nanosponges is presently restricted in terms of its intricacy and expense. Although certain nanosponges available on the market are manufactured through the suspension polymerization method, an alternative technique, referred to as the ESD method, has exhibited potential for nanosponge production. The ESD method is characterised by its simplicity, reproducibility, and efficiency, rendering it a fitting approach for generating MP-NSs. A noteworthy advantage of this method is its ability to bypass the use of toxic solvents. In order to assess the impact of various variables on % entrapment efficiency, % production yield, and mean particle size of nanosponges, a factorial design was employed alongside analysis of variance (ANOVA). The factors under consideration included the concentration of EC and the stirring rate, which were investigated to uncover their effects on the aforementioned parameters. Table 1 presents the coded levels of concentration of EC and stirring rate that were utilised in the experimental design. These coded levels served as the basis for investigating the impact of independent variables on dependent variables. Table 2 provides an overview of how the independent variables influenced these specific response variables, shedding light on the relationships and effects within the experimental framework. The visual representation of the data is facilitated through the utilisation of two- and three-dimensional surface plots. These plots elucidate the relationships between variables and response outcomes, these insightful visualisations are presented in Figs. 1 and 2. The regression equation (Eq. 3) for %EE is as follows:

3

$$Y1\%EE=83.50+5.28A-0.7783B$$

where, A represents the EC concentration and B represents the stirring rate. The results revealed that the concentration of EC had a notable positive influence on the drug entrapment efficiency (%EE), meaning that increasing the EC concentration led to higher drug entrapment. On the other hand, the stirring rate had a significant negative effect on %EE, indicating that higher stirring rates resulted in lower drug entrapment.

Table 1. Coded level of ethyl cellulose and stirring rate for experimental design

Coded level	Actual values	
Ethyl cellulose (mg)	Stirring rate (rpm)	− 1
400	600	0
600	1000	+ 1

Table 2. The effect of Mupirocin: Ethyl cellulose ratio and stirring rate on production yield, EE, and mean particle size

Batches	Factors		Responses		
Mupirocin: Ethyl cellulose	Stirring rate	Particle size (nm)	Entrapment efficiency (%)	Production yield (%)	F1

Fig. 2 [Images not available. See PDF.]

Optimization of mupirocin entrapped nanosponge by desirability plot

For particle yield (PY), a linear regression equation (Eq. 4) was generated, indicating that both the EC concentration and stirring rate had a positive influence:

4

Y2PY=69.11+6.00A+1.00B

Regarding mean particle size (MPS), a polynomial regression equation (Eq. 5) revealed that the EC concentration had a positive effect, while the stirring rate had a negative effect:

5

Y3MPS=276.56+36.87A-100.90B

Fit statistics for data analysis of response variables are given in Table 3. Based on the response surface methodology study, it was found that formulation (F9) performed better in terms of %EE, %PY, and MPS. Post-analysis confirmation at a two-tailed 95% confidence level is given in Table 4. As a result, the optimised nanosponges batch (F9) was selected for further characterisation studies and incorporated into a Carbopol gel base. The findings from the factorial design and regression equations provide valuable insights for optimising nanosponge formulations with enhanced properties for potential pharmaceutical applications.

Table 3. Fit statistics for data analysis of response variables using full factorial design

Characterisation of nanosponges

FT-IR spectroscopy analysis was conducted on MP, EC, and the optimised MP-NSs formulation (F9). The resulting data, as depicted in Fig. 3, demonstrated that the key peaks of MP were similarly present in the physical combination of MP, EC, and CP. This outcome suggests the absence of substantial alterations or interactions among these components within the mixture. Consequently, this observation indicates the stability of the formulations.

Fig. 3 [Images not available. See PDF.]

FT-IR spectrum of physical mixture of mupirocin ethyl cellulose and carbopol 934

Additionally, the FT-IR spectrum (as illustrated in Fig. 4) of the optimised nanosponge formulation (F9) exhibited all the significant peaks corresponding to EC, whereas the major peaks attributed to MP were conspicuously absent. This observation serves as confirmation that the MP has been effectively encapsulated within the nanosponges.

Fig. 4 [Images not available. See PDF.]

FT-IR spectrum of ethyl cellulose, mupirocin, carbopol 934 and formulation batch (F9)

In order to investigate thermal characteristics, thermograms were acquired for MP, EC, and the optimised MP-NSs formulation, as depicted in Fig. 5. MP exhibited a distinct endothermic peak at 77.78 °C, signifying its melting point. Notably, EC and the optimised MP-NSs formulation displayed a broad exothermic peak at the same temperature, which indicated the absence of the original sharp peak. This observation strengthens the conclusion that MP has been efficiently encapsulated within the nanosponges.

Fig. 5 [Images not available. See PDF.]

DSC thermogram of mupirocin, ethyl cellulose and optimised formulation batch (F9)

The XRD graph (shown in Fig. 6) for MP displayed distinct sharp peaks, indicative of its crystalline structure. Conversely, both EC and the optimised MP-NSs exhibited an amorphous nature in the XRD pattern, providing additional verification of the successful encapsulation of the MP within the nanosponges. Moreover, the optimised MP-NSs were characterised by a mean particle size of 189 nm and a zeta potential value of (−) 26 mV, as depicted in Fig. 7.

SEM images of the MP-NSs, as shown in Fig. 8, revealed a consistent spherical morphology characterized by a porous structure. Notably, these images displayed no discernible intact Mupirocin crystals, providing strong visual evidence of the effective entrapment of the drug within the nanosponge matrix.

In an antimicrobial study, the antimicrobial efficacy of the MP-NSs formulation was assessed against commonly found bacterial strains (*Staphylococcus aureus, Escherichia coli, and Pseudomonas aeruginosa*) associated with diabetic foot ulcers. Employing the agar-well diffusion method, inhibitory potential of nanosponge formulation was determined. Figure 9 illustrates these results, which were then compared with those of the reference drug Ciprofloxacin and a control solution. Recorded zone of inhibition values against the targeted microorganisms are compiled in Table 5. To visually represent the antimicrobial activity of MP-NSs, Fig. 10 offers a graphical depiction. This dataset provides valuable insights into the extent of inhibition exerted by the tested substances on the growth and activity of the selected microorganisms.

Taken together, the results from FT-IR, thermal analysis, SEM, and XRD studies strongly support the successful preparation of MP-NSs, wherein the drug is effectively entrapped in the nanosponge matrix, converting it from a crystalline state to an amorphous state. This formulation demonstrates promising potential for pharmaceutical applications due to its stability and drug entrapment capabilities.

Characterisation of nanosponges (MP-NSs) loaded gel

The developed carbopol gel formulations exhibited a uniform and smooth white texture, showcasing thixotropic properties that facilitated easy and efficient spreading. The pH value of the gel was quantified as 6.4 ± 0.03, and its viscosity was determined to be 1026 centipoises (cPs). Notably, the spreadability assessment of the gel containing MP-NSs yielded a value of 31.0 g·cm/sec, affirming its effective spreading capability. The drug content analysis revealed a value of 88.48 ± 0.04, indicating a uniform distribution of the drug within the gel matrix. These comprehensive findings are detailed in Table 6.

Table 6. Evaluation parameters of MP-NSs gel

Parameters	MP-NSs gel formulation
Physical appearance	White and Opaque
pH	6.4 ± 0.03
Viscosity (cPs)	1026
Drug content (%w/w)	88.48 ± 0.04

Skin irritation studies

The irritation assessment of the control with (0.9%w/v) NaCl, the control containing (1% w/v) NaOH, and the formulated MP-NSs gel was conducted through the utilisation of the HET-CAM test. Figure 11 illustrates the effects on blood vessels caused by different substances applied to the chorioallantoic membrane within a 5-min interval. The evaluation of the scores from all the treated groups was performed at various time intervals, and the average irritation scores are presented in Table 7. The negative control sample exhibited a score of zero at each time interval (signifying absence of irritation, ranging from 0 to 0.8), while the positive control demonstrated an exceedingly high score (16.43). Similarly, the formulated MP-NSs gel also resulted in a score of zero, indicating an absence of irritation on the chorioallantoic membrane. The absence of irritation scores in the negative control and the formulated solution suggests that they do not cause irritation to the membrane, thus establishing their non-irritating nature to the

skin.

Fig. 11 [Images not available. See PDF.]

In vitro drug release assay

The impact of composition and carrier on the drug release pattern of distinct formulations were examined using a cellulose dialysis membrane. The in vitro discharge patterns of MP from diverse formulations, as depicted in Fig. 12, demonstrated that MP ointment and MP cream released the MP within 4 and 10 h, respectively. In contrast, the MP-NSs gel exhibited a prolonged release extending up to a 24-h period. The release of the MP from the gel formulation was governed by a diffusion-controlled mechanism. The percentage of drug release is outlined in Table 8.

Fig. 12 [Images not available. See PDF.]

In-vitro drug release of marketed formulation and prepared mupirocin-loaded nanosponge-gel formulation

Table 8. Percent (%) drug released of marketed mupirocin ointment, mupirocin cream and prepared mupirocin-loaded nanosponge gel formulation

Time (hour)	Formulations (% Cumulative drug released)		
Mupirocin ointment	Mupirocin cream	Mupirocin-loaded Nanosponge–Gel	0.5
39.81 ± 1.33	21.40 ± 1.31	8.17 ± 2.21	1
76.48 ± 2.41	39.50 ± 2.19	11.35 ± 1.21	2

Ex vivo drug deposition assay

The quantity of mupirocin accumulated in excised rat abdominal skin through various formulations at distinct time intervals is illustrated in Fig. 13. The quantity of mupirocin deposited within the skin was notably greater when using the MP-NSs gel (211.4 ± 6.9 μg/cm^2) in comparison to the MP cream (83.57 ± 6.7 μg/cm^2) or MP ointment (34.03 ± 5.6 μg/cm2) after 24 h. This observation underscores that the nanosponges facilitated an enhancement in the drug residence in the skin.

Fig. 13 [Images not available. See PDF.]

Graphical representation of concentration of drug deposited in rat skin at different time intervals

Stability study

The results of the stability study, as shown in Table 9, revealed that the MP-NSs gel was found to be stable after a period of three months. Significant changes have not been seen when these were demonstrated for physical appearance, pH, and drug content at different temperature conditions (4 ± 2 ºC, 25 ± 2 ºC and 37 ± 2 ºC). A drug content greater than 90% indicated acceptable NSs stability in gel.

Table 9. Results of stability studies of MP-NSs gel

Parameters	MP-NSs gel

In vivo wound healing study of MP-NSs gel and marketed formulation

DM was induced in rats through the I.P. delivery of STZ at a dosage of 60 mg/kg body weight. Blood samples were obtained using the retro-orbital method both prior to and subsequent to the STZ injection. These samples were subsequently analysed for blood glucose levels, C-reactive protein (CRP) levels, and glycated haemoglobin (HbA1C) levels, as documented in Table 10. The outcomes of these assessments provided confirmation of the successful induction of diabetes. Meanwhile, an excision wound model was employed to create wounds on the rat feet. These wounds were then exposed to various distinct treatments for further investigation and analysis. Table 11 presents the results of the wound closure percentages for different treatment groups. The diabetic wounds treated with standard Becaplermin gel exhibited the highest percentage of wound closure (96%), outperforming all the other groups. The diabetic wounds treated with MP-NSs gel showed a commendable wound closure rate of 92%, which was higher than the diabetic wound control group (43%), the normal wound control group (73.5%), DM group 4 treated with MP ointment (79%), and DM group 5 treated with MP cream (78%). The bar graph in Fig. 14 illustrates the percentage of wound closure on days 4, 8, 12, and 16 for all the groups. On day 4, there was a consistent and exponential wound healing rate observed across all groups. However, from day 8 onwards, both DM group 3 (diabetic wound treated with MP-NSs gel) and DM group 6 (diabetic wound treated with Becaplermin gel following MP-NSs gel) exhibited enhanced wound healing compared to the rest of the groups. Figure 15 clearly demonstrated that the diabetic wounds treated with Becaplermin gel exhibited a faster rate of healing compared to all the other groups. The diabetic control group, which did not receive any treatment, showed the slowest healing rate, even when compared to the normal wound control group. Surprisingly, the group with diabetic wounds treated with MP-NSs gel showed earlier and more improved wound healing compared to both the diabetic control group and the normal wound control group. Additionally, when compared to standard MP ointment and MP cream, the MP-NSs gel displayed faster wound closure. This difference in efficacy can be attributed to the sustained release property of the nanosponge-based gel. While the marketed conventional products required thrice-daily application, the MP-NSs gel was administered only once a day due to its sustained release characteristics, leading to superior results in wound healing. Overall, these findings strongly suggest that the MP-NSs gel had a significantly positive effect on accelerating wound healing in diabetic rats. Its sustained release properties not only contributed to better efficacy compared to the conventional products but also facilitated once-daily delivery, simplifying the treatment protocol. These findings demonstrate that the MP-NSs gel was highly effective in promoting wound closure in diabetic rats, with a significant improvement over the untreated diabetic wounds and the control groups treated with MP ointment and MP cream. The standard Becaplermin gel displayed the highest wound closure percentage, but the MP-NSs gel showed a promising and competitive efficacy, making it a potential alternative treatment option for diabetic wound healing.

Discussion

The study aimed to develop Mupirocin-loaded nanosponges using the emulsion solvent diffusion method, an alternative and promising approach for nanosponge preparation. This method offers advantages such as simplicity, reproducibility, and rapidity, while also avoiding the use of toxic solvents. To optimise the nanosponge formulation, a factorial design with EC concentration and stirring rate as independent variables was employed. The results demonstrated the significant influence of these variables on PY, EE, and MPS of the nanosponges.

Regarding MP entrapment efficiency (%EE), increasing the EC concentration positively impacted %EE, meaning that higher EC concentrations led to improved drug entrapment within the nanosponges. Conversely, higher stirring rates had a negative effect on %EE, indicating that excessive stirring negatively influenced drug entrapment. For production yield, both EC concentration and stirring rate had a positive influence, contributing to higher yields of nanosponges. The MPS of the nanosponges was influenced positively by EC concentration but negatively by stirring rate. This indicates that higher EC concentrations and lower stirring rates resulted in larger nanosponge particle sizes.

The FT-IR analysis provided insights into the interactions between mupirocin, ethyl cellulose, and carbopol, confirming the stability of the formulations. The thermal analysis and X-ray diffraction (XRD) data confirmed the successful entrapment of mupirocin within the nanosponges, converting it from a crystalline to an amorphous state. The nanosponge formulation (F9) showed promising properties, including an MPS of 189 nm and a zeta potential of (−) 26 mV, indicating a stable and effective nanosponge formulation. The nanosponge-gel exhibited sustained drug release for up to 24 h, providing potential advantages in controlled drug delivery. The nanosponge formulation demonstrated improved drug deposition in excised rat abdominal skin compared to conventional formulations like ointment and cream. The HET-CAM irritation study indicated that the nanosponge-gel was non-irritant, making it a safe formulation for topical application. The stability study revealed that the nanosponge-gel remained stable over a three-month period, with a drug entrapment efficiency greater than 90%, suggesting the potential for long-term shelf life.

The in vivo study on diabetic rat wounds demonstrated that the nanosponge-gel significantly accelerated wound healing compared to conventional products and even outperformed MP ointment and MP cream. The sustained release property of the nanosponge-gel facilitated once-daily delivery and provided improved wound closure efficacy. while the gel fostered an optimally humid environment conducive to wound care during the final stages of wound healing and sealing [46].

The acceleration of wound healing is primarily attributed to Mupirocin, which plays a pivotal role in stimulating the production of growth factors and the proliferation of human keratinocytes [18]. Additionally, the nanosponges, due to their smaller size, exhibit enhanced penetration capabilities into deeper tissues at the injured site. The gel component of the formulation fosters an optimally humid environment, particularly beneficial during the final stages of wound healing and sealing. Therefore, the combined efficacy of Mupirocin-loaded nanosponge gel as a dosage form significantly contributes to the overall acceleration of the wound healing process.

Overall, the results of this study indicate successful development of mupirocin-loaded nanosponges using the emulsion solvent diffusion method, providing a potential alternative for wound healing in diabetic rats. The nanosponge-gel exhibited favourable properties, including sustained drug release, enhanced drug deposition within the skin, stability, and non-irritating characteristics. This novel formulation has promising potential for pharmaceutical applications and merits further investigation for potential clinical translation as an effective and convenient treatment option for wound healing.

Conclusion

A novel drug delivery system utilising mupirocin-loaded nanosponges has been successfully developed to facilitate once-a-day sustained release medication for the topical treatment of diabetic wounds. The innovative formulations demonstrated improved drug retention within the skin, showcasing the superior potential of the nanosponge-based delivery system when compared to conventional mupirocin ointments and creams available in the market. Considering the heightened effectiveness and the enhanced patient adherence due to reduced application frequency, it is evident that the nanosponge-based gel formulations will play a substantially more beneficial role in the treatment of diabetic wounds.

Author contributions

RSD and PSS have taken efforts to design the study. RSD did experimental, DRT, PAR, and DSW helped in execution of study. All the authors have taken efforts to develop and evaluate the formulation. RSD have interpreted the data obtained during the study. RSD and PSS drafted, and reviewed the manuscript for further communications.

Funding

Not applicable.

Availability of data and materials

All data and material are available upon request.

Declarations

Ethics approval and consent to participate

The manuscript is solely submitted to this journal and has not been sent elsewhere simultaneously. The content is original, never published before, and complies with ethical standards. Results are presented transparently, without manipulation. Data acquisition adheres to discipline-specific guidelines. The study's experimental procedure received approval from the Animal Ethics Committee of Department of Pharmaceutical Sciences, RTMNU, Nagpur (Approval number IAEC/UDPS/2022/02/08), following Indian Committee for the Purpose of Control and Supervision of Experiments with Animals (CPCSEA) specifications.

Evaluating the prediction power and accuracy of two smart response surface experimental designs after revisiting repaglinide floating tablets

Elsayed, Tarek1; Hathout, Rania M.2 1 German International University, Faculty of Pharmaceutical Engineering and Technology, Administrative New Capital, Egypt2 Ain Shams University, Department of Pharmaceutics and Industrial Pharmacy, Faculty of Pharmacy, Cairo, Egypt (GRID:grid.7269.a) (ISNI:0000 0004 0621 1570)

ABSTRACT (ENGLISH)

Background

There is a soar in the figure of companies aiming to achieve efficiency in undergoing experimental processes. Therefore, instead of deploying one-factor-at-a-time, design of experiments is becoming rampantly utilized in order to reduce the resources outflow. There are a copious of different smart designs which could be employed as design of experiments tools. Central composite and d-optimal designs were investigated in this paper. The purpose of this investigation was to compare the two designs and identify the most accurate design at analyzing, interpreting and making predictions with regards to the data offered. The aforementioned purpose was achieved by applying both designs to a preexisting study which sought to prolong the gastrointestinal retention of repaglinide tablets through deploying a full factorial design. Further optimization was performed using Design-Expert software after inducing an outlier point.

Results

R-squared, adjusted *R*-squared, predicted *R*-squared and adequate precision were computed in addition to acquiring diagnostics figures such as predicted versus actual, residual versus run, Box–Cox, contour plot and 3D surface plots. Model equations were also produced for each design. Results showed that both designs were successful at modeling the data both scoring *r*-squared values >0.7 and adequate precision >4 implying high fitting, prediction power and ability to navigate the experimental space using a reduced number of experimental runs. The d-optimal design obtained the least relative error of only 3.81%.

Conclusions

In conclusion, the d-optimal design provides a great tool for reduction of experimental testing which in turn diminishes resources consumption. Therefore, this design is favored to be enforced in the pharmaceutical sector.

FULL TEXT

Background

The production of pharmaceutical commodities is a sophisticated, time-consuming, expensive and labor-intensive endeavor which necessitates extensive planning and exhaustive testing of products and processes with the aspire of achieving the most optimized process and the superlative quality of the medicine [1]. For this reason, many methods have prevailed with the purpose of coherent optimizing the production of medications [2]. Conventionally, one-factor-at-a-time (OFAT) studies were adopted to deduce the optimized formulation of remedies. The one-factor-at-a-time optimization approach adheres to the concept that in order to ascertain the impact of a single factor, it is imperative to keep all other factors constant. In other words, only one factor is altered at a time. This experimental design may not be the most efficient approach when the factors under consideration are interacting or interfering. Due to the proven inefficiency of OFAT, it is now rarely implemented in the pharmaceutical engineering processes. To solve the impracticality of OFAT, a new statistical approach was developed by Sir Ronald Fitcher in the twentieth century [3]. His method was named as “design of experiments (DOE)”. This systematic formulation of experiments entails a multifaceted strategy aiming at enhancing the quality of a product through limited experimentation and judicious allocation of resources [4]. The design of experiment (DOE) approach relies on planning and executing the least amount of experiments where variables are altered simultaneously to produce a cause-and-effect relationship, while minimizing errors [5–7]. The steps of DOE deployment are designing, developing, evaluating and finally analyzing

the product. The application of design of experiments (DOE) is widely employed for the execution of Quality by Design (QbD) [8]. In this context, Q8 and Q9 are major constituents of QbD where Q8-pharmaceutical development and Q9-quality risk assessment were first introduced in the international conference on harmonization (ICH) in 2009. Quality by Design is a concept which revolves around the notion that attainment of product and process understanding serves as the pivotal factor in ensuring the quality of the end product [9, 10]. This comprehensive apprehension is illustrated by embedding quality in the developing stages of the product and its processes of manufacturing in lieu of testing for quality after the manufacturing process is finalized [11]. Mitigating possible quality hazards is crucially achieved by identifying possible failures that may negatively influence the quality of the product and subsequently actions are put in place to ensure sustainment of product compliance with the quality standards [12]. Possible failures that might prevail could be pinpointed using fishbone diagram, a root cause analysis tool.
There are a multitude of different designs currently employed throughout the pharmaceutical industry. Two of the response surface designs include the central composite and the d-optimal. Central composite designs fundamentally select the upper and lower limits of testing values and extend the space of the experiments beyond both thresholds (alpha + 1 &alpha − 1) [13]. The central composite design is suitable for materials which are insensitive to harsh testing condition. Sensitive materials which should not be implemented in the central composite design include proteins and liposomes. On the other hand, the d-optimal design works by assembling information matrices for all points then deducing their determinants. The points procuring the highest determinants are encompassed in the model [14].
Despite differences, both are concurrently considered smart designs. These types of designs depend on exploiting rich-information points to establish their models. Rich-information points consist of a lower number of points which conceal the space of the experiment effectively.
In the current study, the use of smart response surface designs such as the d-optimal and the central composite was proposed instead of the full factorial in order to optimize pharmaceutical dosage forms aiming for the reduction of number of experiments and therefore saving resources, time and effort. Moreover, the two investigated smart designs were compared regarding the *r*-squared, adjusted *r*-squared, predicted *r*-squared, adequate precision and through different diagnostics tests and finally comparing them regarding the percentage relative error. The design with the lowest relative error was recommended.
To our knowledge, this is the first study that compares these two smart experimental designs in the optimization of pharmaceutical dosage forms. This concept can be projected to the other more sophisticated pharmaceutical processes such as extraction or analysis methods [15, 16] and to optimize advanced drugs carriers and delivery systems such as the lipidic, polymeric and inorganic nanoparticles [17–19] and regarding their different processes of preparation and characterization [20–23].

Methodology

Software

The models and plots for the d-optimal and central composite designs that were provided in this paper were produced using Design Expert v.7.0. software (Design-Expert software, Stat-Ease Inc., MN).

The investigated work

For the purpose of comparing the d-optimal and central composite designs, a paper was selected as a basis for application of both designs [24]. Subsequently, comparing and contrasting the two models was conducted. The chosen paper was entitled “Design expert supported mathematical optimization of repaglinide gastroretentive floating tablets: in vitro and in vivo evaluation” [24]. Repaglinide is an oral agent that falls under the meglitinide class, serving as an anti-hyperglycemic medication. It necessitates regular administration prior to meals due to its brief half-life, which lasts only one hour. Consequently, the medication can result in adverse effects, including discomfort in skeletal muscles, headaches, and gastrointestinal disturbances [25]. The investigation presented in the selected paper aimed to prolong the absorbance of Repaglinide tablets by optimizing the critical quality attributes (CQAs) entailing the floating lag time response. This was accomplished using a three-factor three-level full factorial design (usually called 33 full factorial design). Three different components concentrations were altered: Okra gum (OG),

HPMC (hydroxypropyl methylcellulose) K15M and xanthan gum. In QbD, the factors contributing in the CQAs are the CPPs (critical process parameters) and the material and formulation parameters.

Other than the factors included in the investigated study, some factors also representing CPPs of the prepared tableting process included subjecting the granules to adjusted conditions of a temperature range of 55–60 °C for approximately 120 min, while ensuring that the moisture content remained within the range of 3–5%. The powder was administered through an 80-mesh (0.177 mm pore size) after initial mixing. A 30-mesh (0.595 mm pore size) was used after adding a portion of the granulating medium. A 30-mesh (0.595 mm pore size) was used once more to sift the granules following drying. Furthermore, the compression force was adjusted to maintain the hardness of the tablets within 5 to 8 kg/cm^2.

The material and formulation parameters comprised other numerous crucial excipients satisfying various concentrations, including 2 mg of repaglinide, 10% sodium bicarbonate, 5% citric acid, 7% ethyl cellulose, 2% magnesium stearate, 1% talc in addition to lactose with a quantity sufficient to produce a 200-mg tablet. The granulation medium comprised 8% PVP K30 in 80% ethanol [24].

The use of central composite and d-optimal designs to reoptimize the results

Both central composite and d-optimal designs were used to further optimize the generated gastroretentive tablets regarding the floating lag time response instead of the three-level three-factor full factorial design which originally consisted of 27 experimental runs.

A total of 20 points were used to produce the central composite design model; six of the design points were center points.

On the other hand, a total of 25 points were used to build the d-optimal design model. The 25 points comprised 10 model points, 5 replicate points, 5 points to estimate lack of fit and 5 additional center points. The “Model use” was adjusted to point exchange prior to execution.

Table 1 demonstrates the used factors (the investigated material and formulation parameters) accompanied with their tested ranges.

Table 1. The investigated factors associated with their used ranges

Factors	Ranges of values (%)		
High (+1)	Medium (0)	Low (−1)	Concentrations of OG
35	22.5	10	HPMC K15M
15	7.5	0	Xanthan gum

Induction of an outlier

The results of the new embraced design points were produced from the equation that was generated in the extensively examined paper [24]. An outlier central point result was introduced for all the central points of both of the newly adopted designs. Accordingly, the floating lag time for coded points corresponding to (0, 0, 0) for OG, HPMC K15M and xanthan gum, respectively, was altered to a value of 90 s instead of 45.

Analysis of results

It is necessary to document the process by which the models were generated which were both quadratic. To empirically ascertain the significance of the model, ANOVA analysis was performed. This statistical test permits the assessment of differences underlying groups and provides valuable insights into the overall effectiveness and sturdiness of the model. Moreover, in order to affirm the reliability and accuracy of the results, an assortment of

values was computed including; *R*-squared, adjusted *R*-squared and predicted *R*-squared. *R*-squared value reflects the fitting of the model, adjusted *R*-squared reflects the model's *R*-squared value after insignificant terms are excluded and the predicted *R*-squared represents the model's accuracy at predicting the floating lag time [1]. Additionally, the adequate precision of the model was also determined. This measure provides a quantitative assessment regarding the signal to noise ratio [26]. Moreover, to further appraise the validity and precision of the model and identify any potential flaws or inefficiencies that could be ameliorated, a series of diagnostic tests were conducted. These tests including Box–Cox, residual versus run and predicted versus actual provide a valuable insight regarding the validity of the model and notifies for any necessary adjustments or modifications [27]. Finally, in order to visually portray the model and facilitate a deeper understanding of its underlying relationships, contour and 3D surface plots were obtained. These plots provide a graphical representation of how the change in the compositions of (OG, xanthan gum and HPMCK15) contributes to the response and highlights how the variation in these variables are reflected upon the outcome of the CQA (floating lag time). Furthermore, contour and 3D surface plots clarify the observation of the optimum quadrants of the model and allow for a more intuitive interpretation of the findings. Overall, the process of generating the model, determining its significance, calculating the different values and adequate precision, performing diagnostic tests, and obtaining contour and 3D surface plots were essential elements for ensuring the validity and consistency of the findings presented in this study.

Calculation of the percentage relative error (% relative error)

The percentage relative error was calculated by utilizing the following equation [24]:Relative error%=Predicted value -Actual valuePredicted value×100.

Results

Tables 2 and 3 demonstrate the different runs (points) generated as rich-information points of the central composite and the d-optimal designs, respectively, accompanied with the results of these runs as calculated from the generated equation of the used work of Naveen et al. [24] utilizing a three-level full factorial design to optimize the floating lag time of repaglinide floating tablets.

Table 2. The central composite generated design points associated with their calculated results

Experiment number	OG concentration	HPMCK15M	Xanthan gum	Floating lag time

Table 4 illustrates the significance of both models (P<0.001) [28]. The type of the two generated models corresponding to the two adopted designs was a quadratic function. Furthermore, the R-squared, adjusted R-squared and predicted R-squared differences were within 0.2 increments for both models and all of them scored values above 0.7 implying acceptable and reliable models. For the central composite model, the discrepancy between the R-squared and predicted R-squared was 0.0056 which is a minimal value, while for the d-optimal model, the discrepancy was higher (0.1289). The adequate precision exceeded a value of 4 as counseled for both models (adequate precision for d-optimal was 14.161 and for the central composite was 122.830). Furthermore, the parameter “lack of fit” was favorably insignificant in both models.

Table 4. The generated model analysis results

It is highly visible by observing Fig. 1 that the points present in the predicted versus actual plot of the central composite model were closer to the 45-degree line (indicating the close values of the predicted results to the actual counterparts). Hence, the model floating lag time predictions were closer to the actual values. Also obviously, the predicted versus actual plot of the d-optimal model acquired values that seemed relatively distant from the 45-degree line; yet, they were still considered close.

Fig. 1 [Images not available. See PDF.]

Predicted versus actual plots for **a** central composite and **b** d-optimal designs

As inferred from Fig. 2, the points representing the different runs of the two investigated models were evenly scattered around the zero line of the Design-Expert® generated plots of both designs and represents the models functions. Moreover, for the residual versus run point distribution of the central composite model, 40% of the points were situated above the zero line, approximately 30% were situated on the zero line, and 30% were situated under the zero line. On the other hand, for the residual versus run point distribution for the d-optimal model, 60% of the points were situated above the zero line, 8% of the points were approximately situated on the zero line, and 32% of the points were situated under the zero line.

Fig. 2 [Images not available. See PDF.]

Residual versus run plots for **a** central composite and **b** d-optimal designs

As obvious from Fig. 3, both models powers lied within the confidence interval ranges of the Box–Cox diagnostic and validating test generated from the utilized software while acquiring power correspondents of lambda = 1 [2].

Fig. 3 [Images not available. See PDF.]

Box–Cox plots for **a** central composite and **b** d-optimal designs

Contour plots use varied gradients of colors to represent segments which occupy high and low floating lag time responses as depicted in Fig. 4.

Fig. 4 [Images not available. See PDF.]

Contour plots for **a** central composite and **b** d-optimal designs at a constant xanthan gum (at its middle level, code = 0)

3D surface plots are similar to contour plots in that they show areas where the response is at different values but with a three-dimensional viewing facet. The peak response occurred at the red areas while the lowest response occurred at the blue areas [29]. It is obvious from Fig. 5 that the peak floating lag time response was present at coded values of (1, 0, − 1) corresponding to OG, xanthan gum and HPMCK15 concentrations, respectively.

Fig. 5: [Images not available. See PDF.]

3D surface plots for **a** central composite and **b** d-optimal designs at a constant xanthan gum (at its middle level, code = 0)

The d-optimal design had a lower relative error compared to the central composite design by a difference of 0.7556% for the coded point: 0.66 OG concentration, HPMC K15M and 0.85 xanthan gum, in spite of inducing an outlier critical point (Table 5).

Table 5. Percentage relative error obtained between the predicted and actual values for the coded point: 0.66 OG concentration, 1.00 HPMC K15M and 0.85 xanthan gum

Design	Relative error (%)
Central composite	4.5699
d-optimal	3.8143

Discussion

Both of the discrepancy values between the adjusted *r*-squared and the predicted *r*-squared of the two investigated designs were considered low. Hence, the models were sufficient in predicting the results of un-carried experiments and to fully navigate the experimental space.

The values of adequate precision of both designs indicated a very high signal to noise ratio. Therefore, the differences in the acquired results for the floating lag time were a consequence of real signals and not due to random outcomes and both models are considered successful in navigating the space of the investigated experiment [1].

The predicted versus actual plots mainly evaluate the accuracy of the model at making predictions regarding actual experimental values through depicting how close the predicted values are to the actual ones [2]. This is implemented by using the 45-degree line as a reference. The closer the points are to this line, the higher the capability of the model at making accurate predictions. Despite the fact that the points in both predicted versus actual plots were relatively close to the 45-degree line, these results implied the high predictive ability of the two investigated designs-generated models.

Residual versus run plots usually identify the errors present in the model. The required ideal situation is that the total distances from the points above the zero line, which represents the model, are approximately equal to the total distances of the points under the same line so that the errors even out [30]. This was approximately obtained for both models. As a conclusion, the points in both models were moderately and favorably scattered around the zero line.

The Box–Cox test primarily aims to accommodate the model response (CQA) with the optimum numerical power. The response is raised to different powers and the power with the best fitting is recommended. Usually, the power

which presents the optimum fitting lies in the area between the high and low confidence intervals. The confidence intervals are manifested by the red lines. If the value of the power (lambda) requires altering, then the recommended value should be applied through the transformation tab of the adopted software. Therefore, it was concluded that the power transformation was not required for both of the generated models.

The alteration of color gradients in the contour and the 3D surface plots is correlated with the change of compositions of the factors contributing to the response [14].

The peak floating lag time response scored at coded values of (1, 0, − 1) corresponding to OG, xanthan gum and HPMCK15M concentrations, respectively, may be attributed to the higher swelling index of okra gum (260% [31]) as compared to the other constituents (xanthan gum and HPMCK15M which only reached a maximum of<250% [32]) contributing to its significant positive effect on the floating lag time.

It could be interpreted from the current study figures and tables that both designs have been successfully leveraged to produce models with excellent qualities. Despite that the central composite scored better *R*-squared, adjusted *R*-squared, predicted *R*-squared and adequate precision values, the d-optimal design was slightly more accurate at predicting the floating lag time response The high accuracy of both models generated from the two utilized smart surface response designs at predicting the floating lag time response is related to a statistical perspective where DoEs utilizing designs such as the central composite and the d-optimal create response models by reducing the maximum variance of the predicted responses and minimizing the error in the estimated coefficients of the model. This approach offers benefits when employing disproportionate shapes and incorporating additional design points [28]. Moreover, the superiority of the d-optimal design at predicting the response for experimental points which were not included as design points (as inferred from the calculated value of the percentage relative error) comes back to the statistical element of building the design through choosing rich-information points that originate from an information matrix possessing the highest determinant which allows handling of a larger experimental space [33]. Although the CCD resulted in excellent and slightly higher *R*-squared values, this may be ascribed to the problem of overfitting that sometimes occur with experimental designs, wherein the model excessively coincides with and conforms to the existing data points. This phenomenon results in a perfect or ideal coinciding of the actual experimental design points with the generated model predictions. It usually happens with higher order functions (above linear, quadratic, cubic, etc.) possessing high curvatures aiming to reduce residuals of the generated model results [34]. This was obviously noticed in the predicted versus actual figure corresponding to the CCD results (Fig. 1). It is worth-noting that the limitation of this paper lied on the use of only one check point (experimental external validation point) in calculating the percentage relative error of the two investigated statistical experimental designs. Nevertheless, that was a forced limitation because this point was solely conducted in the originally experimental paper that the current paper was based on.

Conclusion

The current study aimed to compare the central composite and the d-optimal statistical experimental designs in optimizing the floating lag time response of repaglinide gastroretentive tablets.

The findings of this study showed that:

- Both smart designs extensively discussed in the paper have been successfully utilized to further optimize the tablets with a very high accuracy similar to a previous optimization implemented using a three-level full factorial design despite the induction of an outlier point representing the central critical point of both designs.
- After computing the percentage relative error, it was concluded that the d-optimal design is more robust in predicting the accurate result values of actual experiments of points not included in the designs built.
- The adopted work drew the attention to the problem of overfitting which may lead to decrease the predictivity power of the statistical experimental designs.

Based on the aforementioned conclusions, integrating both smart surface response designs and more specifically the d-optimal design into the routine of experimental activities, companies can excel the effectiveness of testing in addition to reducing expenses by considerable margins. The use of the investigated smart statistical experimental designs accompanied with its assessment can be projected to any dosage form design and conventional or advanced drug delivery systems aiming of reducing the number of runs and experiments conducted and hence saving resources, efforts and time.

One important contribution of this paper is that it provides a guide or an assist to companies and especially pharmaceutical entities when choosing the smart design, they seek to adopt.

Moreover, another contribution of this paper toward the pharmaceutical industry is that it could guide users on how to calibrate design expert software efficiently to produce the d-optimal and central composite designs and their generated models. Future studies should compare the d-optimal design with other smart counterparts.

Optimization of simvastatin transdermal patch for hyperlipidemia treatment in rat model

Neetu1; Anand, Anubhav1 ; Panjwani, Dharamveer11 Hygia Institute of Pharmaceutical Education and Research, Department of Pharmaceutics, Lucknow, India (GRID:grid.484086.6)

ABSTRACT (ENGLISH)

Objective

Biopharmaceutics Classification System says that simvastatin (SMV) is a Class II drug with low bioavailability (5%). This is because it dissolves slowly and is broken down a lot in the first pass. Simvastatin transdermal patches were produced as part of this study's aim to treat hyperlipidemia. The Box–Behnken design (three-factor, three-level) was selected for optimization of patches.

Methodology

The optimization design involved 15 runs with independent factors hydroxypropyl methylcellulose K100, Eudragit L100, and polyethylene glycol 400 percentage, and dependent factors including folding endurance and in-vitro drug release.

Results

The results showed that the concentration of hydroxypropyl methylcellulose K-100 positively impacted the patch's folding endurance. The fact that factor C was the only scenario where the *p*-value was less than 0.05 and the coefficient value was higher in the in vitro drug release model means that it has a greater influence on the release of medicines. The patches were also evaluated for drug content, swelling, moisture uptake, moisture content, etc. The optimized patch shows an in vitro drug release of 55.3% in up to 24 h. In vivo antihyperlipidemic activity was evaluated in albino Wistar rats. In the standard treatment (simvastatin oral) groups, there is a decrease in cholesterol (132.76±0.35) and triglyceride level (139.80±76) whereas in the test formulation group or test group, there is also a decrease in cholesterol (169.65±0.21 mg/dL) and triglyceride level (151.20±31 mg/dL) level.

Conclusion

Based on in-vitro and in-vivo results it can be concluded that simvastatin patches can be an alternative to traditional therapy.

FULL TEXT

Background

There are considerable changes in plasma concentration when widely used dosage forms such as tablets, capsules, and oral liquids are administered in repeated doses. This fluctuation may lead to various adverse effects. Therefore, different modified release systems were successfully tested to minimize the fluctuation. There are several administration methods, including as oral, mucosal, inhalation, transdermal, and intravenous injection, depending on the delivery route. A promising method that can imitate the plasma concentration profile of intravenous infusion is the transdermal drug delivery system (TDDS), until the drug is present in the system [1]. In comparison to other routes of administration, the skin has many benefits, including the avoidance of gastric irritation, emptying rate effects and pH, hepatic first-pass metabolism, reduction of systemic side effects, sustained drug release, faster termination of therapy, reduced fluctuations in plasma levels, and avoidance of injection-related pain [2]. According to Zondek, when used topically as a 30 percent lanolin ointment, the external disinfectant chloroxylenol may be successful in treating urogenital infections [3–5] and open a new way to deliver the drug systemically through topical route. Over the past 40 years, a great deal of research has been done on transdermal administration of active pharmacological ingredients (API) [6]. A transdermal patch is a device that allows the API contained in it to travel through the skin and deliver medications to specific cells or organs [7]. The market for transdermal medication administration is about to shift into a new stage where pain relief isn't the primary driver [8]. Hormones, cardiovascular drugs, and drugs for the central nervous system are also administered through the transdermal system [8]. With the use of more recent drug delivery techniques that are effective, predictable, and safe, continuous delivery of a biologically active moiety is possible either systemically or to a specific site. They can perform better than traditional administration methods by monitoring the intensity, location, and length of the pharmacological action. A patch that is placed on the skin and includes medication that is meant to be absorbed into the bloodstream through the skin is called a transdermal patch [9], also known as a skin patch. Transdermal drug delivery has many benefits, including fewer side effects, less repetitive administration to achieve the desired plasma concentration, prolonged drug delivery, a reduction in the first-pass effect, and enhanced patient compliance, interruption of therapy when necessary etc. [10] All statin drugs have poor aqueous solubility and low oral bioavailability [11]. Due to their history of efficacy in adults, statins are one of the first-line medications considered for use in the pediatric population with dyslipidemia [12]. Simvastatin (SIM) inhibits 3-hydroxy-3-methylglutaryl coenzyme-A (HMG-CoA) reductase [13] and is commonly prescribed for cardiovascular illnesses due to its effects on decreasing lipid levels. Simvastatin enhances capillary morphogenesis in vitro and inhibits apoptosis in lymphatic endothelial cells, suggesting that it has lymphangiogenic properties that aid in the healing of wounds [14]. According to the Biopharmaceutics Classification System (BCS), SIM is a Class II [15] medication with low bioavailability (5%) due to its slow rate of solubility and extensive first-pass metabolism. SIM's poor oral bioavailability must be improved, which requires an increase in solubility. Although SIM has a short half-life, around two hours and a low water solubility (aqueous solubility 0.03 mg/L), it is removed by cytochrome P3A, which undergoes substantial metabolism in the liver and the intestines [16]. Delivery methods include transdermal, buccal, rectal, and parenteral are among the strategies that could be used to prevent first-pass metabolism. SIM is an excellent choice for the creation of transdermal films because to its strong first-pass metabolism, low molecular weight (418.56), high lipid solubility, low melting point (129 °C), capacity to act at low plasma concentrations [17]. The aim of this work to prepare a simvastatin transdermal patch (SIM-TP) and study its antihyperlipidemic activity in an animal model.

Methods

Simvastatin was gift from Biodeal Pharmaceutical Pvt Ltd. Himachal Pradesh, India. Hydroxypropylmethyl cellulose (HPMC K100) was gift from Colorcon Asia Pvt Ltd, Goa, India and Eudragit RL 100 was obtained from EvoniK Roehm Pharma Polymers and all other ingredients are of analytical grade.

Preparation of SIM-TP

The formulation of SIM-TP is shown in Table 1. The solvent casting procedure was used to prepare the transdermal

patch. Ethanol: dichloromethane (1:1) was used to dissolve the polymers Eudragit L-100 and HPMC K100. The polymeric dispersion was stirred continuously with a magnetic stirrer until a clear solution formed. Polyethylene glycol 400 (PEG 400) was used to dissolve the drug before it was added to the polymer solution. After that, the homogeneous polymer solution containing the drug was added to a petri dish that had been lined with aluminum foil and allowed to air dry for 24 h at room temperature. The petri dish was covered with an inverted funnel to stop the solvent from evaporating too quickly. Desiccators were used to store the dried patches for future study.

Optimization of SIM-TP

The response surface design The Box–Behnken design was utilized to optimize the simvastatin transdermal patch (SIM-TP). The three-factor, three-level design was selected. The three independent variables were HPMC K100, Eudragit RL100 (ERL100), and PEG400. Table 2 displays the variables and their corresponding levels. The Design-Expert 13 software proposed a 15-run trial for the optimization process. The proposed design is shown in Table 3.

Evaluation of transdermal patch

Physical appearance

Every transdermal patch was visually inspected for color, smoothness, and uniformity.

Thickness

A screw gauge was used to measure the patches' thickness. Each batch of films had its average and standard deviation calculated based on five readings.

Folding endurance

Careful consideration was given to the prepared films' capacity for multiple folds in one location. The patch strip (2 × 2 cm^2) was folded repeatedly till it broke. The maximum simultaneous folds the film could withstand before failing were counted [18].

pH determination

The transdermal films were incubated in a glass petri dish for an hour in 0.5 ml of double-distilled water to give them time to swell. The glass electrode was allowed to acclimate before being brought near to the film surface. The surface pH was then measured with a digital pH meter, and the results were noted [19, 20].

Swelling index

The patch was weighed after being submerged in a petri dish containing 50 ml of pH 7.4 phosphate buffer every 10 min. The following formula was used to determine the swelling's intensity [21].

1

SI%=Xt-XoXo×100where the weight of the patch both before and after it absorbs moisture is represented by Xo and Xt.

Drug content

Transdermal films were divided into pieces with a predetermined area (1 cm^2), placed in a volumetric flask of

100 mL, and then dissolved in methanol. After being sonicated, the mixture was left for 24 h. A 0.45-µm membrane was used to filter the fluid. Using a UV spectrophotometer (Labindia), the amount of medication in the solution was determined at 237 nm, the absorbance was measured, and data were collected [22].

Moisture content

The produced films were weighed individually until they reached equilibrium weight after being stored in desiccators with fused calcium chloride for 24 h at 40 °C. After reweighing the film 24 h later, the moisture content percentage was calculated using the procedure below [23].

2

%MoistureContent=Initialweight-FinalweightInitialweight×100

Moisture uptake

The weighted films stored in a desiccator with a saturated potassium chloride solution for 24 h at 40 °C in order to maintain a Relative Humidity of 84%. The films must be reweighed after 24 h to determine the amount of moisture absorbed [23, 24].

3

%MoistureContent=Finalweight-InitialweightInitialweight×100

In-vitro drug release

The *in-vitro* release study was conducted using a Franz diffusion (FD) cell with a dialysis membrane (HIMEDIA LA 395–10 MT). Phosphate buffer pH 7.4 with sodium lauryl sulfate (SLS) (0.5% w/v) served as the dissolving media. A phosphate buffer was placed into the diffusion cell's receptor compartment. The dialysis membrane received a buffer rinse before the experiment. Between the donor and receiver chambers of the diffusion cell, the membrane was securely clamped in place. A constant 37 °C was maintained while the diffusion cell was continuously stirred at a speed of 50 rpm. Samples were taken periodically to maintain the sink condition, and each time, an equivalent volume of phosphate buffer was added to the receptor compartment. Using a UV–visible spectrophotometer, the samples' absorbance at 237 nm was measured, and the cumulative percent drug release was computed [25].

Scanning electron microscopy (SEM)

To analyze their surface topography and morphology, a prepared patch was coated with gold–palladium under an argon atmosphere at ambient temperature. The surface morphology can then be examined using SEM. SEM can be used to assess the ultra-structure of a broken micro sponge particle.

In-vivo activity (animal study)

Antihyperlipidemic activity

The animals used were albino rats (150–250 g, either sex). The group and their treatment were shown in Table 4. Prior to the experiment, each animal was fasted for 12 h. Blood samples were then collected from each animal's retro-orbital sinus using capillary tubes while they were all under diethyl ether anesthesia to determine their lipid profiles. After being extracted, the serum was centrifuged for 10 min at 5000 rpm before being stored at − 20 °C for analysis. Prior to the test, the abdomen's hair was plucked with a depilatory cream and then rinsed with distilled water. The animals were given anesthesia before being restrained to a supine position on the day of the trial. On the area of the belly that was hair-free, the pressure-sensitive adhesive transdermal patch (2.5 cm^2) was applied. An oral feeding needle was used to provide the medicine solution (10 mg/kg). Following oral and transdermal medication, blood samples of around 0.5 ml were collected via a retro-orbital puncture at intervals of 0.5, 2, 4, 8, 12, 24, and 48 h. A glass tube containing heparin and the anticoagulant ammonium oxalate was filled with blood from a retro-orbital puncture through capillaries (1 percent solution). After being rapidly separated by microcentrifugation at 5000 rpm, the plasma was stored at − 20 °C. An autoanalyzer was used to analyze the samples [26].

Table 4. Groups and their treatment

Group	Treatment

Normal control	Normal Saline
Disease control	Triton (300 mg/kg)
Standard	Oral Simvastatin (10 mg/kg) + Triton (300 mg/kg)
Test	Patch (2 cm^2) + Triton (300 mg/kg)

Skin irritation studies

The ability of the patches to irritate or sensitize the skin of rats was evaluated. 150–250 g albino rats of either sex were used in the experiment. To minimize collateral damage, the dorsal surface of the rat was carefully groomed. The rat's skin was shaved, and the optimized patch was applied, secured with tape. The animal was observed for 24 h to look for any signs of erythema or edema [27, 28].

Results

Discussion

Formulation optimization

The experiment's design called for 15 runs for the set of variables. All the runs recommended by the DOE were developed and tested for responses like folding endurance and drug release. Table 5 displays the design of experimental runs along with their responses.

Table 5. Design of experiment and the responses

Run	Factor A	Factor B	Factor C	Response 1	Response 2

0.2	0.1	30	60±4	54.18±0.02	15

Folding endurance

Folding endurance is the ability of any patch to withstand pressure applied in the form of folding at the same spot without breaking. This is an important need for patches since activity causes the skin at the application site to stretch and contract repeatedly, and the patch needs to have the best folding endurance during those times. The folding endurance equation is represented by Eq. 1, and the ANOVA table is represented as Table 6.

4

$$Foldingendurance=9.2375+97.5*A+0.833333*B+1.63125*C$$

Table 6. ANOVA of Linear model of folding endurance

Source	Sum of Squares	df	Mean Square	F-value	*p*-value	
Model	57,188.25	3	19,062.75	3.24	0.0643	Not significant
A	48,672.00	1	48,672.00	8.27	0.0151	
B	1.13	1	1.13	0.0002	0.9892	
C	8515.13	1	8515.13	1.45	0.2543	
Residual	64,749.48	11	5886.32			
Lack of Fit	44,320.82	9	4924.54	0.4821	0.8184	Not significant
Pure Error	20,428.67	2	10,214.33			
Cor Total	1.219E+05	14				

The Model F-value of 3.24 indicates that there is a 6.43% possibility that noise may result in an F-value this significant. Lack of fit is not significant when compared to pure error, as indicated by the F-value of 0.48 for the lack of fit. A negligible lack of fit is advantageous for the model.

For model terms to be deemed significant, the *P*-value needs to be less than 0.05. In cases where the value exceeds 0.1, model terms are not meaningful. Folding endurance was significantly impacted by Factor A, or HPMC K-100 concentration (*p*-value 0.0151). According to Eq. 1, Factor A has the highest coefficient and is preceded by a positive sign, indicating that Folding endurance improved with increasing HPMC concentration. This means that patches with greater HPMC K100 percentages tend to have higher folding endurance. Although increasing the concentration of PEG and ERL100 has a effect on folding endurance, there is a slight increase in folding endurance due to this effect. Therefore, there is a correlation between higher polymer concentration and increased folding endurance. Figure 1 displays the 3D response surface diagram of folding endurance.

Fig. 1 [Images not available. See PDF.]

3D response surface diagram of folding endurance

In-vitro drug release

The formulation of various drug batches and their related in-vitro release percentages are displayed in Table 5. The formulation's key ingredients are HPMC K100, ERL 100, and PEG, which are altered to produce various release profiles. The amount of medication released from the formulation during a specific time under simulated physiological conditions is measured by the in-vitro release percentage. To achieve the appropriate release profile for the medicine, the formulation can be optimized using the data. Table 7 displays a summary of the model fitting. The linear model for in-vitro drug release was anticipated by the software. Based on its Model F-value of 4.76, the model is deemed significant. Only 2.30 percent of the time is there a probability that noise may result in an F-value this large. The F-value of 1.0 for the lack of fit indicates that it is not significant when compared to the pure error. A non-significant lack of fit is advantageous for the model.

Table 7. Model fit summary of in-vitro drug release

The in-vitro drug release ANOVA table is shown in Table 8. The in-vitro drug release model's *p*-value of 0.0230, which is less than 0.05, shows that it is significant.

Table 8. ANOVA table of in-vitro drug release

Source	Sum of Squares	df	Mean Square	F-value	*p*-value	
Model	228.65	3	76.22	4.76	0.0230	Significant
A-HPMC K100	28.01	1	28.01	1.75	0.2127

C-PEG	190.42	1	190.42	11.89	0.0054	
Residual	176.10	11	16.01			
Lack of Fit	144.20	9	16.02	1.00	0.5932	Not significant
Pure Error	31.90	2	15.95			

Cor Total	404.74	14				

The in-vitro drug release model's ANOVA table reveals that factor C, or PEG400 concentration, is the only scenario where the *p*-value is less than 0.05. PEG400 was used as a permeation enhancer in this optimization design. The increased PEG400 concentration will result in increased in-vitro drug release. Equation 2 represented in terms of coded factors allows one to predict the results for specific values of each variable. The relative importance of the variables can be determined by comparing the factor coefficients using the coded equation. Factors A and B are preceded by a negative sign in the equation, and factor C is preceded by a positive sign. An increase in the value of factor C leads to an increase in the release of drugs in vitro, which is what the positive sign denotes as a synergistic effect. The fact that C has a higher coefficient value means that it has a greater influence on the release of medicines.

5

In - vitrodrugrelease=49.0267-1.87125∗A-1.13∗B+4.87875∗C

The optimized value for factors and their response were predicted by software and shown in Table 9. Based on criteria, the software predicted that the optimized patch's levels of factors *A*, *B*, and *C* would be 1.80, 0.1, and 50, respectively, and that its responses to folding endurance and in-vitro drug release would be 266.36 and 53.17, respectively. An optimized patch of the specified level of factors was constructed, and its performance was assessed.

Table 9. Factors level predicted by software for design

Factor	Name	Level	Low Level	High Level	SD	Coding
A	HPMC K100	1.80	0.2000	1.80	0.0000	Actual
B	ERL 100	0.1000	0.1000	1.0000	0.0000	Actual
C	PEG	50.00	10.00	50.00	0.0000	Actual

Thickness and physical appearance

Table 9 displays the thicknesses of all formulations. The resulting patches were homogenous, opaque, pliable, and smooth at varying polymer concentrations. The thickness of the films ranged from 0.52±0.76 to 0.625±0.85 mm.

Swelling index

The formulation and related swelling index of various samples are shown in Table 10 (F1–F15). The swelling index calculates how much the samples swell in a certain solvent. Sample F12 had the highest swelling index of 62.38±0.69%, while sample F2 had the lowest swelling index of 43.45±0.86%. The research indicates that different formulations may cause varying levels of edema and emphasizes the significance of formulating products that are best suited for a given application.

Table 10. Different parameters of simvastatin transdermal patch

Formulation	Thickness (mm)	Swelling Index (%)	Moisture content (%)	Moisture Uptake (%)	Drug content (%)
SIM-TP1	0.55±0.01	45.02±0.79	6.21±0.11	7.21±0.21	94.52±0.75

SIM-TP14	0.59±0.02	53.17±0.68	5.18±0.10	6.92±0.14	90.76±0.65
SIM-TP15	0.62±0.06	57.24±0.88	6.66±0.09	7.51±0.11	96.64±0.85

Moisture content

Each formulation had a different moisture content ranging from 5.1±0.43% to 8.9±0.51%. All formulas had a mean moisture content of 6.6%, with a standard deviation of 1.27%. Because of the hydrophilic characteristic of HPMC, it was found that high concentrations of HPMC had higher % moisture contents.

Moisture uptake

With a standard deviation of 0.49–0.72, each formulation has a distinct moisture uptake value that spans from 6.2 to 11.6 percent. Patches with high HPMC content exhibited high moisture absorption.

Drug content

The percentages of drugs present in each formulation, designated as F1 through F15, are shown in the Table 9. These percentages show how many active medication components there are in each formulation (measured in mass). The F4 and F14 contain the lowest percentages of drug content, while the F11 and F12 have the highest amounts. The medication concentration in the other formulations is between 90.76 and 98.75%. Pharmaceutical companies employ formulations to enhance the efficacy and delivery of their products (Figs. 2, 3).

Overlay plot of the design predicting the values of individual factors and their response based on input criteria

In-vitro drug release

The in vitro release profile is a vital tool for predicting how drugs will behave in vivo. Release analyzes are necessary to forecast the repeatability of the rate and duration of pharmaceutical activity. Figure 4 displays the optimized transdermal patch's percentage medication release over the course of 24 h. Over time, the cumulative proportion of medication release gradually rises, reaching its peak at 24 h (55.3%). The variation in drug release characteristics among all patch formulations could perhaps be attributed to the presence of polymeric chain cross-linking networks. Different polymeric mixtures used to make transdermal patches have different diffusion pathways, which affect the delivery and intensity of the dispersion.

Fig. 4 [Images not available. See PDF.]

In-vitro drug release of optimized simvastatin patch

In-vivo study

Albino adult male and female in good health Wistar rats weighing between 110 and 240 g were used. Figure 5 depicts the impact of the simvastatin patch that has been optimized on total cholesterol levels. Rats were effectively exposed to Triton to cause hyperlipidemia, which was visible in the disease-control group. In comparison to normal controlled animals, disease-control animals have higher cholesterol and triglyceride levels (173.200.12 mg/dl and 189.02.68 mg/dl, respectively). The cholesterol level was seen to slightly decline in the test formulation. The levels of cholesterol and triglycerides are shown in the Fig. 5. The NC group has the lowest levels of both cholesterol and triglycerides, with average levels of 89.03 ± 0.89 mg/dL and 79.80 ± 0.28 mg/dL, respectively. The DC group rats treated with triton has the highest levels, with average levels of 173.20 ± 0.12 mg/dL for cholesterol and 189.02 ± 0.68 mg/dL for triglycerides, indicating the induction of hyperlipidemia and a higher risk for cardiovascular disease. In the standard treatment (simvastatin oral) groups, there is a decrease in the cholesterol (132.76 ± 0.35) and triglyceride level (139.80 ± 76) whereas, in the test formulation group or test group, there was also a decrease in cholesterol (169.65 ± 0.21 mg/dL) and triglyceride level of (151.20 ± 31 mg/dL) level. The triglyceride level in the standard treatment group and test group were comparable.

Effect of simvastatin patch on **A** Triglyceride **B** Cholesterol in triton-induced hyperlipidemia in rats

Scanning electron microscopy study

Any material's morphological or surface changes can be evaluated using scanning electron microscopy. Various magnifications of the SEM images of the optimized patches before and after drug release were displayed in Fig. 6. Prior to medication release, the optimized simvastatin patch may seem uniformly smooth in SEM pictures. At 10 µm magnification, the patch's surface exhibits a matrix structure with uniformly dispersed drug particles; nevertheless, at 50 µm magnification, the patch surface seems to be nearly smooth. To regulate the medication's release rate, thin film coatings might also be present on top of the drug matrix.

Fig. 6 [Images not available. See PDF.]

SEM images of optimized simvastatin patch before drug release (**A**, **B**) and after drug release (**C**, **D**)

The improved simvastatin patch's SEM pictures after drug release might reveal a rougher surface with fewer drug particles. Contrary to the previous photograph, the drug particles that were remaining on the surface were distributed unevenly. Drug elution may cause wear and tear on the patches, and drug release is confirmed by some porous forms on the surface of the patches, which demonstrate that the medication was gone out of the patches.

Conclusion

The formulation of SIM-TP was prepared by the solution casting method using the polymers Eudragit L-100 and HPMC K100. The Design-Expert 13 software proposed a 15-run trial for the optimization process. The three independent variables were HPMC K100, Eudragit RL100 (ERL100), and polyethylene glycol 400 (PEG400). Physical Appearance, Thickness, Folding Endurance, and pH Determination were evaluated. The results showed that With a *p*-value of 0.0151, factor A—the concentration of HPMC K-100—had a noteworthy effect on folding

endurance. A higher concentration of polymers was associated with greater folding endurance. The linear model for in-vitro drug release is significant, as evidenced by the model's *p*-value of 0.0230, which is less than 0.05. Factor C, or PEG400 concentration, is the only scenario where the *p*-value is less than 0.05. The factor coefficients can be compared using the coded equation to get the relative significance of the variables. The design expert 13 program was used to predict the values of factors A, B, and C and their responses to folding endurance and in-vitro drug release. The optimized patch's levels of factors A, B, and C were 1.80, 0.1, and 50, respectively, and its responses to folding endurance and in-vitro drug release were 266.36 and 53.17%, respectively. In-vitro drug release, in-vivo antihyperlipidemic action, and scanning electron microscopy were used to assess the improved patch. The improved patch released 55.30 percent of the medication during a 24-h period, which corresponded to the projected value. Transdermal patches were evaluated for thickness, physical appearance, swelling index, moisture content, and moisture uptake. All formulations had a mean moisture content of 6.6 percent, with a standard deviation of 1.27. The in-vivo activity of the optimized simvastatin patch was observed in albino adult male and female in good health Wistar rats, with the NC group having the lowest levels of cholesterol and triglyceride levels. The DC group rats treated with triton had the highest cholesterol and triglyceride levels, while the standard treatment (simvastatin oral) groups had a decrease in cholesterol and triglyceride levels. Scanning electron microscopy showed that the optimized simvastatin patch had a rougher surface with fewer drug particles after drug release. Drug elution may cause wear and tear on the patches, and drug release is confirmed by some porous forms on the surface. Based on the results, it can be concluded that the tailored simvastatin patch can be an alternative to treat hyperlipidemia.

Cordycepin alleviates osteoarthritis by inhibiting chondrocyte ferroptosis via Keap1/Nrf2 axis

Li, Jianlei1; Lv, Zuo11 Shaoxing People's Hospital, Department of Orthopedics Surgery, Shaoxing, China (GRID:grid.415644.6) (ISNI:0000 0004 1798 6662)

ABSTRACT (ENGLISH)

Background

Intervertebral disc degeneration (IVDD) is a prevalent condition known to contribute to lower back pain and various spinal disorders. The progression of IVDD is closely associated with cell ferroptosis. This study aimed to explore the therapeutic potential of a reactive oxygen species (ROS)-responsive hydrogel loaded with garlic extract for the inhibition of cell ferroptosis and the treatment of IVDD.

Results

The study encapsulated garlic extract within the hydrogel using physical entrapment and controlled the release of the extract through the ROS-responsive degradation of the hydrogel. Our findings revealed that the hydrogel effectively inhibited the ferroptosis of nucleus pulposus cells induced by hydrogen peroxide. Furthermore, the hydrogel, when loaded with garlic extract, notably downregulated the expression of pro- ferroptosis genes and upregulated the expression of anti- ferroptosis genes.

Conclusions

This study demonstrated that the hydrogel loaded with garlic extract significantly mitigated IVDD. These results highlight the promising potential of ROS-responsive hydrogel loaded with garlic extract as a viable treatment option for addressing IVDD.

FULL TEXT

Background

Osteoarthritis (OA) is a prevalent chronic joint disorder characterized by the progressive degeneration of articular cartilage, remodeling of subchondral bone, and inflammation of the synovium [1]. With a prevalence of approximately 10% worldwide, it ranks among the most common musculoskeletal conditions [2]. OA is a complex ailment influenced by a combination of genetic, mechanical, and biochemical factors. Advanced age, obesity, and joint injuries are recognized as risk factors that contribute to the onset and progression of OA [3, 4]. Given the projected substantial increase in the global burden of OA in the near future, it has become a significant public health concern.

Ferroptosis is a regulated form of cell death characterized by the accumulation of lipid peroxides and reactive oxygen species (ROS), which ultimately leads to cell membrane damage and subsequent cell death. This distinct process stands apart from other known forms of cell death, including apoptosis and necrosis. It has gained recognition as a significant contributor to various human diseases, such as neurodegeneration, cancer, and cardiovascular diseases [5–7].

The Kelch-like ECH-associated protein 1 (Keap1)/nuclear factor erythroid 2-related factor 2 (Nrf2) pathway plays a crucial role in regulating oxidative stress and maintaining cellular redox homeostasis [8]. Keap1, located in the cytoplasm, normally interacts with the transcription factor Nrf2 and promotes its degradation through the ubiquitin–proteasome system under normal conditions [9]. Upon exposure to oxidative stress or electrophilic agents, Keap1 undergoes conformational changes, leading to the stabilization and activation of Nrf2. Subsequently, Nrf2 translocates to the nucleus where it binds to the antioxidant response element (ARE), resulting in the transcriptional upregulation of various cytoprotective genes, including heme oxygenase-1 (HO-1), glutathione peroxidase (GPx), and solute carrier family 7 member 11 (SLC7A11) [10, 11].

Recent studies have demonstrated a close association between the Keap1/Nrf2 pathway and ferroptosis, highlighting its dysregulation as a potential contributor to the pathogenesis of diverse diseases [12]. For instance, in cancer, the constitutive activation of the Keap1/Nrf2 pathway has been demonstrated to enhance tumor growth and confer resistance to chemotherapy through the inhibition of ferroptosis [13]. Conversely, the activation of the Keap1/Nrf2 pathway has been demonstrated to confer protection against ferroptosis-induced cell death across diverse cell types, including neurons, cardiomyocytes, and chondrocytes [14–16]. The involvement of ferroptosis and the Keap1/Nrf2 pathway in osteoarthritis remains poorly understood, necessitating further research to elucidate their respective contributions to the progression of the disease. Nonetheless, emerging studies propose the involvement of ferroptosis in articular cartilage degeneration and indicate the therapeutic potential of activating the Keap1/Nrf2 pathway in averting cartilage destruction in osteoarthritis.

Cordycepin, known scientifically as 3’-deoxyadenosine, is a notable compound isolated from the caterpillar fungus Cordyceps militaris [17]. Historically utilized in traditional Chinese medicine, cordycepin has witnessed a resurgence in scientific interest due to its diverse pharmacological properties, including anti-inflammatory, antioxidant, and anticancer effects [17–19]. This resurgence is supported by a systematic approach to reviewing its biological activities, reflecting a growing recognition of its potential as a therapeutic agent. Notably, cordycepin's structural similarity to adenosine—a key signaling molecule—underpins its broad physiological functions, ranging from immune system activation to potential anticancer activities [20]. Its mechanism of action includes modulation of cell survival, proliferation, migration, and inflammation, positioning cordycepin as a promising candidate for addressing complex diseases like osteoarthritis [21]. Research indicates that cordycepin may treat OA by regulating autophagy and oxidative stress levels, thereby inhibiting the expression of cartilage inflammation [22–24]. Nevertheless, the potential therapeutic effects of cordycepin on OA and its underlying mechanism of action remain incompletely understood. Ziwen Wang et al., suggest cordycepin modulates the Keap1/Nrf2 pathway, inhibiting cellular senescence in rodents [25]. This leads to the hypothesis that cordycepin could regulate the Keap1/Nrf2 pathway to inhibit chondrocyte ferroptosis, potentially improving OA conditions.

In this study, we aimed to investigate the impact of cordycepin on OA pathogenesis and chondrocyte ferroptosis. Our findings demonstrate that cordycepin can alleviate symptoms of OA by inhibiting ferroptosis in chondrocytes through the modulation of the Keap1/Nrf2 pathway. These findings offer novel insights into the molecular mechanisms driving OA pathogenesis and propose cordycepin as a promising therapeutic agent for this condition.

Methods

In vitro experiments

Isolation and culture of chondrocytes

One-week-old C57BL/6 mice were euthanized and disinfected by immersion in 75% alcohol. Using aseptic techniques, an incision was made in the skin and soft tissue surrounding the knee joint of the hind leg to expose the knee joint. The femoral condylar cartilage was excised, minced, and immersed in a Phosphate-Buffered Saline (PBS) solution supplemented with 1% penicillin and streptomycin for 15 min. Subsequently, the tissue was transferred to Dulbecco’s modified eagle's Medium (DMEM) culture medium supplemented with 0.2% collagenase and 5% Fetal Bovine Serum (FBS) and subjected to digestion for 6 h at 37 °C. Collagenase is employed to digest the extracellular matrix for the efficient extraction of chondrocytes and FBS is incorporated into the culture medium to provide vital nutrients, growth factors, and hormones necessary for the optimal growth and maintenance of the

cultured chondrocytes. After digestion, the resulting solution was centrifuged at 1200 rpm for 10 min, and the resulting precipitate was collected. The cells were then suspended in DMEM culture medium supplemented with 5% FBS and cultured at 37 °C under 5% carbon dioxide conditions for subsequent passages.

Cytotoxicity evaluation of cordycepin using the cell counting kit-8 (CCK-8) assay

In the cytotoxicity evaluation of cordycepin using the CCK-8 assay, chondrocytes were seeded at an initial density of 5,000 cells per well in 12-well plates. This seeding density was chosen to achieve logarithmic growth phase within 72 h of culture. The chondrocytes at passage number 3 were treated with DMEM/FBS medium supplemented with cordycepin at concentrations of 0, 10, 20, 40, 80, and 160 μg/mL for a duration of 72 h. In the treatment phase, the DMEM/FBS medium used for chondrocyte culture was composed of DMEM supplemented with 10% FBS, 1% penicillin–streptomycin. Subsequently, for the cytotoxicity evaluation, the CCK-8 solution (MCE, No. HY-K0301)was used at a final concentration of 10 μL per well and the cells were incubated for 2 h. The CCK-8 assay employs a water-soluble tetrazolium salt to produce a colorimetric change in response to cellular metabolic activity, allowing for the quantification of cell viability. The absorbance at 490 nm of each well was measured using an enzyme-linked instrument. The relative cell viability of each group was determined relative to the control group treated with 0 μg/mL cordycepin.

Measurement of Fe^{2+} content in chondrocytes

The Fe^{2+} content in chondrocytes was quantified using an Fe^{2+} assay kit (Elabscience, No. E-BC-F101). This assay kit is specifically designed to quantitatively determine Fe^{2+} levels in biological samples through a colorimetric assay, leveraging a specific ligand that forms a colored complex with Fe^{2+}. Chondrocytes from each group were collected, washed three times with PBS, and subsequently homogenized in an iron detection buffer. Subsequently, 5 μL of iron reductant and 5 μL of assay buffer were added to the standard well, and the resulting mixture was incubated for 30 min. The iron detection buffer provided with the Fe^{2+} Assay Kit, is formulated to optimize the conditions for Fe^{2+} ion interaction with the colorimetric probe, enhancing the specificity and sensitivity of the assay. Its composition ensures the stabilization of Fe^{2+} ions and prevents oxidation, thereby contributing to the precise quantification of Fe^{2+} levels. Following that, 100 μL of iron probe was added, mixed thoroughly, and incubated for 1 h. Subsequently, the absorbance of each well was measured at 593 nm using an enzyme-linked immunosorbent assay (ELISA) reader, and the relative Fe^{2+} content in each group of chondrocytes was calculated. Each experimental group was performed in triplicate.

Quantification of malondialdehyde (MDA) content in chondrocytes

Chondrocytes from each group were collected and washed three times with PBS following the protocol provided by the MDA kit (Elabscience, No. E-BC-K028-M). MDA, a product of lipid peroxidation, reacts with thiobarbituric acid under high temperature and acidic conditions to form a pink product, thiobarbituric acid reactive substances. Subsequently, the cells were lysed using a cell lysis solution, and the resulting supernatant was collected following centrifugation. A total of 0.2 mL of the supernatant was combined with 0.6 mL of the working solution, followed by heating in a 95 °C-water bath for 30 min, cooling in an ice bath, and subsequent centrifugation at room temperature for 10 min at 10,000 g. The resulting supernatant was collected, and the absorbance at 532 nm and 600 nm of each well was measured using an ELISA reader. The MDA content of each group was then calculated. The formula for calculating MDA content in cells is: $\text{MDA (nmol/mg protein)} = (\Delta A1/\Delta A2) \times C \div Cpr$, where ΔA1 is the optical density (OD) of the test tube minus the OD of the blank tube, ΔA2 is the OD of the standard tube minus the OD of the blank tube, C is the concentration of the standard (10 nmol/mL), and Cpr is the protein concentration of the sample (mg protein/mL). Each experimental group was performed in triplicate.

Detection of intracellular ROS levels in chondrocytes using fluorescent probes

Chondrocytes from various groups were gently washed three times with PBS and then incubated with 10 μM of either DCFH-DA fluorescent probes in the dark at room temperature for 30 min. Subsequently, chondrocytes were washed with PBS, and the fluorescence intensity of intracellular ROS was observed using a fluorescence microscope (Leica, No.DM2500). Each experimental group was performed in triplicate.

Quantitative polymerase chain reaction (qPCR) detection

RNA was isolated using the TRIzol reagent provided by Aidlab (Catalog No. 252250AX), following a protocol optimized for chondrocyte samples. For every 5×10^6 cells, 1 mL of TRIzol was added, and the mixture was homogenized thoroughly before transferring to an Eppendorf tube. Chloroform was added in a ratio of 200 µL per 1 mL of TRIzol, followed by vigorous shaking for 15 s and standing for 3 min. The mixture was then centrifuged at 12,000 g for 15 min. The aqueous phase was transferred to a new tube, mixed with an equal volume of isopropanol, and centrifuged at 12,000 g for 10 min at 4 °C. The RNA pellet was washed with an equal volume of 75% ethanol, centrifuged at 6000 g for 5 min, and the supernatant was discarded. The RNA pellet was air-dried and dissolved in 20 µL of DEPC-treated water for further analysis. β-actin was selected as our reference gene for normalization. In the assessment of RNA quality and quantity, we utilized a NanoDrop spectrophotometer. The NanoDrop provided measurements of RNA concentration and purity, with absorbance ratios at 260/280 nm used to assess protein contamination and ratios at 260/230 nm to evaluate organic compound or buffer contamination. Subsequently, the extracted total RNA was reverse transcribed into complementary DNA using a reverse transcription kit (Vazyme, No. R101-01/02). The DNA amplification step was carried out using the Applied Biosystems 7500 Real-Time PCR system, and the obtained results were analyzed using the 2-ΔΔCq method. The primer sequences are listed in Table 1. Each experimental group was performed in triplicate.

Table 1. The primer sequences

Name	Primer	Sequence

Western blot (WB) analysis

Chondrocyte cells were washed gently with PBS, and then lysed using Radioimmunoprecipitation assay buffer containing 1% phenylmethylsulfonyl fluoride and 1% phosphatase inhibitor on ice. The lysate was collected and centrifuged at 12,000 g at 4 °C for 20 min, and the supernatant was collected. Protein concentration of each sample was determined using a bicinchoninic acid assay kit (Beyotime, No. P0012). For the standard curve, a series of bovine serum albumin standards ranging from 0 to 2000 μg/mL were prepared. The assay was performed according to the manufacturer's instructions, with modifications to include a blank correction to account for background absorbance. Samples were diluted as necessary with PBS to fall within the dynamic range of the standard curve. Protein was separated by electrophoresis on a polyacrylamide gel electrophoresis (PAGE) gel and transferred to a polyvinylidene fluoride membrane using a wet transfer method. The PVDF membrane was blocked with 5% non-fat milk for 1 h at room temperature and then incubated with the primary antibody overnight at 4. After washing with Tris-Buffered Saline with Tween for three times, the membrane was incubated with the secondary antibody for 1 h at room temperature. The protein bands were visualized and imaged using an imaging system (ChemiDoc™ XRS+ System, Bio-Rad), and the intensity of each protein band was quantified (BandScan). The antibodies for WB are listed in Table 2.

Table 2. The antibodies for western blotting

Classification	Name	Manufacturer	Catalog number	Dilution ratio
Primary antibodies	β-actin	Abcam	ab227387	1:1000
Keap1	Abcam	ab119403	1:1000	Nrf2

Affinity	AF7006	1:1000	GPX4	Sigma-Aldrich

ab313636	1:1000	Secondary antibodies	HRP Conjugated AffiniPure Goat Anti-rabbit IgG (H+L)	Boster

In vivo experiments

Grouping and modeling of mice

All mice were housed in a clean-level animal facility. The facility maintained a constant temperature of 22±2 °C and a relative humidity of 50±10%. The light/dark cycle was set to 12 h light/12 h dark. The bedding material used was autoclaved aspen wood shavings. Additionally, the mice had ad libitum access to food and water. Twenty 12-week-old C57BL/6 mice were randomly divided into four groups using a random number generator: the sham group, the OA group, the cordycepin group, and the cordycepin+brusatol group, with five mice in each group. All groups, except the sham, were used to create an OA model. The mice were carefully anesthetized with an intraperitoneal injection of pentobarbital sodium (30 mg/kg). During the surgeries, we utilized sterile surgical drapes to cover the operating table and wore sterile gloves throughout the procedure. All surgical instruments were sterilized using high-temperature autoclaving before procedure. For the surgical procedure, the knee joint of the right hind leg was prepared by shaving the surrounding hair to ensure a clean site. The knee joint area of each mouse was thoroughly disinfected with povidone-iodine prior to making any incisions. A precise 5 mm longitudinal incision was made along the medial side of the knee joint for optimal access to the joint cavity while minimizing damage to the surrounding tissues. After making the medial incision in the knee joint, we directly visualized the anterior cruciate ligament by flexing the mouse's knee joint. This approach allowed us clear access to the ligament. In the OA, cordycepin, and cordycepin+brusatol groups, the anterior cruciate ligament was gently transected to induce osteoarthritis-like conditions. The incision was then meticulously sutured for proper healing. In the sham surgery group, we followed the same surgical procedure as in the experimental groups up to the point of ligament manipulation, involving opening the joint cavity and suturing it closed, but without transecting the anterior cruciate ligament, serving as a control.

One week post-surgery, the mice in the sham and OA groups received an intra-articular injection of 10 μL PBS in the right knee joint. The cordycepin group received an injection of 10 μL cordycepin solution (8 mg/kg concentration), and the cordycepin+brusatol group received 10 μL of a combined solution of cordycepin (8 mg/kg) and brusatol (5 mg/kg). Injections were administered weekly for a total of four weeks. Five weeks after surgery, all mice were euthanized, and their right knee joints were harvested. The tissues were then embedded in paraffin, sectioned, and stained with Safranin O, hematoxylin and eosin (HE), and subjected to immunohistochemistry and immunofluorescence experiments.

Evaluation of osteoarthritis degree using the osteoarthritis research society international (OARSI) score

The degree of osteoarthritis was evaluated using the OARSI score, which is determined by multiplying the OARSI grade by the OARSI stage. The OARSI grade is determined based on the following criteria:
Grade 0 indicates an intact joint surface.
Grade 1 represents mild fibrillation or swelling of the joint surface.
Grade 2 indicates moderate fibrillation with superficial cartilage loss, typically affecting approximately one-third of the stained cartilage surface.
Grade 3 signifies deep fibrillation or fissuring with approximately two-thirds of the stained cartilage surface lost.
Grade 4 denotes erosion with exposed subchondral bone.
Grade 5 signifies destruction of a significant portion of the joint surface with extensive subchondral bone exposure.
Grade 6 represents total destruction of the joint surface with bone remodeling and osteophyte formation.
The OARSI stage is determined based on the extent of joint involvement and is categorized as follows:
Stage 0 indicates no involvement.
Stage 1 represents involvement of less than 10% of the joint surface.
Stage 2 signifies involvement of 10–24% of the joint surface.
Stage 3 represents involvement of 25–49% of the joint surface.
Stage 4 denotes involvement of more than 50% of the joint surface.
This comprehensive scoring system allows for the evaluation and classification of osteoarthritis severity based on the OARSI grade and stage, providing valuable insights into the disease progression.

Statistical analysis

Quantitative data were presented as mean ± standard deviation, providing a comprehensive summary of the central tendency and variability. To determine the significance of differences in OARSI scores among the various groups, a rigorous statistical analysis was conducted. This involved utilizing the Kruskal–Wallis analysis, a non-parametric test, followed by the Mann–Whitney U test for pairwise comparisons. Furthermore, for analyzing other statistical data, a one-way ANOVA was employed, followed by Tukey's post-hoc test to identify specific pairwise differences. Notably, a significance level of $P<0.05$ was considered statistically significant (*), while a more stringent level of $P<0.01$ was indicated by (**), ensuring robustness and reliability in our findings across all experiments.

Results

Establishment and verification of the ferroptosis model

Initially, a ferroptosis model was established in chondrocytes by stimulating them with interleukin-1 beta (IL-1β) at a concentration of 10 ng/mL, and the model was subsequently validated. IL-1β stimulation was found to upregulate Fe2 + expression, whereas the IL-1β + Fer-1 (ferroptosis inhibitor) group exhibited a significant reduction in Fe2 + expression compared to the IL-1β group (Fig. 1a). Similar trends were observed in the MDA content among the experimental groups (Fig. 1b). Furthermore, ROS levels in chondrocytes were assessed (Fig. 1c, d). Following IL-1β stimulation, an elevation in ROS levels was observed in chondrocytes, while treatment with Fer-1 demonstrated the ability to mitigate the effects induced by IL-1β. Additionally, to further confirm the establishment of the ferroptosis model, the expression of ferroptosis-related genes was assessed through qPCR analysis (Fig. 1e). The findings revealed that IL-1β treatment upregulated Keap1 expression and downregulated Nrf2, GPX4, and SLC7A11 expression. Notably, Fer-1 treatment successfully mitigated the effects induced by IL-1β. These findings were further supported by Western blotting analysis (Fig. 1g, h). Collectively, our results strongly suggest that IL-1β stimulation at a concentration of 10 ng/mL can induce ferroptosis in chondrocytes.

Cordycepin inhibits chondrocyte ferroptosis

Cordycepin's toxicity on chondrocytes was assessed using a CCK-8 assay (Fig. 2a, b). Chondrocytes were cultured in DMEM media supplemented with cordycepin at concentrations of 0, 10, 20, 40, 80, and 160 μM for three days. The results indicated that chondrocyte viability significantly decreased with 80 μM cordycepin compared to the control group. Consequently, a concentration of 40 μM cordycepin was selected for subsequent experiments. Furthermore, chondrocytes were divided into three groups: IL-1β group, IL-1β + cordycepin group, and IL-1β + cordycepin + brusatol group, where brusatol was used as a unique inhibitor of the Nrf2 pathway. Fe2 + detection results showed a significant decrease in its expression in the IL-1β + cordycepin group compared to the IL-1β group, while the IL-1β + cordycepin + brusatol group exhibited higher Fe2 + expression than the IL-1β + cordycepin group (Fig. 2c). Similar trends were observed in MDA detection (Fig. 2d). Moreover, cordycepin exhibited inhibitory effects on IL-1β-stimulated ROS expression, whereas brusatol counteracted this effect (Fig. 2e, f). Additionally, the expression of mitochondria in chondrocytes was observed using TEM in each experimental group (Fig. 2g). Our observations revealed a reduction or disappearance of mitochondria cristae in the IL-1β group, which could be mitigated by cordycepin treatment. qPCR and Western blotting results further confirmed the inhibitory effect of cordycepin on chondrocyte ferroptosis (Fig. 2h-j). The findings demonstrated that cordycepin treatment led to the inhibition of Keap1 expression and the promotion of Nrf2, GPX4, and SLC7A11 expression. However, the inhibitory effect of cordycepin was counteracted by brusatol (Fig. 2h-j).

Cordycepin attenuates chondrocyte matrix degradation

The effect of cordycepin on the matrix of chondrocytes was investigated by examining the expression of matrix metalloproteinase 13 (MMP13), a disintegrin and metalloproteinase with thrombospondin motifs 5 (ADAMTS-5), collagen type II alpha 1 chain(col2a1), and aggrecan genes using qPCR in the IL-1β group, IL-1β + cordycepin group, and IL-1β + cordycepin + brusatol group (Fig. 3a). Compared to the IL-1β group, the IL-1β + cordycepin group exhibited significantly reduced expression of matrix-degrading enzymes MMP13 and ADAMTS-5, along with increased expression of col2a1 and aggrecan (Fig. 3a). WB analysis demonstrated similar findings (Fig. 3b, c). These findings suggest that cordycepin inhibits matrix degradation in chondrocytes. Additionally, brusatol, an Nrf2 inhibitor, can counteract the effect of cordycepin.

Cordycepin inhibits ferroptosis of chondrocytes in vivo

A mouse model of osteoarthritis was established, and the mice were divided into the sham group, OA group, cordycepin group, and cordycepin + brusatol group. Figure 4a is the experimental timeline for the animal study, outlining the key time points throughout the research, starting with mice grouping and surgery (Week 0), followed by weekly injections (Weeks 1 to 4), and culminating in euthanasia and sample collection at Week 5. Immunohistochemistry results demonstrated that the cordycepin group exhibited decreased Keap1 expression and increased Nrf2 expression compared to the OA group (Fig. 4b–e). In contrast, the cordycepin + brusatol group showed increased Keap1 expression and decreased Nrf2 expression compared to the cordycepin group. The results were further confirmed using immunofluorescence (Fig. 4f–i). These findings suggest that cordycepin can inhibit chondrocyte ferroptosis by modulating the Keap1/Nrf2 axis.

Fig. 4 [Images not available. See PDF.]

Cordycepin inhibits osteoarthritis in vivo

Immunohistochemistry was conducted to assess the expression of col2a1 and aggrecan in the sham, OA, cordycepin, and cordycepin + brusatol groups (Fig. 5a–d). The results demonstrated that cordycepin upregulated the expression of col2a1 and aggrecan in joint cartilage, whereas brusatol attenuated the effect of cordycepin. Furthermore, Safranine-O and HE staining was performed on cartilage slices from each group (Fig. 5e). The results indicated that the cordycepin group exhibited better preservation of joint cartilage, as evidenced by a significantly lower OARSI score compared to the OA group (Fig. 5f). However, in the cordycepin + brusatol group, the OARSI score was higher than that observed in the cordycepin group.

Discussion

The present study aimed to investigate the potential therapeutic effects of cordycepin on OA by inhibiting chondrocyte ferroptosis via the Keap1/Nrf2 signaling pathway. Our findings provide valuable insights into the specific mechanisms underlying the protective effects of cordycepin in OA and contribute to the broader understanding of targeted therapies for this debilitating joint disease.

Ferroptosis is an iron-dependent form of regulated cell death characterized by the accumulation of lipid peroxides and reactive oxygen species ROS, ultimately leading to cellular damage and dysfunction [26]. Emerging evidence suggests that ferroptosis plays a critical role in the pathogenesis of OA, contributing to the progressive degradation of articular cartilage [27, 28]. Therefore, identifying compounds that can inhibit chondrocyte ferroptosis represents a promising therapeutic strategy for OA.

We focused on cordycepin, a natural compound derived from Cordyceps species, and its potential role in alleviating OA by modulating ferroptosis. However, its specific effects on chondrocyte ferroptosis and its underlying mechanisms in the context of OA have not been thoroughly investigated. Our results demonstrated that cordycepin treatment significantly reduced the expression of iron metabolism-related proteins and oxidative stress markers in chondrocytes, indicating its inhibitory effect on ferroptosis. This suggests that cordycepin may act as a potent regulator of iron homeostasis and oxidative stress in chondrocytes, thereby protecting them from ferroptosis cell death. Importantly, we observed that cordycepin administration attenuated cartilage degradation and improved joint function in OA mice, further supporting its potential therapeutic benefits in managing OA progression.

The activation of the Keap1/Nrf2 signaling pathway was identified as a key mechanism underlying the protective effects of cordycepin against chondrocyte ferroptosis. The Keap1/Nrf2 pathway is known for its crucial role in cellular antioxidant defense mechanisms, regulating the expression of antioxidant enzymes and promoting the cellular adaptive response to oxidative stress [29]. Crucially, the role of Keap1 as a negative regulator of Nrf2, through its interaction and ubiquitination leading to Nrf2's degradation, emphasizes the importance of Keap1 in the balance of cellular responses to oxidative stress. We highlight the intricate balance controlled by the Keap1/Nrf2 axis and how cordycepin's modulation of this pathway contributes to its protective effects. Specifically, our findings suggest that

cordycepin interferes with the Keap1-mediated degradation of Nrf2, thereby enhancing the cellular defense against oxidative stress and ferroptosis.

To further validate the specificity of cordycepin in inhibiting chondrocyte ferroptosis, future studies could explore whether other compounds with similar structures or mechanisms of action exhibit comparable effects. Comparing the efficacy of cordycepin with other potential ferroptosis inhibitors would provide valuable insights into its specificity and potential advantages in the context of OA treatment.

Moreover, a deeper exploration into Keap1's regulatory mechanisms, particularly its interaction with Nrf2 and subsequent effects on ferroptosis-related molecules, would enrich our understanding of cordycepin's mode of action. Exploring the cross-talk between the Keap1/Nrf2 pathway and other cellular signaling pathways involved in OA pathogenesis, such as inflammation and apoptosis, may reveal additional targets for therapeutic intervention.

It is important to acknowledge the limitations of the current investigation. Firstly, our experiments were conducted primarily using in vitro and in vivo models of OA, which may not fully capture the complexity and heterogeneity of human OA. Further studies using human-derived chondrocytes and animal models that better recapitulate the pathophysiology of human OA are warranted. Secondly, while our results provide insights into the potential therapeutic effects of cordycepin, additional preclinical and clinical studies are needed to validate its efficacy, safety, and long-term effects in OA patients.

In conclusion, this research sheds light on the potential of cordycepin as a therapeutic agent for OA by inhibiting chondrocyte ferroptosis through the Keap1/Nrf2 axis. We provide evidence that cordycepin effectively protects chondrocytes from iron-induced cell death, attenuates cartilage degradation, and improves joint function. These findings contribute to the growing body of research on targeted therapies for OA and highlight the importance of ferroptosis as a potential therapeutic target. Future investigations should focus on further elucidating the molecular mechanisms underlying cordycepin-mediated chondroprotection and translating these findings into clinically applicable strategies for OA management. Ultimately, the development of novel therapeutic interventions that can modulate ferroptosis may offer new hope for patients suffering from OA and improve their quality of life.

Conclusion

This research demonstrates the significant therapeutic potential of the ROS-responsive hydrogel loaded with garlic extract in mitigating IVDD. By effectively inhibiting the ferroptosis of nucleus pulposus cells and regulating the expression of key ferroptosis genes, the hydrogel loaded with garlic extract exhibited promising results both in vitro and in an animal model. These findings underscore the critical role of oxidative stress in the pathogenesis of IVDD and suggest that the targeted delivery of garlic extract using the ROS-responsive hydrogel could serve as a novel and effective therapeutic strategy for combating IVDD. The development of such targeted interventions holds considerable promise in the advancement of treatments for IVDD and related spinal disorders, providing new insights for future research in the field of spinal health.

Efficacy evaluation of Berberis aristata and Silybum marianum fixed dose combination on glycaemic and insulin resistance parameters in adult population: a systematic review and meta-analysis of randomized controlled trials

Dubey, Vishal1 ; Kansagra, Jignesh1; Sureja, Varun1; Kheni, Dharmeshkumar11 Sundyota Numandis Probioceuticals, Pvt. Ltd., Department of Scientific and Medical Affairs, Ahmedabad, India

ABSTRACT (ENGLISH)

Background

Diabetes is one of the most prevalent metabolic diseases with high rate of morbidity and mortality. The increased level of blood glucose level and increased insulin resistance is the hallmark of diabetes. Currently, various non-pharmacological and pharmacological therapeutic options are used for lowering the glucose level and improving the insulin activity. The current systematic review and meta-analysis study was conducted to evaluate the efficacy of *Berberis aristata* and *Silybum marianum* fixed dose nutraceutical combination on serum glucose and glycated haemoglobin level and insulin resistance parameters.

Main Body

Randomized controlled trials, identified from three online databases, evaluating the efficacy of *Berberis aristata* and *Silybum marianum* fixed dose combination were identified and evaluated as per pre-defined protocol. Quality of studies was evaluated using PEDro scale, and risk of bias was assessed using Cochrane Risk of Bias Tool. Pooled effect was reported as mean difference (MD) and 95% confidence interval, while the complete study was conducted as per PRISMA and Cochrane guidelines. After complete literature screening and evaluation process, seven studies were included in the final analysis. Data of 825 participants (active group: 416 participants and control group: 409 participants) were utilized for the statistical analysis. All included studies (except one) were of good quality. Supplementation of fixed dose combination significantly reduced glucose level (MD: − 5.26 mg/dl; $p=0.02$) and glycated haemoglobin (HbA1c) level (MD: − 0.69%; $p<0.0001$) as compared to control therapy, while greater insulin resistance reduction was observed in active group and the difference approached significance (MD: − 0.64 HOMA-IR score; $p=0.08$). Risk of bias analysis revealed some concerns regarding biasness (mainly due to randomization, outcome measurement and selected reporting biasness). All included studies had moderate risk of biasness. Sensitivity analysis revealed effect of particular study on overall heterogeneity observed, while neither significant publication bias nor any missing study was observed.

Conclusion

The results of current study suggest that *B. aristata* and *S. marianum* fixed dose combination is effective in improving glycaemic and insulin parameters and can be effective in diabetic population. The observed sensitivity of certain studies on overall heterogeneity and the moderate risk of biasness warrants further well-designed clinical studies to strengthen the results of current study.

FULL TEXT

Background

Diabetes mellitus (DM) is a chronic metabolic disorder characterized by hyperglycaemia resulting from defects in insulin secretion, insulin action, or both. Diabetes is a major and the most prevalent metabolic disease affecting millions of people worldwide [1]. In 2021, around 537 million adult population is estimated to have diabetes and it is estimated to reach 783 million by 2045 [2]. If left untreated, diabetes can lead to serious complications, such as cardiovascular disease [3, 4], chronic kidney disease [5, 6], blindness [7, 8] and lower limb amputations [9, 10]. The consequences of diabetes are far-reaching and can have a significant negative impact on the quality of life of individual. Diabetes is one of the top 10 causes of death globally, with an estimated 4.2 million deaths attributed to the disease in 2019, equivalent to 11.3% deaths from all causes and accountable to eight deaths every minute [11, 12]. In addition to its physical and emotional toll on individuals and families, diabetes also imposes a significant economic burden on healthcare systems and societies. According to the International Diabetes Federation (IDF), the global healthcare expenditure for diabetes was estimated to be $966 billion in 2021 and is projected to reach $1,054

billion by 2045 [13].

Pharmacological and non-pharmacological treatments are available to manage diabetes and reduce the risk of complications. The American Diabetes Association (ADA) and European Association for the Study of Diabetes (EASD) recommend a patient-centred approach to diabetes care, which includes individualized treatment plans based on patient medical condition and preference [14]. Pharmacological treatments for diabetes include oral hypoglycaemic agents, injectable medications such as insulin and glucagon-like peptide-1 receptor agonists, and other medications that target specific complications of diabetes, such as hypertension and dyslipidaemia, while non-pharmacological interventions such as lifestyle modifications, including diet and exercise, are also recommended to manage diabetes [15, 16]. The use of nutraceutical and herbal supplements in treating DM has raised in recent years due to their better efficacy and less side effects [17]. Nutraceuticals is a broad term which includes botanicals, herbal supplements, probiotics, prebiotics, vitamins, minerals, dietary fibres, polyunsaturated fatty acids, protein and amino acids, and other related substances [17]. Various herbal supplements have been studied for their efficacy in DM, including *Acacia arabica*, *Aegle marmelos*, *Allium cepa*, *Allium sativum*, *Aloe vera*, *Annona squamosa*, *Artemisia pallens*, *Azadirachta indica*, *Andrographis paniculata*, *Biophytum sensitivum*, *Beta vulgaris*, *Brassica juncea*, *Cassia auriculata*, *Boerhavia diffusa*, *Caesalpinia bonducella*, *Citrullus colocynthis*, *Cajanus cajan*, *Coccinia indica*, *Casearia esculenta*, *Catharanthus roseus*, *Camellia sinensis*, *Enicostemma littorale*, *Eugenia jambolana*, *Helicteres isora*, *Ipomoea batatas*, *Morus alba*, *Scoparia dulcis*, *Murraya koenigii*, *Ocimum sanctum*, *Punica granatum*, and many others [17].

Berberis aristata (Berberidaceae family) is a shrub native to the Himalayas and widely used in traditional medicine for its various therapeutic properties [18]. Its roots and stem bark contain several bioactive compounds, including berberine, which has been shown to have antidiabetic effects [18]. The AMP-activated protein kinase pathway (AMPK), that have a key role in glucose and lipid metabolism, is one of the key pathway which is activated by berberine supplementation, leading to improved glucose uptake and insulin sensitivity [19, 20]. Several clinical studies have demonstrated the efficacy of berberine in improving glycaemic control in patients with type 2 diabetes [21].

Silybum marianum (Asteraceae family), also known as milk thistle, is a plant native to the Mediterranean region and widely used for its hepatoprotective effects. The active component of milk thistle is silymarin, a complex mixture of flavonolignans that has been shown to have antioxidant, anti-inflammatory and neuroprotective properties [22]. Silymarin has been found to improve insulin sensitivity of insulin receptors, ameliorates insulin resistance and reduces hepatic glucose production [23, 24]. Silymarin has also been shown to protect against diabetes-related complications, such as diabetic nephropathy, by reducing oxidative stress and inflammation [25]. Clinical studies in humans have demonstrated the potential of silymarin to improve glycaemic control and reduce markers of oxidative stress in patients with type 2 diabetes [26].

Berberol is an herbal fixed dose combination containing 588 mg hydro-ethanolic extract from cortex from *B. aristata* standardized to contain at least 85% berberine and 105 mg hydro-ethanolic extract from fruits of *S. marianum* standardized to contain 60–80% flavanol-lignans calculated as silybin. The efficacy of this herbal fixed dose combination supplement has been evaluated in various clinical studies and has been shown to have a range of positive effects on human health, including the management of lipid and glucose metabolism, but no meta-analysis study has been previously conducted to synthesize the results of published clinical studies evaluating the efficacy of the fixed dose combination on markers of diabetes. Hence, the current systematic review and meta-analysis study was conducted to evaluate the effectiveness of a fixed dose combination of *B. aristata* and *S. marianum* supplementation in diabetes condition.

Main text

Study conduct

The current systematic review and meta-analysis study was conducted in accordance with the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA), Cochrane Handbook for systematic reviews of intervention and the Cochrane statistical method guidelines [27, 28]. The study was conducted based on a pre-

designed protocol, and randomized controlled clinical trials were evaluated as per pre-defined inclusion and exclusion criteria. The current study was based on the questions framed as per the PICOS (population, interventions, comparator, outcomes, study design) criteria (Table 1). Based on the PICOS criteria, the study question was as follows: Is *Berberis aristata* and *Silybum marianum* fixed dose combination effective in improving glycaemic index and insulin resistance parameters in participants with impaired glucose level and/or insulin resistance?

Table 1. PICOS criteria for study determination

Parameter	Description
Population	Participants with increased blood glucose and/or insulin resistance level
Intervention	Fixed dose combination of *Berberis aristata* and *Silybum marianum* (either as single therapy or in combination with other therapies)
Comparator	Either placebo, standard therapy alone, or any other supplementation other than the fixed dose combination of *Berberis aristata* and *Silybum marianum*
Outcomes	1. Blood glucose level 2. Glycated haemoglobin (HbA1c) level 3. Insulin resistance level (HOMA-IR score)
Study design	Randomized, controlled clinical study

HOMA-IR homeostatic model assessment for insulin resistance

Search strategy

The Google scholar, PubMed, and Science Direct online databases were searched independently from the year 2000 until November 2023 by two review authors. The literature search was conducted by using combination of Medical Subject Heading (MeSH) terms along with free-text words related to *B. aristata* and *S. marianum* fixed dose combination supplementation and its effect on glycaemic and insulin parameters. The complete search strategy is as follows: '(Berberol) OR (((*Berberis aristata*) OR (*B.aristata*) OR (*B. aristata*)) AND ((*Silybum marianum*) OR (*S. marianum*) OR (*S.marianum*))) AND ((glucose level) OR (glucose) OR (sugar level) OR (sugar) OR (glycated haemoglobin) OR (glycated haemoglobin) OR (HbA1c) OR (insulin resistance) OR (insulin sensitivity) OR (HOMA)) AND ((clinical trial) OR (clinical study) OR (randomized study) OR (randomized trial) OR (controlled study) OR (controlled trial))'.

Eligibility criteria

The articles were evaluated and screened based on pre-defined inclusion and exclusion criteria. Articles of randomized controlled clinical studies, available as full-text articles in the English language, evaluating the efficacy of *B. aristata* and *S. marianum* fixed dose combination on the serum glucose level, serum glycated haemoglobin level and insulin resistance parameters were included in the current study. Articles of in vitro studies, pre-clinical animal model studies and clinical studies of study design other than randomized controlled design, evaluating the efficacy of different interventions other than the *B. aristata* and *S. marianum* fixed dose combination on parameters other than the serum glucose level, serum glycated haemoglobin level and insulin parameters and not available as full-text article or available in language other than the English language were excluded from the current study.

Study selection and data extraction

After retrieval of articles from online databases and after duplicate removal, two review authors independently

screened the title and abstract of the studies for eligibility. Studies deemed eligible after initial screening were evaluated using full-text article evaluation.

Data from included studies were extracted by one review author and independently validated by other review author. Using a pre-designed excel worksheet, the following study characteristics were extracted from the included studies: lead author, publication year, indication, sample size, age, interventions provided and duration of study. Additionally, the data regarding glucose level (in mg/dl), glycated haemoglobin (HbA1c) level (in percentage) and homeostatic model assessment for insulin resistance (HOMA-IR) score were extracted in a separate pre-designed excel worksheet.

Study quality and risk of bias assessment

The Physiotherapy Evidence Database tool (PEDro scale) was used to evaluate the biasness within studies, while the Cochrane Risk of Bias Tool (RoB2) was used to evaluate the biasness between studies as both these scales have demonstrated high validity and inter-rater reliability [29, 30]. The PEDro scale evaluation and the RoB2 assessment were conducted independently by two review authors, and the overall judgment of assessment was discussed among authors. Any discrepancy(s) between the result of assessment were discussed among the authors by joint consensus.

The PEDro scale evaluates the internal and external validity, statistical sufficiency and the overall study quality and categorises the studies into following: high quality (≥8 points), moderate quality (4 – 7 points) and low quality (≤3 points).The criteria assessed by the tool are as follows: eligibility criteria specified, subject randomisation, allocation concealment, the similarity of baseline prognosis between groups, blinding of subjects, therapists and assessors, a primary outcome measurement on≥85% of initial subjects, use of intention-to-treat analysis, use of variability measures and use of between-group comparison methods [31, 32].

RoB2 tool assesses overall biasness that might have influenced the results of study based on five domains, namely randomization process, deviations from intended interventions, missing outcome data, measurement of the outcome and selection of reported result [33]. As per the study details, the RoB2 tool pre-designed form is filled and based on the tool algorithm, an outcome of low, some concern, or high risk of bias is generated along with the overall judgement. The overall judgement of independent assessment was discussed among authors, and any disagreement was discussed between the authors along with other review authors by considering the full-text of article for final conclusion.

Statistical analysis

The RevMan statistical software (Desktop v5.4) provided by Cochrane collaboration network was used for conducting meta-analysis. Data for individual evaluation parameter were presented separately as mean difference (difference between baseline and final value) and standard deviation (change from baseline) (SD_{change}). The data were evaluated using continuous evaluation method, and the pooled analysis effect was presented as pooled mean difference (MD) with 95% confidence interval (95% CI). SD_{change} for individual parameters was adopted from respective articles, and in case SD_{change} was not provided; then, it was estimated using the following formula adopted as per Cochrane recommendations [34].SDchange=(SDB2+SDF2)-(2×r×SDB×SDF)where "SD_B" and "SD_F" denote standard deviation at baseline and final visit, respectively, while "r" denotes the correlation coefficient, either obtained from other studies or considered to be 0.7 to provide a conservative estimate as undertaken from previous studies [35]. The effect of interventions on individual evaluation parameter was visually presented as forest plots for individual evaluation parameter. The model of effect analysis was decided based on the heterogeneity significance (I^2 value). If the heterogeneity was found to be low ($I^2 \leq 50\%$), the fixed effect model was utilized for the analysis of final data outcome, and if the heterogeneity was found to be high ($I^2 > 50\%$) then random effect model was utilized for the analysis of final data outcome. Sensitivity analysis was conducted by using leave-one-study-out analysis approach using the OpenMeta [Analyst] software. By using the sensitivity analysis, the effect of individual included studies on overall pooled effect and observed heterogeneity was evaluated. The Meta-Essential (v1.5) software package was used for publication bias assessment. Publication bias was statistically assessed using egger regression test and Begg–Mazumdar test, while publication bias was visually assessed using forest plot of individual

evaluation parameter. Additionally, the trimming and filling analysis was conducted to identify any missing study(s) and its effect on overall effect size (Cohen's d value). The *p*-value of<0.05 was considered to determine significance.

Results and discussion

Study selection process, study characteristics and quality assessment

The initial literature search revealed 811 articles and after duplicate removal, 633 articles were initially screened for eligibility. Eight studies were evaluated completely using full-text screening out of which seven studies [36–42] were included in the study and one study [43] was excluded from the study after the eligibility screening. The complete study selection process is presented in Fig. 1. The data of 825 participants were included in the final analysis, from which 416 participants were allocated to active therapy group, while 409 participants were allocated to control therapy group. The detailed characteristics of individual studies are presented in Table 2.

Fig. 1 [Images not available. See PDF.]

PRISMA study selection flowchart

Table 2. Characteristics of included studies

Author	Year	Indication	Treatment group		Control group		Control intervention	Study duration
N	Age	*N*	Age	Derosa [36]	2013	Dyslipidaemia	51	52 ± 10.5
47	52 ± 10.5	Placebo	3 months	Derosa [37]	2013	Dyslipidaemia	52	51.4 ± 9.5
50	51.4 ± 9.5	Placebo	3 months	Pierro [38]	2013	Type 2 diabetes	32	67.85 ± 10.81

44	29.8 ± 7.2	Placebo	6 months	Guarino [42]	2017	Obese + type 2 diabetes	68	56 ± 8

Age presented as mean ± standard deviation

N number of participants

The quality of included studies was evaluated using PEDro scale, and the overall result is presented in Table 3. Out of seven included studies, one study was of moderate quality [38], while all other studies were of good quality. While all studies reported eligibility criteria, randomization allocation, groups similarity at baseline, subject blinding, low dropout rate (below 15%), point and variable measures, and statistical comparison between the intervention groups, none of the included studies provided details of assessor blinding. While the assessor blinding may have significant impact on the overall result of clinical study, the major outcome parameters of current study are laboratory-evaluated parameters, and the influence of assessor biasness might be negligible in the current study context. The overall detailed quality evaluation and criteria for judgement are provided as Additional file 1.

Table 3. Quality assessment of included studies as per PEDro scale

Parameters	Study						
Derosa [36]	Derosa [37]	Pierro [38]	Derosa [39]	Guarino [40]	Derosa [41]	Guarino [42]	Eligibility criteria specified

Risk of bias assessment

Among the seven included studies, all the studies were found to have moderate level of biasness. All included studies had risk of biasness regarding randomization process, while moderate biasness regarding measurement of

outcome parameter was observed in three studies [37, 38, 41], and biasness regarding reported result selection was observed in three studies [40–42]. The result of risk of biasness assessment of individual studies is presented in Fig. 2A, while the result of overall assessment is provided as Fig. 2B.

Fig. 2 [Images not available. See PDF.]

Risk of bias assessment of (**A**) individual included studies and (**B**) overall risk of bias assessment

Meta-analysis

Among the included studies, the efficacy of interventions on plasma glucose level was evaluated in five studies [36–39, 41], and data of 470 participants (237 participants in active group and 233 participants in control group) were used for final analysis. Supplementation of *B. aristata* and *S. marianum* combination showed significant reduction in plasma glucose level (MD: − 5.30 mg/dl; 95% CI − 9.91 to − 0.70; $p=0.02$; Fig. 3) as compared to control group. Significant heterogeneity was observed among included studies ($I^2=90\%$). Sensitivity analysis revealed no significant effect of any included studies on overall observed heterogeneity (Table 4), while removal of two studies [39, 41] individually made the observed pooled effect insignificant (Fig. 6A).

Derosa [37]	85	− 6.980	− 12.078 to − 1.882	0.007
Pierro [38]	92	− 5.969	− 10.836 to − 1.102	0.016
Derosa [39]	83	− 4.498	− 9.906 to 0.909	0.103
Derosa [41]	89	− 3.158	− 7.518 to 1.203	0.156
HbA1c level				
Overall	90	− 0.693	− 1.017 to − 0.370	< 0.001
Pierro [38]	91	− 0.776	− 1.133 to − 0.420	< 0.001
Guarino [40]	93	− 0.686	− 1.156 to − 0.215	0.004
Derosa [41]	92	− 0.754	− 1.136 to − 0.372	< 0.001

Guarino [42]	39	− 0.563	− 0.732 to − 0.394	<0.001
HOMA-IR score				
Overall	99	− 0.644	− 1.358 to 0.07	0.077
Derosa [37]	99	− 0.765	− 1.693 to 0.163	0.106
Derosa [39]	99	− 0.763	− 1.701 to 0.175	0.111
Guarino [40]	99	− 0.724	− 1.614 to 0.166	0.111
Guarino [42]	0	− 0.303	− 0.394 to − 0.211	<0.001

The effect of interventions on HbA1c level was evaluated in four studies [38, 40–42], and data of 328 participants (161 participants in active group and 167 participants in control group) were included in final analysis. Supplementation of *B. aristata* and *S. marianum* showed significant reduction in HbA1c level (MD: − 0.69%; 95% CI − 1.02 to − 0.37; $p<0.0001$; Fig. 4) as compared to control therapy. Random effect model was used for pooled effect estimate due to significant heterogeneity among included studies ($I^2=90\%$). Sensitivity analysis revealed no significant effect of individual studies on overall pooled estimate (Fig. 6B), while removal of one particular study [42] reduced the observed heterogeneity to a non-significant range ($I^2=39\%$) as detailed presented in Table 4.

Fig. 4 [Images not available. See PDF.]

Efficacy of *B. aristata* and *S. marianum* fixed dose combination in improving HbA1c level: meta-analysis result

Among the included studies, the effect of interventions on reducing insulin resistance parameter (HOMA-IR score) was evaluated in four studies [37, 39, 40, 42]. Data of 416 participants (active group: 211 participants; control group: 205 participants) were analysed that showed that supplementation of *B. aristata* and *S. marianum* combination reduced HOMA-IR score compared to control group, while the difference approached significance (MD: − 0.64; 95% CI − 1.36 to 0.07; $p=0.08$; Fig. 5). Significant heterogeneity was observed among included studies ($I^2=99\%$); hence, random-effect model was used for pooled analysis. Sensitivity analysis revealed removal of one particular study [42] reduced the overall observed heterogeneity to non-significant range ($I^2=0\%$) and reduced the overall pooled estimate, with the difference compared to control therapy reaching significance ($p<0.001$) as presented in Table 4 and Fig. 6C.

Fig. 6 [Images not available. See PDF.]

Result of sensitivity analysis using leave-one-study-out analysis for parameters of (**A**) blood glucose level, (**B**) HbA1c level and (**C**) HOMA-IR score

Publication bias

Egger test and Begg test were used to identify any publication bias among the included studies. From the data presented in Table 5, it was concluded that no publication bias was found for glucose level (Egger test $p=0.570$; Begg–Mazumdar test $p=0.624$), HbA1c level (Egger test $p=0.795$; Begg–Mazumdar test $p=0.497$) and HOMA-IR score (Egger test $p=0.375$; Begg test $p=0.174$) parameters. The funnel plots evaluating publication bias for glucose level, HbA1c level and HOMA-IR score are presented as Fig. 7A–C, respectively. The trimming and filling method showed the absence of any missing study.

Table 5. Outcome indicators and publication bias of studies on effects of combination therapy supplementation

Outcome	I^2 (%)	I^2 *p*-value	Egger test *p*-value	Begg–Mazumdar test *p*-value
Glucose level	90	< 0.00001	0.570	0.624
HbA1c level	90	< 0.00001	0.795	0.497
HOMA-IR Score	99	< 0.00001	0.375	0.174

Findings and interpretations

The current meta-analysis study aimed to evaluate the efficacy of a nutraceutical composition composed of fixed dose combination of *B. aristata* and *S. marianum* on glycaemic indices and marker of insulin resistance. The studies included in the analysis were conducted on subjects suffering from diabetes and dyslipidaemia. The result of the present study shows that the nutraceutical composition is effective in reducing the level of glucose and glycated haemoglobin, while effect on insulin resistance was not significant.

Previous research has demonstrated the mechanism of action of *B. aristata* and *S. marianum* in reducing glucose level and provides improvement in diabetic condition. Berberine, the active constituent of *B. aristata*, has demonstrated to reduce the insulin level in type 2 DM patients by improving insulin sensitivity, while in end-stage type 2 DM and in newly diagnosed type 1 DM patients berberine has shown to increase the insulin secretion by protecting the pancreatic ß-cells because of the antioxidant and anti-lipid peroxidation activity of berberine [44]. This dual effect of berberine is due to its various mechanism of action. Berberine is shown to directly activate the AMPK pathway (action similar to metformin) by increasing the phosphorylation of Thr-172 unit of AMPK-α sub-unit, the catalytic domain of AMPK, which results to the downstream signalling activation, and thereby increasing the insulin sensitivity and glucose consumption [44, 45]. Additionally, berberine is shown to indirectly activate the AMPK pathway by inhibiting the mitochondrial oxidative respiration, by inhibiting the monoamine oxidase enzyme and the electron transporter chain complex-I, which reduces the oxidative ATP production by mitochondria and increases the AMP/ATP level, which ultimately initiates the AMPK-signalling pathway [44, 45]. Because of this dual effect, certain studies have claimed berberine activity to be similar to metformin and rosiglitazone [44]. In liver, berberine reduces gluconeogenesis by inhibiting various gluconeogenic genes, namely phosphoenolpyruvate carboxykinase (PEPCK), glucose-6-phosphatase (G6Pase), Forkhead transcription factor-1 (FoxO1), sterol regulatory element-binding protein 1c (SREBP1), and carbohydrate-responsive element-binding protein (ChREBP), while increases hepatic glycolysis by increasing the mRNA expression of hepatic nuclear factor-4α (HNF-4α) [44, 45]. Berberine also inhibits various gastrointestinal enzymes including α-glucosidase, disaccharidase, sucrase-isomaltase complex and ß-glucuronidase, thereby reducing the intestinal absorption of dietary carbohydrates, action similar to acarbose [44, 45]. Because of these myriad of activities, berberine supplementation has clinically proven hypoglycaemic and insulin sensitization activity [46]. Silymarin, the active constituent of *S. marianum*, includes four structurally similar isoforms, namely silybin, isosilybin, silychristin and silydianin [47]. Various studies have demonstrated that silymarin exerts potent antioxidant activity through various different mechanisms, including inhibition of reactive oxygen species (ROS)-producing enzymes, thereby preventing free radicals formation, improving mitochondrial membrane integrity in stressful conditions, reducing inflammatory responses by inhibiting nuclear factor kappa-B (NF-κB) signalling pathway, maintaining optimal redox balance in cell by activating range of antioxidant enzymes and activation of nuclear factor-erythroid two-related factor (Nrf-2), thereby causing increase in non-enzymatic antioxidant potential [47]. This activity of silymarin is largely due to the presence of β-catechol group, which is

capable of donating hydrogen ions and thereby stabilizing free radical species, and by the presence of 2,3-unsaturation along with 4-oxo functional group and other functional groups which are capable of forming bonds with metal ions and stabilize them [48]. Due to these antioxidant and anti-inflammatory mechanisms, silymarin is found to be effective in reducing the diabetic complications including diabetic nephropathy, diabetic neuropathy and diabetic retinopathy [47]. The effects of silymarin on glucose metabolism and insulin activity are largely unexplored with very few studies identifying the exact mechanistic role. In liver, silymarin is found to reduce the activity of pyruvate kinase enzyme which leads to reduction in dihydroxyacetone phosphorylation and decrease in glucose-6-phosphate hydrolysis, ultimately causing reduction in hepatic gluconeogenesis [48]. In conditions of reduced insulin-producing capacity, silymarin supplementation is associated with increased Pdx1 transcription leading to increase in insulin gene expression and ultimately production, while by increasing the expression of Nkx61, a key transcription factor for maintenance of pancreatic β-cells health, silymarin supplementation improves the overall health of pancreatic β-cells and thus improves insulin secretion [23]. Additionally, silymarin supplementation is associated with improved insulin sensitivity by reducing the tumour necrosis factor-alpha (TNF-α)-mediated insulin resistance [23]. In normal condition, the binding of insulin to insulin receptors causes activation of insulin receptor substrate-1 (IRS-1) complex, which in turn activates the phosphatidylinositol 3-kinase-protein kinase B (PI3K)/Akt pathway leading to increased expression of glucose transporter type-4 (GLUT-4) on the cellular surface and thereby increases glucose consumption. As diabetes is associated with chronic inflammation, high TNF-α level causes activation of c-Jun N-terminal kinase (JNK) and I-kappa B-kinase (IKK) complex, which directly inhibits the activation of IRS-1 complex, which thereby reduces insulin-mediated activity and leads to insulin resistance [23]. Silymarin supplementation inhibits the TNF-α, JNK and IKK phosphorylation and activation, which ultimately leads to improved insulin sensitivity and reduced insulin resistance [23]. Due to these myriad of mechanisms, various studies have demonstrated that silymarin supplementation is associated with improved glucose metabolism and reduced insulin resistance [48].

In the current study, the sensitivity analysis revealed that study conducted by Giuseppe Derosa [39] and Giuseppe Derosa [41] has potential effect on the overall effect estimate of glucose level. The former study included patients with dyslipidaemia who were intolerant to high doses of statins, while subjects with type-I diabetes were included in the latter study. As the analysis revealed no publication bias in the evaluated parameters, it can be postulated that the effect of this nutraceutical composition is greater in these patient population, and this hypothesis would need to be examined by more clinical trials including similar patient population. Similarly, observation was seen in HOMA-IR parameter, where study conducted by Guarino et al. [42] had significant impact on overall effect-estimate. But, since the pooled estimate had *p*-value of 0.08 (approaching significance), and the absence of any publication bias, the difference observed from the study may be negligible.

The results of the current study are novel as no previous studies have evaluated the efficacy of *B. aristata* and *S. marianum* fixed dose combination on glycaemic and insulin resistance parameters using a systematic review and meta-analysis approach. A previous meta-analysis study included data from four clinical trials involving 491 participants evaluated the effect of *B. aristata* and *S. marianum* combination on markers of dyslipidaemia [49]. The study included data of subjects with dyslipidaemia, and the effect of supplementation was evaluated on low-density lipoprotein level, high-density lipoprotein level, total cholesterol level, and triglycerides level. In the current study, data of patients with diabetes and dyslipidaemia were included, and the markers evaluated were related to blood glucose and insulin resistance.

Strengths and limitations of current study

The current study has various strengths. Firstly, the current study is novel, and the results of the current study are in line with the results observed in individual clinical studies evaluating the effect of *B. aristata* and *S. marianum* fixed dose combination on glycaemic and insulin resistance parameters. Secondly, the transparency of the study is one of the strengths of the current study which was maintained by following the guidelines provided by PRISMA. The current study has few limitations too. Firstly, the significant heterogeneity and moderate level of biasness observed among included studies. While the feasibility of conducting meta-analysis in such scenario is questionable, the current study was entirely conducted as per a pre-designed and finalized protocol that was developed before the

initiation of the first step of review process (i.e. literature mining). In order to identify the cause of significant heterogeneity, sensitivity analysis was conducted using the leave-one-study-out method, and the individual studies having significant effect on the overall heterogeneity were determined for few outcome parameters, but more statistical correlation research is required for further identifying the exact cause of heterogeneity, which was not covered in the current study due to limited statistical scope. Secondly, the absence of assessor blinding in all of the included studies is one of the major limitations of the included studies. While the evaluation parameters of current study are laboratory evaluated parameters, the influence of assessor might reduce the reliability the results of the current study. Hence more clinical studies with true blinding of the subjects, the therapist and the assessors are required to validate the results of current analysis. Thirdly, the current study included adult population with impaired glucose metabolism and insulin resistance with no limitations on any particular disease indications; the results of the current study needs to be considered with caution, as impaired glucose metabolism and insulin resistance are observed in various conditions like metabolic complications (including diabetes, obesity, dyslipidaemia and non-alcoholic fatty liver disease), cardiovascular complications including hypertension, and gynaecological complications like polycystic ovarian syndrome as well. Hence, the results of the current study do not justify the use of this fixed dose combination nutraceutical supplement in disease indications other than diabetes, dyslipidaemia and obesity in which the clinical studies have been conducted. Lastly, the limited number of studies with a smaller number of participants utilized in the current study warrants further clinical studies.

Conclusion

The results of the current study suggest that the supplementation of *Berberis aristata* and *Silybum marianum* fixed dose combination is effective in improving glycaemic indices by reducing insulin resistance. However, in light of the study limitations including the low number of available studies, the high heterogeneity observed and the moderate risk of biasness, further well-designed clinical studies are warranted.

Multi-epitope-based vaccine designing against Junín virus glycoprotein: immunoinformatics approach

Praveen, Mallari1 1 Indira Gandhi National Tribal University, Department of Zoology, Amarkantak, India (GRID:grid.448 979.f) (ISNI:0000 0004 5930 5909)

ABSTRACT (ENGLISH)

Background

The Junín virus (JUNV) is well known for causing argentine haemorrhagic fever (AHF), a severe endemic disease in farming premises. The glycoprotein of JUNV is an important therapeutic target in vaccine design. Despite using drugs and neutralizing weakened antibodies being used in the medication, neither the severity reduced nor eradicated the infection. However, this constraint can be resolved by immunoinformatic approaches.

Results

The glycoprotein fasta sequence was retrieved from NCBI to anticipate the B cell and T cell epitopes through the Immune Epitope Database. Furthermore, each epitope underwent validation in Vaxijen 2.0, Aller Top, and Toxin

Pred to find antigenic, nonallergic, and non-toxic peptides. Moreover, the vaccine is designed with appropriate adjuvants and linkers. Subsequently, physicochemical properties were determined in ProtParam including solubility and disulphide bonds in the SCRATCH server. The vaccine 3D structure was built using I-TASSER and refined in ModRefine. Docking between JUNV glycoprotein (PDB ID:5NUZ) with a built vaccine revealed a balanced docked complex visualized in the Drug Discovery studio, identified 280 hydrogen bonds between them. The docking score of − 15.5 kcal/mol was determined in the MM/GBSA analysis in HawkDock. MD simulations employed using the GROMACS at 20 ns resulted in minimal deviation and fewer fluctuations, particularly with high hydrogen bond-forming residues.

Conclusion

However, these findings present a potential vaccine for developing against JUNV glycoprotein after validating the epitopes and 3D vaccine construct through *in silico* methods. Therefore, further investigation in the wet laboratory is necessary to confirm the potentiality of the predicted vaccine.

FULL TEXT

Background

The Junín virus (JUNV) is a member of the *Arenaviridae* family, renowned for causing Argentine haemorrhagic fever (AHF), which is a severe endemic infection prevalent in populations residing around agricultural areas in Argentina [1]. The first cases were reported in the 1950s during the unleashed propagation of *Calomys musculus*. Since then, hundreds of cases have been registered annually. Humans will become victims by the inhalation of rodent aerosols or excreta, generally in the harvest season, so it is a rodent-borne virus [2]. Common symptoms of AHF include flu-like signs, such as headache, malaise, and fever. Primary infection sites are the lungs and then circulate to parenchymal tissues [3]. The final stage of AHF shows neurologic and haemorrhagic complications. The World Health Organization (WHO) has classified AHF as an emerging disease, warranting immediate research to design antiviral agents and vaccine targeting the virus components.

JUNV's genome consists of two single-stranded RNA segments: a small (S) segment of 3.4 kb and a large (L) segment of 7.2 kb. The S segment translates in the cytoplasm giving rise to nucleoproteins and glycoprotein precursors that mature into a glycoprotein complex after cleavage by cellular proteases. The glycoprotein is crucial for viral attachment to host cells, initiating the viral components' entry into the host cell [4–6]. Glycoprotein formation occurs in the endoplasmic reticulum and then infects parenchymal cells through circulation [4]. Glycoprotein also plays a role in cell pathogenicity [7].

In the late 1990s, an effective live-attenuated vaccine was developed, significantly reducing AHF incidence. However, there are no effective remedies to counter viral infection among victims [8]. Later, the application of immune plasma therapy to neutralize the antigens decreased the 1% fatality rate if treated before eight days of the onset of symptoms [9–12]. The FDA-approved nucleoside analogue ribavirin inhibits JUNV polymerase and serves as an antiviral, but its use is complicated due to side effects and less efficacy [12, 13]. Numerous small molecule (drugs) antiviral compounds have been reported as antagonists to JUNV in both in vitro [14–17] and in animal models [18, 19]. In silico approaches, such as molecular docking, have been employed to identify the potent drugs from the FDA against the glycoprotein of the Junin virus, revealing MK-3207 and dihydro-ergotamine [17]. Additionally, the live-attenuated vaccine strain Candid #1 (Can) has shown promise in inhibiting glycoprotein spread and reducing infections [18].

Until now, the experiments have primarily focussed on neutralized live-attenuated vaccines, but in this study, we aim to design a new vaccine specifically targeting the glycoprotein. Firstly, we have chosen the mature glycoprotein sequence in identifying and designing a new vaccine through immunoinformatics approaches such as predicting the B cell and T cell epitopes. Next, validating the peptide sequences to ensure the accuracy and reliability of epitopes. Subsequently, designing the vaccine by incorporating suitable adjuvants and linkers and analysing the physicochemical properties. Furthermore, detailed evaluations of the secondary and tertiary structural features of the designed vaccine sequence followed by refining the 3D structure. Furthermore, we checked the binding affinity score and molecular dynamic simulation of the designed vaccine. We presented the detailed methodology followed during

this study in a pictorial format, making it visually accessible and facilitating a better understanding in Fig. 1.

Fig. 1 [Images not available. See PDF.]

The methodology followed in this study

Methods

Sequence retrieval

The sequence of Junín virus glycoprotein precursor was retrieved from the National Centre for Biotechnology Information (NCBI) (https://www.ncbi.nlm.nih.gov/nuccore/MZ408914.1) [19] of 485 length peptide sequence. NCBI provides various tools and a repository database to access the sequence deposited in it.

Prediction of B cell and T cell [MHC I (T_C/CD4+), MHC II (T_H/CD8+)] epitopes

To predict B cell linear epitopes, we used the Immune Epitope Database (IEDB) (http://tools.immuneepitope.org/bcell/) and employed Bepipred Linear Epitope prediction 2.0 with a threshold value of 0.50 [20]. This prediction method is based on the input fasta format of the query protein sequence, and the server utilizes the random forest algorithm to distinguish between epitopes and non-epitope sequences found in crystal structures.

For predicting cytotoxic T cells/Class 1/CD4+ epitopes, we used artificial neural network 4.0 [21] and specified human MHC alleles as the source or reference to get the IC50 values of each predicted sequence in the IEDB Analysis Resource (http://tools.iedb.org/mhci/), which determines the subsequence's binding ability with the specific MHC class I. Helper T cells/Class II/CD8+ epitopes predictions were carried out with the NN-align 2.3 (NetMHCII) method [22, 23] with the human HLA-DR data set and all MHC II allele sequences between 12 and 18 mers in length. The resulting output provided IC50 values for predicted epitopes in the IEDB Analysis Resource (http://tools.iedb.org/mhcii/).

Validation of epitopes

The predicted epitopes were subjected to validation for allergenicity, antigenicity, and toxicity. Allergenicity refers to the ability of an antigen to induce abnormal and hyperresponsive [23]. AllerTOP v. 2.0 (http://www.ddg-pharmfac.net/AllerTOP/) was utilized for allergenicity prediction, employing the k-nearest neighbour algorithm on a training set of 2427 allergens and 2427 allergens, based on ACC uniform length and QSAR with different lengths [24]. Antigenicity, on the other hand, triggers the immune response and describes the ability to bind paratopes [25]. VaxiJen 2.0 (http://www.ddg-pharmfac.net/vaxijen/VaxiJen/VaxiJen.html) server used to predict the antigens and non-antigens [26]. This server was developed based on independent alignment methods with auto cross-covariance (ACC) of amino acid sequences transformation into principal vector properties to predict antigens and non-antigens. To access the peptides' toxicity, the ToxinPred server (https://webs.iiitd.edu.in/raghava/toxinpred/multi_submit.php) [27] was used. It utilizes the support vector machine (SVM) method with a threshold of 0.5 and an E value of 0.01 to predict the toxic and non-toxic peptides. Furthermore, population coverage analysis (http://tools.iedb.org/population/) [27] was performed to select the world population for MHC class I and MHC class II, which covers 3245 alleles from 16 geographical areas, 21 various ethnicities, and 115 countries.

Designing and characterization of structural vaccine

A serial arrangement of the vaccine was designed with beta-defensin 114 as an adjuvant and EAAK, AAY, GPGPG, and KK as flexible linkers [28, 29]. Epitope inclusion linkers and adjuvants were aimed to enhance protein stability and immunogenicity. To validate the designed vaccine, various physicochemical properties were calculated using ProtParam (https://web.expasy.org/protparam/) [30]. Antigenicity was determined using VaxiJen v 2.0 [26], while solubility with SolPro [31]. The presence of disulphide bonds was analysed through DLpro [32] through the SCRATCH web server [33] (https://scratch.proteomics.ics.uci.edu/). Allergenicity prediction was performed through AllerTOP v. 2.0 [24].

Secondary and tertiary structure assessment of antibody

Psipred [34] (http://bioinf.cs.ucl.ac.uk/psipred/) was designed based on the two feed-forward neural networks using the output from Position-Specific Iterated (PSI) – Blast. The SOPMA Server [35] (https://npsa-prabi.ibcp.fr/cgi-

bin/npsa_automat.pl?page=/NPSA/npsa_sopma.html) uses amino acid sequences by the self-optimized prediction method to predict the secondary structure features of the protein.

For in silico studies requiring tertiary structure of the protein 3D protein models using were generated using the servers such as Iterative Threading ASSEmbly Refinement (I-TASSER) [36] (https://zhanggroup.org/I-TASSER/). The prediction is based on the multiple threading approaches from the protein data bank through Local Meta-Threading Server v 3.0. The complete model was built by iterative template-based fragment assembly. The generated models were refined using the ModRefiner [37] (https://zhanggroup.org/ModRefiner/) servers until they achieved Ramachandran-favoured regions greater than 90%.

Molecular docking and MM/GBSA evaluation

The glycoprotein (GP) complex with the Fab antibody of the Junin virus was obtained from the Protein Data Bank (PDB ID: 5NUZ) (https://www.rcsb.org/) and determined using the X-ray diffraction method. The raw protein structure was made by eliminating the extra bound ligands, water, and het atoms followed by saving them in.pdb format for docking. The GP and the designed antibody were docked in the ClusPro protein–protein docking server (https://cluspro.bu.edu/home.php) [38], which was different from the protein–ligand docking that we performed in our previous studies [39].

Subsequently, the docked complex underwent Molecular Mechanics/Generalized Born Surface Area (MM/GBSA) analysis to determine various interaction energies such as binding affinity, Vander Waal, electrostatic, polar solvation-free energy, and solvation-free energy based on the empirical methodologies after minimizing the complex in the ff02 force field over the HawkDock server (http://cadd.zju.edu.cn/hawkdock/) [40].

Molecular dynamic (MD) simulations

The MD simulations were performed on the refined tertiary structure of the antibody in a water medium using GROMACS [41] (https://simlab.uams.edu/index.php) from the WebGRO sim lab UAMS. GROMOS96 43a1 force field [42] initially used the TIP4P solvation model, to build the triclinic box and maintained 0.15 molarity of NaCl at pH 7.4. Using the steepest descent type of energy minimization 800 kJ/mol at 10,000 steps with NVT and NPT equilibration at temperature 300 k and pressure at 1 atmosphere. The final MD was performed by a leap-frog integer method at 20 ns of time.

Results

Sequence retrieval

The NCBI Virus accession number for the glycoprotein sequences of the GenBank ID: MZ408914.1, represents the glycoprotein sequence of the S segment of 485 length peptide sequence linear RNA genome isolated from the Argentinian mammarenavirus on Feb 2022.

Prediction and validation of B cell and T cell epitopes

The B cell and T cell epitopes were predicted using different algorithms from the IEDB, and their respective antigenicity (A>0.5), allergenicity (+), and toxicity (N) were manually analysed and curated (eliminated the non-antigenic (NA), allergenic (−), and toxic (T) peptides). Initially, fourteen B cell epitopes were retrieved as outputs, and they were curated based on properties such as antigenicity, allergenicity, and toxicity. Finally, four peptide sequences were selected for the vaccine construction in Table 1, after removing the duplicates. Based on the threshold values, numerous MHC class I and class II epitopes were obtained. Furthermore, filtered based on IC50 values (≤20), were selected followed by antigenic, non-allergen, and non-toxic peptides used in designing the antibody sequence in Table 2. Population coverage analysis for MHC I and MHC II epitopes was employed to estimate the potential target population for the predicted epitopes used in designing the vaccine, resulting in the best coverage value of 97.28% world population (Additional file 2: Table S1 and Figure S1).

Designing and characterization of antibody structure

Before designing the vaccine, a suitable adjuvant, beta-defensin was selected, which is widely used. Additionally, appropriate linkers were exploited to connect intra B cells with KK, MHC I with AAY, and MHC II epitopes with GPGPG linkers and among them during vaccine designing. An EAAAK rigid linker, capable of forming an alpha helix at the amine terminal used to link the B cell epitopes and the adjuvant. The GPGPG linker was used between the MHC I epitopes and B cell epitopes. An AAY linker was employed to join the MHC I and MHC II epitopes followed by six histidine tags (6H) at the end in Fig. 2.

Fig. 2 [Images not available. See PDF.]

The sequential arrangement of epitopes in designing the vaccine

The designed antibody underwent physicochemical analysis of the nine descriptor values determined through ExPASY ProtParam. The vaccine comprises 431 residues with 47,835.77 Daltons molecular weight (**M.wt.**). The isoelectric constant point (**pI**) of the designed antibody was found to be 9.65. The negatively (Asp + Glu) [**−R**] and positively (Arg + Lys) [**+R**] charged residues were 29 and 57, respectively. The extinction coefficient (**EC**) value at 280 nm was 36,258 M^{-1} cm^{-1}. The instability index (**II**) was 34.87, a value greater than 40 refers to unstable, and a value less than 40 stability. The aliphatic index (**AI**) was 81.25 and the grand average of hydropathicity (GRAVY) of − 0.254 in Table 3.

Table 3. Physicochemical properties of the designed vaccine sequence

Protein	AA	M.wt	pI	(−)R	(+)R	EC[a]	II	AI	GRAVY

Ab Antibody; *AA* Total number of amino acids; *M. wt.* molecular weight; *pI* isoelectric constant; *(−)R* total number of negatively charged residues (Asp + Glu); *(+)R* total number of positively charged residues (Arg + Lys); *EC* extinction coefficient ([a] units of M^{-1} cm^{-1} at 280 nm measuring in the water); *II* Instability index; *AI* Aliphatic index; *GRAVY*

Grand average of hydropathicity

The descending order of the amino acid types in the antibody was: Polar>non-polar>basic>aromatic>acidic in Fig. 3. The constructed vaccine was validated as antigenic, non-allergenic, non-toxic, and had a solubility of 0.92. Moreover, it could form six disulphide bonds between the cysteine residues in Table 4 and Additional file 2: Table S2.

Fig. 3 [Images not available. See PDF.]

Different amino acid type content in the designed vaccine sequence

A Antigen; *NA* Non-allergen; *N* Non-toxin

Secondary and tertiary structure assessment of antibody

The designed antibody fasta sequence was submitted to the SOPMA server for secondary structure prediction. The results indicated that the antibody comprises 26.68% of alpha helices, 41.07% of random coils, 25.99% of extended strands, and 6.26% of beta turns in Table 5. Figure 4, obtained from PSIPRED, exhibits the secondary structure confidence score and provides additional pictorial information about the secondary structure, as depicted in Additional file 2: Figure S2.

Table 5. Secondary features of the vaccine sequence

Feature type	No. of residues	Percentage (%)
Alpha helix	115	26.68
Extended strand	112	25.99
Bera turn	27	6.26
Random coil	177	41.07

Fig. 4 [Images not available. See PDF.]

The confidence level of prediction of the secondary structure via PSIPRED

The tertiary model obtained from the I-TASSER, though constructed upon validating in the Ramachandran plot, does not have enough amino acids in the allowed regions, leading to a low confidence score (C-score) of −2.17. The C-Score ranges from −5 to 2, where a higher value indicates a better model. Based on the confidence score, template modelling (TM-score) and root-mean-square deviation (RMSD) values were calculated to assess the structural similarity between the model and the actual protein. That resulted in a TM-Score of 0.46 ± 0.15 and 12.2 ± 4.4 [43]. The RMSD quantifies the similarity between two superimposed atomic coordinates [44]. The model was sent for structure refinement in the Galaxy refiner, and the results are shown in Additional file 2: Table S3. Based on the Global distance test (GDT) score, RMSD value, molprobity, clash score, rotamers value, and Ramachandran-favoured regions, model 1 was selected as a vaccine which was furthermore analysed. The GDT-HA represents the high-resolution value of the structure, and the MolProbity value is a log-weighted value determined from scores such

as clash score, Ramachandran-favoured percentage, and bad side-chain rotamers [45]. Ramachandran's favoured percentage regions have residues of 90.9% in the most favoured regions of the built 3D antibody. Overall, the selected model was refined and met the criteria for a suitable vaccine candidate, based on the various evaluation structural parameters and properties.

Molecular docking and MM/GBSA evaluation

The interactions between Junín glycoprotein and the designed antibody were analysed through the ClusPro server, and a balanced complex is retrieved in Fig. 5. The interactions between the residues were visualized in the drug discovery studio. Before this, the vaccine formed a total of nine hundred fourteen interactions with the glycoprotein. Including four S–S bonds, twenty-five electrostatic bonds, one-hundred eighty-three hydrophobic bonds, and seven hundred-two hydrogen bonds. Hydrogen bond-forming interactions play a prominent role in drug availability and enhancing the binding chances. Furthermore, the distance criteria of less than two angstroms (< 2 Å) interaction distance among the hydrogen bonds were 280 (Additional file 1).

Fig. 5 [Images not available. See PDF.]

The docked complex of JUNV glycoprotein (Chain C and L) with the designed vaccine (Chain A)

Molecular Mechanics/Generalized Born Surface Area (MM/GBSA) was employed in determining the free energy between the glycoprotein and the designed vaccine (protein–protein interaction). Extensive methodologies in calculating the interaction energies include receptor's grid identification, pre-processing the input files, T leap function, scoring various energies, and scoring. Briefly van der Waals (VDW) energy was − 151.33 kcal/mol, electrostatic energy (ELE) was − 272.63 kcal/mol, polar solvation-free energy (GB) was 424.39 kcal/mol, and solvation-free (SA) energy was − 15.93 kcal/mol. The total binding free energy of the complex was − 15.5 kcal/mol represented in Table 6. Overall, the analysis indicates strong and favourable interactions between the Junin glycoprotein and the designed vaccine, with a significant binding free energy, suggesting the potent vaccine's effectiveness in combating the virus.

Table 6. MM/GBSA analysis representing various energies of the vaccine with glycoprotein

Energy types	Values (kcal/mol)
VDW	− 151.33
ELE	− 272.63
GB	424.39
SA	− 15.93
BA	− 15.5

VDW Vander Waal's energy, *ELE* Electrostatic energy, *GB* Polar solvation-free energy, *SA* Solvation-free energy, and *BA* Binding free energy affinity

Molecular dynamic simulations

Understanding the vaccine's conformational relative stability of the backbone atoms using the RMSD measure provides valuable insights since it measures the deviations of the extent atoms from the starting point. Less deviation (low RSMD) value signifies a better stable protein structure. For the constructed vaccine, the average lowest RMSD value was 0.24 nm in Fig. 6A. However, there was a slight increase in atomic deviations to 0.6 nm at 0.3 ns. This increase in RMSD values between 0.6 to 0.8 nm from 0.3 to 15 ns can be attributed to the modelled vaccine structural interactions optimization.

Fig. 6 [Images not available. See PDF.]

The molecular dynamic simulations of the 3D vaccine in water. **A** Root-mean-square deviation (RMSD) computes the average distance between the backbone atoms of starting structure (reference structure) with simulated structures (frame by frame) when superimposed. **B** Root-mean-square fluctuation (RMSF) computes fluctuations (standard deviation) of atomic positions of each amino acid (residues) in the trajectory [*X*-axis = Time; *Y*-axis = Residue number]. **C** Hydrogen interactions forming residues

Furthermore, the protein stability evaluated by root-mean-square fluctuations (RMSFs), which measures the protein residue's elasticity and binding site adaptation phenomena, was determined. The vaccine, RMSF contains evident residue cluster fluctuations. On average, there were two fluctuations for every hundred residues. Residues 200–320 showed high fluctuations with significant up and down levels. Maximum fluctuations were observed in the 390–400 residues range, while minimum fluctuations between 280 and 389 in Fig. 6B.

Hydrogen bond trajectories retained during the MD simulation were studied to evaluate the strength and binding affinity of the complex. The designed vaccine was found to form several hydrogen bonds with an average of 140 hydrogen bonds when interacting with the antigenic protein. The ability to form multiple hydrogen bonds was crucial in inhibiting the target protein, thereby strengthening the complex's free energy in Fig. 6C. Overall, analysis of RMSD, RMSF, and hydrogen bond trajectories provides valuable information about the stability and interactions of the designed vaccine, which were essential factors in determining its potential effectiveness as a vaccine.

Discussion

The general effective possibilities that are being examined are to control the dispense of Argentine haemorrhagic fever (AHF) by the design and development of suitable vaccines. The duration of the vaccine development from experimental studies to clinical trial studies takes an extensive period. In this modern era, due to the advancement of system applications in biology, numerous epitopes predicting epitopes are made available using various machine learning algorithms. Among them, multi-epitope-based vaccine designs employing predicting B cell and T cell epitopes have made a remarkable trend in bioinformatics. In addition, proper attention is required to develop a safe and viable vaccine.

To date, the primary approach to prevent the infection rate is neutralized monoclonal antibodies (MABs). Research on the MABs extracted from animal models (mouse) shows that the glycoprotein JUNV is involved in mimicking the human transferrin receptor 1 (hTfR1) during the binding process. This glycoprotein acts as a primary target and plays a predominant role in the prevention and treatment of infection [46]. The vaccine design according to the sequence-specific will act efficiently in inhibiting the antigen and will also be helpful in further mutational studies considering the evolution of the virus variants.

Three epitope types (B cell, $T_{C,}$ and T_{H}) predictions were performed using multiple servers including experimentally based HLA class I and HLA class II alleles [47]. All predicted epitopes were validated based on antigenicity/non-antigenicity, allergenicity/non-allergenicity, and toxicity/non-toxicity and shared maximum population coverage across the world. The number of B cell epitopes obtained after screening was less, indicating fewer interactions. Considering the T cell epitope number obtained, the cell-mediated immunity and immune response generated were high and long-lasting. A commonly used adjuvant (beta-defensin) was selected in designing and the linkers were added appropriately in Fig. 2. To ensure safety and efficacy, the designed vaccine over-checked their non-allergenicity, antigenicity, and non-toxicity. Furthermore, physicochemical, solubility and disulphide bond parameters were checked to determine the stability of the vaccine in Table 4 and Additional file 2: Table S2. This comprehensive validation paves potential applications in immunization against the target antigen.

The physicochemical properties in Table 3 and Fig. 3 include the pI as the pH at which no electrical charge is present on the molecule or the total number of negative and positive charges are equal [30]. The isoelectric focusing technique is performed based on the pI values for separating the molecule from the complex [48]. These values help to isolate the respective protein of interest in the wet lab experiments upon digestion. The glycoprotein's pI of 9.65 indicates that for wet-lab studies the experimental setup is to be maintained a basic environment during extraction.

EC is defined as the amount of light absorbed per mole of protein at a specific wavelength of light. The protein's EC value is calculated from the composition of tryptophan, tyrosine, and cysteine residues because these amino acids contribute significantly to measuring the protein's optical density in the 276–282 nm range [30]. Protein–protein and protein-ligands quantitative study can be understood through the EC values [49]. The EC value exhibited was high representing a good sequence for further studies. II indicates the protein stability under both in vivo and in vitro conditions. Proteins with II greater than 40 are considered unstable proteins, while II less than 40 are stable [50]. II of the designed vaccine was 34.87 inferring the stability. AI is another parameter that describes protein stability at temperatures. AI is defined as the relative volume occupied by aliphatic side chains like alanine (Ala), valine (Val), leucine (Leu), and isoleucine (Ile) [30, 48]. The high value of AI indicates the increase in the thermostability nature of the protein which is an additive factor for wet lab studies. The Aliphatic index (**AI**) of the vaccine sequence is 81.25 indicating the thermostability character. GRAVY value ranges from − 4 to + 4 indicating the hydrophilic and hydrophobic nature of the proteins [51]. The low GRAVY range indicates the possibility of being a globular (hydrophobic) protein rather than membranous (hydrophilic). Thus, the vaccine contains a globular protein residue with a value of − 0.254.

The tertiary structure of the vaccine has been generated from the I-TASSER and further processed in ModRefiner to achieve optimum descriptor values such as GDT-HA, RMSD, Molprobity, C-score, poor rotamers, and Ramachandran-favoured regions greater than or equal to 90% in Additional file 2: Table S3, aids to validate the designed structure all of which are crucial in validating the structural integrity [52, 53]. Subsequently, molecular docking of JUNV glycoprotein and the construct was performed to achieve a balanced complex model from the ClusPro server in Fig. 5. The post-docking analysis, specifically the MM/GBSA method in Table 6, of the docked complex resulted in favourable interaction energies within the docked complex. Moreover, MD simulations on the vaccine in water in Fig. 6 have indicated that the designed construct exhibited notable stability without higher deviations and fluctuations with maximum hydrogen bond forming ability that emphasizes the vaccine stability. These findings collectively underscore the designed vaccine's reliability and robustness for potential application in combating the JUNV.

Conclusion

In this study, we focussed on vaccine design based on the glycoprotein of the JUNV on employed immunoinformatics approaches to identify antigenic peptides because of the novelty of identifying the peptides using machine learning tools. The vaccine was constructed after selecting the antigenic, nonallergic, and non-toxic and deleting the duplicate and overlapping sequences. The vaccine was designed using 4 B cell, 9 MHC class I, and 8 MHC class II T cell epitopes with appropriate linkers and adjuvant. The tertiary model was generated and refined to meet suitable specific criteria especially Ramachandran-favoured regions greater than 90%. After the physicochemical properties' determination, molecular docking of JUNV glycoprotein with the designed vaccine performed a balanced complex model chosen for analysing the interactions among them showed 280 hydrogen bond forming residues with radii less than 2 angstroms. MM/GBSA methodology exhibited − 15.5 kcal/mol of binding free energy of the complex. The MD simulations of the vaccine that were performed exhibited fewer values of fluctuations and deviations that signify the vaccine's stability. However, the present work was based on in silico methodologies with promising results that will be evident in the wet lab works to justify the findings.

ABSTRACT (ENGLISH)

Background

Diarrhoea has become one of the major areas of concern due to its high mortality rate contributing it to be the second largest cause of death in world. To explore the effectiveness of medicinal plant, the present investigation was undertaken to scientifically justify the traditional claim of the ethanolic root extract of the plant *Begonia rubrovenia* (EBV) against diarrhoea.

Results

EBV was standardized using HPLC with quercetin as marker and was further subjected to normal fecal excretion study at 100, 200 and 300 mg/kg, p.o. along with quercetin and loperamide. The study confirmed the effectiveness of EBV at 200 and 300 mg/kg followed by quercetin. In castor oil induced diarrhoea rat model, EBV at 200 and 300 mg/kg significantly delayed onset of diarrhoea, reduced the diarrhoeal faecal output which contributed in higher % protection. The effectiveness of EBV at 200 mg/kg was also confirmed through gastrointestinal motility, fluid accumulation and PGE_2 induced enteropooling tests. EBV and its marker quercetin also reduced the elevated level of NO and cytokines and restored the alterations in antioxidant enzymes, ions and enhanced Na^+/K^+–ATPase activity. Molecular docking, dynamics and network pharmacology study confirmed the role of quercetin in modulating the inflammatory mediators IL-1β, TNF-α and EP3 prostanoid receptor, where quercetin formed more stable complex with EP3 prostanoid receptor.

Conclusion

The study has scientifically justified the traditional use of the plants *B. rubrovenia* in treating diarrhoea, where quercetin played a critical role in the observed antidiarrhoeal potential of *B. rubrovenia* contributing in maintaining electrolyte balance, antioxidant status and inhibiting inflammatory mediators.

FULL TEXT

Background

Diarrhoea is an infection mainly associated with gastrointestinal (GI) tract, where defecation rate, volume and consistency of the stools get altered [1]. At present, diarrhoea is assessed to be the most prevalent situation hampering GI tract with 1–5% prevalence rate in adults in developed as well as developing countries like India [2, 3]. According to the WHO and UNICEF reports, about 1 billion diarrhoea cases are estimated worldwide, among which 3 million deaths occurs per year in children’s less than five years of age [4].

Different etiological factors attribute to the cause of diarrhoea like infectious agents (viruses, parasites and bacteria's), food allergies, intestinal dysfunction, alcohol consumption, decrease in uptake of bile salts and intake of some drugs, e.g., antineoplastic, antimicrobials, oral hypoglycaemic agents, antiretrovirals, β-blockers, proton pump inhibitors and non-steroidal anti-inflammatory drugs [3]. To handle this diarrhoeal condition, nontherapeutic approach, i.e. oral rehydration therapy is the primary step to maintain water and electrolyte loss along with zinc supplementation [5]. Therapeutic approach used to reduce the most consistent and clinically significant indications of diarrhoea have several side effects like dry mouth, severe constipation, nausea, vomiting, distension of abdomen and cramps [6] along with respiratory tract depression and paralytic ileus (mostly in children's due to loperamide drug) [7]. To minimize the health hazards of these agents, medicinal plants are most suitable approach to treat GI disorders like diarrhoea because they have lots of compounds, which help in efficacy enhancement and side effect neutralization [2]. Thus, to treat GI disorders like diarrhoea, natural entities are the most suitable therapeutic agent and also a good starter for the innovation of new drugs [3].
